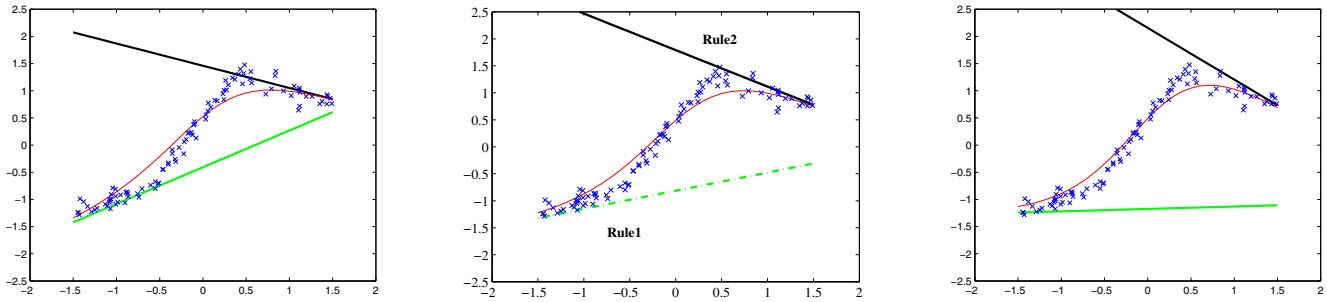
As shown in Equation (2), the *then*-part of TSK fuzzy rules is identical to a "linear" *perceptron*. Given M fuzzy rules, TSK combines (at most) M perceptrons in a fuzzy fashion on each datum. This can be organized into our familiar MLP-type architecture. In this perspective, a single-output TSK can be expressed as an S-M-1 MLP with M "linear" *hidden* nodes (hence, $P_1 = S$; $P_2 = M$; $P_3 = 1$). Each hidden-node output is given by h_p, as defined in Equation (2), where the parameters $\theta_{i,p}$ are the weights between the input layer and hidden layer (with bias $\theta_{0,p}$). The weights (with no bias) between the terminal and hidden layers correspond to firing strengths w_p, which are *data-dependent* values.

Example: A single-input single-output TSK with two rules.

A TSK with two fuzzy rules ($M=2$) can be constructed as a CANFIS neuro-fuzzy network with two perceptrons since



(a) $\tau = 0.7$ (b) $\tau = 0.8$ (c) $\tau = 0.9$

Fig. 3. Data fitting results obtained by on-line hidden-node teaching with three choices of τ (for designating the local-expert region) in Equation (8): (a) $\tau = 0.7$; (b) $\tau = 0.8$; and (c) $\tau = 0.9$. The results indicate that $\tau \approx 0.7$ would be a good choice in the posed problem. Compared with Figure 1, where no hidden-node teaching is applied, it is clear that hidden-node teaching is effective in maintaining rules' *then*-part interpretability to meaningful limits. In each case, all the parameters in both *if*-part and *then*-part are updated on-line until the same error level is achieved.

it can be put in a three-layer ($N = 3$) 1-2-1 MLP mold having single-input and single-output nodes ($P_1 = P_3 = 1$) with two *linear* hidden-node functions ($P_2 = 2$), as illustrated in Figure 2: Here, two terminal weights, denoted by w_1 and w_2, are the *firing strengths* calculated at the integrating unit of fuzzy MFs in response to each input x, and two hidden-node "linear" outputs h_i correspond to *then*-part of fuzzy rules; that is, Equation (2) reduces to

$$h_i = \theta_{0,i} + x\theta_{1,i} \quad \text{for } i = 1, 2. \tag{7}$$

The final output y is generated by $y = w_1 h_1 + w_2 h_2$, as shown in Equation (1) with $M = 2$. □

The above transformation of a fuzzy system to such an MLP-type network as in Figure 2 is a key ingredient in design for CANFIS (see p.371 [5] for more details).

C. TSK hidden-node teaching effects in a motivating example

On-line first-order BP-based algorithms may be attractive in attacking a large-scale problem. However, when on-line BP is applied to optimizing both *if*-part and *then*-part of fuzzy rules, after-learning knowledge extraction may not always be possible. Here, for the initial setup of fuzzy rules, the *then*-part *linear* parameters are randomly initialized in a small range, as usually done for MLP-learning. In order to attain a higher input-output mapping precision, on-line BP may adapt the parameters of initial fuzzy rules significantly, ending up with meaningless fuzzy rules. This is a dilemma between mapping precision and interpretability (see pp.382–387 [5]). Back to our motivating example, Figure 1 illustrates such a dilemma; this phenomenon is partly due to a fact that the standard supervised learning uses a terminal cost alone, as in Equation (4), and thus only encourages the final combined output to be close to the desired output; this is the nature of *complementary* learning. In the spirit of fuzzy systems, however, the *then*-part linear output of each rule should match up to the desired output when its firing strength is large enough; this is the original claim made for a TSK (see p.118 in [22]).

Hidden-node teaching can handle this situation with a CANFIS network depicted in Figure 2. The posed two-rule CANFIS has two terminal weights: $\mathbf{\Theta}_{\text{void}} \equiv [w_1, w_2]$. Now, suppose that a "terminal" teacher signal, denoted by t^3, is presented to the terminal node at layer 3 and another "hidden" teacher signal, t_i^2, to hidden-node i at layer 2; then, the scalar version of the on-line hidden-node teaching BP-formula (6) is given by

$$\xi_i^2 = w_i(y_1^3 - t^3) + (y_i^2 - t_i^2) = w_i(y - t^3) + (h_i - t_i^2),$$

where $\xi^3 = \delta^3 = (y - t^3)$; y_k^s is the kth node output at layer s; and the last equality holds owing to Equations (1) and (2). In our numerical experiments that follow, we introduce scalar τ as a threshold for designating local-expert regions, and the same desired outputs t are presented at both terminal and hidden layers in our model, yielding the following BP-formula (with superscripts omitted for simplicity):

$$\xi_i = \begin{cases} w_i(y - t) + (h_i - t), & \text{if } w_i \geq \tau \\ w_i(y - t), & \text{otherwise.} \end{cases} \tag{8}$$

Since the hidden-node functions are also *linear*, as shown in Equation (7), we have $\delta_i = \xi_i$ at hidden node i. We thus obtain the gradient vector below for then-part parameters $\boldsymbol{\theta}$ in response to input x:

$$\frac{\partial J}{\partial \boldsymbol{\theta}} = \left[\frac{\partial J}{\partial \theta_{0,1}}, \frac{\partial J}{\partial \theta_{1,1}}, \frac{\partial J}{\partial \theta_{0,2}}, \frac{\partial J}{\partial \theta_{1,2}}\right]^T = [\delta_1, x\delta_1, \delta_2, x\delta_2]^T,$$

for which the weight-decay term is omitted from Equation (5). Once a (scalar) gradient element $g = \frac{\partial J}{\partial \theta}$ is evaluated for any parameter θ, it is used to update θ on-line by

$$\begin{cases} \Delta\theta = -\eta g + \beta \Delta\theta_{\text{old}}, \\ \theta_{\text{new}} = \theta_{\text{old}} + \Delta\theta, \\ \Delta\theta_{\text{old}} \leftarrow \Delta\theta, \end{cases} \tag{9}$$

where η is a learning rate and β a momentum term.

Figure 3 shows our numerical demonstration with three different choices of τ for the hidden-node teaching BP-formula (8). The larger the value τ is, the smaller each local-expert region is. When $\tau = 1$ in Equation (8), essentially no hidden-node teaching applies. This preliminary investigation

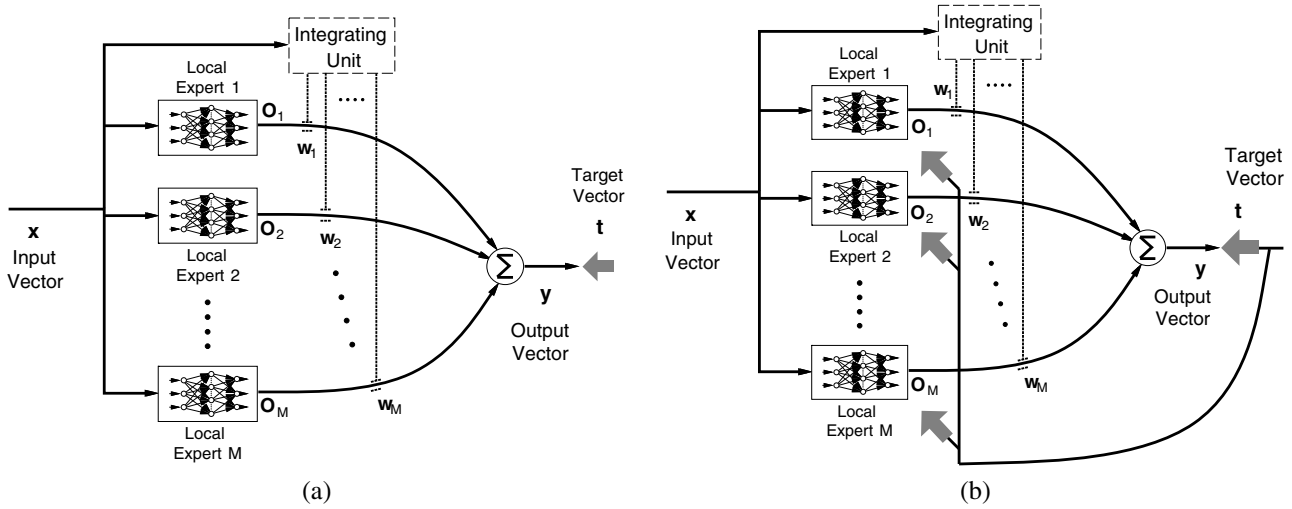


Fig. 4. An architectural comparison between CANFIS modular networks (a) without and (b) with hidden-node teaching [see Eq.(11)]. Here, *then*-part local-expert MLPs are encouraged to cooperate with each other within overlapped regions, where their corresponding *if*-part fuzzy MFs are overlapped in the input space.

suggests $\tau \approx 0.7$. Compared with Figure 1, the then-part outputs are kept within the data-distribution limits. In this way, hidden-node teaching can maintain fuzzy rules' interpretability.

D. CANFIS modular networks

Next, we advance to "non-linear" then-part of fuzzy rules that can circumvent many problems arising in "linear" then-part fuzzy rules. In Equation (7), each then-part h_i is a simple "linear" perceptron (with only two weights in a single-input case). If each h_i is expanded to include any number of "hidden" layers (with nonlinear hidden-node functions), then each amounts to an MLP (see p.377 [5] for such a transformation); the resulting model is a CANFIS with "neural" rules; or, a CANFIS modular network with local-expert MLPs. Figure 4 describes a typical CANFIS modular network, in which the final combined output is given by

$$\mathbf{y} = \sum_{i=1}^{M} w_i \mathbf{o}_i, \tag{10}$$

where w_i is the firing strength of Rule i, and $\mathbf{o}_i$ the output of *then*-part local-expert MLP i. To emphasize the usefulness of the posed model, we later show how to approach the UCI letter recognition benchmark (26-class pattern classification) problem that involves with 16 input features.

As described earlier for Figure 1, in standard supervised learning with terminal residuals in Equation (4) alone, the output of each then-part expert-MLP may differ substantially from the desired output even in its own local-expert region (e.g., see Fig.13.15 on p.391 [5]) due to the nature of *complementary learning*. That is, when a modular network (that consists of M local-expert MLPs) is optimized simultaneously, only the final outcome $\mathbf{y}$ is made close to the terminal desired output $\mathbf{t}$; here, each local-expert output $\mathbf{o}_i$ may not reproduce the terminal desired output $\mathbf{t}$ accurately even when the input $\mathbf{x}$ comes right into its own territory. In the spirit of fuzzy systems, it may be adequate to encourage each expert to generate the terminal desired outputs when the input $\mathbf{x}$ falls into its own local-expert area. For this reason, hidden-node teaching may apply to a CANFIS modular network, as shown in Figure 4(b).

By hidden-node teaching, we may designate a "principal" local-expert MLP based on the magnitude of firing strengths w_i. From the concept behind Equation (8), we say that on each datum, local-expert MLP i is a principal expert if its firing strength w_i is greater than or equal to a threshold τ. By hidden-node teaching, the principal local-expert MLP is encouraged to reproduce the same target $\mathbf{t}$ as presented at the terminal layer. To this end, Equation (8) is modified as

$$\boldsymbol{\xi}_i = \begin{cases} w_i(\mathbf{y}-\mathbf{t}) + (\mathbf{o}_i - \mathbf{t}), & \text{if } w_i \geq \tau \\ w_i(\mathbf{y}-\mathbf{t}), & \text{otherwise} \end{cases}, \tag{11}$$

where term $(\mathbf{o}_i - \mathbf{t})$ is a "hidden" residual vector for each expert-MLP i evaluated at its final output layer [see Fig.4(b)].

We summarize a general computing procedure below for CANFIS modular-network learning with hidden-node teaching using the same symbols used in Figure 4:

Algorithm for CANFIS with M local-expert MLPs in Fig.4:

(1) Do forward pass in the integrating unit of fuzzy (Gaussian) MFs to calculate M rules' firing strengths w_i (typically by the product rule).
(2) Do forward pass in each local-expert MLP i to evaluate MLP's output vector $\mathbf{o}_i$, the output of *then*-part of Rule i, (when $w_i > 0$) for $i = 1, ..., M$.
(3) Evaluate the final CANFIS output $\mathbf{y} = \sum_{i=1}^{M} w_i \mathbf{o}_i$, and then compute the terminal residual vector $\mathbf{r} = \mathbf{y} - \mathbf{t}$.
(4) For each local-expert MLP i ($i = 1, ..., M$), repeat the following backward-pass procedure:
   (a) Propagate back the terminal after-node sensitivity vector, residual vector $\mathbf{r}$, to local-expert MLP i.
   (b) If Rule i is fired strongly enough [i.e., $w_i \geq \tau$ in Eq.(11); see also Eq.(8)], then compute the hidden

residual vector and add it to the back-propagated after-node sensitivity signals.

(c) Continue the backward pass for the remaining stages to update the weights.

(5) Do backward pass on the integrating unit of fuzzy MFs. □

General parameter-updating formulas for use in Steps (4) and (5) can be found on p.379 [5]. In Step (5), MF-parameters may be updated on-line (on each datum); alternatively, the gradient information of MF-parameters may be accumulated over all the training data for the "batch-mode" fine-tunings (see [4], [10]), while the other parameters of local-expert MLPs are updated on-line.

Furthermore, a so-called *truncation filter* function (see p.380 [5]) may be introduced; for instance, in attacking classification problems with binary target values, the kth residual at node k is set equal to zero for any final output y_k beyond the target value t_k, *ON* $(+1)$ or *off* (-1); this implies the following residual evaluation:

$$r_k = \begin{cases} 0 & \text{if } t_k = \textit{ON} \text{ and } y_k \geq \textit{ON} \\ 0 & \text{if } t_k = \textit{off} \text{ and } y_k \leq \textit{off} \\ y_k - t_k & \text{otherwise.} \end{cases} \quad (12)$$

Here, the kth element of final outputs $\mathbf{y}$ [see Equation (10) and Figure 4(b)] is given by

$$y_k = \sum_{i=1}^{M} w_i o_{i,k},$$

when M expert-MLPs are employed. The posed scheme is related to a threshold least-mean-square procedure (e.g., see [20]). If "hidden" target signals at the output layer of each expert-MLP are the same as the "terminal" target ones for hidden-node teaching [see Fig.4(b)], then those associated hidden residuals may also be subject to Equation (12), for which y_k is replaced with $o_{i,k}$, the kth output of expert-MLP i.

III. Numerical Experiments

We explain more about the learning capacity of CANFIS models, showing numerical evidence obtained in the well-known XOR (two-class pattern classification) problem and the UCI letter recognition benchmark problem.

A. The XOR problem by CANFIS with two linear rules

In the literature, the XOR problem is usually solved by a 2-2-1 MLP; yet, when the so-called weight-sharing is applied to hidden weights, it can be solved by a 1-2-1 MLP with $x_1 + x_2$ as input. The solution weights of the 1-2-1 MLP can be always expanded as those of a corresponding 2-2-1 MLP (see [14] for details). Similarly, for attacking the XOR problem, a conventional fuzzy system usually needs four rules: two MFs on each input x_i $(i = 1, 2)$. In this section, we demonstrate a 1-2-1 MLP-structured CANFIS in Figure 2 for solving the XOR problem. By the weight-sharing concept, the original four XOR-data reduce to three data, as shown in the right-most column in Table I. In "standard" MLP-learning, the hidden-node activation function should be nonlinear. For instance, an MLP with any number of "linear" hidden nodes is unable to solve the XOR problem because a linear transformation of another linear transformation is just *linear*. One may wonder why a CANFIS with two *linear* hidden nodes has a "nonlinear" mapping capacity. This is simply because the terminal weights w_i are firing strengths, whose values are data-dependent (see Figure 2).

TABLE I

FOUR DATA OF THE XOR, TWO-BIT PARITY, PROBLEM: (COLUMN 1) TARGET VALUE, t; (COLUMNS 2 AND 3) TWO-BIT INPUTS, x_1 AND x_2; AND (COLUMN 4) $x_1 + x_2$ FOR THE WEIGHT-SHARING CASE.

Target	Two inputs		Sum of inputs
t	x_1	x_2	$x_1 + x_2$
-1	$+1$	$+1$	$+2$
$+1$	-1	$+1$	0
$+1$	$+1$	-1	0
-1	-1	-1	-2

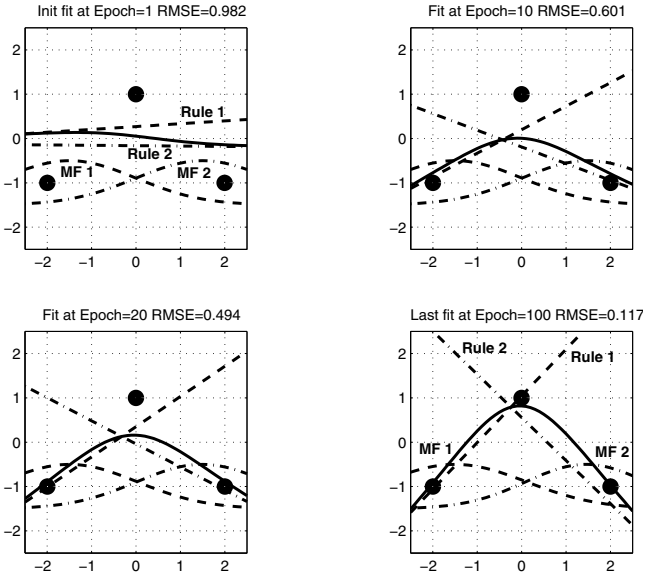

Fig. 5. A learning progress of a CANFIS with two linear rules, a 1-2-1 MLP-structured CANFIS in Figure 2, for solving the XOR problem: Displayed are the terminal CANFIS output (solid line) as well as two *if*-part MF outputs & two *then*-part linear outputs at epochs 1 (upper left), 10 (upper right), 20 (lower left), and 100 (lower right). The three dots denote the three data points, resulting from our weight-sharing; see the right-most column in Table I. The CANFIS is trained by on-line hidden-node teaching with $\tau = 0.95$ in Equation (8).

Figure 5 shows four snapshots of the CANFIS output during on-line learning. As the number of epochs increases, the output approaches the three data points. In this way, it can be readily confirmed that the CANFIS with only two *linear* rules solves the XOR problem perfectly. The 1-2-1 MLP-structured CANFIS (in Figure 2) even with (two) *linear* hidden nodes has a great nonlinear mapping capacity, which is derived from the *data-dependent* terminal weights, firing strengths of two linear rules. By contrast, in the standard MLP-learning, terminal weights are *common* to all data points (hence, an MLP with "linear" hidden nodes would never solve XOR). This is a fundamental distinction between a MLP-structured CANFIS

and a standard MLP.

In the XOR or higher-dimensional parity problems, a standard MLP (with sigmoidal-shaped hidden-node functions) tends to fail due to hidden-node saturations. Originally, our hidden-node teaching scheme has been designed to alleviate such malicious hidden-node saturation problems for MLP-learning [9], although saturations may be necessary to some extent for parity solutions (see [14] for proofs). In seven-bit parity, for instance, a 7-4-1 MLP (with only four tanh hidden nodes) can develop *insensitivity* to initial weights owing to hidden-node teaching; that is, it can always solve the 7-bit parity problem (128 data) * "perfectly."

The above *weight-sharing* concept is applicable to any number of (input) bits of parity; in 21-bit parity, for instance, the weight-sharing concept leads to a 1-11-1-MLP-structured CANFIS with 11 linear rules; this is because 21-bit parity can be readily solved by a standard 1-11-1 MLP, which yields a solution weight vector for a 21-11-1 MLP (see [14]). By contraries, the standard TSK fuzzy system needs to use at least 2^{21} rules since at least two fuzzy MFs, the minimum number of MFs, must be set up on each input feature. This is the so-called "curse of dimensionality" problem, which commonly arises in the design of many other fuzzy systems also. Unfortunately, the weight-sharing concept may not apply in general (see the letter recognition problem). In such a case, CANFIS modular networks may be useful in bypassing the curse of dimensionality through the subset selection of input features (see other applications in [4], [10]).

B. The UCI letter recognition benchmark problem

Next, we attack a larger and more realistic letter recognition (26-class pattern classification) benchmark problem available at the UCI machine learning repository [1]. The problem contains 16,000 patterns for training and 4,000 for test; each pattern consists of 16 extracted attributes (inputs) and 26 capital letters, English alphabet: A to Z (of 20 different fonts); hence, 26 classes in total. As a preprocessing, the training data set is normalized to *zero mean* and *unit variance* for each attribute. Accordingly, the test data set is preprocessed using the average of the training data set; here, we did not use any information of the average of test data. A straightforward application of TSK-type fuzzy system may end up with 2^{16} *then*-part linear functions (i.e., linear local-expert perceptrons in Figure 2) when two MFs, the minimum number of MFs, are designed on each input feature. This is the aforementioned "curse of dimensionality" problem, which often occurs in many fuzzy systems. To circumvent this dimensionality obstacle, we apply fuzzy partitioning only to a subset of inputs (see [4], [10]) and use local-expert MLPs as nonlinear *then*-part of fuzzy rules.

In the UCI-letter recognition problem, the 12th input (x_{12}) alone may be partitioned in a fuzzy fashion; e.g., with two "intuitively-obvious" linguistic labels on it: *small* and *large*.

*The Matlab code for 7-bit parity attacked by a 7-4-1 MLP is available at www.ieor.berkeley.edu/People/Faculty/dreyfus-pubs/hidteach.m for reference.

TABLE II
THE ERROR-RATE RESULTS IN THE UCI-LETTER RECOGNITION, AVERAGED OVER TEN TRIALS, OBTAINED AT (PRE-SET LIMIT) EPOCH 500 BY CANFIS HAVING TWO 16-70-50-26 (LOCAL EXPERT) MLPS, (IN COLUMNS 2 AND 3) WITH HIDDEN-NODE TEACHING ($\tau = 0.7$) AND (IN COLUMNS 4 AND 5) WITHOUT IT, IN CONJUNCTION WITH THE TRUNCATED FILTER FUNCTION FOR BOTH HIDDEN AND TERMINAL RESIDUALS. THE LAST ROW SHOWS THE ERROR RATE OBTAINED BY A SIMPLE COMMITTEE METHOD THAT EMPLOYED TEN TRAINED CANFIS MODELS.

	With hid-teach		No hid-teach	
	Train	Test	Train	Test
Average error (%)	0.19	3.43	0.35	3.42
Committee error (%)	0.13	2.35	0.25	2.43

This is because the distribution of x_{12} appeared to spread relatively widely, but our "improvisatory" choice of a single input feature x_{12} is purely for our testing purpose of CANFIS modeling to the letter recognition problem. In our experiment, we employ a CANFIS modular network with two local experts ($M = 2$), each of which is a two-hidden-layer 16-70-50-26 MLP (with 6,066 weights), the same-size MLP architecture used in [19], [12] with tanh hidden-activation and *linear*-output nodes. The posed CANFIS is optimized by *on-line* first-order BP (with or without hidden-node teaching) using momentum term 0.8 [$\beta = 0.8$ in Eq.(9)] and learning rates: $\eta_{h1} = 1 \times 10^{-4}$ for the hidden weights at Stage 1, $\eta_{h2} = 8 \times 10^{-5}$ for those at Stage 2, $\eta_o = 5 \times 10^{-5}$ for terminal weights. The integrating unit consists of two Gaussian MFs having the initial center positions -1.5 and 1.5 with the same width 1.0 initially. Those MFs are updated in batch-mode with a very small learning rate 1×10^{-8} merely for the fine-tuning purpose, whereas the two local-expert MLPs are trained in on-line mode with the above learning rates.

Table II shows the results obtained (at the pre-set limit epoch 500) by a CANFIS modular network with two local-expert 16-70-50-26 MLPs with or without hidden-node teaching. The last row shows the results obtained by the simple committee method (for model-averaging; see Ch.8 in [2]) using ten weight-value sets obtained at final (i.e., pre-set limit) epoch; each of those resulted from the ensemble over ten optimized CANFIS models. In general, hidden-node teaching may serve as a constraint, slowing down the learning process and resulting in a lower mapping precision. In this application, however, the hidden-node teaching results allude to an improvement in speed and accuracy with respect to training error rates; this may be due to increased "hidden" residuals (in addition to terminal residuals).

IV. CONCLUDING REMARKS AND FUTURE DIRECTIONS

The CANFIS design methodology may be regarded most simply as a way of converting an original TSK model into an MLP-type structure, but it can be readily extended to a more sophisticated CANFIS modular network (see p.377 [5]). This perspective makes CANFIS conceptually differ greatly from other network-based fuzzy models including a fuzzy neural network (e.g., see [3]). A key concept behind CANFIS modular-network learning is that, by selecting an appropriate

subset of input features, we can circumvent the so-called curse of dimensionality that frequently arises in any fuzzy systems. Since each local-expert MLP has a great learning capacity, any choice of small input subsets to the integrating unit may not deteriorate the overall learning performance. In the preceding application examples, we have designed CANFIS models by choosing only one feature for fuzzy partitioning, but our numerical test shows encouraging results (see also [4], [10] for other applications).

Yet another advantage of our CANFIS design is that all the parameters of any-size CANFIS modular network can be readily optimized by what we have developed, the (on-line) hidden-node teaching backpropagation algorithm, which exploits its multi-stage structure. Our hidden-node teaching method, which was originally developed to avoid hidden-node saturations in MLP-learning [9], may be significant for neuro-fuzzy learning for several different reasons: (1) for attacking a large-scale problem due to its easy on-line implementation; (2) for maintaining rules' interpretability in the spirit of a fuzzy system; (3) for improving generalization capacity; (4) for escaping from plateaus in learning. Merit (1) is obvious, and (2) was explained for Figure 3. For (3), in our experiments; the same target signals were presented at the hidden layer [i.e., the final output layer of each expert-MLP; see Figure 4(b)] as well as at the terminal layer of a CANFIS network. In consequence, the output variance of local experts could be reduced. Furthermore, the variance of linear weights may be decreased as well, compared with some other (neural) fuzzy systems that employ RLSE to determine the linear weights, as mentioned in Section I, because such a least squares estimator tends to yield quite large linear weights in magnitude; this is an important issue common to *separable nonlinear least squares* learning algorithms (e.g., see [17]). In any event, smaller variance in either output or weight or in both would furnish a better performance in response to previously unseen (test) data. Lastly, item (4) is new (our future work): The problem is that if hidden-node outputs get very similar to each other on all (training) data during learning, then a matrix of hidden-node outputs becomes *rank-deficient*, giving rise to plateaus in learning (e.g., see in [16] our Hessian-matrix analysis for indefiniteness in MLP-learning and references therein). Since the Hessian matrix of J in Equation (3) can be evaluated efficiently by our recently-developed second-order stagewise backpropagation [13], [15], [18], it would be of our great interest to investigate plateaus in CANFIS neuro-fuzzy modular-network learning.

ACKNOWLEDGMENT

Eiji Mizutani would like to thank Stuart Dreyfus (UC Berkeley) for a countless number of useful discussions on discrete-time optimal-control methods that led to the development of hidden-node teaching.

***Abstract*—In this paper, formal representations for user preferences will be provided, which also take fairness in the achievement of probably conflicting goals into account. The analysis of the Bottleneck Flow Control (BFC) algorithm for congestion avoidance in traffic networks will serve as a base to specify extensions of relations among preference sets. In particular, these relations are the lexicographic minimum, the maxmin fairness, and the newly introduced ordered-ordered weighted averaging operator. All of them are shown to become, in a relational sense, maximized by the BFC algorithm. Their further expansion by introducing fuzzy fusion operators in their formal definitions than establishes a comprehensive sets of relations. The application of these relations to the Multiple Relation Analysis (MRA) of subjective video quality evaluation data is demonstrated and gives the conclusion that also fairness criterions are present in such evaluations, at least as a secondary preference criterion.**

***Keywords*-fairness; maxmin fairness; ordered weighted averaging operator; preference modelling; fuzzy information fusion**

I. Introduction

Preference modelling, and the related preference prediction have become research fields of increasing importance. This tendency has been established by the wide-spread use of the internet, social networks, and vendor systems, all of them comprising systems that receive a strong impact from the user's attitude. So far, the focus of user preference modelling was on either binary systems ("yes-no", "like-neutral") or numerical evaluations given by the user (ratings, stars). However, recent research is already focussing on the limitations of such a point a view. For example, CP-nets were introduced as graphical representations of conditional preferences [1]. Also older works that were not considered for a long time newly came under focus, as for example the Landau theorems on scoring sequences (i.e. necessary and sufficient conditions for scoring systems in a network context) [2]. In this work, we also want to promote the point of view to represent preferences by means of (set-theoretic) relations, in order to allow for a rich analysis of various aspects of user decisions. In particular, the goal is to extend the analysis to additionally represent (possibly hidden) trade-offs that are inherent in user preferences, by a formalization of the concept of user fairness. As a means for such an analysis, a field was choosen were much progress in the modelling of fairness was achieved for a long time, i.e. the introduction of maxmin fairness in the field of data communication [3]. By a rigorous analysis of one of the fundamental algorithms in this field, the so-called Bottleneck Flow Control (BFC) algorithm [4] for congestion avoidance in traffic networks, we could find opportunities for the generalization of relations that are established by this algorithm. The generalization of these relations can be successfully achieved by employing concepts from fuzzy fusion. At the end of our exposition, we will have a suite of formal relations at hand that is capable to issue a Multiple Relation Analysis (MRA) for general data analysis, also taking the attitude of users towards unachievable goals into account. The MRA will be demonstrated on a subjective video quality evaluation dataset.

This paper is organized as follows: the following Section II will recall the BFC algorithm, and discuss the relevant aspects of the state that is achieved at the end of this algorithm. These characteristics of the algorithm will guide to the specification of a suite of formal relations for MRA in Section III, and the application of this suite to the video quality dataset will be given in Section IV. The paper ends with a short conclusion section.

II. Fairness Relations

In this section, we will focus on the formal representations of fairness. In general, fairness, as a daily life concept, can be understood in many ways and fashions. Problems with global optimization easily lead to a motivation to also take fairness into account [5][6]. We can find various attempts to represent fairness in the past, but mostly there was no notable progress. For example, in processor scheduling tasks, often related to hard combinatorial optimization problems, the concept of n-fairness was introduced, with the notion meaning that in a processor regime, each processor should ensure that the processor before can perform at least n tasks [7]. Also in common means like credit granting, fairness can be used as an indicator for a relevant assessment. Here, the criterion could be that two customers that have the same evaluation criterions should receive the grant with the same likelihood.

However, all such specifications do not guide to a formal representation of fairness in such a way that it can be effectively used for the finding of suitable "fair" states. Here, the best progress so far was achieved in the field of data communications. Starting with the proposal of the Bottleneck

Flow Control (BFC) algorithm, an effective way of a fair resource assessment was introduced, probably for the first time [4].

A. The Bottleneck Flow Control Algorithm

We assume a traffic network congestion avoidance problem. A network for carrying traffic is given as an un-directed graph G with nodes N and links L. Also, a *maximum capacity* is assigned to each link. Then, there are a number of users that want to send traffic units through this network. Thus, also a set of n triples (Π_i, s_i, r_i) of sender-receiver pairs and paths connecting them is given, where s_i represents the sending node, r_i the receiver node for user u_i. Paths Π_i are given as a sequence of joined links starting from s_i and ending at r_i. We also consider the union of all links l_i used by all paths, each link with a multiplicity w_i according to the number of paths using the link l_i. Then the Bottleneck Flow Control algorithm assigns traffic amounts t_i to all users u_i in the following way:

Bottleneck Flow Control

---

1) Set the *remaining paths* to the set of all paths. Set the traffics t_i for users u_i along their corr. paths Π_i to 0.
2) While the *remaining paths* set is not empty, perform the following steps:
3) For all links l_i used by the *remaining paths*, get the number w_i of paths that pass through this link.
4) Find the links with minimum value of $m_i = c_i/w_i$.
5) Add m_i to the traffics for all users through the links with minimal m_i.
6) Remove the paths of all users of links, for which m_i is minimal, from the *remaining paths*.
7) Set new capacities of network links $c_i \rightarrow c_i - m_i * w_i$.

An example for the BFC algorithm is given in Fig. 1. It shows a network with 7 nodes and links between these nodes as indicated in the figure. It is assumed that the link connecting nodes 3 and 4 has a maximum capacity of 200 units, and the link connecting nodes 4 and 7 has a maximum capacity of 100 units. All other links will have some higher maximum capacity. Three users wants to send traffic through this network: user 1 sends traffic t_1 via the nodes 1, 3, 4 and 7; user 2 sends traffic t_2 via the nodes 2, 4 and 7; and user 3 sends traffic t_3 via 5, 3, 4 and 6. It means that some users have to share links for their traffic: users 1 and 3 share the link between nodes 3 and 4, and users 1 and 2 share the link between nodes 4 and 7. The BFC algorithm now will assign specific values for the traffic amounts t_1, t_2 and t_3, starting with amount 0, and increasing equally for a subgroup of users. At the beginning (Level 0) the amount will increase for all users. In some later stage, for example at Level 20, the traffic amount assignment of 20 (units) to all users is still feasible. However, at Level 50, the link between nodes 4 and 7 has to transport a total traffic of 100: 50 from user 1, and 50 from user 2. This gives a so-called *bottleneck*. Any attempt to further increase the traffic for either user 1 or user 2 will result in exceeding the maximum capacity of this link. Thus, the BFC algorithm stops to further

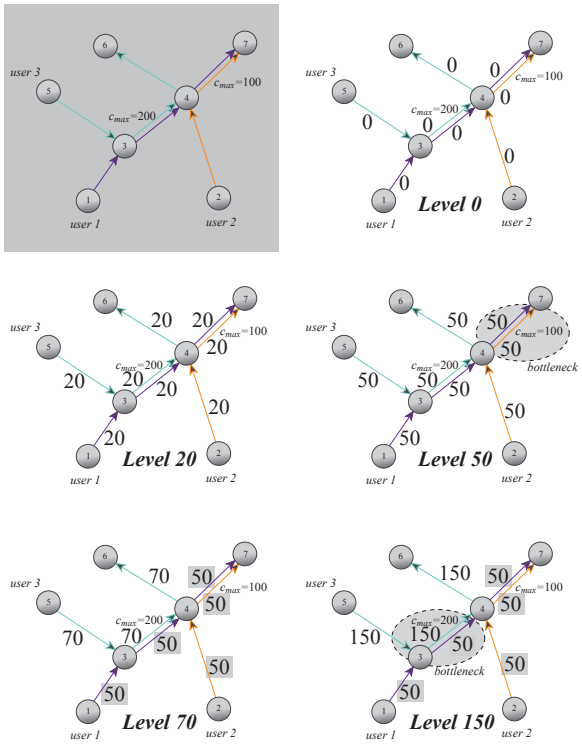

Fig. 1. Example for the Bottleneck Flow Control Algorithm: the algorithm starts traffic assignments for users along given paths at level 0, and gradually increases this level until bottlenecks are appearing. Then, the algorithm stops the further increase for the affected users, but continues for the other users. Thus, it is attained to assign the same traffic to subsets of users as long as possible. This algorithm also utilizes the specific network in the best way.

increase the traffic amount for users 1 and 2, and fixes the assignment $t_1 = 50$ and $t_2 = 50$.

However, user 3 is not affected by this bottleneck, since her traffic is not using the link between nodes 4 and 7. So, the BFC algorithm continues. Later on, for example at Level 70, the traffic assignment $t_3 = 70$ (while keeping $t_1 = t_2 = 50$) is still feasible. This level increase will continue until Level 150. Now, the total traffic for the link between nodes 3 and 4 becomes 200: user 1 was fixed before at the level $t_1 = 50$, and $t_3 = 150$ for user 3.

Any further increase of traffic is not possible, and the BFC algorithm stops. Thus, the final traffic assignment is $t_1 = 50, t_2 = 50, t_3 = 150$. In the implementation of this algorithm, of course, there are no increasing level sets, as the values of bottlenecks can be directly inferred from the network configuration and the values of maximum capacities.

It has to be noted that the BFC algorithm also specifies the feasible space of traffic assignments. We can write the result of the algorithm by a set of linear equalities (bottleneck equations):

$$\begin{aligned}\lambda_{11}t_1 + \cdots + \lambda_{1n}t_n &= b_1\\ \lambda_{21}t_1 + \cdots + \lambda_{2n}t_n &= b_2\\ &\cdots\\ \lambda_{k1}t_1 + \cdots + \lambda_{kn}t_n &= b_k\end{aligned} \quad (1)$$

where all $\lambda_{ij} \in \{0, 1\}$, t_i is the traffic amount allocated to the sender-receiver pair (s_i, r_i) and k is the number of bottlenecks found by the BFC algorithm, in the same order by which they are found by the algorithm. It can also be seen that the t_i can be numbered (arranged) in such a way that the set of equations fulfills the following properties:

- In row 1, all t_i with $\lambda_{1i} = 1$ are equal.
- In each row $r > 1$ there exists a "border" index i_r such that for all $i < i_r$ and $\lambda_{ri} = 1$ in at least one row $r_1 < r$ also $\lambda_{r_1,i} = 1$, and for $i \geq i_r$, all t_i are equal, larger than any t_j with $j \leq i_r$, and there is an index $r_2 \leq r$ such that $\lambda_{r_1,i} = 0$ for all $r_1 < r_2$ and $\lambda_{r_1,i} = 1$ for all $r_2 \leq r_1 < r$. This means that the traffics comprising a particular bottleneck equation (their λ-values are 1) can be divided into two groups: the first group contains only traffic amounts already assigned by foregoing bottleneck equations. Thus, in the progress of the algorithm, while reaching another maximum capacity (bottleneck), the remaining traffic amount at that bottleneck will be equally shared among another new group of sender-receiver pairs. These traffics then comprise the second group. Note that the first group might be empty.
- If $i > j$ then for the largest k_i and k_j from $\{1, \ldots, n\}$ with $\lambda_{i,k_i} = 1$ and $\lambda_{j,k_j} = 1$ resp. it holds that $t_{k_i} \geq t_{k_j}$. This means the last elements in the equations are sorted in non-decreasing order, according to the flow of the BFC algorithm.

For clarity (we will need this structure of the bottleneck equations later on) here the bottleneck equations for the example given above:

$$\begin{aligned}t_1|_{=50} + t_2|_{=50} &= 100\\ t_1|_{=50} + t_3|_{=150} &= 200\end{aligned}$$

thus, for the second row the index i_2 is 2: all traffics appearing in the equation (i.e. their λ factor is 1 and not 0) with lower index appear in at least one foregoing bottleneck equation (here, t_1 appears in the first equation and was fixed to 50), and the remaining capacity of $200 - 50 = 150$ at the second bottleneck will be equally shared for the third traffic. Since there is only one sender-receiver pair, its value will become 150.

Writing the bottleneck equations in such an index-ordered way has the additional advantage that, after replacing each equal sign in the Eqns. (1) with a lower-or-equal sign specifies the feasible space of all possible traffic assignments.

After this analysis of the BFC algorithm, the question is about the characterization of the final state achieved by the algorithm. The BFC algorithm is effective in the sense that for any given network structure, and given sender-receiver pairs, it will uniquely assign traffic amounts to all sender-receiver pairs, and thus select one and only one element of the feasible space. How is this element be qualified against all other elements of the feasible space?

In the following, we will recall two already known notations of that final state, and provide another (up to our best knowledge) new characteristic. Then, we will discuss the extension of these characteristics into the fuzzy fusion domain.

B. Characterization of the BFC result

There are several ways to characterize the final state of the BFC algorithm. Here, we will focus on three ways. In a less formal way, the BFC algorithm can be seen as a prototype to achieve fairness in the assignment of traffic amounts among the various users (i.e. sender-receiver pairs) in such a network model. The algorithm assigns the same traffic to all user as long as possible. Then, when this increase is no longer possible, as the assignment is reaching a bottleneck, it is no longer possible to give a larger same amount to all users. But, in contrary to other "equalizing" approaches to fairness, the BFC algorithm does not stop here. It acknowledges the fact that a number of users is *not* affected by this bottleneck, and continues to raise their traffic amounts equally — until the next bottleneck is reached.

From this argument, we can see the first characteristic of the BFC algorithm.

(1) **Lexmin relation**. The lexmin relation is defined as a relation between two points from R^n. Given two vectors x and y from R^n, we consider the coordinates of both vectors sorted in increasing order. It is said that $x >_{lexmin} y$ if and only if the first coordinate of x, in that sorting, which is different from y, is larger than the corresponding coordinate of y, in that sorting. For simplicity, if the smallest coordinate of x is larger than the smallest coordinate of y or if both are equal but the second-smallest coordinate of x is larger than the second-smallest coordinate of y etc. - than x is lexmin-related to y.

We also want to recall here that for any relation $>_R$, formally seen as a subset of $A \times A$, where A is an arbitrary but fixed set, we can define a *maximum set* and a *best set*: the maximum set contains all elements x from A such that there is no different $y \neq x$ in A with $y >_R x$. The best set, on the other hand, contains all elements x of A such that for each different $y \neq x$ $x >_R y$ holds.

In this sense, the best set of the feasible space of a network traffic assignment problem under the lexmin relation contains exactly one element, and this is the one found by the BFC algorithm. This can be seen from the index-ordered bottleneck equations: the minimum traffic is given in the first of the equations, and it cannot be increased. Then, for states with the same minimum traffic, the second-smallest traffic will appear in the second equation. Also this one cannot be increased without exceeding the second bottleneck. The argument can be continued for the third-smallest traffic, fourth-smallest traffic etc.

(2) **Maxmin fair dominance relation**. It has already been established [3][8] that the BFC algorithm is selecting the best set element of another relation, the so-called *maxmin fairness dominance*.

Definition 1. *An element x of the feasible space is* maxmin fair dominating *an element y of same space, if for each component y_i of y, which is larger than the corresponding component x_i of x there is another component x_j of x which is (already) smaller than or equal to x_i and such that y_j is smaller than x_j.*

This can be directly seen from the index-ordered bottleneck equations. If one traffic is increased, there will be a bottleneck equation r where this traffic appears for the first time (and there belonging to the second group, i.e. with index $i \geq i_r$, using former convention). To maintain the bottleneck equation, another traffic has to be decreased in order to compensate for the increase (note that the compensation can be larger than the increase). But each other traffic in this equation will be the same (before increase) or smaller (if belonging to the first group with indizes $i < i_r$). So, any increase of a traffic amount can only happen if some other traffic amount, which is already the same or smaller, is decreased. This is exactly the definition of the maxmin fair dominance relation. Note that maxmin fair dominance relation and lexmin relation are different relations.

In the next subsection, we will introduce a generalization of the maxmin fair dominance relation, based on using fuzzy fusion operators. Here, we will already note that *maxmin fairness* (referring to the quality of the best element of this relation) has already found a number of alternatives in the data network domain (where it was first introduced). The most popular one is the so-called *proportional fairness*. It can be defined as follows:

Definition 2. *A point x of feasible space (a subset of R_n^+) is considered proportional fair dominating another feasible point y, if and only if*

$$\sum_{i=1,\ldots,n} \frac{y_i - x_i}{x_i} \leq 0 \tag{2}$$

holds.

The reason to introduce proportional fairness were a number of problems with maxmin fairness, including the negligence of user utility, and the overvaluation of the least element, for example as it was noted by Kelly[9]: "*The maxmin fairness criterion gives an absolute priority to the smaller flows, in the sense that if $x_{s^*} < x_s$ then no increase in x_s, no matter how large, can compensate for any decrease in x_{s^*}, no matter how small.*"

We can find the further extension of proportional fairness to the so-called weighted alpha fairness dominance relation:

Definition 3. *A point x of feasible space (a subset of R_n^+) is considered weighted alpha fair dominating another feasible point y, if and only if for a given fixed set of weights w_i*

$$\sum_{i=1,\ldots,n} w_i \frac{y_i - x_i}{x_i^\alpha} \leq 0 \tag{3}$$

holds.

It can be shown that for $\alpha \to \infty$ alpha-fairness nearly everywhere converges to maxmin fairness, but equals proportional fairness for $\alpha = 1$.

(3) **Exponential OOWA**. While the former two definitions show how to use a relation between points in the feasible space, and to characterize the BFC algorithm as the one that finds the best element for each relation, the question comes up if there is also a scalar function that is directly maximized by the BFC algorithm. As a new result, we will show that there is such a function. We define a special case of the ordered weighted averaging (OWA) operator. As a reminder, the OWA of a point x of R_n, given a weight vector $w \in R_n$, is defined as $\sum w_i x_{(i)}$. In this expression, $x_{(i)}$ indicates the i-th largest element of all coordinates of x. We specialize the OWA by also requiring the weights to be sorted in the opposite order.

Definition 4. *Given a point x from R_n and a set of weights $w \in R_n$, the Ordered-Ordered Weighted Averaging (OOWA) of x by w is defined as*

$$OOWA_w(x) = \sum_{i=1}^{n} w_{(n-i+1)} x_{(i)} \tag{4}$$

Thus, in the OOWA, the largest value is multiplied with the smallest weight, the second-largest value with the second-smallest weight etc. As a special case of the OOWA, we also introduce the exponential OOWA. The additional requirement here is

$$w_{(i)} > \sum_{k=1}^{i-1} w_{(k)} \tag{5}$$

so that the weights itself are exponentially increasing. A possible choice is $w_i = 2^i$ for any n. Then it holds:

Theorem 1. *The BFC algorithm is maximizing any exponential OOWA.*

For an outline of the proof, see the Appendix.

Back to the example from the former subsection, and using the weights $(1, 2, 4)$ to compute

$$OOWA_{exp}(t_1, t_2, t_3) = t_{(1)} + 2t_{(2)} + 4t_{(3)} \tag{6}$$

we can see that any feasible modification of the t_i will reduce this expression for the state $(50, 50, 150)$ assigned by the BFC algorithm. This state has the exponential OOWA value $1 \cdot 150 + 2 \cdot 50 + 4 \cdot 50 = 450$. If for example t_2 is increased, this has to be compensated by a decrease of t_1. The increase can be at most 50 due to the first bottleneck at 100, and t_2 will always become the second largest traffic, and the exponential OOWA is changing to

$$f^* = 1 \cdot 150 + 2 \cdot (50 + \delta) + 4 \cdot (50 - \delta_1) \tag{7}$$

where $\delta_1 \geq \delta$. This expression is clearly smaller than 450, as it reduces the former value by at least 2δ. If t_1 is increased, than

t_2 and t_3 have to be decreased, and the argument is basically the same. An increase of t_3 forces a decrease of t_1. Since the increased t_3 will still be the largest value, and thus weighted by 1, the smaller t_1 now will be weighted by 2 or 4 (which depends on a possible modification of t_2). So, also here the net change in the exponential OOWA expression will be negative.

The exponential condition is also necessary. It suffices to consider a network structure, where one traffic shares links with k other users, all of same maximum capacity and exactly one other user per link to share, and the remaining $n-k$ links will have only one sending user, all with a lower maximum capacity. Then, an increase of all the k sharing users will require the one sharing user to compensate all k traffics. This, its weight must be at least as large as the sum of the weights of all other k increased traffics.

As a last comment, we may note that the exponential condition is a result of link sharing. With regard to fairness, single user sharing links with many other users at once can be considered the worst case, as assigning any traffic to such a user affects the traffic of many other users, in fact enforces their reduction.

III. Suite of Relations

In order to apply the concepts that were presented in the foregoing section, we will have to study the unrevealed relations independently from the BFC algorithm and the underlying network traffic assignment problem. In fact, there are a number of formal ways to expand these definitions, and they will be discussed in the following.

A. Maxmin fairness and fuzzy fusion

The definition of maxmin fair dominance is rather complex. However, its implementation can be much simplified [5]: in general it would need to check the fairness condition for all pairs of components, but for simplification, we define index sets as follows (see Fig. 2). Given two vectors x and y we want to test if x maxmin fair dominates y. Then, we compute

- $A = \{i \,|\, x_i > y_i\}$
- $B = \{i \,|\, x_i = y_i\}$
- $C = \{i \,|\, x_i < y_i\}$
- $min_A = \min_{i \in A} x_i$, or ∞ if A is empty
- $min_C = \min_{i \in C} x_i$, or ∞ if C is empty

The definition of maxmin fairness requires to check the following for every increasing component x_i: is there any $j \neq i$ such that $x_j \leq x_i$ and $y_j < x_j$? It means that $i \in C$ and $j \in A$. We omit the case that either A or C is empty at the moment. Then, for such an index j to exist, it is necessary that for every $i \in C$ there is at least one element j of A with $x_j \leq x_i$, in particular it is necessary that there is a $j \leq min_C$ and thus $min_A \leq min_C$. We can see that this is a sufficient condition as well: for any i from C, already one j with $x_j = min_A$ fulfills the check: the j-th component (min_A) is smaller than or equal to any x_i with $i \in C$, and $x_j > y_j$ since $j \in A$. If we also take formally $z < \infty$ for any real z, we can evaluate maxmin fair dominance as follows: *Given two vectors x and y, then x will maxmin fair dominate y if and only if $min_A \leq min_C$.*

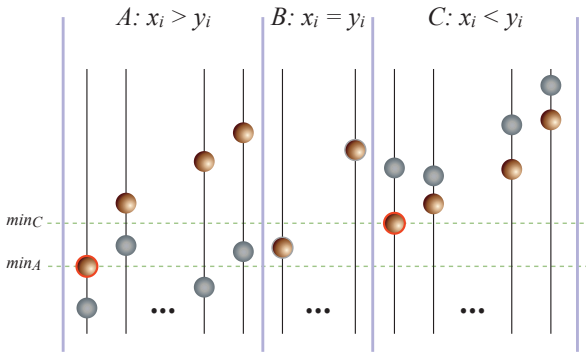

Fig. 2. Maxmin fairness relation can be more easily defined, if we consider the sets of components of x larger (set A) and smaller (set C) than corresponding components of y. Vector x will maxmin fair dominate y if and only if the smallest larger component of x is smaller than or equal to the smallest smaller component of x [5]. In the figure, corresponding components of x and y are placed on the same line, with height indicating their magnitude, and the lines are re-arranged to show first x-components larger than the corr. y-component, then equal components, and third smaller components (each of the three sections are additionally arranged by increasing size of the corr. x-component).

Note that equal components do not have any influence on maxmin fair dominance, and that the definition includes Pareto dominance. If C is empty, but A not, then each component of x is larger than or equal to the corresponding component of y, and at least one is larger.

From this way of testing the maxmin fair dominance relation, we can see that the relation actually refers to a fusion of all smaller and all larger components of a vector, compared to another vector. The fusion used here is the minimum operation. In this regard, we consider an extension of the maxmin fair dominance by formally generalizing on the fusion aspect. Thus, instead of comparing $\min A$ and $\min C$ we use other means to fuse the information of the sets A and C into single values. In present study, we will use other t-norms (incl. Dubois Prade t-norm, and algebraic t-norm), and OWA operators with different weights.

B. OOWA

Also the exponential OOWA that was shown to be maximized by the BFC algorithm offers some straightforward extensions, esp. by requiring a different law of weights increase. Here, we will consider also a linear OOWA, where weight i is choosen to be i.

Such operations will reflect sharing aspects. In the network problem, the exponential increase of weights was necessary in order to ensure that even the situation where one sender shares links with ALL other users is covered. In the simple scenario of no link sharing at all, a linear OOWA would be sufficient to ensure maximization by BFC algorithm. Thus, comparing linear and exponential OOWA in a situation, where the interpretation of "link sharing" is not obvious, it can still refer to a relevant problem of the studied feasible space -

technically, these expressions can be computed without any reference to a networking problem at all.

C. Data processing suite of relations

With the modifications mentioned in the former subsections, we propose a suite of relations that can be used together for a Multiple Relation Analysis.

- Fuzzy fusion fairness relations fff_{op}, where op indicates the used fuzzy fusion operator. To decide for two points x and y whether $x >_R y$ or not, we first compute the set A of all components of x that are larger than the corr. component of y, and the set C of all components of x that are smaller than the corr. component of y. Then, if A is not-empty, op is applied to A, giving a value f_A, and if C is not-empty, op is applied to the set C, giving a value f_C. If either of these sets is empty, the corr. f-value is set to ∞. Then, $x >_R y$ if and only if $f_A \leq f_C$. More specifically, we will consider Dubois-Prade T-norm for fusion (which is for two reals a and b from $(0, 1)$ and a parameter α defined as $ab/\max[a, b, \alpha]$, and for more than two arguments by associativity of the expression for two arguments), the "simple" algebraic t-norm as product of components, and several OWA operators, with larger weights for smaller values, or nearly equal weights, thus focussing on averaging. Also, plain average of the sets A and C will be considered.
- Other fairness relations, as introduced in subsection II-B(2): proportional fair dominance, and alpha fair dominance with various values of α.
- Exponential OOWA, as introduced in section II-B(3), the variant linear OOWA as discussed in the foregoing subsection, and in this context also the lexmin relation.
- Other general relations that are not primarily related to the concept of fairness: more than half of the components of x is larger than the corresponding components of y; the largest component of x is larger than the largest component of y; and the average of the components of x is larger than the average of the components of y in order to x be in relation to y.
- We also consider Pareto dominance relation with regard to maximization and minimization. For maximization, x is larger than (or: in relation to) y iff all components of x are larger or equal to the corresponding components of y, and at least one component is larger (minimization Pareto dominance is defined accordingly).

D. Mathematical properties

For space reasons, we will not provide a thorough analysis of the mathematical properties of the introduced relations. Here we only mention that the introduced fuzzy fusion fairness relations are all not complete (i.e. it is possible that for some x and y neither $x >_R y$ nor $y >_R x$ holds) and not (always) transitive. For example, for the maxmin fair dominance relation, consider the tripel of vectors $x = (70, 50), y = (40, 40), z = (30, 60)$. Here x maxmin fair dominates y, and y maxmin fair dominates z but x does not maxmin fair dominate z. Nevertheless, the relations will not produce conflicts, as from $x >_R y$ and $y >_R z$ always $z >_R x$ can be excluded. On the other hand, the lexmin relation as well as the OOWA are complete and transitive.

IV. Experimental Validation: Subjective Evaluation of Video Quality

A. Used data and recent findings

For the application of the relations, we are considering a dataset of subjective evaluations of video data quality. The dataset contains two kinds of information for 1139 sample videos: five objective measures of video quality, in particular values numerically representing overall noise, degradation caused by block distortion, degradation associated with blurring, local spatial degradation, and freeze degradation, and an average ranking of a number of users for each of these 5-tuples of data. The dataset is part of a larger experiment performed at NTT Corp.[1]

The data have already been analyzed in a recent publication[10]. There, the goal was to use a newly-proposed fuzzy integral, the inclusion-exclusion integral, to derive the user ranking from the quality measures by direct computation. The approach was shown to improve the recommended rule by the Telecommunication Standardization Sector of International Telecommunication Union (ITU-T), and an approach based on the Choquet integral as well. It was also confirmed that the 5-th quality measure shows a logarithmic utility for the user, while the other four correspond directly to the user utility.

B. Data Pre-Processing

Here, we are interested in specifying the user attitude towards increase or decrease of the quality measures in total. While it can be expected that video material with lower degradation measures will be more likely higher ranked, the question that can be handled by the introduced fairness relations is also about the acceptance of trade-offs by the user. So, the question for the analysis is if an increase in quality according to one criterion is less favored, if the cost for this increase is the decrease of another criterion, which is already lower in quality.

For this processing, we have to represent the quality values by their utility. Also we have to consider that the introduced relations are focussing on increasing magnitudes of components. Thus, the following pre-processing of the data was performed:

1) Data sets containing unsafe measurements (about 20) were removed.
2) All 5-th measurements x_{i5} were replaced by the decimal logarithm $\log_{10} x_{i5}$.
3) All datasets were normalized by their average and standard deviation (μ_j is the average of the j-measurement, and σ_j the corresponding standard deviation):
$$x_{ij} \leftarrow \frac{x_{ij} - \mu_j}{2\sigma_j} \tag{8}$$
4) Datasets with strong outliers were removed (about 200), as we are more focussing on the average behaviour.

[1]The dataset itself is not publicly available.

5) The single data were rescaled to the $(0, 1)$ range, such that larger values represent better quality:

$$x_{ij} \leftarrow 1 - \frac{x_{ij} + 1}{2} \tag{9}$$

After preprocessing, the frequency correlation for each proposed relation was computed. Thus, we are considering the normalized measurements for each possible pair (x, y) of datasets in two ways:

- Precision: in case that x is in relation to y, we are counting how often then also $s_x > s_y$ holds, i.e. how often the users also ranked the video higher.
- Recall: in case that $s_x > s_y$, we count how often this is indication for the relation $x >_R y$ to hold as well.

In the processing, equal pairs of values were ignored. It was also noted how often the relation was actually occurring. The total number of pairs used in the comparison for each relation was 938961.

C. Results and Discussion

The result for all used relations can be seen in Table I.

We describe the main properties of the result by the following items, see also Fig. 3.

- Most of the relations achieve precision and recall measures between 0.1 and 0.8. The largest precision value is achieved by the Pareto dominance (maximizing), but it is accompanied by a low recall value. This indicates that an improvement in ALL measures usually also results in a higher rating of the videos, but that it is not required from the user perspective. The low measures for the Pareto dominance minimizing strengthen this conclusion: a higher rating of a video with all lower quality measures is highly unlikely. Note the small number of occurrences of the Pareto dominance relation as well.
- We find the fuzzy fusion fairness relations located in the lower right part of the precision-recall plot, in an area with the maxmin fair dominance relation (as a special case of fuzzy fusion fairness) in its center. This indicates that these relations are focussing on related aspects of user preferences. Remember that these relations are focussing on the modality of accepting a decrease in some quality measures for the benefit of increasing other measures. In a fair state, the decrease should not happen to quality measures that are already lower. The rather low recall values indicates that the user is not considering this a primary criterion, and is more focussing on general improvements. Nevertheless, the recall values can become rather large, esp. when the algebraic t-norm is used for fuzzy fusion. This is a relevant issue, as most t-norms have the tendency to depend (in their numerical range) strongly from the number of arguments, and this effect is most extreme for the product. It can also be seen from the tendency of the Dubois-Prade t-norm to provide larger recall values with increasing α parameter. It is known that this parameter smoothly transits the operation result from the minimum ($\alpha \to 0$) to the product of its arguments for $\alpha \to 1$.
- We can find OOWA and lexmin rather close together, and with comparable large precision and recall values. Especially, there is the same result for exponential and linear OOWA. Recalling the discussion of the introduction of these operators, and their motivation from the maximizing property of the BFC algorithm, this is an indication that there is no strong "sharing" between the quality measures. It means that the increase of a quality measure can be gracefully done without the need to decrease other quality measures. On the other hand, lexmin can also be seen as an OOWA with weights converging to infinity, and the results are rather similar, just a little bit smaller.
- Averaging relations in general do perform less well, compared to other relations. Especially for the fuzzy fusion fairness with nearly equal OWA weights it gives the lowest precision and recall values (except Pareto minimum). Also the largest component alone is not much indicative for the user rating.
- The default suite of relations, esp. the number of larger components relation, confirms the findings from the other relations: the number of larger quality measures can be seen as the primary criterion for the user rating, and the corr. trade-off as secondary criterion. But it seems in this trade-off the user is not much considering the choice of which of the other measures is actually decreased.

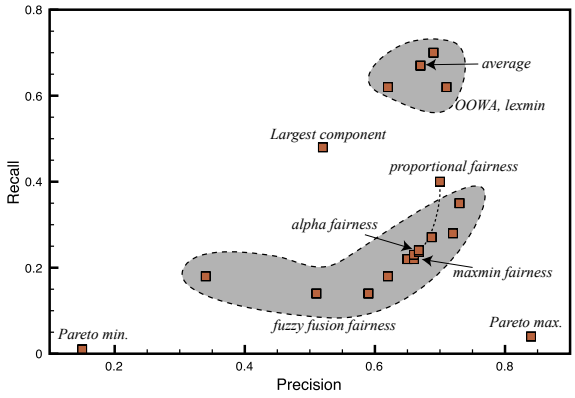

Fig. 3. Precision vs. Recall for the used relations.

V. Conclusions

We have provided formal representations for user preferences, also taking fairness among the achievement of probably conflicting goals into account. Their further expansion by introducing fuzzy fusion operators in their formal definitions than established a comprehensive set of relations. The application of these relations for a Multiple Relation Analysis (MRA) for the analysis of subjective video quality evaluation data is demonstrated and gives the conclusion that also fairness criterions are present in such evaluations, at least as a secondary preference criterion. Further work will have to focus on the

APPENDIX

Outline of the proof for Theorem 1

The following lemma indicates a minimizing property of the OOWA against all OWA using the same set of weights:

Lemma 1. *Given a set of n weights w in non-decreasing order, and any permutation $w*$ of these weights. Then for any $x \in R^n$*

$$OOWA_w(x) \leq OWA_{w*}(x) \tag{10}$$

Proof: We will use bracketed subscripts to refer to the different orderings. By $x_{(i)}$ we indicate the i-th largest element of x, by $w_{(i*)}$ the i-th element in the permutation $w*$ of the weights. We also define $h_i = x_{(n-i+1)} - x_{(n-i+2)}$ for $i > 1$ and $h_1 = x_{(n)}$. Then, $x_{(i)} = \sum_{k=1}^{n-i+1} h_k$ and it follows:

$$
\begin{aligned}
OWA_{w*}(x) &= \sum_{i=1}^{n}\left[w_{(i*)}\sum_{k=1}^{n-i+1}h_k\right] \\
= \sum_{i=1}^{n}\left[h_i\sum_{k=1}^{n-i+1}w_{(k*)}\right] &\geq \sum_{i=1}^{n}\left[h_i\sum_{k=1}^{n-i+1}w_k\right] \\
= \sum_{i=1}^{n}\left[w_i\sum_{k=1}^{n-i+1}h_k\right] &= OOWA_w(x)
\end{aligned}
$$

since the weights are sorted in non-decreasing order and thus, the sum of the first k weights will be always smaller or equal to the sum of the first k permuted weights. ■

We indicate the assignment T^* of traffics achieved by the BFC algorithm with a star t_i^*. Now we have to consider any other feasible assignment T of t_i traffic values to users. By T^+ we indicate the set of traffics that become larger in T and by T^- the set of values that become smaller (if needed, arrange the traffic indices such that for equal t^* values, T^+ traffics appear before T^- traffics). We consider a bipartite directed graph with nodes set (T^+, T^-) constructed as follows: each node represents a traffic that was modified when changing from T^* to T and keeps two values: the change δ and the weight of the traffic in the original order O. A directed link goes from a node t_1 in the "right" set of the T^--nodes to a node t_2 in the "left" set of the T^+-nodes if t_1 appears in the same bottleneck equation(s), where t_2 appears for the first time. Thus, we use a link to indicate that a reduced traffic can *compensate* for an increase in traffic in the same bottleneck equation.

Now we generate the following sum S: for each link, we multiply the weight of the incident node (i.e. for an increased traffic) and the δ-value of the outgoing node (i.e. of a decreased traffic) and sum up all products for all links. Then, from the condition for the weight increase of the exponential OOWA we can see that

$$\sum_{i,t_i\in T^-}\delta_i w_i > S \tag{11}$$

since each node on the right side is at most connected to $(k-1)$ nodes to the left, where k is the index of its weight, and all links will have a different weight factor in S with smaller weight index. On the other hand

$$S \geq \sum_{i,t_i\in T^+}\delta_i w_i \tag{12}$$

since S contains, for each increasing node, the compensating terms in the same bottleneck equation (the δ-values of decreasing traffics, to which it is connected) with the same weight as the increase appears in the modified $oowa^*$ expression. Thus, by this modification, the original OOWA expression becomes smaller. By Lemma 1, after re-arranging the weights into the correct order, the value will not increase. Thus, the total OOWA expression becomes smaller.

For assisting these arguments, figure 4 gives an example. Assuming a setup with the following bottleneck equations as a result T^* of the BFC algorithm:

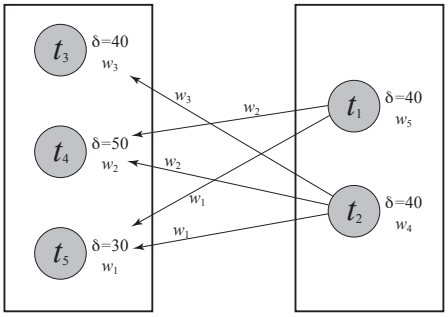

Fig. 4. Example for the bi-graph used in the proof.

$$
\begin{aligned}
t_1|_{=50} + t_2|_{=50} &= 100 \\
t_2|_{=50} + t_3|_{=60} &= 110 \\
t_1|_{=50} + t_2|_{=50} + t_4|_{=70} + t_5|_{=70} &= 240
\end{aligned}
$$

Then, we assume a change to another feasible state T as follows: $t_1 = 10, t_2 = 10, t_3 = 100, t_4 = 120, t_5 = 100$.

The set T^+ contains the elements t_3, t_4 and t_5, and the set T^- the two elements t_1 and t_2. The directed links are as shown in the figure, for example, node t_2 is connected to node t_5, since t_5 appears the first time in the 3rd bottleneck equation, and t_2 as element of T^- appears also in the same bottleneck equation.

Now there are five links and the value of S is computed as follows:

$$40 \cdot w_1 + 40 \cdot w_1 + 40 \cdot w_2 + 40 \cdot w_2 + 40 \cdot w_3 \tag{13}$$

and from $w_4 > w_1 + w_2 + w_3$ and $w_5 > w_1 + w_2 + w_3 + w_4 > w_1 + w_2$ it can be seen that the weighted sum for the right nodes exceeds S: $40 \cdot w_4 + 40 \cdot w_5 > S$.

For the left nodes, we can see that S contains all terms needed to compensate the weighted sum of all T^+ changes as well:

- For t_3, which increases the $oowa^*$ value by $40w_3$, S contains the (necessary) compensation of the increase in the second bottleneck equation from node t_2 ($40w_3$).
- For t_4, which increases the $oowa^*$ value by $50w_2$, S contains a compensation from decreasing t_1 by 40 and t_2 by 40, both weighted by w_2 in S.
- For t_5 with increase $30w_1$, the connecting links from t_1 and t_2 provide a compensation for the increase by a decrease of 40 and are weighted with w_1 in S.

So it can be seen that the sum of all changes for T^+ nodes (smaller or equal to S) increases the original OOWA by a smaller amount than the sum of all changes for T^- nodes (larger than S).

***Abstract*—In this paper, the triangular interval type-2 fuzzy set extension of the Analytic Hierarchy Process is introduced. The priority vectors are elicited from the pairwise comparison matrix with triangular interval type-2 fuzzy sets which represent the linguistic relative importance judged by experts. First, the triangular interval type-2 fuzzy set logarithmic regression function is defined with respect to the pairwise comparison matrix of the criteria. Then, the sets of linear systems corresponding to the end points of the upper and lower membership functions are formulated by minimizing the logarithmic regression function. The non-normalized weights are solved. It is shown in this paper that the sets of linear systems are all dependent. Accordingly, the final normalized weights can be obtained. A quadratic programming model for finding the optimum normalized weights is constructed in the sense of minimizing the fuzziness of the interval type-2 fuzzy weights. Analogously, if the pairwise comparisons are for the alternatives, then the final normalized triangular interval type-2 fuzzy rates are also obtained. The aggregation process of the triangular interval type-2 fuzzy sets is proposed to obtain the overall rate of each alternative. The interval type-2 fuzzy set ranking method is proposed and used to find the final preference of the alternatives. A numerical example about selecting the best professor candidate is examined.**

Keywords: Analytic Hierarchy Process, Interval Type-2 Fuzzy Sets, Multiple Criteria Decision Making, Pairwise Comparison Matrix

I. Introduction

Analytic hierarchy process (AHP) is developed by Saaty[1] to find the priority of a set of alternatives under the given relative importance opinions to the pairs of criteria. In real life, some judgments might not be given as an exact relative scale. The linguistic scales are used instead. The fuzzy version of the extensions of Saaty's priority theory was proposed by de Graan[2] and Loostma[3]. Based on their fuzzy extension, van Laarhoven and Pedrycz[4] formally presented a method to find the fuzzy priority vector from a fuzzy pairwise comparison matrix(FPCM) with the triangular fuzzy numbers(TFN) as the matrix elements. By proposing a normalization modification of the fuzzy priority vector from Loostma's LSMR algorithm, Boender, Graan and Lootsma[5] pointed out that the normalized solution violates the first-order conditions, i.e. the applied normalization destroys optimality. Another approach to find the priority vector was based on the row and column geometric means(RCGM) which was studied by Uppuluri[6], Aczel[7] and Koczkodaj[8]. Buckley[9] was the first one to develop the fuzzy geometric mean method to find the fuzzy priority vector(weights). Actually, Buckley developed the interval geometric mean method for obtaining the interval priority vector for interval comparison matrix. His algorithm can be applied to any general fuzzy numbers and not just for TFN. However, the numerical evaluation process is tedious. The original Saaty's AHP model is of crisp opinions, which is too restrictive for experts to judge. Almost all the studies dealing with the extension to fuzzy criteria are using type-1 fuzzy sets. The uncertainty of the relative importance among criteria can be further given by words which are modelled by interval type-2 fuzzy sets(IT2FSs)([10]).

In this paper, the triangular IT2FS extension of the classical AHP is introduced and the IT2FS priority vector(weighting vector) are elicited from the pairwise comparison matrix with triangular IT2FS elements which represent the linguistic relative importance judged by experts. First, the triangular IT2FS logarithmic regression function is defined with respect to the triangular IT2FS pairwise comparison matrix of the criteria. Secondly, five sets of linear systems corresponding to the end points of the upper and lower membership functions are formulated by minimizing the logarithmic regression function. Finally, the non-normalized triangular IT2FS weight of the criteria are solved. It is shown in this paper that the sets of linear systems are all dependent. Accordingly, the final normalized weights can be obtained. A linear programming model for finding the optimum normalized weights is constructed in the sense of minimizing the fuzziness of the interval type-2 fuzzy weights. The final normalized weights can be obtained. Analogously, if the pairwise comparison are given for the alternatives, then the final normalized triangular IT2FS rates are also obtained by the same mathematical analysis. The aggregation process of the triangular IT2FS is also proposed to obtain the overall rate of each alternative. After obtaining the triangular IT2FS overall rates of the alternatives, the IT2FS ranking method is introduced and used to find the preference of the alternatives.

The rest of this paper is organized as follows: Section 2 presents definitions of the triangular IT2FS and some arithmetic and transcendental operations. Section 3 formulates the mathematical model by proposing the triangular IT2FS logarithmic regression function. The non-normalized solutions are obtained. Section 4 proposes the normalized solutions by applying the dependent conditions of the linear systems. It is shown that the sets of linear systems are all dependent. Accordingly, the final normalized weights can be obtained. A quadratic programming model for finding the optimum

normalized weights is constructed in the sense of minimizing the fuzziness of the interval type-2 fuzzy weights. Section 5 proposes the aggregation process of the triangular IT2FS weights of the criteria and the rates of the decision alternatives. Section 6 proposes the IT2FS ranking method. Section 7 is a numerical example about the decision of selecting the best candidate of a college professor in Operations Research.

II. Triangular Interval Type-2 Fuzzy Sets

A. Some Definitions of Expressions

We need to define some terms and approximation operations for the model.

The triangular interval type-2 fuzzy number is defined as in the following.

Let $\tilde{\tilde{a}} = \left(\left[\underline{l}, \overline{l}\right], m, [\underline{u}, \overline{u}]\right)$ be a triangular interval type-2 fuzzy number. The upper and lower membership functions of $\tilde{\tilde{a}}$ is

$$\mathrm{UMF}_{\tilde{\tilde{a}}}(x) = \begin{cases} \dfrac{x-\underline{l}}{m-\underline{l}}, & \underline{l} \le x \le m \\ \dfrac{x-\overline{u}}{m-\overline{u}}, & m \le x \le \overline{u} \end{cases},$$

$$\mathrm{LMF}_{\tilde{\tilde{a}}}(x) = \begin{cases} \dfrac{x-\overline{l}}{m-\overline{l}}, & \overline{l} \le x \le m \\ \dfrac{x-\underline{u}}{m-\underline{u}}, & m \le x \le \underline{u} \end{cases}.$$

The footprint of uncertainty(FOU) of the membership function is depicted on Fig. 1.

Some approximation operations are defined as follows.

Definition 1. The inverse of a triangular interval type-2 fuzzy number is defined as

$$\frac{1}{\tilde{\tilde{a}}} = \left(\left[\frac{1}{\overline{u}}, \frac{1}{\underline{u}}\right], \frac{1}{m}, \left[\frac{1}{\overline{l}}, \frac{1}{\underline{l}}\right]\right).$$

Definition 2. The logarithm of a triangular interval type-2 fuzzy number is defined as

$$\ln \tilde{\tilde{a}} = \left(\left[\ln \underline{l}, \ln \overline{l}\right], \ln m, [\ln \underline{u}, \ln \overline{u}]\right).$$

Definition 3. The exponential of a triangular interval type-2 fuzzy number is defined as

$$\exp \tilde{\tilde{a}} = \left(\left[\exp \underline{l}, \exp \overline{l}\right], \exp m, [\exp \underline{u}, \exp \overline{u}]\right).$$

Definition 4. The power to the positive integer n of a triangular interval type-2 fuzzy number is defined as

$$\tilde{\tilde{a}}^n = \left(\left[\underline{l}^n, \overline{l}^n\right], m^n, [\underline{u}^n, \overline{u}^n]\right).$$

Definition 5. The negative of a triangular interval type-2 fuzzy number is defined as

$$-\tilde{\tilde{a}} = \left(\left[-\overline{u}, -\underline{u}\right], -m, \left[-\overline{l}, -\underline{l}\right]\right).$$

Based on the definitions above, we can define the binary operations as follows.

Definition 6. Let $\tilde{\tilde{a}} = \left(\left[\underline{a}^l, \overline{a}^l\right], a^m, [\underline{a}^u, \overline{a}^u]\right)$ and $\tilde{\tilde{b}} = \left(\left[\underline{b}^l, \overline{b}^l\right], b^m, \left[\underline{b}^u, \overline{b}^u\right]\right)$ be two triangular interval type-2 fuzzy numbers. The sum of $\tilde{\tilde{a}}$ and $\tilde{\tilde{b}}$ is

$$\tilde{\tilde{a}} + \tilde{\tilde{b}} = \left(\left[\underline{a}^l + \underline{b}^l, \overline{a}^l + \overline{b}^l\right], a^m + b^m, \left[\underline{a}^u + \underline{b}^u, \overline{a}^u + \overline{b}^u\right]\right).$$

Definition 7. Let $\tilde{\tilde{a}} = \left(\left[\underline{a}^l, \overline{a}^l\right], a^m, [\underline{a}^u, \overline{a}^u]\right)$ and $\tilde{\tilde{b}} = \left(\left[\underline{b}^l, \overline{b}^l\right], b^m, \left[\underline{b}^u, \overline{b}^u\right]\right)$ be two triangular interval type-2 fuzzy numbers. The difference of $\tilde{\tilde{a}}$ and $\tilde{\tilde{b}}$ is defined thru the negation as $\tilde{\tilde{a}} - \tilde{\tilde{b}} = \tilde{\tilde{a}} + \left(-\tilde{\tilde{b}}\right)$.

Definition 8. Let $\tilde{\tilde{a}} = \left(\left[\underline{a}^l, \overline{a}^l\right], a^m, [\underline{a}^u, \overline{a}^u]\right)$ and $\tilde{\tilde{b}} = \left(\left[\underline{b}^l, \overline{b}^l\right], b^m, \left[\underline{b}^u, \overline{b}^u\right]\right)$ be two triangular interval type-2 fuzzy numbers. The product of $\tilde{\tilde{a}}$ and $\tilde{\tilde{b}}$ is

$$\begin{aligned} \tilde{\tilde{a}} \cdot \tilde{\tilde{b}} = \Bigg(\Bigg[& \min\left\{\underline{a}^l \cdot \underline{b}^l, \underline{a}^l \cdot \overline{b}^l, \overline{a}^l \cdot \underline{b}^l, \overline{a}^l \cdot \overline{b}^l\right\}, \\ & \max\left\{\underline{a}^l \cdot \underline{b}^l, \underline{a}^l \cdot \overline{b}^l, \overline{a}^l \cdot \underline{b}^l, \overline{a}^l \cdot \overline{b}^l\right\}\Bigg], \\ & a^m \cdot b^m, \Big[\min\left\{\underline{a}^u \cdot \underline{b}^u, \underline{a}^u \cdot \overline{b}^u, \overline{a}^u \cdot \underline{b}^u, \overline{a}^u \cdot \overline{b}^u\right\}, \\ & \max\left\{\underline{a}^u \cdot \underline{b}^u, \underline{a}^u \cdot \overline{b}^u, \overline{a}^u \cdot \underline{b}^u, \overline{a}^u \cdot \overline{b}^u\right\}\Big]\Bigg). \end{aligned}$$

Definition 9. Let $\tilde{\tilde{a}} = \left(\left[\underline{a}^l, \overline{a}^l\right], a^m, [\underline{a}^u, \overline{a}^u]\right)$ and $\tilde{\tilde{b}} = \left(\left[\underline{b}^l, \overline{b}^l\right], b^m, \left[\underline{b}^u, \overline{b}^u\right]\right)$ be two triangular interval type-2 fuzzy numbers, where $\underline{b}^l > 0$ or $\overline{b}^u < 0$. The quotient $\tilde{\tilde{a}}$ and $\tilde{\tilde{b}}$ is defined thru the inverse and multiplication as $\tilde{\tilde{a}}/\tilde{\tilde{b}} = \tilde{\tilde{a}} \cdot \left(1/\tilde{\tilde{b}}\right)$.

All the definitions above are well-defined, because if the type-2 fuzzy numbers are reduced to the type-1 fuzzy numbers or even further to the crisp numbers, then the operations would result in the ordinary traditional definitions of the operations of real numbers.

III. Mathematical Model of Logarithmic Regression Function

The interval type-2 fuzzy pairwise comparison matrix (IT2FPCM) is like

$$\begin{pmatrix} 1 & \tilde{\tilde{\mathbf{r}}}_{12} & \cdots & \tilde{\tilde{\mathbf{r}}}_{1n} \\ \tilde{\tilde{\mathbf{r}}}_{21} & 1 & \cdots & \tilde{\tilde{\mathbf{r}}}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{\tilde{\mathbf{r}}}_{n1} & \tilde{\tilde{\mathbf{r}}}_{n2} & \cdots & 1 \end{pmatrix}$$

where $\tilde{\tilde{\mathbf{r}}}_{ij} = \left[\tilde{\tilde{r}}_{ij1}, \tilde{\tilde{r}}_{ij2}, \cdots, \tilde{\tilde{r}}_{ij\delta_{ij}}\right]^T$ and δ_{ij} is the number of judgments given by experts for the preference of the criterion i to the criterion j. The triangular interval type-2 fuzzy number $\tilde{\tilde{r}}_{ijk}$ is the relative comparison judgment of the criterion i to the criterion j given by the k^{th} expert. Note that $\delta_{ij} = \delta_{ji}$ and some δ_{ij} could be 0 but not all $\delta_{ij} = 0$ for $i = 1, 2, \cdots, n; i \neq j$. In other words, it is not reasonable that no any judgments of criterion i to other criteria are given.

Let $\tilde{\tilde{w}}_i$ be the absolute weight for the criterion i. Based on the assumption that $\tilde{\tilde{r}}_{ijk} \approx \tilde{\tilde{w}}_i / \tilde{\tilde{w}}_j$, and to obtain the optimal solutions for $\tilde{\tilde{w}}_i$, it is required that

$$\text{Min} J = \sum_{i=1}^{n} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \tilde{\tilde{r}}_{ijk} - \ln \frac{\tilde{\tilde{w}}_i}{\tilde{\tilde{w}}_j} \right)^2. \quad (1)$$

Let $\tilde{\tilde{r}}_{ijk} = \left(\left[\underline{r}^l_{ijk}, \overline{r}^l_{ijk} \right], r^m, \left[\underline{r}^u_{ijk}, \overline{r}^u_{ijk} \right] \right)$ and $\tilde{\tilde{w}}_i = \left(\left[\underline{w}^l_i, \overline{w}^l_i \right], w^m_i, [\underline{w}^u_i, \overline{w}^u_i] \right)$. Using the definitions, the logarithmic regression equation (2) can be expressed as

$$\begin{aligned} \text{Min } J &= \sum_{i=1}^{n} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \tilde{\tilde{r}}_{ijk} - \ln \frac{\tilde{\tilde{w}}_i}{\tilde{\tilde{w}}_j} \right)^2 \\ &= \sum_{i=1}^{n} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \tilde{\tilde{r}}_{ijk} - \ln \tilde{\tilde{w}}_i + \ln \tilde{\tilde{w}}_j \right)^2. \quad (2) \end{aligned}$$

Extending the type-1 fuzzy models from [4], [5], [11] and using the definitions 2, 5, 9, the approximation of (2) can be expressed as

$$\begin{aligned} &\text{Min } J = \\ &\sum_{i=1}^{n} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \underline{r}^l_{ijk} - \ln \underline{w}^l_i + \ln \overline{w}^l_j \right)^2 \quad (3) \\ &+ \sum_{i=1}^{n} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \overline{r}^l_{ijk} - \ln \overline{w}^l_i + \ln \underline{w}^l_j \right)^2 \quad (4) \\ &+ \sum_{i=1}^{n} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln r^m_{ijk} - \ln w^m_i + \ln w^m_j \right)^2 \\ &+ \sum_{i=1}^{n} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \underline{r}^u_{ijk} - \ln \underline{w}^u_i + \ln \overline{w}^l_j \right)^2 \quad (5) \\ &+ \sum_{i=1}^{n} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \overline{r}^u_{ijk} - \ln \overline{w}^u_i + \ln \underline{w}^l_j \right)^2. \quad (6) \end{aligned}$$

To get the minimum of J, it is required that

$$\frac{\partial J}{\partial \underline{w}^l_i} = \frac{-2}{\underline{w}^l_i} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \underline{r}^l_{ijk} - \ln \underline{w}^l_i + \ln \overline{w}^l_j \right) = 0, \quad (7)$$

$$\frac{\partial J}{\partial \overline{w}^l_i} = \frac{-2}{\overline{w}^l_i} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \overline{r}^l_{ijk} - \ln \overline{w}^l_i + \ln \underline{w}^l_j \right) = 0, \quad (8)$$

$$\frac{\partial J}{\partial w^m_i} = \frac{-2}{w^m_i} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln r^m_{ijk} - \ln w^m_i + \ln w^m_j \right) = 0, \quad (9)$$

$$\frac{\partial J}{\partial \underline{w}^u_i} = \frac{-2}{\underline{w}^u_i} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \underline{r}^u_{ijk} - \ln \underline{w}^u_i + \ln \overline{w}^l_j \right) = 0, \quad (10)$$

$$\frac{\partial J}{\partial \overline{w}^u_i} = \frac{-2}{\overline{w}^u_i} \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \left(\ln \overline{r}^u_{ijk} - \ln \overline{w}^u_i + \ln \underline{w}^l_j \right) = 0, \quad (11)$$

for $i = 1, 2, \cdots n$. The equations (7)~(11) can be divided into three uncoupled linear systems,

$$\begin{aligned} \begin{bmatrix} D & E \\ E & D \end{bmatrix} \begin{bmatrix} \underline{\mathbf{l}} \\ \overline{\mathbf{u}} \end{bmatrix} &= \begin{bmatrix} \underline{\mathbf{b}}^l \\ \overline{\mathbf{b}}^u \end{bmatrix}, \quad (12) \\ [D+E]\,\overline{\mathbf{m}} &= \mathbf{b}^m, \quad (13) \\ \begin{bmatrix} D & E \\ E & D \end{bmatrix} \begin{bmatrix} \overline{\mathbf{l}} \\ \underline{\mathbf{u}} \end{bmatrix} &= \begin{bmatrix} \overline{\mathbf{b}}^l \\ \underline{\mathbf{b}}^u \end{bmatrix}., \quad (14) \end{aligned}$$

where $D = diag(\sum_{j=2}^{n} \delta_{1j}, \sum_{\substack{j=1 \\ j\neq 2}}^{n} \delta_{2j}, \cdots, \sum_{j=1}^{n-1} \delta_{nj})$, and $E = [e_{ij}]$ with $e_{ij} = \begin{cases} 0, & i = j \\ -\delta_{ij}, & i \neq j \end{cases}$, and the unknowns are $\mathbf{t} = [\ln w^t_i]$, $t = l$ or u, the knowns are $\mathbf{b}^t = [b^t_i]$, $b^t_i = \sum_{\substack{j=1 \\ j\neq i}}^{n} \sum_{k=1}^{\delta_{ij}} \ln \underline{r}^l_{ijk}$, $t = l$ or u or m. Both $\mathbf{t}$ and $\mathbf{b}$ can be appended the underline or overline. Furthermore, let $A = \begin{bmatrix} D & E \\ E & D \end{bmatrix}$, $A^m = D + E$, the linear systems (12)~(14) can be expressed as

$$\begin{aligned} A\mathbf{w}_1 &= \mathbf{b}_1, \quad (15) \\ A^m \mathbf{w}^m &= \mathbf{b}^m, \quad (16) \\ A\mathbf{w}_2 &= \mathbf{b}_2. \quad (17) \end{aligned}$$

The linear systems (15)~(17) which are uncoupled can be solved independently. If each $\delta_{ij} \neq 0$, then it can be easily shown that A and A^m are not of full rank. Each of the linear system (15)~(17) has infinite many solutions. The solutions exist for systems (15)~(17).

A. Theorems

Since the judgment matrix is reciprocal, we have $\tilde{\tilde{r}}_{jik} = 1/\tilde{\tilde{r}}_{ijk}$ and $\ln \tilde{\tilde{r}}_{jik} = -\ln \tilde{\tilde{r}}_{ijk}$. It follows that

$$\begin{aligned}&\ln\left(\left(\left[\underline{r}^l_{jik}, \overline{r}^l_{jik}\right], r^m_{jik}, \left[\underline{r}^u_{jik}, \overline{r}^u_{jik}\right]\right)\right)\\ &= -\ln\left(\left[\underline{r}^l_{ijk}, \overline{r}^l_{ijk}\right], r^m, \left[\underline{r}^u_{ijk}, \overline{r}^u_{ijk}\right]\right).\end{aligned}$$

The rank of A and the rank of the augmented matrices $\left[\begin{array}{cc} A & \mathbf{b}_1 \end{array}\right]$ and $\left[\begin{array}{cc} A & \mathbf{b}_2 \end{array}\right]$ are the same and the dimension of the null space of A is 1. Also, the rank of A^m and the augmented matrix $\left[\begin{array}{cc} A^m & \mathbf{b}^m \end{array}\right]$ are the same and the dimension of the null space of A^m is equal to 1. Therefore, all the three linear systems (15)~(17) have infinite many solutions.

It is suffice to assume that each of δ_{ij}, $i = 1, 2, \cdots, n; i \neq j$ is not equal to 0 on the following theorems and corollaries. Let $\mathbf{1} = [1, 1, \cdots, 1]^t$ in the sequel.

Theorem 1. *The nullity of the coefficient matrix A of the linear system (15) is 1 and the null space of A is span $\{\mathbf{1}\}$.*

Proof: The proof can be easily followed by the row reduced echelon form of A. ■

Theorem 2. *The rank of A is the same as the augmented matrix $\left[\begin{array}{cc} A & \mathbf{b}_1 \end{array}\right]$ of the linear system (15).*

Proof: The proof can be easily followed by the row reduced echelon form of the augmented matrix $\left[\begin{array}{cc} A & \mathbf{b}_1 \end{array}\right]$. ■

Theorem 3. *The rank of A is the same as the augmented matrix $\left[\begin{array}{cc} A & \mathbf{b}_2 \end{array}\right]$ of the linear system (17).*

Proof: The proof is the same as in Theorem 2. ■

Corollary 1. *The linear system (15) has infinite solutions with two degrees of freedom.*

Proof: The solution space has two degrees of freedom, because the nullity of the coefficient matrix is 1. ■

Corollary 2. *The linear system (17) has infinite solutions with two degrees of freedom.*

Proof: The proof is the same as in 1. ■

Let A^+ be the Moore-Penrose pseudo-inverse of A[12, p.432], then the particular solutions of (15) and (17) are

$$\mathbf{w}^p_1 = A^+\mathbf{b}_1, \tag{18}$$
$$\mathbf{w}^p_2 = A^+\mathbf{b}_2. \tag{19}$$

The general solution can be expressed as

$$\mathbf{w}_1 = A^+\mathbf{b}_1 + p_1\mathbf{1},\ p_1 \in \mathbb{R}. \tag{20}$$
$$\mathbf{w}_2 = A^+\mathbf{b}_2 + p_2\mathbf{1},\ p_2 \in \mathbb{R}. \tag{21}$$

Theorem 4. *The nullity of the coefficient matrix A^m of the linear system (16) is 1 and the null space of A^m is span $\{\mathbf{1}\}$.*

Proof: The proof can be easily followed by the row reduced echelon form of A^m. The nullity of A^m is 1, and the null space is span $\{\mathbf{1}\}$. ■

Theorem 5. *The rank of A^m is the same as the augmented matrix $\left[\begin{array}{cc} A^m & \mathbf{b}^m \end{array}\right]$ of the linear system (16).*

Proof: The proof can be easily followed by the row reduced echelon form of the augmented matrix $\left[\begin{array}{cc} A^m & \mathbf{b}^m \end{array}\right]$. The rank of the augmented matrix $\left[\begin{array}{cc} A^m & \mathbf{b}^m \end{array}\right]$ is $(n-1)$ which is equal to the rank of A^m. ■

Corollary 3. *The linear system (16) has infinite solutions with one degrees of freedom.*

Proof: The solution space has one degrees of freedom, because the nullity of the coefficient is 1. ■

Let A^{m+} be the Moore-Penrose pseudo-inverse of A^m[12, p.432], then the particular solution $\mathbf{w}^{m,p}$ is $A^{m+}\mathbf{b}^m$. The general solution can be expressed as

$$\mathbf{w}^m = A^{m+}\mathbf{b}^m + p_m\mathbf{1},\ p_m \in \mathbb{R}. \tag{22}$$

IV. Normalization

The weight $\tilde{\tilde{w}}_i = \left(\left[\underline{l}_i, \overline{l}_i\right], m_i, \left[\underline{u}_i, \overline{u}_i\right]\right)$ is a triangular interval type-2 fuzzy weights for the criteria. It should be well-defined and satisfied the inequalities

$$\underline{l}_i \leq \overline{l}_i \leq m_i \leq \underline{u}_i \leq \overline{u}_i. \tag{23}$$

From Corollaries 1 and 3, the final solution of the weight of a certain criterion has three degrees of freedom. The suitable or the optimal parameters can be selected such that the final solution of the weight is a well-defined triangular interval type-2 fuzzy number.

From (20) and (22), we have

$$\ln \tilde{\tilde{w}}_i = \left(\left[\underline{l}_i + p_1, \overline{l}_i + p_2\right], m_i + p_m, \left[\underline{u}_i + p_2, \overline{u}_i + p_1\right]\right),$$

where s, t, v are three arbitrary parameters. The parameter v can be independently determined by normalizing modal vector in the sense of unit vector sum. Namely, $\sum_{i=1}^n \exp(m_i + p_m) = 1$,then we have

$$p_m = -\ln\left(\sum_{i=1}^n \exp m_i\right). \tag{24}$$

The other two parameters s, t can be determined by minimizing the spans of the supports of the FOU. A quadratic programming(QP) model can be constructed to find the optimal

solution for p_1 and p_2.

$$\begin{aligned}
&\min J \\
&= \sum_{i=1}^{n} \Big(\big((\bar{l}_i + p_2) - (\underline{l}_i + p_1) \big)^2 \\
&+ \big((m_i + p_m) - (\bar{l}_i + p_2) \big)^2 \\
&+ \big((\underline{u}_i + p_2) - (m_i + p_m) \big)^2 \\
&+ \big((\overline{u}_i + p_1) - (\underline{u}_i + p_2) \big)^2 \Big) \\
&\underline{l}_i + p_1 \le \bar{l}_i + p_2,\ i = 1, 2, \cdots, n \\
&\underline{u}_i + p_2 \le \overline{u}_i + p_1,\ i = 1, 2, \cdots, n \\
&\bar{l}_i + p_2 \le m_i + p_m,\ i = 1, 2, \cdots, n \\
&m_i + p_m \le \underline{u}_i + p_2,\ i = 1, 2, \cdots, n \\
&p_1, p_2 \text{ unbounded.}
\end{aligned}$$

Let

$$\begin{aligned}
J' = J - \sum_{i=1}^{n} \big(& \underline{l}_i^2 + 2\bar{l}_i^2 + 2\underline{u}_i^2 + \bar{u}_i^2 \\
& + 2m_i^2 + 2p_m^2 - 2p_m \bar{l}_i \\
& - 2\bar{l}_i \underline{l}_i - 2m_i \underline{u}_i - 2p_m \underline{u}_i \\
& - 2\bar{u}_i \underline{u}_i + 4p_m m_i - 2m_i \bar{l}_i \big)
\end{aligned}$$

and introduce the following matrices and vectors,

$$\mathbf{x} = \begin{bmatrix} p_1 \\ p_2 \end{bmatrix},\ Q = \begin{bmatrix} 4n & -4n \\ -4n & 8n \end{bmatrix},$$
$$\mathbf{c} = \begin{bmatrix} \sum_{i=1}^{n} \left(-2\bar{l}_i + 2\underline{l}_i + 2\bar{u}_i - 2\underline{u}_i \right) \\ \sum_{i=1}^{n} \left(4\bar{l}_i - 2\underline{l}_i - 2\bar{u}_i + 4\underline{u}_i - 4m_i - 4v \right) \end{bmatrix},$$

the objective function of the QP model can be expressed as

$$\text{Min } J' = \frac{1}{2}\mathbf{x}^t Q \mathbf{x} + \mathbf{x}^t \mathbf{c}.$$

Since Q is a positive definite matrix, the minimizer exists and is unique. Suppose the optimal solution exists at $p_1 = p_1^\star$ and $p_2 = p_2^\star$, the optimal normalized ith IT2 triangular fuzzy weight can be expressed as

$$\begin{aligned}
\tilde{\tilde{w}}_i = & \Big(\left[\exp(p_1^\star) \cdot \exp \underline{l}_i, \exp(p_2^\star) \cdot \exp \bar{l}_i \right], \\
& \frac{\exp m_i}{\sum_{j=1}^{n} \exp m_j}, \\
& \left[\exp(p_2^\star) \cdot \exp \underline{u}_i, \exp(p_1^\star) \cdot \exp \overline{u}_i \right] \Big).
\end{aligned}$$

V. Aggregation

Let $\tilde{\tilde{r}}_i = \left(\left[\underline{r}_i^l, \overline{r}_i^l \right], r_i^m, \left[\underline{r}_i^u, \overline{r}_i^u \right] \right)$ be the rate for a certain alternative corresponding to the i^{th} criterion whose weight is $\tilde{\tilde{w}}_i = \left(\left[\underline{w}_i^l, \overline{w}_i^l \right], w_i^m, \left[\underline{w}_i^u, \overline{w}_i^u \right] \right)$. We propose two approaches to find the IT2 fuzzy weighted average(FWA) for IT2 TFNs. One is using the linear programming models to find the uncertainty supports of the lower membership function (LMF) and upper membership function(UMF). The other is a direct extension from the interval weighted average to the IT2 FWA of the IT2 TFNs.

A. Aggregation by Linear Programming

Model-I(lower bound of UMF)

$$\begin{aligned}
\text{Min } \underline{r}_{\text{ave}}^l &= \sum_{i=1}^{n} \underline{r}_i^l \cdot w_i, \\
\frac{\underline{w}_i^l}{\sum_{j=1}^{n} \overline{w}_j^u} &\le w_i \le \frac{\overline{w}_i^u}{\sum_{j=1}^{n} \underline{w}_i^l},\ i = 1, 2, \cdots n, \\
\sum_{i=1}^{n} w_i &= 1.
\end{aligned}$$

Model-II(lower bound of LMF)

$$\begin{aligned}
\text{Min } \overline{r}_{\text{ave}}^l &= \sum_{i=1}^{n} \overline{r}_i^l \cdot w_i, \\
\frac{\overline{w}_i^l}{\sum_{j=1}^{n} \underline{w}_j^u} &\le w_i \le \frac{\underline{w}_i^u}{\sum_{j=1}^{n} \overline{w}_j^l},\ i = 1, 2, \cdots n, \\
\sum_{i=1}^{n} w_i &= 1.
\end{aligned}$$

Model-III(upper bound of LMF)

$$\begin{aligned}
\text{Max } \underline{r}_{\text{ave}}^u &= \sum_{i=1}^{n} \underline{r}_i^u \cdot w_i, \\
\frac{\overline{w}_i^l}{\sum_{j=1}^{n} \underline{w}_j^u} &\le w_i \le \frac{\underline{w}_i^u}{\sum_{j=1}^{n} \overline{w}_j^l},\ i = 1, 2, \cdots n, \\
\sum_{i=1}^{n} w_i &= 1.
\end{aligned}$$

Model-IV(upper bound of UMF)

$$\begin{aligned}
\text{Max } \overline{r}_{\text{ave}}^u &= \sum_{i=1}^{n} \overline{r}_i^u \cdot w_i, \\
\frac{\underline{w}_i^l}{\sum_{j=1}^{n} \overline{w}_j^u} &\le w_i \le \frac{\overline{w}_i^u}{\sum_{j=1}^{n} \underline{w}_i^l},\ i = 1, 2, \cdots n, \\
\sum_{i=1}^{n} w_i &= 1.
\end{aligned}$$

Let $\underline{r}_{\text{ave}}^{l\star}, \overline{r}_{\text{ave}}^{l\star}, \underline{r}_{\text{ave}}^{u\star}, \overline{r}_{\text{ave}}^{u\star}$ be the optimal solutions of the above four linear programming models, respectively, and let the modal weighted average be $r_{\text{ave}}^m = \frac{\sum_{i=1}^{n} r_i^m \cdot w_i^m}{\sum_{j=1}^{n} w_i^m}$, then interval type-2 fuzzy weighted average is

$$\tilde{\tilde{r}}_{\text{ave}} = \left(\left[\underline{r}_{\text{ave}}^{l\star}, \overline{r}_{\text{ave}}^{l\star} \right], r_{\text{ave}}^m, \left[\underline{r}_{\text{ave}}^{u\star}, \overline{r}_{\text{ave}}^{u\star} \right] \right).$$

B. Aggregation from Extension of Type-1 FWA

By extending the type-1 fuzzy weighted average, [13] introduced a set of formulas which can be used to find the supports of the LMF and UMF of the IT2 FWA as follows,

$$\underline{r}_{ave}^{l} = \frac{\sum_{i=1}^{\underline{k}^{l}} \underline{r}_{i}^{l} \cdot \overline{w}_{i}^{u} + \sum_{i=\underline{k}^{l}+1}^{n} \underline{r}_{i}^{l} \cdot \underline{w}_{i}^{l}}{\sum_{i=1}^{\underline{k}^{l}} \overline{w}_{i}^{u} + \sum_{i=\underline{k}^{l}+1}^{n} \underline{w}_{i}^{l}}, \quad (25)$$

$$\overline{r}_{ave}^{l} = \frac{\sum_{i=1}^{\overline{k}^{l}} \overline{r}_{i}^{l} \cdot \underline{w}_{i}^{u} + \sum_{i=\overline{k}^{l}+1}^{n} \overline{r}_{i}^{l} \cdot \overline{w}_{i}^{l}}{\sum_{i=1}^{\overline{k}^{l}} \underline{w}_{i}^{u} + \sum_{i=\overline{k}^{l}+1}^{n} \overline{w}_{i}^{l}}, \quad (26)$$

$$\underline{r}_{ave}^{u} = \frac{\sum_{i=1}^{\underline{k}^{u}} \underline{r}_{i}^{u} \cdot \underline{w}_{i}^{l} + \sum_{i=\underline{k}^{u}+1}^{n} \underline{r}_{i}^{u} \cdot \underline{w}_{i}^{u}}{\sum_{i=1}^{\underline{k}^{u}} \underline{w}_{i}^{l} + \sum_{i=\underline{k}^{u}+1}^{n} \underline{w}_{i}^{u}}, \quad (27)$$

$$\overline{r}_{ave}^{u} = \frac{\sum_{i=1}^{\overline{k}^{u}} \overline{r}_{i}^{u} \cdot \underline{w}_{i}^{l} + \sum_{i=\overline{k}^{u}+1}^{n} \overline{r}_{i}^{u} \cdot \overline{w}_{i}^{u}}{\sum_{i=1}^{\overline{k}^{u}} \underline{w}_{i}^{l} + \sum_{i=\overline{k}^{u}+1}^{n} \overline{w}_{i}^{u}}, \quad (28)$$

where $\underline{k}^{l}$, $\overline{k}^{l}$, $\underline{k}^{u}$, $\overline{k}^{u}$ are the indexes satisfying the following inequalities respectively,

$$\begin{aligned} \underline{r}_{\underline{k}^{l}}^{l} &\leq \underline{r}_{ave}^{l} \leq \underline{r}_{\underline{k}^{l}+1}^{l}, \\ \overline{r}_{\overline{k}^{l}}^{l} &\leq \overline{r}_{ave}^{l} \leq \overline{r}_{\overline{k}^{l}+1}^{l}, \\ \underline{r}_{\underline{k}^{u}}^{u} &\leq \underline{r}_{ave}^{u} \leq \underline{r}_{\underline{k}^{u}+1}^{u}, \\ \overline{r}_{\overline{k}^{u}}^{u} &\leq \overline{r}_{ave}^{u} \leq \overline{r}_{\overline{k}^{u}+1}^{u}. \end{aligned}$$

These indexes are commonly referred to as the thresholds for the supports of the LMFs and UMFs of the IT2 fuzzy weights and have been proved to be unique[14], [13]. Some algorithms [15], [14], [16] were developed to determine these thresholds. We adopt the algorithm from [16]. The algorithm for finding $\underline{r}_{ave}^{l}$ is as follows:

Stage1: Sort $\underline{r}_{i}^{l}$, for $i = 1, 2, \cdots, n$ in non-decreasing order and rearrange $\left[\underline{w}_{i}^{l}, \overline{w}_{i}^{u}\right]$ with respect to the reordered $\underline{r}_{i}^{l}$.

Stage2: Construct the function of index

$$\tau(i) = \frac{\sum_{j=1}^{i} \left(\underline{r}_{j}^{l} - \underline{r}_{i}^{l}\right) \cdot \overline{w}_{i}^{u} + \sum_{j=i+1}^{n} \left(\underline{r}_{j}^{l} - \underline{r}_{i}^{l}\right) \cdot \underline{w}_{i}^{l}}{\sum_{j=1}^{i} \overline{w}_{j}^{u} + \sum_{j=i+1}^{n} \underline{w}_{j}^{l}}.$$

Stage3: The threshold $\underline{k}^{l}$ exists at the index where $\tau\left(\underline{k}^{l}\right) > 0$ and $\tau\left(\underline{k}^{l}+1\right) \leq 0$.([16] proved that such index exists and is unique.)

Stage4: Substitute the threshold $\underline{k}^{l}$ into (25) to get $\underline{r}_{ave}^{l}$.

The algorithms for determining the thresholds for other supports can be constructed similarly by defining the corresponding specific index functions.

VI. Ranking of IT2FSs

The final stage of the decision making process is to rank the overall ratings of the alternatives. It is not trivial to rank a set of IT2FSs. Most of the ranking algorithms are for type-1 FSs. So far there are two mature ranking algorithms proposed in literature. [17] adopted a statistical viewpoint and interpret each type-2 fuzzy number as an ensemble of ordinary fuzzy numbers. By ranking the 32 IT2FSs which represents words for computation, [18] pointed out that Mitchell's method is highly impractical and prohibitive. Wu and Mendel proposed an extension of the type-1 FSs centroid method to obtain the centroids of a set of IT2FSs, which are used for ranking these IT2FSs. The centroid of an IT2FS is approximated by discretizing the primary domain. Let x_i be the ith sample point of the primary variable x in ascending order with index i, then the IT2FS centroid can be obtained from the following formulas

$$\begin{aligned} c_{l}(j) &= \frac{\sum_{i=1}^{j} x_i \overline{\mu}(x_i) + \sum_{i=j+1}^{n} x_i \underline{\mu}(x_i)}{\sum_{i=1}^{j} \overline{\mu}(x_i) + \sum_{i=j+1}^{n} \underline{\mu}(x_i)}, \\ c_{u}(j) &= \frac{\sum_{i=1}^{j} x_i \underline{\mu}(x_i) + \sum_{i=j+1}^{n} x_i \overline{\mu}(x_i)}{\sum_{i=1}^{j} \underline{\mu}(x_i) + \sum_{i=j+1}^{n} \overline{\mu}(x_i)}, \end{aligned}$$

for a specific switching indexes is $c = [c_l, c_u]$ where indexes k_l and k_u are the switching index such that

VII. Numerical Example

The fuzzy logarithmic least squares for fuzzy pairwise comparison matrix was proposed by [4] and modified by [5]. We investigate the same numerical example in both papers in which the type-1 fuzzy judgments are all extending to the IT2 triangular fuzzy numbers.

One of the three candidates (A, B and C) seeking for a post of professor in Operations Research is to be determined by a committee of three members. The following four criteria are identified by the committee for selecting the best candidates.

C1: Mathematical creativity,
C2: Implementation creativity,
C3: Administrative capability,
C4: Human maturity.

Fig. 2 shows the hierarchy structure of the decision making problem.

The committee members need to give the pairwise comparison judgments. All the linguistic judgments from committee members are transformed to the corresponding IT2 triangular fuzzy numbers. The set of IT2 triangular fuzzy scales that is the type-2 fuzzy extension of Saaty's scale ([19]) defined as

$$\begin{aligned} \tilde{\tilde{1}} &= ([1,1], 1, [3/2, 2]), \\ \tilde{\tilde{2}} &= ([1, 3/2], 2, [5/2, 3]), \\ \tilde{\tilde{3}} &= ([2, 5/2], 3, [7/2, 4]). \end{aligned}$$

Additionally, the reciprocals are defined by Definition 1.

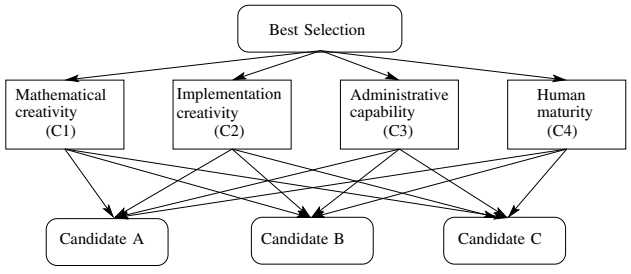

Figure 2. Hierarchy structure for the best candidate decision problem

Table I
THE PAIRWISE COMPARISON JUDGMENTS OF THE FOUR CRITERIA

$C_1 - C_2$	$C_1 - C_3$	$C_1 - C_4$	$C_2 - C_3$	$C_2 - C_4$	$C_3 - C_4$
$\left\{\tilde{\tilde{1}}, \tilde{\tilde{\frac{1}{2}}}, \tilde{\tilde{2}}\right\}$	$\left\{\tilde{\tilde{1}}\right\}$	$\left\{\tilde{\tilde{\frac{1}{3}}}, \tilde{\tilde{\frac{1}{3}}}, \tilde{\tilde{\frac{1}{2}}}\right\}$	$\left\{\tilde{\tilde{3}}, \tilde{\tilde{3}}\right\}$	$\left\{\tilde{\tilde{1}}, \tilde{\tilde{1}}, \tilde{\tilde{2}}\right\}$	$\left\{\tilde{\tilde{\frac{1}{2}}}\right\}$

Table II
PAIRWISE COMPARISONS OF THE THREE CANDIDATES WITH RESPECT TO THE FOUR CRITERIA

	A-B	A-C	B-C
C1	$\left\{\tilde{\tilde{1}}, \tilde{\tilde{1}}\right\}$	$\left\{\tilde{\tilde{1}}, \tilde{\tilde{\frac{1}{2}}}\right\}$	$\left\{\tilde{\tilde{\frac{1}{2}}}\right\}$
C2	$\left\{\tilde{\tilde{3}}\right\}$	$\left\{\tilde{\tilde{2}}\right\}$	
C3	$\left\{\tilde{\tilde{5}}, \tilde{\tilde{3}}, \tilde{\tilde{2}}\right\}$	$\left\{\tilde{\tilde{3}}\right\}$	$\left\{\tilde{\tilde{1}}\right\}$
C4		$\left\{\tilde{\tilde{2}}, \tilde{\tilde{\frac{1}{2}}}\right\}$	$\left\{\tilde{\tilde{2}}\right\}$

Table I shows the pairwise comparison judgments of the four criteria. Note that, not each of the committee members is required to give judgment for pairs of criteria. For example, only one member gives the judgment $\tilde{\tilde{\frac{1}{2}}}$ for the pair (C_3, C_4).

Table II contains the pairwise comparison judgments of the three candidates with respect to the four criteria.

Using the IT2 FLLSM and the optimal normalization process developed in this paper, the IT2 TFN weights for the four criteria are obtained and is shown in Table III and Fig. 3.

Table IV shows the IT2 fuzzy rates for three candidates with respective to the four criteria.

We apply two approaches from Section V-A and Section V-B to finding the overall aggregated IT2 fuzzy rates of the three candidates as in Tables V and VI.

Fig. 4 and Fig. 5 show the overall aggregated IT2 fuzzy rates for the three candidates. It is clear that candidate A is the best candidate.

making problems with uncertain judgments. Since most decision making problems exist in real world. The judgments are always made by human beings. Not all the experts are familiar with the mathematical properties of the decision making process. If the type of judgments given by experts can be allowed to as flexible as possible, then the collected decision data would be much more valuable. Type-2 fuzzy sets are the better mathematical quantities than type-1 fuzzy sets and even better than the crisp scales. Using type-2 fuzzy sets on decision making problems can lead to more realistic and accurate results. This paper proposes a very important approach on decision making problem with type-2 fuzzy sets specifically on the very popular decision tool, Analytic Hierarchy Process.

We extend the logarithmic least squares method proposed by [4] and formulate a quadratic model for the optimal solutions of the interval type-2 fuzzy priority weights. We also give a detail discussion about the simultaneous linear equations of the logarithmic decision variables. After obtaining these interval type-2 fuzzy weights, we construct a linear programming model to get the overall rate of interval type-2 fuzzy rates. Finally, the individual overall type-2 fuzzy rates are sorted using the centroids of the type-2 fuzzy sets.

The proposed model is for triangular type interval type-2 fuzzy sets. For different purposes, other kinds lower and upper membership functions can be used. For example, one can use triangular membership function for lower membership function and trapezoidal membership function for upper membership function or both trapezoidal membership functions for lower and upper membership function. In addition to the logarithmic least square method, other algorithms (for example, [9]) can be used to obtain the optimal type-2 fuzzy priority weights and rates. We need further studies on these topics.

***Abstract*—Document classification is critical due to explosive increasing of text in modern world. However, most of existing document classification algorithms are easily affected by noise data. Therefore, in document classification tasks, the ability of noise control is as important as the ability to classify exactly. In this paper, we propose a novel classification framework based on fuzzy formal concept analysis to moderate the impact from noise. In addition, the well-organized concepts also provide inherent relations, which support knowledge codification and distribution effectively. Experimental results using Reuters 21578 dataset demonstrates significant noise control benefit and superior classification accuracy.**

Keywords-text classification; fuzzy formal concept analysis; noise control; information retrieval

I. INTRODUCTION

The explosive increasing of text in modern world contributes the increasing need to provide automatic document classification and categorization. The well-organized categories of document are efficient in browser, retrieval and dissemination. Most existing document classification algorithms operate in a high dimensional vocabulary space while computing document similarities and relevance. However, the document classification procedure are easily affected by term-based inner product, cosine coefficient operations and noise data, such as synonym, antonym or words with multiple meanings [1]. Thus, the ability of handling noise is one of the important indicators for a text analysis algorithm and the reason why it can produces more useful results than others [2]. Moreover, for effectively controlling noise without eliminating relevant information, the parameter setting is another delicate topic. For example, when excessive parameter is applied for filtering irrelevant data, it is possible to remove some significant messages as well. Thus, the tradeoff parameter settings may vary regarding to different sources of data and needs to be careful examined especially in practical implementations.

One way to solve the noise problem in document classification is to decrease the impact from terms in document vectors. Since a vector is composed of a document and key terms, we consider that the technique, which can transforms the inherent relations between document and terms to a more abstract form, may appropriate for noise control. The more general elements are capable of resisting specific noise-sensitive variations. Formal concept analysis (FCA) formulates concepts in terms of documents and their properties, terms, and provides a way of combining and organizing individual concepts of a given context into a hierarchical ordered conceptual structure [3]. In the last few years, several researches have shown the capacity of FCA in information retrieval and management. In FCA lattice, the document collection can be organized into a reasonable consensus with good efficiency in retrieval performance, its structural comprehension is valuable to extract implication rules and classify documents in a suitable category [4], [5]. The path, location and hierarchical relations of concepts in FCA are successful to provide significant relations of keywords and documents [6]. While the weight of each term in a document is not simply belongs or does not belongs, we further utilize fuzzy formal concept analysis (FFCA) to take uncertain information into consideration.

The objective of this research is to develop a document classification scheme which can tolerate noise data. The structure of the paper is organized as follows. Section 2 reviews underlying technologies on formal concept analysis and Section 3 describes the specifics of the research methodology and system development process. Section 4 illustrates the results and discusses performance evaluation. Finally, Section 5 draws conclusions on the paper and provides insights on future work.

II. FUZZY FORMAL CONCEPT ANALYSIS

A. Formal Concept Analysis

Formal concept analysis (FCA) is a mathematical approach proposed by Wille[7] used for structuring, analyzing and visualizing data, based on a notion of duality called Galois connection[8]. Data consisting of a set of entities and their features are structured into formal abstractions called formal concepts, which together form a concept lattice ordered by a partial order relation. Concept lattices are constructed by identifying the objects and their corresponding attributes for a specific domain, called conceptual structures, and then displaying the relationships between them.

In FCA, a context is represented as a triple *(O, A, R)* where *O* is a set of objects, *A* is a set of elements and *R* is a binary relation between *O* and *A*. If for an object o and an attribute a, *oRa* holds, when we say that "object *o* has attribute *a*", or "attribute *a* applies to object *o*". Table 1 shows an context of an animal environment, where each row is an object representing

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

an animal, each column is an attribute, and each X represents the existence of the relationship.

TABLE I. THE CONTEXT OF A ANIMAL ENVIRONMENT

	Hunt	Fly	Bird	Mammal
Lion	×			
Warbler		×	×	
Eagle	×	×	×	
Rabbit				×
Ostrich			×	

Two sets can be derived from a given formal context (*O, A, R*), one from the perspective of objects and another form the viewpoint of attributes. The former is a subset of objects $I \subseteq O$ such that I' is defined by the attributes that apply to all objects belonging to I and the later is a subset of attributes $J \subseteq A$ such that J' is defined by the objects that have all attributes belonging to J. Correspondingly,

$$I' = \{a \subseteq A | oRa \ \forall o \in I\},$$

$$J' = \{o \subseteq O | oRa \ \forall a \in J\},$$

thus the pair *(I, J)*, where $I \subseteq O$ and $J \subseteq A$, is a formal concept of the context (*O, A, R*) if *I'=J* and *J'=I*. The formal concept (*I, J*) is a pair where I consist of those objects that have all attributes from the set J, and equally, J consists of those attributes that apply to all objects from the set I. additionally, the set of objects is known as the extent of the concept and the set of attributes as the intent.

B. *Fuzzy Formal Concept Analysis*

Fuzzy formal concept analysis (FFCA) was introduced by Tho et al.[9] by incorporating fuzzy logic into FCA in order to represent vague information. Traditional FCA uses a binary approach indicating the presence or absence of the relation between an object and an attribute and cannot take uncertain information into consideration, while FFCA extends the relation into a value in the interval of real numbers between 0 and 1 called membership value. In this way, the relation is not simply belongs or does not belong anymore, but can take a set of values indicating a degree of belonging. This membership value of an attribute towards an object is proportional to its significance and can be used to calculate a similarity value between two formal concepts. These notions are represented in the following definitions.

Definition 1 (Fuzzy formal context) A fuzzy formal context is a triple (G, M, F=φ(G×M)). Where G is a set of objects, M is a set of attributes, and F is a fuzzy relation between G and M. Each relation $(g, m) \in F$ has a membership value $\mu(g, m)$ in [0, 1].

Definition 2 (Fuzzy formal concept). A fuzzy formal concept of a fuzzy formal concept of a fuzzy context (G, M, F) is a pair $(\varphi(Y), Z)$ for $Y \subseteq G$ and $Z \subseteq M$, where each object $g \in \varphi(Y)$ has a membership value $\mu_Y(g) = \min_{m \in Z} \mu(g, m)$ with $\mu(g, m)$ being the membership value of $(g, m) \in F$.

Definition 3 (Fuzzy formal concept cardinality). The fuzziness of a fuzzy formal concept is represented by membership values of objects of the concept, hence the cardinality of a fuzzy formal concept $(\varphi(Y), Z)$ is defined as $|\varphi(Y)|$, where $|\varphi(Y)|$ is the cardinality of the fuzzy set $\varphi(Y)$.

Definition 4 (Fuzzy formal concept similarity). The similarity of a fuzzy formal concept $(\varphi(Y_1), Z_1)$ and its subconcept $(\varphi(Y_1), Z_1)$ is defined as (1)

$$E\big((\varphi(Y_1), Z_1), (\varphi(Y_1), Z_1)\big) = E\big(\varphi(Y_1), \varphi(Y_2)\big) = \frac{|\varphi(Y_1) \cap \varphi(Y_2)|}{|\varphi(Y_1) \cup \varphi(Y_2)|} \quad (1)$$

where $\cap$ and $\cup$ are the intersection and union operations of fuzzy sets $\varphi(Y_1)$ and $\varphi(Y_2)$, respectively.

III. TEXT CLASSIFICATION WITH FFCA

This research uses FFCA to generalize documents to concepts in order to decrease the impact from noise term features. The documents are preprocessed by natural language processing to identify significant terms. Subsequently, FFCA is employed to provide the more generalized perspective, concept, by the way of analyzing inherent relationships between documents and its term features. Every formal concept on lattice diagram is used to recommend the precise category for new documents. An overview of the proposed FFCA document classification system is shown in Fig. 1. Five main phases, namely natural language processing, lattice construction, attribute-concept transformation, document-concept mapping and collaborative recommendation, are discussed in the following subsections.

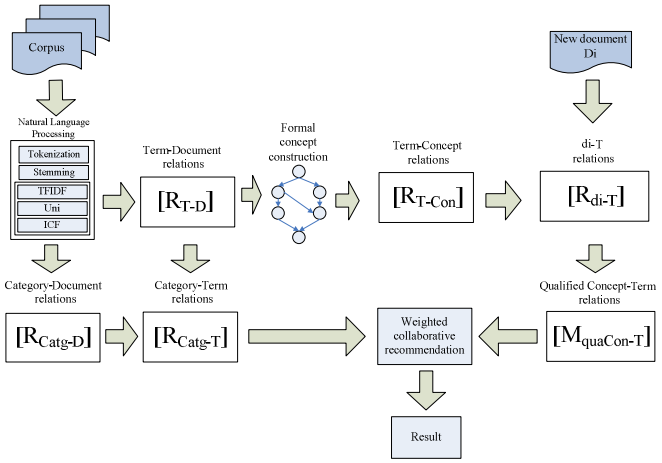

Figure 1. The FFCA classification framework

A. *Natural Language Processing*

Documents containing data in natural language format are useful sources of information, but due to the several variations in human language, it is problematical for automated systems to understand its meaning accurately. Natural language using computers, but has faced numerous problems and limitations since in order to really understand its connotation, extensive

knowledge about the outside world is required. The general process starts by separating textual input into tokens, followed by stemming to map related words to the same root and reduce the amount of tokens, stop-word elimination, part-of-speech tagging and finally syntax analysis.

In order to retrieve significant features from the corpus, information retrieval technique is applied to estimate the importance of retrieved tokens. Three indexes, term frequency and inverse document frequency (TF-IDF), Uni and ICF provide effective criteria to identify important keywords, which are TF-IDF> 26, Uni<0.2 and ICF>log2. Terms, which meet these three criteria, are treated as significant features of a specific document[10].

B. Lattice Construction

The source of lattice is composed of the relationships between key terms and documents. For more precisely demonstrate the degree of significance of the key terms, the traditional binary relations are improved to fuzzy numbers. The TF-IDF values that previously calculated for terms are used as membership degrees to build up fuzzy formal context. A α-cut acting as a membership degree threshold is set to eliminate relations that have low membership and in this way, reduce a accordingly the complexity of the analysis process. All membership values below the α-cut are considered equivalent to zero. Fig. 2(b) shows the fuzzy formal context in Fig. 2(a) with α=0.5, where the null values signify the absence of the topic or its exclusion due to low significance. In each row, d, represents a document, and each column, t, represents a key term.

	t1	t2	t3
d1	0.8	0.12	0.61
d2	0.9	0.85	0.13
d3	0.1	0.14	0.87

(a)

	t1	t2	t3
d1	0.8	-	0.61
d2	0.9	0.85	-
d3	-	-	0.87

(b)

Figure 2. The formal context with α-cut=0.5

The lattice organizes the documents and key terms via partial order which reveals the inherent hierarchical relationships of knowledge. The formal concepts which produced by FFCA further provide more general perspective than documents to represent the content of corpus. Therefore, this research focuses on operating concepts instead of documents in classification problems. The relationships between concepts and key terms are transformed from lattice structure with matrix shows in Fig. 3.

	t1	t2	t3
B	0.8	-	-
C	0.9	0.85	-
D	-	-	0.61
E	0.8	-	0.61

Figure 3. The transformation from lattice structure to concept-term relations

C. Term-category Transformation

The objective of this research is to provide concepts, a more general perspective than document, to facilitate noise control in document classification issue. However, the category information is mainly tagged on documents. Neither terms nor concepts can be the basis to decide the category of a new document. Therefore, the term-category transformation is necessary for a concept-based classification approach. The transformation mechanism is based on fuzzy compositions[11]. The standard composition of two fuzzy relations $P(X, Y)$ and $Q(Y, Z)$ is represented by $P(X, Y) \circ Q(Y, Z)$ which generate $R(X, Z)$ on $X \times Z$. The $R(X, Z)$ is calculated by (2).

$$R(x,z) = [P \circ Q](x,z) = \max_{y \in Y} \min [P(x,y), Q(y,z)] \quad (2)$$

where all $x \in X$ and all $z \in Z$. Therefore, the relations between terms and categories, M_{T-Catg}, can be derived by compositing term-document relations, and document-category relations, as shown in (3).

$$R_{T-Catg} = R_{T-D} \circ R_{D-Catg} \quad (3)$$

where R_{T-D} is term-document relations and M_{D-Catg} are document-category relations. The values in M_{T-D} are the previously calculated TF-IDF value. In traditional approaches, each row represents a document vector which is used for similarity calculation of documents. In M_{D-Catg}, the binary data, 1 or 0, is used to represent document and category relations. The value 1 indicates the document belongs to the category. Otherwise, the value will be 0.

D. Concept-category Transformation

Since the a more abstract perception, concepts, are proposed to replace documents in text classification task, the category information for each concept is essential to conclude the appropriate category for a new incoming document. As mentioned above, the category information from documents has been transformed to terms in M_{T-Catg}, the next challenge is how to reveal the concept-category relations, $M_{Con-Catg}$. Similarly, the standard composition of concept-key term and key terms-category relations can be composited by $M_{Con-T} \circ M_{T-Catg}$. Thus, the category information, which previously based on documents, has been successively transformed to concepts.

E. Unclassified document mapping

The main objective of FFCA classification approach is to classify new documents based on well-organized concepts in the lattice space. As $M_{Con-Catg}$ has provided concept-category relations, it is capable of mapping unclassified documents to a set of relevant concepts and assigning the most appropriate category by collaborative recommending of its significant neighbor concepts. In order to search relevant concepts for a new document, we represent the new document as fuzzy formal concepts with TF-IDF values. Further, the fuzzy similarity operation, (1), is applied to calculate the similarity measure between new document and fuzzy formal concepts. The parameter δ is designed to determine the similarity criterion that the qualified fuzzy formal concepts should include in classification procedure. A more detailed pseudo code is presented in Fig. 4.

Procedure $Build_MSC(d_i, \delta, R_{Con-T})$
d_i : new document
δ : most similar concept threshold, $0 < \delta < 1$
R_{Con-T} : concept-term relations
MSC : the most similar concept set

$MSC = \varnothing$
FOR each $concept_i$ exists in R_{Con-T}
  IF $fuzzysimilarity(d_i, concept_i) > \delta$
    $MSC \leftarrow concept_i$
  END IF
END FOR

return MSC

Figure 4. Algorithm to find relevant concepts of new document

F. Classification

After retrieving the qualified concepts which highly correlated with a new document, the classification procedure are based on weighted collaborative recommendation of retrieved concepts as (4).

$$\text{weighted_sum}(C_i) = \sum_{k=1}^{j} fuzzysimilarity(d, concept_k) \times membership(concept_k, C_i) \quad (4)$$

where $fuzzysimilarity(d, concept_k)$ is the fuzzy similarity between document, d, and $concept_k$. As $membership(concept_k, C_i)$ is the part of $M_{Con-Catg}$ which provide the category information of qualified concepts. A more detailed pseudo code is presented in Fig. 5.

Procedure $Categorize(d_i, MSC)$
d_i : new document
MSC : the most similar concept set
C : assigned category

FOR each C_i
  FOR each $concept_j \in MSC$
    $weighteds_sum(C_i) = fuzzysimilarity(d_i, concept_j) \times membership(concept_j, C_i)$
  END FOR
END FOR
$C = \arg\max_{c_i} weighteds_sum(C_i)$
return C

IV. Experiments and Analysis

We conduct several experiments to evaluate the effectiveness of proposed FFCA classification. In the first experiment, we demonstrate the performance in terms of f-measure, the weighted harmonic mean of recall and precision, based on ten-fold cross-validation. In the second experiment, we investigate the impact of different parameter settings on classification performance. Further, the information which contributed from various lattice construction perspectives are analyzed with regards to their structure to affect the classification results. In the following section, we first describe the experimental dataset and then analyze the evaluation results.

A. Data Collection

In this research, we choose a public corpus, Reuters 21578, to evaluate the performance of classification. Reuters 21578 is the main benchmark for text classification evaluation. Each article is well tagged with several properties. The tag, TOPIC, indicates what categories each article belongs to. Articles with multiple classes are allowed in Reuters 21578, which means there are multiple values in TOPIC tag. However, our research is mainly focus on the single classification problem. Thus, articles belongs to multiple classes are ignored in this experiment. In order to avoid the effects of small sample, the classes which have less than one hundred articles are not included in this experiment as well. The qualified five classes containing 5550 articles are implemented using ten-fold cross-validation experiment. The statistics of experimental data are demonstrated in table 2.

TABLE II. THE STATISTICS OF EXPERIMENTAL DATASET

Category	Testing data	Training data	Total
acq	151	1359	1510
crude	26	234	260
earn	355	3195	3550
ship	10	90	100
trade	13	117	130

B. Evaluation of accuracy

Since the FFCA classification approach is affected by two parameters, α and δ, we investigate their effect and correlation by conducting different parameter settings. α represents the tfidf threshold of terms in new documents based on the training data. Only terms with tfidf value higher than α are included in

lattice construction. Higher α denotes less keywords are qualified as the features of new document and vice versa. δ depicts the similarity criterion between new document and concepts. Since k concepts which are similar enough to new document are chosen as neighbors to predict the category, δ provides the information to manipulate the number of concepts participating in classification. The range of δ is between 0 and 1. When δ=0, all concepts are involving in classification procedure. On the contrary, only the concept which is exact the same with new document is involving the classification procedure when δ=1. The results of different combinations of α and δ are shown in Fig 6.

Fig. 6 depicts that the highest classification f-measure is when α=0.1 and δ=0.1. α=0.1 demonstrates that the terms of new document should be kept as factors to provide information in classification. The same situation, δ=0.1, also shown in deciding δ, the results also support that when more the concepts involving in classification the accuracy is higher.

	α								
δ	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9
0.1	**96.03%**	95.86%	95.80%	95.58%	94.53%	93.80%	88.39%	88.46%	87.14%
0.2	93.56%	93.49%	95.42%	95.34%	92.47%	89.32%	86.87%	86.65%	85.39%
0.3	90.43%	91.17%	91.57%	90.18%	81.85%	85.36%	85.29%	85.39%	84.38%
0.4	85.82%	87.14%	83.33%	81.78%	65.79%	72.10%	85.00%	85.13%	84.29%
0.5	74.74%	84.10%	75.29%	71.45%	63.13%	67.68%	85.07%	84.95%	84.17%
0.6	66.60%	73.55%	63.79%	62.57%	62.65%	67.49%	85.07%	84.95%	84.17%
0.7	63.95%	68.85%	58.96%	61.53%	62.65%	67.49%	85.07%	84.95%	84.17%
0.8	63.77%	67.36%	58.70%	61.52%	62.65%	67.49%	85.07%	84.95%	84.17%
0.9	63.77%	67.36%	58.70%	61.52%	62.65%	67.49%	85.07%	84.95%	84.17%
1	63.77%	67.36%	58.70%	61.52%	62.65%	67.49%	85.07%	84.95%	84.17%

Figure 6. Prediction accuracy for different parameter combinations

C. *Implications for KNN-based approaches*

For KNN-based approaches, how to decide the most appropriate *K* neighbors remains a great challenge. Information may lose when choosing small *K*, but choosing big *K* may also produce poor results due to too many noise data. In practical KNN applications, *K* is always suggested to be neither too big nor too small, but lack of an efficient way to determine the most appropriate number. In this research, the parameters, α and δ, are used to determine the number of terms and concepts for classification, which is comparable to *K* in KNN approaches. Therefore, we further investigate the results from different levels of parameters and analyze the impacts of different parameter setting strategies.

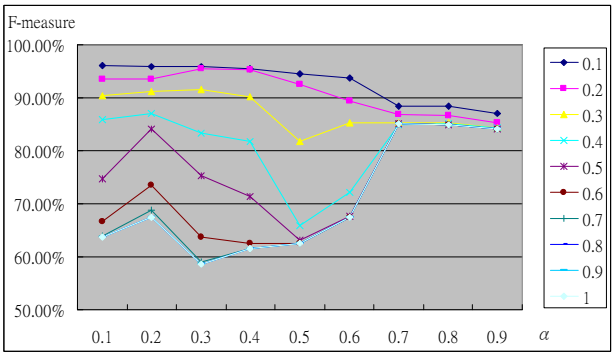

Figure 7. F-measure curves under different level of α

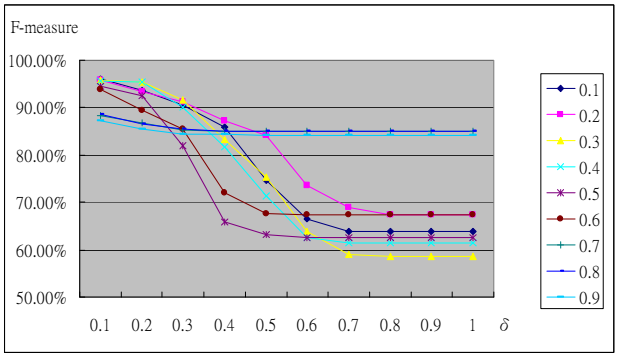

Figure 8. F-measure curves under different level of δ

Fig. 7 demonstrates the curves of δ under different levels of α. For all δ F-measure curves, their rank from high to low under different level of α are the same sequence as its value from 0.1 to 1. This fact indicates that under different thresholds of TF-IDF, more concepts are capable of providing information for document classification. As for the perspective of each single δ curve, we observe that drop and up patterns obviously appears except when δ=0.1. Since α represents TF-IDF which controls the amount of key terms involving in classification task, the drop F-measure tendency between α equals 0.2 and 0.5 reflects that the valuable key terms are eliminated by rising α and contribute decline in performance. However, tendencies reverse when α>0.5 indicate that the rising α further eliminate moderate terms and strictly keep significant ones facilitate the performance of F-measure. The F-measure for all levels of δ are stable when α is larger than 0.7. It is worth noting that, the drop and up pattern is not obvious when δ is 0.1 and 0.2. The

reason is that when δ is low indicates most of the concepts are engaging in classification task, thus, the impact of reducing key terms is negligible in F-measure.

As for Fig. 8, the tendencies of different α are divided into two different typical patterns. The first pattern, when α is between 0.1 and 0.6, demonstrate that the F-measure is declined when δ is rising. This pattern reveals that the decreasing concept caused by rising δ not only neglect relevant information but also impede the F-measure significantly. However, the disproportional relations between α and δ are limited when δ<0.7. While only important concepts are kept for document classification, δ>0.7 , the impact from key term selection also becomes not significant. The second pattern appeals when α>0.6 which are stable confronting the variation of δ. The second pattern reveals that the number of concept involving in document classification is slightly affected F-measure when only high TF-IDF value key terms are selected. It is worth noting that there is no drop and up tendency appears in Fig. 8. As mentioned above, the drop and up tendency is caused by eliminating noise data, however, each tendencies of α in Fig. 8 are monotonically decreasing, which means every concept is capable of providing valuable information and none of them should be eliminated in the process of document classification. In traditional k-means methodology, how to decide *K* is very critical and may vary from different parameter settings. Thus, finding appropriate *K* remains a great challenge. In this experiment, the monotonically descending reveals that all concepts are suitable for providing valuable information. The highest F-measure of all α are consistently located when α=0.1. This fact indicates that the transformation from terms to concepts can successively retrieve the abstractness of terms and avoid the noise terms, which is inevitable in feature selection phase.

V. CONCLUSION

Nowadays, with the fast increasing of text, document classification is important to knowledge management and distribution. However, noise data is inevitable in practical document classification tasks. How to eliminate the impact from noise data is as important as achieving high classification accuracy. For this purpose, we develop a novel classification approach to generalize document to concept and successively reduce the impact from noise. Furthermore, according to accuracy assessment results, FFCA method demonstrates the impressive ability by achieving 96.17% in Reuters 21578 dataset. By further investigate the result tendencies of different parameter settings, FFCA method also provide benefits in determining parameter settings. Future research directions may include exploring more experimental data for evaluation and retrieving IF-THEN rules from lattice to support decision-making issues.

Abstract—**Most fuzzy controllers, type-1 (T1) or type-2 (T2), have been used and treated as black boxes in that their explicit mathematical input-output mappings (i.e., analytical structures) are unknown. Revealing and analyzing the analytical structure is important as it will lay a solid foundation for better understanding, more insightful analysis, and more effective design of fuzzy control systems. We previously developed a general technique to derive the analytical structures of the type-1 fuzzy controllers that employed Zadeh AND operator. We now extend our study to a class of typical interval type-2 fuzzy controller that adopt Zadeh AND operator and the popular Karnik-Mendel iterative center-of-sets type reducer. A novel analytical structure deriving technique is developed. And the resulting input-output mathematical relationship for the controller is received.**

Keywords- Type-2 fuzzy control; analytical structure; input-output mathematical relationship

I. INTRODUCTION

In the past several years, research results on type-2 (T2) fuzzy control have started to emerge in the literature [1-5]. Many results claim that T2 fuzzy control outperforms its counterpart type-1 (T1) fuzzy control (e.g., traditional fuzzy control). Logically, many questions arise. Why is this the case? Do the T2 fuzzy controllers work well because their input-output structures are more peculiar than T1 fuzzy controllers and other conventional nonlinear controllers? What are their structures then? All these questions are of considerable importance. And moreover, once the mathematical relationship information becomes available, analyzing and designing T2 fuzzy control systems can be studied in the framework of the well-developed conventional (nonlinear) control theory as the fuzzy control problems will be transformed to nonlinear control problems.

Actually, deriving the input-output mathematical relationship is no easy in most cases. The reality is that many fuzzy controllers are constructed via the "knowledge engineering approach" as opposed to the mathematical approaches exclusively adopted in conventional control. All the fuzzy controllers have been treated and used as black-box controllers in the sense that their analytical structures are unknown. And for conventional control, this is never an issue because the analytical structure of the conventional control, linear or nonlinear, is always readily available for analysis and design. For T1 fuzzy controller, we previously did a lot of research on its analytical structure [6, 7]. Our research methods and results on the analytical structure of T1 fuzzy controllers create great help for better analysis and design of fuzzy controller, which have been widely used in literature [8]. Few of the present literatures about T2 fuzzy control, however, are concerned with mathematical input-output relationship of a T2 fuzzy controller [9, 10].

In the present paper, the input-output relationship of a class of interval T2 Mamdani fuzzy controller is derived. Their configurations are typical - any types of input fuzzy sets and output fuzzy sets, arbitrary fuzzy rules, Zadeh AND operator, the Karnik-Mendel center-of-sets type reducer, and the centroid defuzzifier.

II. CONFIGURATION OF A CLASS OF INTERVAL T2 MAMDANI FUZZY CONTROLLERS

The T2 fuzzy controllers in this study have two input variables, $x_1(n)$ and $x_2(n)$, and one output variable, $\triangle u(n)$, which is the change of controller output, where n represents the sampling instance. For simplicity, x_1, x_2 and $\triangle u$ will be used instead of $x_1(n)$, $x_2(n)$ and $\triangle u(n)$. We suppose that x_1 is defined on $[L_1, R_1]$ that is divided into $N_1 - 1$ subintervals: $[S_1, S_2]$,..., $[S_i, S_{i+1}]$,..., $[S_{N_1-1}, S_{N_1}]$, $1 \le i \le N_1$. There are N_1 interval T2 fuzzy sets, $A_1, \cdots, A_i, \cdots, A_{N_1}$. A_i is defined over $[S_{i-1}, S_{i+1}]$ and its membership value is zero everywhere else. The upper and lower primary membership functions of A_i are designated as $\overline{\mu}_{A_i}(x_1)$ and $\underline{\mu}_{A_i}(x_1)$, respectively. We assume that: (1) $\overline{\mu}_{A_i}(x_1) \ge \underline{\mu}_{A_i}(x_1)$, and (2) $\overline{\mu}_{A_i}(x_1)$ (and $\underline{\mu}_{A_i}(x_1)$) increases from 0, reaches its maximum (can be a range of the same maximum), and then decreases to 0. Most of the widely-used fuzzy sets in the literature (e.g., the trapezoidal ones) meet the assumptions. To illustrate the assumptions, Fig. 1 provides some example T2 fuzzy sets. Likewise, we suppose that x_2 is

This work was supported in part by National Natural Science Foundation of China under Grant 51005253.

defined in $[L_2, R_2]$ that is divided into $N_2 - 1$ subintervals, namely $[M_1, M_2]$,..., $[M_j, M_{j+1}]$,..., $[M_{N_2-1}, M_{N_2}]$, over which N_2 interval T2 fuzzy sets meeting the same assumptions above are defined. Each of them is denoted B_j $(1 \le j \le N_2)$ whose upper and lower primary membership functions are $\overline{\mu}_{B_j}(x_2)$ and $\underline{\mu}_{B_j}(x_2)$, respectively.

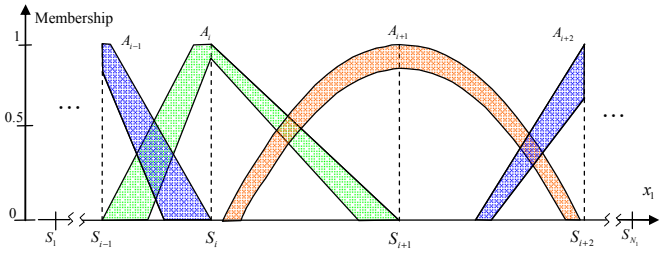

Fig. 1. Example interval T2 fuzzy sets for input variable x_1.

We use a total of $N_1 \times N_2$ Mamdani fuzzy rules to cover all the possible combinations of the input fuzzy sets. At any sampling instance, only two adjacent A_i and two adjacent B_j will be involved in the fuzzification of x_1 and x_2, respectively, due to the manner that the fuzzy sets are defined. Without losing generality, we assume that A_i, A_{i+1}, B_j, B_{j+1} are the ones that are involved. Accordingly, the following four fuzzy rules are executed:

IF x_1 is A_i AND x_2 is B_j THEN Δu is $G_{h(i,j)}$. (Rule 1)

IF x_1 is A_i AND x_2 is B_{j+1} THEN Δu is $G_{h(i,j+1)}$. (Rule 2)

IF x_1 is A_{i+1} AND x_2 is B_j THEN Δu is $G_{h(i+1,j)}$. (Rule 3)

IF x_1 is A_{i+1} AND x_2 is B_{j+1} THEN Δu is $G_{h(i+1,j+1)}$ (Rule 4)

where Zadeh fuzzy AND operator (i.e., min()) is used and $G_{h(i,j)}$, $G_{h(i,j+1)}$, $G_{h(i+1,j)}$ and $G_{h(i+1,j+1)}$ are interval T2 fuzzy sets for Δu, which can be any continuous T2 fuzzy sets, interval type or not. These output fuzzy sets are indexed by integer subscripts whose values are computed using function $h(\cdot)$ so that the input and output fuzzy sets are mathematically linked. Because $h(\cdot)$, chosen by the controller designer, can be any function, the fuzzy rules subsequently can be arbitrary in terms of input and output relation.

The firing interval for the input fuzzy sets in Rule k ($k = 1,2,3,4$), denoted $[\underline{f}_k(x_1,x_2), \overline{f}_k(x_1,x_2)]$, is first calculated [2]:

$$\begin{aligned} f_1(x_1,x_2) &= [\underline{f}_1(x_1,x_2), \overline{f}_1(x_1,x_2)] \\ &= [\min(\underline{\mu}_{A_i}(x_1), \underline{\mu}_{B_j}(x_2)), \min(\overline{\mu}_{A_i}(x_1), \overline{\mu}_{B_j}(x_2))] \end{aligned} \quad (1)$$

$$\begin{aligned} f_2(x_1,x_2) &= [\underline{f}_2(x_1,x_2), \overline{f}_2(x_1,x_2)] \\ &= [\min(\underline{\mu}_{A_i}(x_1), \underline{\mu}_{B_{j+1}}(x_2)), \min(\overline{\mu}_{A_i}(x_1), \overline{\mu}_{B_{j+1}}(x_2))] \end{aligned} \quad (2)$$

$$\begin{aligned} f_3(x_1,x_2) &= [\underline{f}_3(x_1,x_2), \overline{f}_3(x_1,x_2)] \\ &= [\min(\underline{\mu}_{A_{i+1}}(x_1), \underline{\mu}_{B_j}(x_2)), \min(\overline{\mu}_{A_{i+1}}(x_1), \overline{\mu}_{B_j}(x_2))] \end{aligned} \quad (3)$$

$$\begin{aligned} f_4(x_1,x_2) &= [\underline{f}_4(x_1,x_2), \overline{f}_4(x_1,x_2)] \\ &= [\min(\underline{\mu}_{A_{i+1}}(x_1), \underline{\mu}_{B_{j+1}}(x_2)), \min(\overline{\mu}_{A_{i+1}}(x_1), \overline{\mu}_{B_{j+1}}(x_2))] \end{aligned} \quad (4)$$

In this paper, the Karnik-Mendel center-of-sets type reducer is used to reduce the T2 output sets to $\Delta U = [\Delta u_L, \Delta u_R]$, a T1 fuzzy set, which is then defuzzified to produce a crisp number Δu. In the Karnik-Mendel type reducer, the centroid for Rule k's output fuzzy set, denoted $[\alpha_k, \gamma_k]$, is computed first, on-line or off-line [1]. The rather complex calculation procedure is described in [1]. Because we will only need the outcome of the reducer prior to the structure derivation and do not care how it is produced, the procedure is omitted here for better presentation. γ_k's and α_k's are then respectively arranged in the ascending orders and the results are represented by: $\gamma_1^* \le \gamma_2^* \le \gamma_3^* \le \gamma_4^*$ and $\alpha_1^* \le \alpha_2^* \le \alpha_3^* \le \alpha_4^*$. We then arrange $\overline{f}_k(x_1,x_2)$ and $\underline{f}_k(x_1,x_2)$ to correspond to $\gamma_1^* \le \gamma_2^* \le \gamma_3^* \le \gamma_4^*$ and $\alpha_1^* \le \alpha_2^* \le \alpha_3^* \le \alpha_4^*$, respectively, resulting in $\overline{f}_1^*(x_1,x_2) \le \overline{f}_2^*(x_1,x_2) \le \overline{f}_3^*(x_1,x_2) \le \overline{f}_4^*(x_1,x_2)$ and $\underline{f}_1^*(x_1,x_2) \le \underline{f}_2^*(x_1,x_2) \le \underline{f}_3^*(x_1,x_2) \le \underline{f}_4^*(x_1,x_2)$. The left-most point Δu_L and right-most point of the interval ΔU_R can then be represented as [2]:

$$\Delta u_L = \frac{\sum_{i=1}^{P_L} \overline{f}_i^*(x_1,x_2)\alpha_i + \sum_{j=P_L+1}^{4} \underline{f}_j^*(x_1,x_2)\alpha_j}{\sum_{i=1}^{P_L} \overline{f}_i^*(x_1,x_2) + \sum_{j=P_L+1}^{4} \underline{f}_j^*(x_1,x_2)} \quad (5)$$

$$\Delta u_R = \frac{\sum_{i=1}^{P_R} \underline{f}_i^*(x_1,x_2)\gamma_i + \sum_{j=P_R+1}^{4} \overline{f}_j^*(x_1,x_2)\gamma_j}{\sum_{i=1}^{P_R} \underline{f}_i^*(x_1,x_2) + \sum_{j=P_R+1}^{4} \overline{f}_j^*(x_1,x_2)} \quad (6)$$

where integers P_L ($1 \le P_L \le 3$) and P_R ($1 \le P_R \le 3$) are switching points that depend on the input and output fuzzy sets and the values of x_1 and x_2, and hence vary with n. Their calculation procedure is fully described in [2]. Since ΔU_R is an interval set, the centroid defuzzifier is used to produce the crisp output Δu [4]:

$$\Delta u = \frac{1}{2}(\Delta u_L + \Delta u_R) \quad (7)$$

III. New Technique for Deriving Analytical Structure of the Fuzzy Controllers

Without loss of generality, suppose arbitrarily that A_i, A_{i+1}, B_j, and B_{j+1} are as shown in Fig. 2 with the mathematical

definitions given in Table 1 (outside the intervals in the right column of Table 1, the membership values are 0).

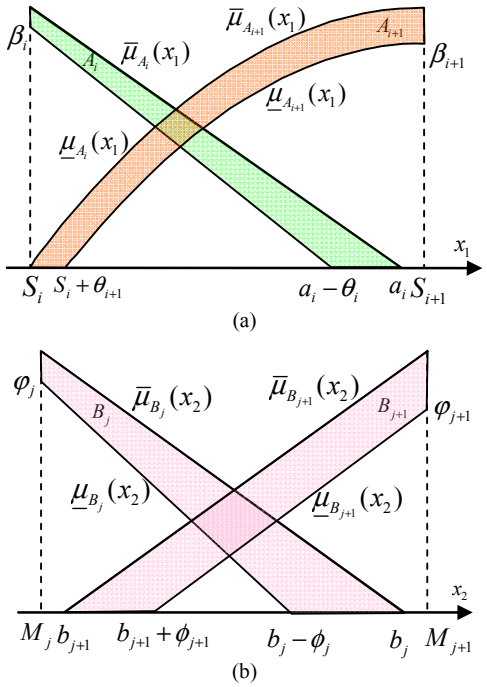

Fig. 2. Example interval T2 fuzzy sets used for (a) x_1, and (b) x_2 at sampling time n.

TABLE I. MATHEMATICAL DEFINITIONS FOR THE PARTS OF THE PRIMARY MEMBERSHIP FUNCTIONS OF A_i, A_{i+1}, B_j, AND B_{j+1}.

Mathematical definition	Interval
$\bar{\mu}_{A_i}(x_1)=\frac{-1}{a_i-S_i}x_1+\frac{S_i}{a_i-S_i}+1$	$x_1\in[S_i,a_i]$
$\underline{\mu}_{A_i}(x_1)=\frac{-\beta_i}{a_i-\theta_i-S_i}x_1+\frac{S_i\beta_i}{a_i-\theta_i-S_i}+\beta_i$	$x_1\in[S_i,a_i-\theta_i]$
$\bar{\mu}_{A_{i+1}}(x_1)=-\left(\frac{x_1-S_{i+1}}{S_i-S_{i+1}}\right)^2+1$	$x_1\in[S_i,S_{i+1}]$
$\underline{\mu}_{A_{i+1}}(x_1)=-\beta_{i+1}\left(\frac{x_1-S_{i+1}}{S_i+\theta_{i+1}-S_{i+1}}\right)^2+\beta_{i+1}$	$x_1\in[S_i+\theta_{i+1},S_{i+1}]$
$\bar{\mu}_{B_j}(x_2)=\frac{-1}{b_j-M_j}x_2+\frac{M_j}{b_j-M_j}+1$	$x_2\in[M_j,b_j]$
$\underline{\mu}_{B_j}(x_2)=\frac{-\varphi_j}{b_j-\phi_j-M_j}x_2+\frac{M_j\varphi_j}{b_j-\phi_j-M_j}+\varphi_j$	$x_2\in[M_j,b_j-\phi_j]$
$\bar{\mu}_{B_{j+1}}(x_2)=\frac{1}{M_{j+1}-b_{j+1}}x_2-\frac{M_{j+1}}{M_{j+1}-b_{j+1}}+1$	$x_2\in[b_{j+1},M_{j+1}]$
$\underline{\mu}_{B_{j+1}}(x_2)=\frac{\varphi_{j+1}}{M_{j+1}-b_{j+1}-\phi_{j+1}}x_2-\frac{M_{j+1}\varphi_{j+1}}{M_{j+1}-b_{j+1}-\phi_{j+1}}+\varphi_{j+1}$	$x_2\in[b_{j+1}+\phi_{j+1},M_{j+1}]$

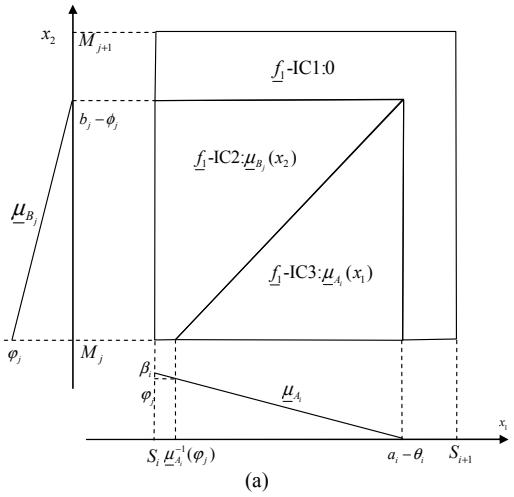
To derive the explicit Δu expressions from (7), one must first determine the resulting membership value for each of the four rules involving the min() operation in (1)-(4) as a mathematical expression, as opposed to a numerical value. The only way to achieve this goal is to divide the area $[S_i,S_{i+1}]\times[M_j,M_{j+1}]$ into a number of regions, each of which is called IC (input combination) so that in each region, the inequality relationship between x_1 and x_2 is exclusive [6]. Without loss of generality, we assumed that $\varphi_{j+1}\le\beta_{i+1}\le\varphi_j\le\beta_i$ in Table 1. Fig. 3 and 4 then show the input space division results for (1)-(4), where $\underline{\mu}_{A_i}^{-1}(\varphi_j)$, $\underline{\mu}_{A_i}^{-1}(\varphi_{j+1})$, $\underline{\mu}_{B_j}^{-1}(\beta_{i+1})$ and $\underline{\mu}_{A_{i+1}}^{-1}(\varphi_{j+1})$ are the inverse functions of the linear parts of the these four lower membership functions. For instance, Fig. 3(a) shows the divisions for $\underline{f}_1(x_1,x_2)=\min(\underline{\mu}_{A_i}(x_1),\underline{\mu}_{B_j}(x_2))$ from Rule 1. There are three regions and they are labeled as $\underline{f}_1$-IC1, $\underline{f}_1$-IC2 and $\underline{f}_1$-IC3. In $\underline{f}_1$-IC3, $\underline{\mu}_{A_i}(x_1)\le\underline{\mu}_{B_j}(x_2)$, thus $\underline{f}_1(x_1,x_2)=\underline{\mu}_{A_i}(x_1)$. For $\underline{f}_1$-IC1, because either $\underline{\mu}_{A_i}(x_1)=0$ or $\underline{\mu}_{B_j}(x_2)=0$, the result of min() is always 0. Accordingly, there should be eight different divisions for whole input space to determine the firing intervals in (1)-(4): division for $\underline{f}_1$ in (1), for $\bar{f}_1$ in (1), for $\underline{f}_2$ in (2), for $\bar{f}_2$ in (2), for $\underline{f}_3$ in (3), for $\bar{f}_3$ in (3), for $\underline{f}_4$ in (4), for $\bar{f}_4$ in (4). For space limitation, just two of them list in Fig. 3. And take Fig. 3(b) as another example. Boundary A, on which $\underline{\mu}_{A_{i+1}}(x_1)=\underline{\mu}_{B_j}(x_2)$, is obtained by solving the following equation:

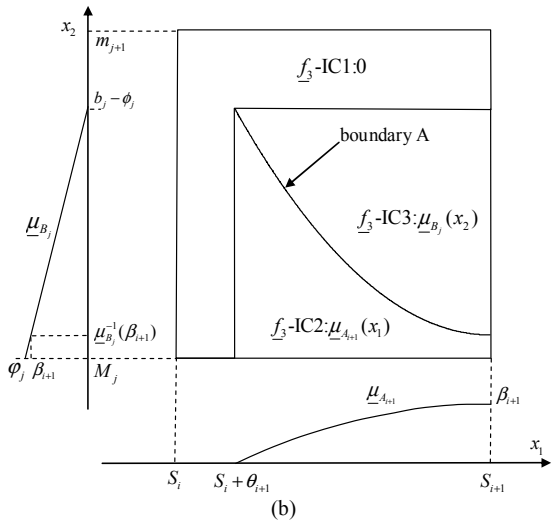
$$\varphi_j-\frac{\varphi_j}{b_j-\phi_j-M_j}x_2+\frac{M_j\varphi_j}{b_j-\phi_j-M_j}=\beta_{i+1}-\beta_{i+1}\left(\frac{x_1-S_{i+1}}{S_i+\theta_{i+1}-S_{i+1}}\right)^2 \quad (8)$$

Yielding

$$x_2=\frac{\beta_{i+1}(b_j-\phi_j-M_j)}{\varphi_j(S_i+\theta_{i+1}-S_{i+1})^2}(x_1-S_{i+1})^2+\frac{(\varphi_j-\beta_{i+1})(b_j-\phi_j-M_j)}{\varphi_j}+M_j \quad (9)$$

Once the boundary is determined, just compute the values of $\underline{\mu}_{A_{i+1}}(x_1)$ and $\underline{\mu}_{B_j}(x_2)$ using any pair of x_1 and x_2 in either IC. The function producing the smaller value should be the result of min( ) for that IC.





(b)

Fig. 3. Part of eight divisions of the input space to determine the firing intervals in (1)-(4): (a) for $\underline{f}_1$ in (1), (b) for $\underline{f}_3$ in (3).

These divisions are for each individual fuzzy rule only. Because all the rules are involved in calculating controller output $\triangle u$, all the four rules must be simultaneously considered to derive the controller structure. This simultaneous consideration is achieved if we superimpose the eight individual input space divisions shown in Fig. 3 to form an overall input space division (Fig. 4). It turns out that there are a total of 78 regions, labeled from IC1 to IC78.

Now, for each region in Fig. 4, we can decide $f_k(x_1, x_2)$ (i.e., $[\underline{f}_k(x_1, x_2), \overline{f}_k(x_1, x_2)]$). For example, for IC40 (i.e., the region labeled 40 in Fig. 4), $\underline{f}_1(x_1, x_2) = \underline{\mu}_{B_j}(x_2)$, $\underline{f}_2(x_1, x_2) = \underline{\mu}_{A_i}(x_1)$, $\underline{f}_3(x_1, x_2) = \underline{\mu}_{B_j}(x_2)$, $\underline{f}_4(x_1, x_2) = \underline{\mu}_{B_{j+1}}(x_2)$, $\overline{f}_1(x_1, x_2) = \overline{\mu}_{B_j}(x_2)$, $\overline{f}_2(x_1, x_2) = \overline{\mu}_{A_i}(x_1)$, $\overline{f}_3(x_1, x_2) = \overline{\mu}_{B_j}(x_2)$ and $\overline{f}_4(x_1, x_2) = \overline{\mu}_{B_{j+1}}(x_2)$. This process is carried out for all the 78 ICs. We do not list all the results here for space limitation. We emphasize that the result can be different if the input fuzzy sets are different.

For better notations, assume $\gamma_k^* = \gamma_k$ and $\alpha_k^* = \alpha_k$, and accordingly, $\overline{f}_k^*(x_1, x_2) = \overline{f}_k(x_1, x_2)$ and $\underline{f}_k^*(x_1, x_2) = \underline{f}_k(x_1, x_2)$. Putting the eight membership functions resulted from the min() operations in the four rules and the resulting centroids for an IC into the type reducer represented by (5) and (6), we will obtain $\triangle u_R$ and $\triangle u_L$. Putting them into the defuzzifier (7) and making some algebraic simplifications, we will attain the analytical structure of the fuzzy controller for that particular IC if P_L and P_R in (5) and (6) are known.

According to the Karnik-Mendel type reducer, the exact values of P_L and P_R can always be computed as long as all the parameters of the input fuzzy sets, controller inputs, and the centroids of all the output fuzzy sets are numerically available. Hence, in principle for any specific fuzzy controller, the structure can always be derived. Nevertheless, our interest is on general controller configuration where these parameter values are not specified. As a result, P_L and P_R are unknown, making the analytical structure derivation significantly more complicated. Given that P_L=1~3 and P_R=1~3, there are a total of 3×3 =9 possible outcomes, each of which is called a case, that (5) and (6) can produce for an IC. When P_L=1 and P_R=1, we define the case number as 1, the corresponding analytical structure of the T2 fuzzy controller with the general configuration is (10), the other eight cases can also be easily computed by Karnik-Mendel type reducer, which are omitted here.

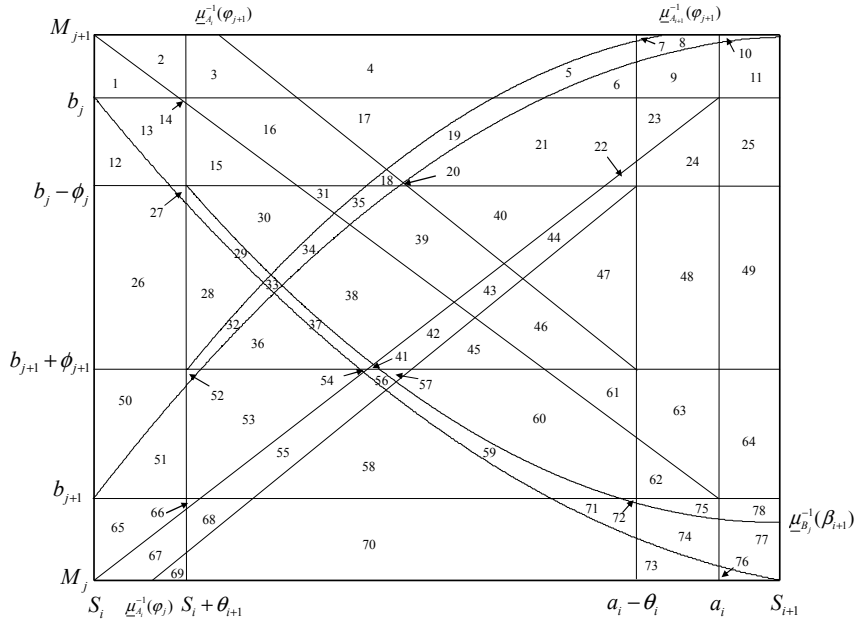


Fig. 4. Superimposing the ICs in Figs. 3(a)-3(h) to create an overall input space division (each region is labeled by an IC number)

$$\Delta u = \frac{1}{2}\left(\begin{array}{l} \dfrac{\overline{f}_1^*(\cdot)\alpha_1 + \underline{f}_2^*(\cdot)\alpha_2 + \underline{f}_3^*(\cdot)\alpha_3 + \underline{f}_4^*(\cdot)\alpha_4}{\overline{f}_1^*(\cdot) + \underline{f}_2^*(\cdot) + \underline{f}_3^*(\cdot) + \underline{f}_4^*(\cdot)} \\ + \dfrac{\underline{f}_1^*(\cdot)\gamma_1 + \underline{f}_2^*(\cdot)\gamma_2 + \overline{f}_3^*(\cdot)\gamma_3 + \overline{f}_4^*(\cdot)\gamma_4}{\underline{f}_1^*(\cdot) + \underline{f}_2^*(\cdot) + \overline{f}_3^*(\cdot) + \overline{f}_4^*(\cdot)} \end{array} \right) \tag{10}$$

Continuing the IC40 example above, with different inputs, one can derive nine different analytical structures from the nine cases. We provide case No. 1 below: Eq. (11). As another instance, the analytical controller structure for another case number (P_L=1 and P_R=2) for IC28 is Eq.(12). For the 78 ICs shown in Fig. 4, there exist a total of 9×78 = 702 analytical structure expressions. We have derived all of them and found that their mathematical structures to be all similar to either (11) or (12).

The new structure-deriving method presented above is not restricted to the T2 fuzzy controllers with two input variables. Its principle is applicable to the fuzzy controllers involving more than two input variables. Nevertheless, the derivation task will be more challenging. The biggest difficulty is to divide the n-dimension input space ($n \geq 3$) into a number of n-dimensional ICs. Take n=3 as example - one must properly divide the 3D input space into many 3D ICs so that Zadeh AND operation can be carried out for each of the fuzzy rules (at least 2^3 = 8 rules). This step is the same, in spirit, as what is shown in Fig. 3 except each IC is no longer two-dimensional, but 3D. Also, for all the 2^3 = 8 rules, there will be $2\times2^3=16$ individual divisions that will be superimposed to generate overall 3D ICs, as suppose to $2\times2^2=8$ individual divisions in Fig. 3. The number of switching points will be more - P_L=1~7 and P_R=1~7, resulting in a total of 7×7 =49 different cases.

IV. CONCLUSION

A novel general analytical structure-deriving technique for a class of interval T2 Mamdani fuzzy controllers that employ Zadeh fuzzy AND operator is developed. The mathematical input-output mapping of this class of T2 fuzzy controllers is derived then. From the results we concluded that the universe of inputs can be divided into several regions, the mathematical input-output structure is not the same in different region. It depends on controller and controller inputs. The mathematical input-output relationships are complicated nonlinear function of inputs.

***Abstract*—This paper presents a novel interval type-2 fuzzy logic control architecture for flocking system when the system has noisy sensor measurements. The traditional type-1 fuzzy logic controller (FLC) using precise type-1 fuzzy sets cannot fully model and handle the uncertainties of sensor data. However, type-2 FLC using type-2 fuzzy sets with a footprint of uncertainty (FOU) produces better performances under noisy environments. In this paper, therefore, we present a reactive control architecture for flocking algorithm that is based on interval type-2 FLC to implement the flocking behaviors consisting separation, obstacle avoidance, and velocity matching behaviors. The type-2 based control system could cope with the uncertainties of noisy sensor measurements and resulted in good performances that outperformed the type-1 FLC.**

Keywords-Type-2 fuzzy logic controller (FLC), flocking algorithm, reactive control, multi-agent systems

I. INTRODUCTION

In 1970s, the concept of type-2 fuzzy logic system (FLS) was first introduced by Zadeh [1]. Compared to traditional type-1 fuzzy sets which have membership functions that are precise, the type-2 fuzzy sets are described by membership functions that are themselves fuzzy. Thus, type-2 FLS can be successfully used to model and handle data uncertainties in many applications. However, the type-2 FLS has some difficulties in 1) characterization of type-2 fuzzy sets; 2) performing operations; 3) inferencing, and 4) obtaining a defuzzified value which is type-0 set from the output of a type-2 inference engine which is type-2 fuzzy set [2]. After the publication of Karnik and Mendel [3] which introduces some new concepts to overcome the difficulties stated above, a lot of papers up to recently have been published about type-2 FLS [4]- [6].

Fuzzy logic controllers (FLCs) have been successfully implemented for reactive control of robots. However, most of the researches in robot control fields are based on the traditional type-1 FLC [7]-[10]. Recently, several researchers have applied type-2 FLC to mobile control. For instance, Hagras [4] applied type-2 FLS to mobile robot control in real-time for changing and dynamic environments, and the type-2 FLC resulted in good control responses compared with the type-1 FLCs. Martinez *et al*. [5] have investigated the usage of tuning technique to tune the parameters of type-2 FLC for mobile robots by using genetic algorithms.

There have been many studies for flocking behavior of multi-agent systems. For the simulation of flocking birds, Reynolds [11] introduced three heuristic rules that lead to the creation of the first computer animation model of flock. The three rules are for cohesion, separation, and alignment. In Reynolds' model, there is no leader in the flock and each bird has a local control strategy. After that, several researches on flocking motion applied the heuristic rules used in Reynolds' model to their algorithms. Olfati-Saber [12] designed artificial potentials based on graph theory to form a lattice-shape formation of robots and Bennet and McInnes [13] proposed bifurcating potential field by considering pattern formation and reconfigurability in flocking system. Moshtagh and Jadbabaie [14] proposed a method that considered velocity alignment in a group of kinematic nonholonomic robots. By analyzing the velocity vectors on a circle or sphere, they proposed a distributed control law that results in an agreement of velocity vectors and flocking. Recently, fuzzy logic based approaches to flocking algorithm are developed. Gu and Hu [15] proposed a fuzzy logic solution to the separation control problem by applying Takagi-Sugeno (TS) rules and Gaussian membership functions. Yu *et al*. [16] designed an attractive/repulsive potential function based on fuzzy logic.

To date there have been many studies on type-1 FLC for multi-robot and flocking control [15], [16], whereas few studies on control of flocking robots with considering uncertainty in environments are found in the literatures. There is one paper written by Gu and Hu [15] which discusses robustness of flocking algorithm with bounded random noise, but it has limitations in handling the noise because they used type-1 fuzzy sets.

In this paper, we use the interval type-2 fuzzy logic to design controllers for flocking algorithm. The controllers enable robots to behave toward flocking by Reynolds' model. The robots used in this paper are modeled by second order dynamical system which is fully actuated. The simulation results of type-2 FLCs are presented and their results are compared with the results of type-1 FLCs to verify the robustness of type-2 FLCs with noisy sensor measurements.

The rest of the paper is organized as follows. Section II presents a flock model for robots with second order dynamical system. Section III proposes interval type-2 FLCs for flocking algorithm. The simulation results of the proposed type-2 FLCs are provided and discussed in Section IV. Finally, conclusions are presented in Section V.

II. FLOCK MODEL

A. Robot Dynamics

Let us consider a group of n robots (or particles) modeled by second order dynamical system with the following equation of motion:

$$\begin{aligned} \dot{q}_i(t) &= p_i(t) \\ \dot{p}_i(t) &= u_i(t) \end{aligned} \tag{1}$$

where $q_i(t)$, $p_i(t) \in \mathbb{R}^m$ are the position and velocity vectors of robot i, respectively, and $u_i(t) \in \mathbb{R}^m$ is a control vector which will be introduced later. It is assumed that all robots can communicate with each other and are fully actuated. The states of all n robots can be joined into vectors $q=[q_1,\ldots,q_n]^T \in \mathbb{R}^{mn}$, $p=[p_1,\ldots,p_n]^T \in \mathbb{R}^{mn}$, and $u=[u_1,\ldots,u_n]^T \in \mathbb{R}^{mn}$.

Let $q_d(t)$ and $p_d(t)$ be the desired position and velocity states for the group center. To track the desired position and velocity, a state feedback control law is applied to all robots in a group as follows:

$$u_i^{track} = -c_1(q_i - q_d) - c_2(p_i - p_d) \tag{2}$$

where c_1 and c_2 are the feedback gains, which can be represented by n-dimensional diagonal matrices. Then, the collective dynamics of a group of robots with the control input $u^{track} = [u_1^{track},\ldots,u_n^{track}]^T \in \mathbb{R}^{mn}$ can be represented in the following form:

$$\begin{aligned} \dot{q}(t) &= p(t) \\ \dot{p}(t) &= u^{track}(t). \end{aligned} \tag{3}$$

By using the control input $u^{track}(t)$, all robots belonging to the same group move to follow the desired trajectory.

The center of the group can be represented by the average of all states as follows:

$$q_c = \frac{1}{N}\sum_{i=1}^{N} q_i(t), \quad p_c = \frac{1}{N}\sum_{i=1}^{N} p_i(t). \tag{4}$$

From (1)-(4), the control input of the group center has the following form:

$$u_c^{track} = -c_1(q_c - q_d) - c_2(p_c - p_d). \tag{5}$$

Then, the dynamics of the center of the group can be represented by:

$$\begin{aligned} \dot{q}_c(t) &= p_c(t) \\ \dot{p}_c(t) &= u_c^{track}(t). \end{aligned} \tag{6}$$

B. Definition of Flocking Model

The flocking model was proposed by Reynolds [11] in 1986 for computer simulation of flocking behavior like flocking birds. The flocking model consists of the following three heuristic rules:

1) Cohesion behavior: attempt to stay close to nearby flockmates

2) Separation behavior: avoid collisions with nearby flockmates

3) Velocity matching behavior: attempt to match velocity with nearby flockmates

In this paper, not only the three rules of Reynolds but also obstacle avoidance behavior is designed through three interval type-2 FLCs in order to achieve the flocking behavior in environments with obstacles. Here we use interval type-2 fuzzy sets to design the FLCs, and then the robustness of the internal type-2 FLCs is tested with noisy sensor measurements. The three FLCs are designed to achieve cohesion-separation, velocity matching, and obstacle avoidance behaviors respectively.

III. TYPE-2 FUZZY LOGIC CONTROLLERS (FLCS) FOR FLOCKING ALGORITHM

In developing type-2 FLC for flocking algorithm, fuzzy sets are represented by Gaussian interval type-2 fuzzy sets. In Gaussian type-2 fuzzy sets, uncertainties are associated with the value of mean or standard deviation. In this paper the fuzzy sets with uncertain mean value is considered because uniform random noise is used to test the robustness of the type-2 FLCs.

For the simulation of flocking behaviors, three FLCs corresponding to each of the flocking behaviors are designed as shown in Fig. 1. Each FLC receives a crisp input value and then produces control output u_i^{sep}, u_i^{vel}, and u_i^{obs}. To determine the movement of each robot in the next step, the sum of the control outputs including u_i^{track} in (2) is used as u_i in (1). Thus, the total control function u_i is

$$u_i = u_i^{sep} + u_i^{vel} + u_i^{obs} + u_i^{track}. \tag{7}$$

In the rest of this section, three FLCs for each behavior in flocking algorithm based on interval type-2 fuzzy sets will be described to verify the robustness of the interval type-2 FLCs in the presence of uncertainty.

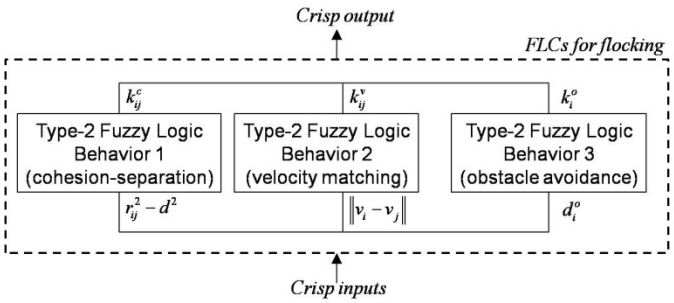

Fig. 1. Type-2 FLCs for flocking

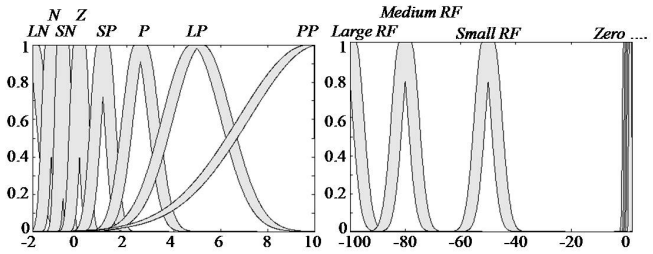

Fig. 2. Input (left) and output (right) membership functions for cohesion-separation behavior

A. Type-2 FLC for Cohesion-Separation Behavior

The FLC for cohesion-separation behavior make the robots in a group gather together around the group center while keeping robots with constant distance from others to avoid collisions with nearby robots. In order to achieve the cohesion-separation behavior, the type-1 FLC developed by Gu and Hu [15] is reformulated into an interval type-2 FLC, and it is used for cohesion-separation control. In developing the type-2 FLC for cohesion-separation control, eight type-2 Gaussian fuzzy sets which have a footprint of uncertainty (FOU) to model and handle the uncertainties of sensor data are designed as shown in Fig. 2. In the figure, the area of FOU is shaded in gray. Also eight fuzzy rules are designed as follows in a similar manner to [15]:

IF	$r_{ij}^2 - d^2$	is	*LN*	**THEN**	k_{ij}^s	is	*Large RF*
IF	$r_{ij}^2 - d^2$	is	*N*	**THEN**	k_{ij}^s	is	*Medium RF*
IF	$r_{ij}^2 - d^2$	is	*SN*	**THEN**	k_{ij}^s	is	*Small RF*
IF	$r_{ij}^2 - d^2$	is	*Z*	**THEN**	k_{ij}^s	is	*Zero*
IF	$r_{ij}^2 - d^2$	is	*SP*	**THEN**	k_{ij}^s	is	*Small AF*
IF	$r_{ij}^2 - d^2$	is	*P*	**THEN**	k_{ij}^s	is	*Medium AF*
IF	$r_{ij}^2 - d^2$	is	*LP*	**THEN**	k_{ij}^s	is	*Large AF*
IF	$r_{ij}^2 - d^2$	is	*PP*	**THEN**	k_{ij}^s	is	*Very Large AF*

where r_{ij} is the distance between robot i and robot j and d is desired distance between two robots. The control function of the robot i which include all effects from all robots in the group is

$$u_i^{sep}(t) = -\sum_i^n k_{ij}^s \left(q_i - q_j\right) \tag{8}$$

where $k_i^s=[k_{i1},\ldots,k_{in}]^T \in \mathbb{R}^n$ is the fuzzy output vector. The control function acts as a potential function on the robots, i.e. if the fuzzy input $r_{ij}^2 - d^2$ becomes negative value, then repulsive force (RF) acts on the robots; on the contrary, if the value becomes positive, then attractive force (AF) acts on the robots. In this manner, robots in a group can congregate without collisions with each other.

To measure the degree in which robots take the cohesion-separation behavior, we introduce the following *potential energy function*:

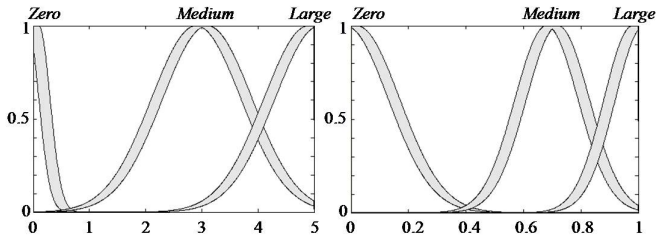

Fig. 3. Input (left) and output (right) membership functions for velocity matching behavior

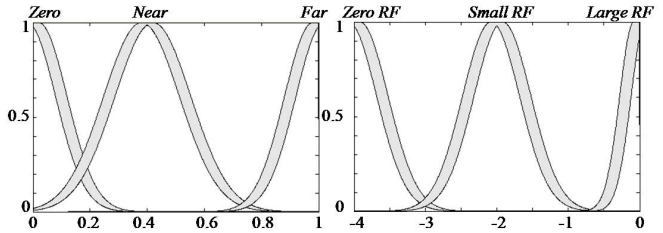

Fig. 4. Input (left) and output (right) membership functions for obstacle avoidance behavior

$$E(q) = \sum_i^n \sum_{j=i}^n \psi\left(\left\|q_i - q_j\right\| - d\right) \tag{9}$$

where $\psi(x)=x^2$. With this potential energy function, if the value becomes smaller, the flocking of robots is more stable.

B. Type-2 FLC for Velocity Matching Behavior

The FLC for velocity matching behavior is designed to align the velocity of each robot considering the others. The FLC receives only one crisp input value $\|v_i - v_j\|$ to determine fuzzy output value k_i^v. For the FLC, we represented the input and output fuzzy membership functions as *Zero*, *Medium*, and *Large* with FOU as shown in Fig. 3, and three simple fuzzy rules are designed as follows:

IF	$\left\|v_i - v_j\right\|$	is	*Zero*	**THEN**	k_{ij}^v	is	*Zero*
IF	$\left\|v_i - v_j\right\|$	is	*Medium*	**THEN**	k_{ij}^v	is	*Medium*
IF	$\left\|v_i - v_j\right\|$	is	*Large*	**THEN**	k_{ij}^v	is	*Large.*

The control function of robot i for velocity matching behavior is

$$u_i^{vel}(t) = -\sum_i^n k_{ij}^v \left(v_i - v_j\right) \tag{10}$$

where $k_i^v=[k_{i1},\ldots,k_{in}]^T \in \mathbb{R}^n$ is the fuzzy output vector. With this control function, a robot tends to align its velocity with other robots which have large velocity difference with it.

To measure the degree of velocity alignment, we use the following *deviation energy function*:

$$V(p) = \sum_i^n \sum_{j=i}^n \psi\left(\left\|p_i - p_j\right\|\right). \tag{11}$$

If the velocity $p_i(t)$ reaches an average velocity of all the robots, their headings and speed will be the same. Thus, the deviation energy function $V(p)$ becomes zero.

C. Type-2 FLC for Obstacle Avoidance Behavior

The obstacle avoidance behavior is needed for safe navigation in environments with obstacles. To design the type-2 FLC, we assume that there is one static obstacle and each robot has a range sensor which can detect the range from a robot to the obstacle when the obstacle is located within the r_{max} maximum detectable range of the sensor. Under this assumption, the range sensor value is represented by three interval type-2 fuzzy sets; *Zero*, *Near*, and *Far*; and the output fuzzy sets *Zero RF*, *Small RF*, and *Large RF* as shown in Fig. 4. The three simple fuzzy rules are designed as follows:

IF d_i is *Zero* **THEN** k_i^o is *Zero RF*
IF d_i is *Near* **THEN** k_i^o is *Small RF*
IF d_i is *Far* **THEN** k_i^o is *Large RF*.

The control function of robot i for obstacle avoidance behavior is as follows:

$$u_i^{obs}(t) = -\sum_i^n k_i^o \left(q_i - q^{obs}\right) \tag{12}$$

where k_i^o is the fuzzy output and q^{obs} is the position of obstacle. If the distance between the robot and the obstacle becomes smaller, then the robot feels large repulsive force from the obstacle. Thus, the type-2 FLC results in obstacle avoidance behavior.

IV. Simulation Results and Discussions

In this section, we present several simulation results of interval type-2 FLCs for flocking and compare their results with those of type-1 FLCs. In the simulations, a group of 10 robots in 2-D (i.e. m=2) is used, and all of them are networked with each other, i.e. the locations and velocity vectors of all robots are available to any robots belonging to the group for cohesion-separation and velocity matching behaviors.

For simulations, the robots are initially located randomly within a square of [-2.5m, 2.5m] and [-2.5m, 2.5m] in X and Y directions, respectively. The velocities are initially set randomly in the interval of [-1m/s, 1m/s]. The following parameters remain fixed throughout all simulations: d=0.3m for the cohesion-separation behavior, r_{max}=1m for the obstacle avoidance (range sensor), c_1=1 and c_2=1 for tracking a given reference trajectory. The reference trajectory which should be followed by the center of the flock is given by a straight line represented by

$$q^d = \begin{bmatrix} 0.5t & 0 \end{bmatrix}^T. \tag{13}$$

A. Tracking reference trajectory without obstacles

In the first test, the type-1 and type-2 FLCs for flocking are tested without obstacle avoidance behavior. To test the robustness of the FLCs, uniform random noise which produces data points that have the standard uniform distributions is applied to the measurements of range and velocity.

Figs. 5-6 show robot trajectories controlled by type-1 and type-2 FLCs respectively. As shown in the figures, the robots are initially located at random, and congregate around a center of the flock. As time goes on, the flocking becomes stable, and

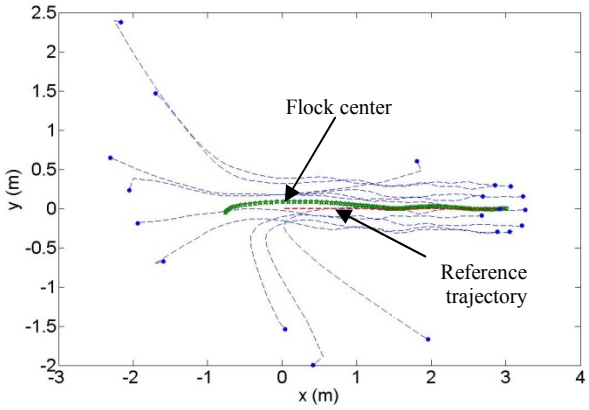

Fig. 5. Trajectories of robots by type-1 FLCs

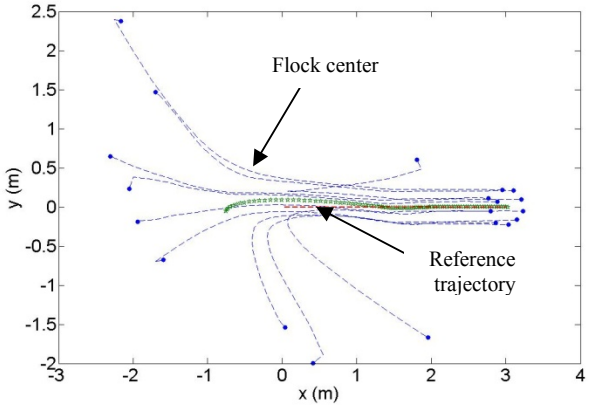

Fig. 6. Trajectories of robots by type-2 FLCs

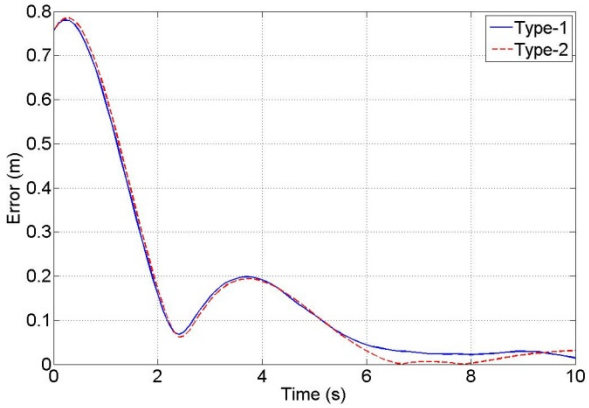

Fig. 7. Tracking error of the flock center

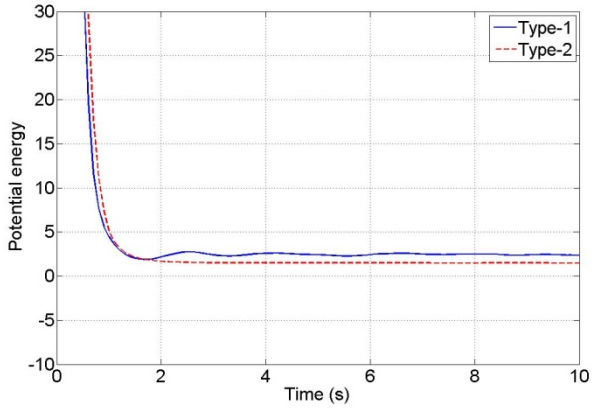

Fig. 8. Potential energy of flocking robots

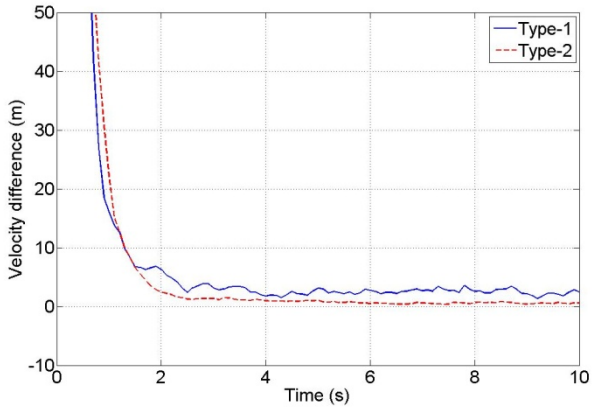

Fig. 9. Degree of velocity difference between robots

its center tracks the reference trajectory q_i^d. As shown in Fig. 5, the type-1 FLC-based cohesion-separation and velocity matching behaviors produce wobbling paths in tracking the reference path. In contrast to the type-1 FLCs, the type-2 FLCs produce smooth paths during flocking even though noisy sensor measurements are used as shown in Fig. 6. Fig. 7 shows the errors between the reference path and the center of flock trajectory. Fig. 8 shows that the potential function of type-2 have lower energy level compared with that of type-1. Also, considering the degree of velocity difference of type-1 and type-2, we can find that the type-2 shows not only lower degree but also smoother than type-1 as shown in Fig. 9. As can be seen in the results, the type-2 FLCs show robust performances under noisy environments compared to the type-1 FLCs.

B. Tracking reference trajectory with static obstacle

In the second test, the FLCs for the total flocking behaviors including obstacle behavior are tested, where the range sensors for detecting obstacles are noisy. For obstacle avoidance behavior, we assume that there is a static obstacle modeled by single point (i.e. no volume) located at q^{obs} = (3m, 0.3m). Figs. 10-11 show obstacle avoidance behaviors of type-1 and type-2 during flocking. As seen in the figures, the type-2 FLCs perform obstacle avoidance more smoothly than the type-1 FLCs, when robots detect an obstacle. Fig. 12 shows that the tracking error of the type-2 show slightly better performance than type-1. With respect to the potential energy, the type-2 show lower level of potential energy than the type-1 as shown in Fig. 13. Also, considering the degree of velocity difference, we can find that the value of the degree of robots controlled by

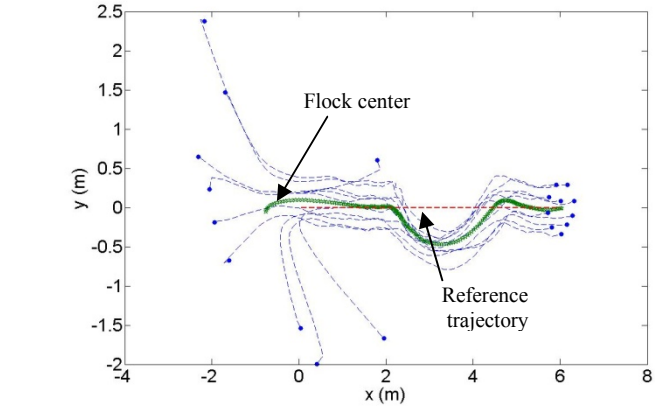

Fig. 10. Trajectories of robots by type-1 FLCs

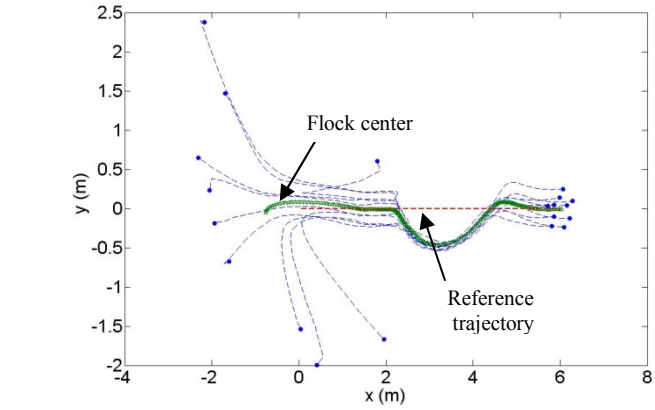

Fig. 11. Trajectories of robots by type-2 FLCs

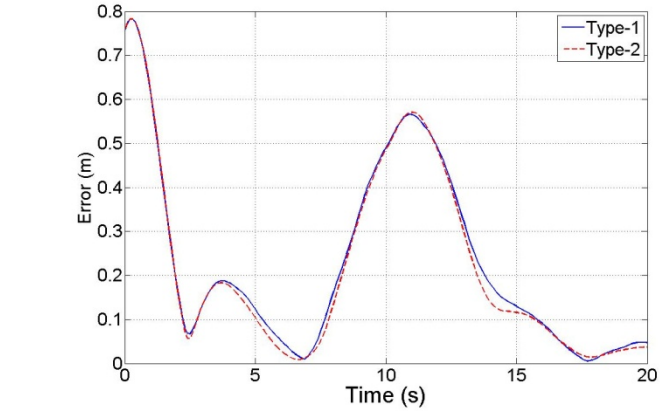

Fig. 12. Tracking error of flock center

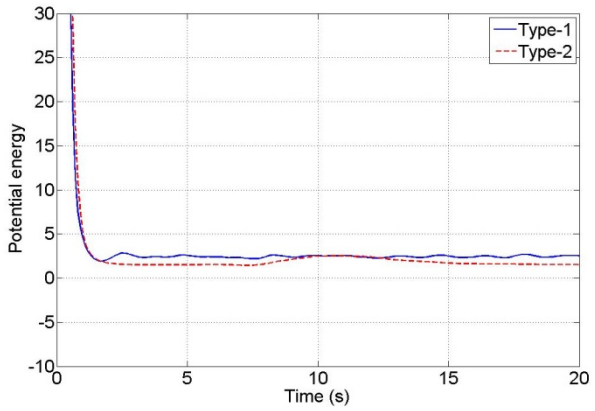

Fig. 13. Potential energy of flocking robots

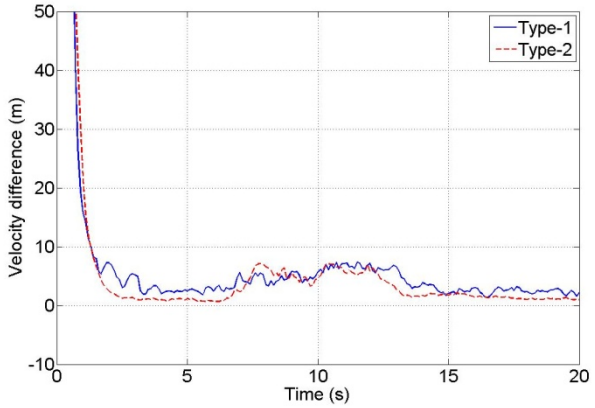

Fig. 14. Degree of velocity difference between robots

the type-2 FLCs shows better performance than the type-1 FLCs as shown in Fig. 14.

V. CONCLUSIONS

In this paper, we presented interval type-2 FLCs for flocking behaviors of robots which are modeled by the second order dynamical system, and its simulation results are compared to the type-1 FLCs with noisy sensor measurements. For flocking simulation, we proposed a structure composed of the three FCLs corresponding to flocking behaviors which consist of three components: cohesion-separation, velocity matching, and obstacle avoidance behaviors. From several simulations, we conclude that the interval type-2 FLCs are robust under uncertainties and that they resulted in better control responses than type-1 FLCs. As the use of interval type-2 FLC enables to model and handle the uncertainties effectively, the suggested FLC could provide robust performance on systems with uncertainties.

***Abstract*—Many interesting papers have been written in the recent past on kernel clustering and many attractive results have also been demonstrated. Here we question the rationality behind such clustering approaches. Using simple data sets we argue and demonstrate that it is not a good idea to find clusters in the kernel space when the objective is to look for clusters in the original data because in the kernel space the data may have a different geometry from that in the original feature space. In particular we demonstrate the following : (1) improper choice of the number of clusters may lead to very counterintuitive clusters (e.g., instead of merging nearby clusters, it may merge clusters that are far from each other) and (2) improper choice of kernel parameters has a significant effect on the extracted clusters and it can even impose arbitrary cluster structures that are undoubtedly absent in the original data. However, we definitely do not imply that kernel clustering can never produce desirable results. In fact, kernel clustering could be useful provided we can choose right kernel parameters. But the process being unsupervised, we do not have a solution to this issue yet. In this study, for illustration, we use one variant of the kernel Fuzzy C-Means (KFCM) clustering algorithm in conjunction with Polynomial kernels.**

Keywords: Fuzzy C-means, FCM, Kernel fuzzy C-means, feature space, Kernel space.

I. Introduction

A cluster seeking algorithm partitions a given data set $X = \{\mathbf{x_1}, \mathbf{x_2}, ..., \mathbf{x_n}\}$, $\mathbf{x}_i \in R^p$ into c number of clusters so that members of the same cluster are similar to one another and members of different cluster are dissimilar. Clustering has many applications covering almost all areas of science and technology [1], [2] and hence there are many algorithms [1], [3], [4], [5], [6] and the research efforts are still going on to develop more effective algorithms. Some algorithms use probabilistic concepts, while others use fuzzy and/or possibilistic modeling [3], [4], [7].

Crisp clustering methods assume that each data point belongs to one and only one cluster, which may not be true in some real life applications such as land-cover classification. In such cases, fuzzy clustering is considered a better alternative for extracting sub-structures in the data. In a fuzzy cluster, a data point may partially belong to more than one cluster and the membership degrees/grades lie in [0,1]. The most popular fuzzy clustering algorithm is the Fuzzy C-Means (FCM) [3] which works fine when the data set has hyperspherical clusters. However, if a pair of clusters is not linearly separable (eg., two nested spherical-shells), such algorithms usually fail. To identify such clusters there have been many extentions/variants of the FCM algorithm [8], [9], [10], [11]. In the recent past there have been many attempts to kernelize clustering algorithms. These algorithms are demonstrated to be useful in clustering data such as a disk surrounded by a shell, which are otherwise difficult to cluster [5], [12], [13], [14], [15], [16], [17]. These algorithms project the data implicitly into a high dimensional space with a hope that the "clusters" in the original space (we shall call it feature space) will be well separated in the kernel space. These algorithms then find the clusters in the kernel space.

There are different types of kernelized version of FCM. We shall consider a version which assumes that the cluster centers/prototypes are in the Kernel space [18], [19], [20], [21]. This family of algorithms requires an inverse mapping of prototypes from the kernel space to feature space. This type of algorithms will be called as KFCM-K (Kernel FCM with prototypes in the kernel space).

The objective of any clustering algorithm is to find the clusters (i.e., natural groups) in the *original* data space. Does a kernel clustering algorithm do so? Sometimes 2-Dimensional data sets are used to demonstrate the success of a kernel clustering algorithm. Usually some "suitable" kernel parameter values are chosen and results are demonstrated. Do we know if the algorithm will work for a wide range of choices of parameters? We shall see that even for some simple data sets, the answer to the previous question is "No". When the data sets are in 2-D we can visualize easily the performance. But when the data are in high dimension visual assessment is difficult. For such cases, usually the cluster centroids or the partition are used in conjunction with a labeled data set (the data set is for a classification problem) to assess the resubstitution or classification error. This approach makes an assumption that number of natural clusters is equal to the number of classes. But this may not necessarily be true as clustering and classification are philosophically two different problems. For example, a two class problem may have four distinct clusters and we may not know it (A high dimensional generalization of the Ex-OR problem). If the resubstitution or classification error is low, we should be happy, but if not, we cannot make any inference because the number of clusters may be equal

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

to the number of classes but the clustering could be poor or the number of clusters could be more than the number of classes and that may lead to poor classification performance. So assuming number of classes equal to the number of clusters and then checking the resubstitution error or classification error is not a good way of justifying kernel clustering.

Here we investigate whether clustering in the kernel space is justified or not. Our investigation suggests that Kernel clustering can lead to strange (counterintuitive) results if the choice of number of clusters and/or the choice of kernel parameters are not appropriate. We discuss and demonstrate this issue using some simple data sets.

II. Kernelized Version FCM

A data set may have clusters in it, but it may be difficult for an algorithm like FCM to extract those clusters. One reasons for this may be that a pair of clusters is not linearly separable. In such a case, the original data can be mapped to a higher dimensional space (kernel space) with a hope that clusters will be easily identifiable [19], [20], [21]. For this a non linear mapping function f is used such that $\phi : R^d \longrightarrow H$, where H is the kernel space. Typically kernel-clustering algorithms use the kernel trick that takes the advantage of the fact that the dot products in the kernel space can be represented by a Mercer kernel K where $K(\mathbf{x},\mathbf{y}) = \phi(\mathbf{x})^T\phi(\mathbf{y})$, where, $\mathbf{x},\mathbf{y} \in R^p$. Thus the distance/similarity in the kernel space can be replaced by the Mercer kernel. Some of the popular kernel functions are:

1) RBF kernel : $e^{-||\mathbf{x}-\mathbf{y}||^2/\sigma^2}, \sigma^2 > 0$
2) Polynomial kernel : $(\mathbf{x^T}.\mathbf{y}+a)^b, a \geq 0, b \in N$
3) Hyper-tangent : $tanh(\mathbf{x^T}.\mathbf{y}+a), a \geq 0$

In this study, we shall consider only one Kernel based FCM algorithm, KFCM-K and use only the Polynomial kernel (PK). We shall not consider the other versions, such as KFCM-F [18], [5], [22], where cluster centers are considered in the feature space itself.

A. KFCM-K [13], [14], [15], [16], [18]

Here the prototypes are located in the kernel space, so the pre-images of prototypes in the feature space have to be computed by taking the inverse mapping from kernel space to feature space. KFCM-K algorithm minimizes the following objective function at (1).

$$Q = \sum_{i=1}^{c}\sum_{k=1}^{n} u_{ik}^m ||\phi(\mathbf{x_k}) - \mathbf{v_i}||^2 \tag{1}$$

subject to the constraints

1) $u_{ik} \in [0,1] \forall i,k$
2) $0 < \sum_{k=1}^{n} u_{ik} < n \ \forall i$
3) $\sum_{i=1}^{c} u_{ik} = 1 \ \forall k$

In (1) $\mathbf{v}_i$ is i^{th} prototype in the kernel space. Using the Lagrange Multiplier technique, optimization of Q with respect to $\mathbf{v}_i$, results in

$$\mathbf{v_i} = \frac{\sum_{k=1}^{n} u_{ik}^m \phi(\mathbf{x_k})}{\sum_{k=1}^{n} u_{ik}^m} \tag{2}$$

Similarly, the expression for the membership values are derived as

$$u_{ik} = \frac{1}{\sum_{j=1}^{c} (\frac{||\phi(\mathbf{x_k}) - \mathbf{v_i}||}{||\phi(\mathbf{x_k}) - \mathbf{v_j}||})^{\frac{2}{m-1}}}; i = 1, \cdots, c; k = 1, \cdots, n \tag{3}$$

where

$$\begin{aligned} ||\phi(\mathbf{x_k}) - \mathbf{v_i}||^2 &= (\phi(\mathbf{x_k}) - \mathbf{v_i})^T(\phi(\mathbf{x_k}) - \mathbf{v_i}) \\ &= \phi(\mathbf{x_k})^T\phi(\mathbf{x_k}) - 2\phi(\mathbf{x_k})^T\mathbf{v_i} + \mathbf{v_i}^T\mathbf{v_i}. \end{aligned} \tag{4}$$

Using the expression for the prototypes (2) into the expression (4) , one gets

$$\begin{aligned} ||\phi(\mathbf{x_k}) - \mathbf{v_i}||^2 \quad = \quad & K(\mathbf{x_k},\mathbf{x_k}) - 2\frac{\sum_{j=1}^{n} u_{ij}^m K(\mathbf{x_k},\mathbf{x_j})}{\sum_{j=1}^{n} u_{ij}^m} \\ & + \frac{\sum_{j=1}^{n}\sum_{l=1}^{n} u_{ij}^m u_{il}^m K(\mathbf{x_k},\mathbf{x_l})}{(\sum_{j=1}^{n} u_{ij}^m)^2} \end{aligned} \tag{5}$$

Following, [18], [14], the expression for the prototypes in the feature space $V = \{\tilde{\mathbf{v}}_i; i = 1, 2, ..., c\}$ with Polynomial kernel is given in (6).

$$\tilde{\mathbf{v}}_i = \frac{\sum_{k=1}^{n} u_{ik}^m (\mathbf{x_k^T}\tilde{\mathbf{v}}_i + a)^{b-1}\mathbf{x_k}}{(\tilde{\mathbf{v}}_i{}^T\tilde{\mathbf{v}}_i + a)^{b-1}\sum_{j=1}^{n} u_{ij}^m} \tag{6}$$

Algorithm KFCM-K

1) Fix $c, t_{max}, m > 1$ and $\epsilon > 0$, the tolerance level for termination.
2) Initialize membership matrix U.
3) Repeat
   Update $U = [u_{ik}]$ according to equation (3) via (5).

   until $\sum_{i=1}^{c}\sum_{k=1}^{n} |u_{ik}^{(t+1)} - u_{ik}^{(t)}| < \epsilon$ is satisfied. (7)
4) Return U.
5) Initialize prototypes V
6) Repeat
   Update $\tilde{\mathbf{v}}_i$s according to equation (6) for Polynomial kernel

   until $\sum_{i=1}^{c}\sum_{k=1}^{p} |\tilde{v}_{k,i}^{(t+1)} - \tilde{v}_{k,i}^{(t)}| < \epsilon$ is satisfied. (8)
7) Return V.

Note that, there are many other equivalent termination criteria that can be used in place of (7) and (8).

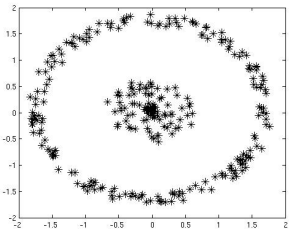
III. Experimental studies

We use three synthetic data sets, all in R^2:Ring, Five-Cluster, and Uniform-Disc.

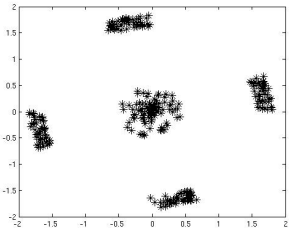
- **Ring** : The Ring Data set is depicted in Fig.1a, where the inner disk contains 100 points and the outer ring contains 200 points.

- **Five-Cluster** : Fig.1b shows the Five-Cluster data set where the inner disk, like Ring contains 100 data points forming a cluster. Surrounding this cluster, there are four smaller clusters, each with 50 points.
- **Uniformdisk** : Fig.1c depicts the Uniform data set with 441 points that are uniformly distributed. This data set does not have any cluster in it.

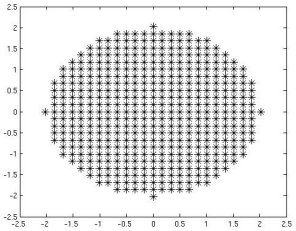
For each data set, X, every feature x is normalized by $\frac{(x-\mu)}{\sigma}$, where μ and σ are the mean and standard deviation of x as estimated from the given data set. This protocol is followed in [18].



(a) Ring dataset



(b) FiveCluster dataset



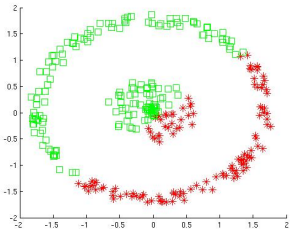
(c) Uniform dataset

Fig. 1: The three Synthetic datasets used in this study

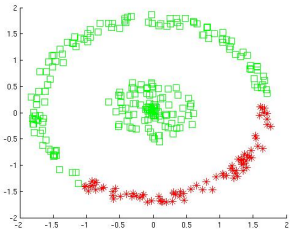
A. Kernel Clustering with Polynomial Kernel

We study the behavior of FCM, and KFCM-K with Polynomial kernel on the three data sets Ring, Five-Cluster, and Uniform. We use $m = 1.2, \epsilon = 10^{-8}, t_{max} = 100$. For the Polynomial Kernel,we have experimented with different choices for $a \in \{1, 2, 3, 4, 5, 7, 10, 15\}$ and $b \in \{2, 4, 6, 8, 10, 12, 14, 16\}$, a total of 64 combinations. The initial prototypes are taken randomly from the input data set.

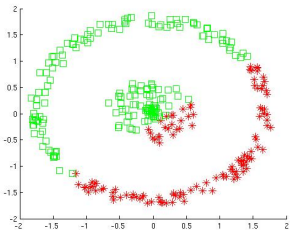
First we consider the Ring data, Fig.1a. Clearly there is a disk-shaped cluster at the center. Many authors share the view that the shell around the disk is also a cluster. We also share the same view here. For this data set with c=2, FCM, as expected, divides the data set as shown in Fig.2a. For some choices of a and b, the KFCM-K behaves similar to FCM, but for none of the 64 choices of parameters, KFCM-K could extract the shell as a separate cluster. Sometimes, part of the shell is extracted as a cluster and the remaining data points as another cluster. One such partition is exhibited in Fig. 2b. We also noticed that when a is high and b is low, then for this data set KFCM-K behaves like FCM. Fig 2c shows one such partition with a=15 and b=2. For this data set we find that the choice of a and b has a significant influence on the clustering output. Moreover, in this case, KFCM-K failed to produce the desired partition. Hence we do not make any further analysis on this data set.



(a) FCM



(b) KFCM-K (a=1,b=2)



(c) KFCM-K (a=15,b=2)

Fig. 2: Clustering of Ring data with FCM and KFCM-K for c=2

Next we focus our attention on the Five-Cluster data set (Fig.1b), which has five distinct clusters. As expected, FCM finds all the five clusters correctly when c=5 (Fig.3g), so does KFCM-K with a=1, b=2 (Fig.3h). Fig.3, also compares the results with c=2,3, and 4. For example, when c= 4 (with a=1,b=2), the FCM result is quite intuitive (Fig.3e), while KFCM-K merges two clusters, which are on the *opposite sides* of the central disk, into one clusters (Fig. 3f). Thus KFCM-K

merges two small clusters when they are quite far from each other. Note that, we have run the clustering algorithms with different initializations, and we got similar results in several runs. However, for c=2 and c=3, FCM produces intuitively acceptable results (Fig.3a and Fig. 3c), while KFCM-K does not (Fig.3b and Fig. 3d) as it merges two clusters which are not nearby. In this case, since the data are in 2-D we can assess the results visually. But for high dimensional data, we may not know the desired number of clusters and hence we may end up with very undesirable results (merging of two distant clusters) and we would not even know that. This is one facet of the problems associated with kernel clustering.

The other problems is associated with the choice of kernel parameters. To demonstrate this issue, we consider c=5, the best choice for number of clusters for this data set. Then we ran KFCM-K for all 64 combinations of a and b as mentioned above. Table I, summarizes the results. Table I reveals that when a=1, and b is high (12 or higher), KFCM-K fails to extract the correct partition. Fig.4 (a) reveals that with a=1 and b=12, a few points of the cyan (plus) and blue (circle) clusters get merged with the central disk. Similarly, with a=2 and b=14 or higher, the partition starts departing from the desirable one (Fig.4 (b)). Thus we find that the choice of kernel parameters is crucial to the success of the algorithm even for very simple data sets. Since, for high dimensional data we would not know the sub-structures present in the original data, we shall not know whether KFCM-K has found a good solution or not. One can make the same arguments with FCM, but the differences are : (a) with improper choices of c, the number of clusters, FCM splits or merges clusters in such a manner that they agree with our intuition and FCM does not impose strange geometric structures on the data and (b) FCM does not have these two extra parameters, which may change the geometry of the data.

Now we consider the data set, Uniform (Fig.1c). Clearly Uniform does not have any sub-structure or cluster. Hence any clustering algorithm, with c=2, should partition the data into approximately two halves, where the approximate line partitioning the data may have one of many possible orientations. Fig. 5a shows that FCM does the same. Similarly, KFCM-K also does the same with a=1, b=2 (Fig.5b); as b increases, one of the clusters starts becoming bigger (Fig.5c). With a=1,

b=12 or above, KFCM-K extracts a *nice shell* (Fig. 5d) as one of the clusters. This behavior is also repeated with other choices of a. In fact, when a is increased, KFCM-K starts extracting a shell for further high values of b. This is a very serious limitation of the KFCM-K algorithm. As an illustration in Fig. 6 we show the membership values of different points to the cluster they belong to. Figure 6 corresponds to Fig. 5d. In Fig. 6, for each point we find the maximum membership value and depending on its cluster label we plot it either in green (square) or in red (circle). Figure 6 shows that for most of the points in the central big cluster the membership values to the cluster are very high, while for most points belonging to the imposed outer-shell cluster, the membership values are above 0.6. There are some points in the bigger cluster with memberships varying from values slightly higher than 0.5 to further high values suggesting a kind of gradual transition from one cluster to the other. In this data set, there is no reason to assume such a strange cluster structure.

(c) KFCM-K (a=1, b=6) (d) KFCM-K (a=1, b=12)

Fig. 5: Results on the Uniform dataset by FCM and KFCM-K for different parameters

Table I summarizes the visual assessment of quality of the partitions generated by kernel clustering for some illustrative sets of a and b. In Table I, Medium indicates minor departure from ideal partition while Bad indicates significant departure from the ideal partition.

So what do we learn from these experiments?

- Knowledge of the number of clusters present in the data is essential for the success of KFCM-K; otherwise, some cluster may include data points which are far from each other. In particular when c is less than the actual number clusters, KFCM-K may merge two subclusters which are far from each other in the actual data (feature) space ignoring nearby clusters. Thus producing counterintuitive clusters.

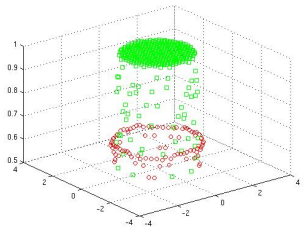

Fig. 6: Pictorial representation of the maximum membership values to the clusters.

- When a data set does not have any cluster structure, depending on the choice of kernel-parameters, it can impose very artificial substructures (e.g., the KFCM-K extracts a shell from the uniform data). To summarize, KFCM-K may impose arbitrary structures on the data.
- Even when the number of clusters is known, appropriate choice of the kernel parameters is essential to get the desirable results.

These problems are quite serious because for any real life application, data are usually in a high dimensional space. But why do all these happen? We think, this happens because we are trying to extract clusters in a space which may alter the geometry of the original data. This does not mean that for some data set KFCM-K type clustering cannot help. For example, if we have two touching clusters and in the projected space the two clusters become separated, then it would be easy to find the clusters in the kernel space. There could be other interesting cases where kernelized version could be useful. For example, using RBF kernel with an appropriate choice of the kernel width, it is possible to extract the shell and the central disk as two different clusters [18], but we need to use the right kernel with the right choice of parameters.

IV. Discussion and Conclusion

The performance of the kernel clustering algorithm, KFCM-K raises a very fundamental question : Should we really cluster a given data set in the kernel space? Although in the kernel space the data points might be more sparsely distributed, we cannot say that the clusters that we find in the kernel space will represent the same groups as those in the original feature space. We have illustrated this using a few synthetic data sets. In some of the studies involving kernel clustering the results are justified by matching the clusters with the classes [18]. In other words, one starts with a data set on k classes where every point has an associated class label indicating the class that the data point comes from. Such a data set is then clustered into c=k clusters ignoring the class labels. Finally, one assesses how good the partition matches with class structure. If there is a good match we should be happy. But we need to remember that cluster structure in a data set may be quite different from the structure imposed by class labels. The situation is actually more complicated because most kernel needs specification of some parameters. We have demonstrated that the choice of the kernel parameters has a

significant impact on the performance of clustering algorithm. When the problem is of classification, we can use different ways, such as cross-validation, to choose a desirable value for the kernel parameters. But for cluster seeking problems, it is difficult to choose the optimal parameters because the problem is unsupervised.

We have demonstrated / justified that Kernel clustering may lead to very unexpected results. When the goal of clustering a data set is to find the clusters / substructures in the original data (feature) space, unless one is careful, kernelization may impose undesirable structures on the data and hence the clusters obtained in the kernel space may not exhibit the structure of the original data. But, this does not mean that kernel clustering cannot be useful at all. If one wants to cluster in the kernel space, then proper choice of the parameters of the kernel function has to be used. We do not have a mechanism to choose the desirable parameters and currently we are investigating this issue. We hope to report our findings on this in near future.

***Abstract*—This article presents a strategy to solve thermal unit commitment (UC) integrated with an equivalent solar-battery system using Fuzzy based Quantum inspired Evolutionary Algorithm (FQEA). As a renewable power source, solar power is injected stochastically with the model. To handle the uncertainty and intermittency involved while integrating solar power and load forecasting, the trivial crisp problem formulations are modified by fuzzification. An evolutionary algorithm based on the concept and principle of quantum computation is applied to solve the UC problem. The conventional Quantum Evolutionary Algorithm (QEA) is advanced by using several operators such as binary differential operator, mutation and crossover along with trivial rotation operator with a re-defined rotational angle look-up table. The QEA is further modified by introducing multi-population based scheme. The fitness function is formulated by combining the objective function, penalty function and the aggregated fuzzy membership function. The proposed FQEA is applied to UC problem in different scaled power systems up to 100 units. Provided simulation results will show the effectiveness of FQEA.**

Keywords*—Unit Commitment, Fuzzy Logic, Quantum Computation, Evolutionary Method.

I. Introduction

The generation planning problem is an important problem in planning and operation of power system which required to be solved very carefully in order to accomplish maximum benefit. UC requires determining the on/off schedules of thermal units over a particular schedule horizon as well as resolves the hourly thermal output power (known as economic load dispatch; ELD) as well as satisfying a large set of system and operational constraints while keeping the production cost as minimum as possible. UC is introduced as one of the most complex combinatorial optimization problems in power system economics. A bibliographical survey on UC discloses that a good amount of numerical and meta-heuristic optimization techniques such as priority list [1], Lagrangian relaxation (LR)[2,3], genetic algorithm (GA)[4,5], evolutionary programming (EP)[6], particle swarm optimization (PSO)[7,8], simulated annealing (SA)[9,10], dynamic programming (DP)[11], constraint logic programming (CLP)[13] have been successfully applied to achieve efficient and near optimal solutions for UC problem. The concept of applying quantum mechanics in the field of computer science is a new prototype in the research of evolutionary programming. Some key principles of quantum mechanics such as uncertainty, superposition, interference are the main working force in quantum inspired evolutionary programming [14,15]. QEA is also successfully applied on thermal UC problem [16]. Moreover, one variant of QEA coupled with binary particle swarm optimization was skillfully deployed on UC problem [17], showing its versatility in power system economical optimization field. Thermal unit generation requires extensive use of fossil fuels which have negative effect on environment. Renewable energy sources come as a remedy of such scenarios and rightfully receive significant importance in recent researches and studies. Solar power is widely investigated such renewable source. However its integration with UC is imprecise due to the prediction error in forecasted load demand, solar radiation and spinning reserve requirement. Hence the crisp methods fell short especially when imprecise solar power system is coupled. Such uncertainties in imprecise parameters have been considered in mainly two ways: fuzzy systems approach [12] and stochastic/probabilistic approach.

This paper proposes a fuzzy logic based thermal UC strategy integrated with solar-battery by facilitating a modified quantum inspired evolutionary algorithm. Battery is modeled with solar system to supply power in case of peak load shaving and also to smooth out the load leveling. The solutions are initialized by a sophisticated weighted priority list method which helps to determine feasible as well as diverse solutions. The solutions are then 're-observed' and converted into quantum individuals. The QEA process, comprised with multi-population scheme is applied on the quantum individuals. The load demand, solar radiation, spinning reserve and total production cost is re-formulated by defining fuzzy membership degrees considering their uncertain nature. To evaluate the individual's fitness and contribution, a fitness function is defined which includes the aggregated fuzzy membership function and penalty function for constraints violations. The individuals are updated using several operators to facilitate the exploration and

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

exploitation syndrome.

The organization of the paper is briefed as follows: Section II details about the quantum computation. The problem formulation including the objective function and constraints is elucidated in Section III. Section IV shows the fuzzy formulation of the imprecise constraints. The details algorithms with associated technical aspects are briefed in Section V. Numerical simulations and results analysis are detailed in Section VI. Finally concluding remarks are described in Section VII.

II. Quantum Computation

The combination of quantum mechanical computers and quantum algorithms is the key concept of quantum computation. Many efforts on quantum computers, such as Grover's database search algorithm, and Shor's quantum factoring algorithm, have been progressed actively due to its superiority to classical computers in various fields. To begin with, a novel Q-bit chromosome representation is adopted based on the concept and principles of quantum computing such as Q-bits and linear superposition. The smallest unit of information stored in two-state quantum computer is called a quantum bit (Q-bit), which may be in the "1" stage, or in the "0" state, or in any superposition of the two. The state can be represented as

$$| \Phi\rangle = \alpha \mid 0\rangle + \beta \mid 1\rangle \tag{1}$$

where α and β are complex numbers that specify the probability amplitude of the corresponding states. $|\alpha|^2$ and $|\beta|^2$ give the probabilities that Q-bit will be located in "0" state and "1" state, respectively. Normalization of the state to the unity guarantees

$$|\alpha|^2 + |\beta|^2 = 1 \tag{2}$$

A Q-bit individual as a string of λ Q-bits is defined as

$$\left[\begin{array}{c|c|c|c} \alpha_1 & \alpha_2 & \dots & \alpha_\lambda \\ \beta_1 & \beta_2 & \dots & \beta_\lambda \end{array}\right] \tag{3}$$

where the normalization condition holds for each of the λ Q-bits as per Eq. (2). Q-bit representation has advantages such as to present a linear superposition of states and able to represent 2^λ states in probabilistic manner. For example, the following 2 Q-bit

$$\left[\begin{array}{c|c} 1/\sqrt{2} & 1/2 \\ 1/\sqrt{2} & \sqrt{3}/2 \end{array}\right] \tag{4}$$

can represent 4-states, each of which with a specific probability ($|00\rangle$ is $1/8$, $|01\rangle$ is $3/8$, $|10\rangle$ is $1/8$ and $|11\rangle$ is $3/8$. The high-level (three levels) outline of quantum evolutionary algorithm (QEA) is shown in Figure 1. The following subsections will brief the components of QEA.

A. Quantum individuals

The lowest level of QEA corresponds to Q-individuals. As shown in Eq. (3), it contains a number of Q-bits. $Q_i(t)$ denotes the Q-individual i at tth generation. Each Q-individual has to be viewed as a distribution of bit strings of length λ. The fitness

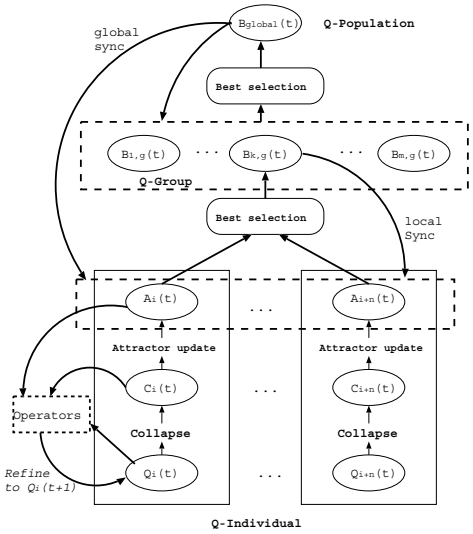

Fig. 1. High level outline diagram of QEA.

of Q-individual is re-evaluated at every generation according to a realization of distribution even if the individual is unchanged. Which is why, each $Q_i(t)$ is measured to form a binary corresponds namely $C_i(t)$ by the process called $collapse$ or $observe$. Q_i is the genotype while C_i is the phenotype in the context of classical EA. The individual Q_i is further attached to a binary string A_i which acts as an $attractor$ for Q_i. In every generation, C_i and A_i are compared in terms of both fitness and bit values. Operators, such as quantum gate, bit flipping, etc. trigger to a corresponding Q-bit when A_i is better than C_i and their bit values differ. Thus the distribution of Q_i is slightly moved toward a given solution A_i. On the other hand, $attractor$ is updated if C_i is better than A_i.

B. Quantum groups

The population is divided into m Q-groups each containing n Q-individuals having the ability to synchronize their attractors. Therefore, the best attractor of group k, $B_{k,g}$ is stored at every generation and is periodically distributed to the group attractors.

C. Quantum population

The set of all $n \times m$ Q-individuals forms the *quantum population*. As for Q-groups, the individuals of a Q-population can synchronize their attractors. Therefore, the best attractor (in terms of fitness) among all Q-groups, noted B_{global}, is stored every generation and is periodically distributed to the group attractors.

III. Formulation of UC Problem

A. Objective function

The objective function of thermal unit commitment problem is to minimize the total production cost (TC) while satisfying several constraints.

$$Min\ TC = \sum_{i=1}^{N}\sum_{t=1}^{T}[F(P_{i,t} + SC_i(1 - I_{i,t-1})]I_{i,t} \quad (5)$$

where $F(P_{i,t}) = a + b.P_{i,t} + c.P_{i,t}^2$, is the quadratic fuel cost function of $P_{i,t}$ which is the thermal power output of unit i at hour t, $I_{i,t}$ is the status of i-th unit at hour t, N and T are the number of production units and time horizon, respectively. a, b and c are the fuel coefficients and SC_i is the startup cost for unit i which is defined as follows

$$SC_i = \begin{cases} hcost_i & :T_i^{off} \le X_i^{off} \le H_i^{off} \\ ccost_i & :X_i^{off} > H_i^{off} \end{cases}$$
$$H_i^{off} = T_i^{off} + cshour_i. \quad (6)$$

where $T_i^{on/off}$ is the minimum up/down time for unit i, while $X_i^{on/off}$ is the duration for which unit i is being on/off. $hcost$ and $ccost$ are the hot and cold start cost for unit i, respectively. $cshour$ is the cold start hour of unit i.

B. Constraints

The following constraints are considered in this study which needs to be satisfied while optimizing the total production cost.

1) System power balance: The total power output from the thermal generators and solar-battery source should satisfy the load demand for that hour. Thus the system power balance equation for hour t can be expressed as

$$\sum_{i=1}^{N} P_{i,t} + P_{s,t} = D_t. \quad (7)$$

where $P_{s,t}$ is the solar power output at hour t and D_t is the forecasted load demand. The power output from solar energy system is expressed as the following equation

$$P_{pv}(S(t)) - p_{b,t} - P_{s,t} = 0 \quad (8)$$

where $S(t)$ is the solar radiation at hour t (in W/m^2), P_{pv} is the conversion function regarding solar radiation to energy and $p_{b,t}$ is the output of the battery at hour t. P_{pv} is defined as

$$P_{pv}(S(t)) = \begin{cases} P_{sn}\frac{S(t)^2}{S_{std}R_c} & 0 < S(t) < R_c \\ P_{sn}\frac{S(t)^2}{S_{std}} & S(t) > R_c \end{cases} \quad (9)$$

where S_{std} is the solar radiation for standard environment and set as 1,000 W/m^2 and R_c is the cut in radiation point set as 150 W/m^2. Since the solar energy system is incorporated with battery, trivial battery constraints such as charge/discharge limit, initial and ending state of charge, penetration limit are considered in this study.

2) Generation limit: The power output of each generating unit must be limited within a specified range.

$$P_i^{min} \le P_{i,t} \le P_i^{max}. \quad (10)$$

where $P_i^{min/max}$ is the minimum/maximum power output limit for unit i.

3) Ramp constraint: For each unit in each hour output is limited by the following ramp constraint:

$$P_{i,t}^{min} \le P_{i,t} \le P_{i,t}^{max}. \quad (11)$$

where $P_{i,t}^{min} = max(P_{i,t-1} - DR_i, P_i^{min})$ and $P_{i,t}^{max} = min(P_{i,t-1} + UR_i, P_i^{max})$. UR_i and DR_i are the up and down ramp limit for unit i, respectively.

4) System spinning reserve requirements: In order to ensure reliability, the system spinning reserve requirement must be satisfied. The spinning reserve requirement is expressed by following equation

$$\sum_{i=1}^{N} I_{i,t}P_{i,t}^{max} \ge D_t + SR_t. \quad (12)$$

where SR_t is the required spinning reserve for hour t.

5) Unit minimum up/down time: Due to operational limitations, once a unit is committed/decommitted it should be kept stable for a minimum period of time before a transition. This scenario can be expressed as

$$\left.\begin{array}{rcl} T_i^{\text{on}} & \le & X_{i,t}^{\text{on}} \\ T_i^{\text{off}} & \le & X_{i,t}^{\text{off}} \end{array}\right\}. \quad (13)$$

6) Emission constraint: Burning fuel emit contaminated gases which should be limited by the following equation

$$\sum_{i=1}^{N}\sum_{t=1}^{T} H_i(P_{i,t}) \le E_{limit}. \quad (14)$$

where $H_i(P_{i,t})$ is a quadratic function associated with several emission types and E_{limit} is the emission limit.

IV. Fuzzy Formulation

In thermal UC, the constraints related to the imprecise hourly load demand the system load balance, spinning reserve requirement invite uncertainty. Therefore, they can be treated as fuzzy constraints instead of crisps constraints. Moreover, the solar power generation, which is directly related to the solar radiation, is also a contender of fuzzy representation. The following subsections describe the fuzzy constraints with associated membership functions.

A. Fuzzy load demand

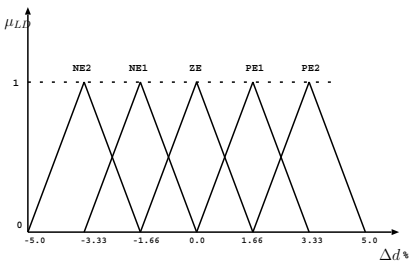

Fig. 2. Load demand error membership function.

The forecasted load demand is imprecise and can vary with the actual load demand. Therefore, the crisp notation is changed into the fuzzified load demand. The predicted load

demand usually deviates (Δd) from the actual one by $\pm 2\%$ to $\pm 5\%$. The membership function for fuzzy load percentage (Δd vs. μ_{LD}) error is shown in Figure 2. The load deviation error is equally distributed in $\pm 5\%$. Five linguistic values (NE2, NE1, ZE, PE1, PE2) are defined for negative, zero and positive errors. The load demand error thus can be represented as the following fuzzy equality relation

$$D_{f,t} \cong \sum_{i=1}^{N} P_{i,t}. \tag{15}$$

where $D_{f,t}$ is the calculated forecasted load demand for tth hour.

B. Fuzzy spinning reserve

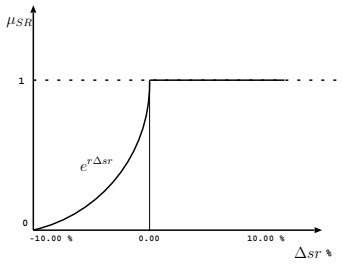

Fig. 3. Spinning reserve error membership function.

To ensure the secure operation during the outage, spinning reserve is required. Since the load demand is modeled by fuzzy logic, spinning reserve requirement can also be represented as non-crispy notations. In this proposed method, the spinning reserve membership function μ_{SR}, shown in Figure 3, can be defined as following equations

$$\mu_{SR} = \begin{cases} 1 & if\ Eq.(17)\ holds \\ e^{r.\Delta sr} & Otherwise \end{cases} \tag{16}$$

$$\sum_{i=1}^{N} I_{i,t}.P_{i,t}^{max} \geq SR_t + D_{f,t}. \tag{17}$$

where r is the weighting factor and Δsr is the error percentage of spinning reserve.

C. Fuzzy cost function

The total production cost can also be taken under fuzzy wings by imposing the lower membership function value to a higher production cost schedule. The membership function is a reverse one of that of spinning reserve which can be define as follow

$$\mu_{TC} = \begin{cases} 1 & if\ \Delta tc < 0 \\ e^{-w.\Delta tc} & Otherwise \end{cases} \tag{18}$$

$$\Delta tc = \frac{TC - \sigma TC_{max}}{\sigma TC_{max}} \tag{19}$$

where w is the weighting factor, σ is the cost tolerance factor and TC_{max} is a predefined value elucidates the maximum production cost.

D. Fuzzy solar power

Solar radiation error needs to be fuzzified in order to deal with such uncertainty. The membership function μ_{LR}, for solar radiation is equated as follows

$$\mu_{LR} = \begin{cases} \frac{1}{1+2.33(\Delta v/v^{+})^2}, & if\ \Delta V \geq 0 \\ \frac{1}{1+2.33(\Delta v/v^{-})^2}, & if\ \Delta V < 0 \end{cases} \tag{20}$$

where $v^{\pm}$ is the average error percentage of the error deviation, ranging from ± 0.40 to ± 0.13 depending on the margin of error.

V. FQEA Details

This section details about the key components of FQEA method. The following subsections are presented for this purpose.

A. Solution structure

The control variables of the UC method are the units' on/off status for the entire horizon. Therefore, the data structure for each individual contains the binary status, the corresponding power output, etc. Moreover, the Q-bit representation is also needs to be incorporated. Figure 4 shows the data structure of the entire population (of size P). The usage of flag vector will

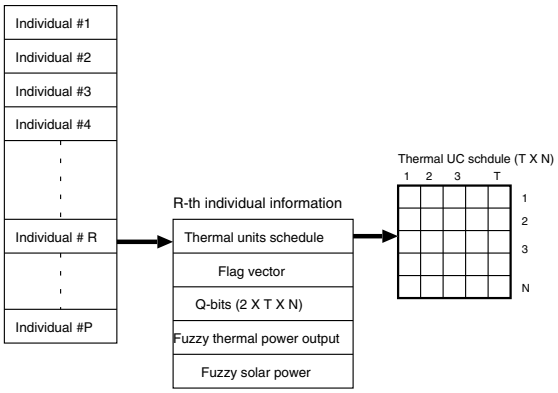

Fig. 4. High level data structure for FQEA population.

be used to boost up ELD performance.

B. Generating initial solution

In trivial QEA algorithm for mixed integer problem, the Q-bits are initialized as $[\sqrt{(0.5)}, \sqrt{(0.5)}]^T$ in order to make units' status equally probable of ON/OFF. But such initialization may produce highly infeasible individuals which eventually lead to slower convergence. In FQEA method, the initialization process is done by providing priority list depending on the load demand. The process is shown in Figure. 5. The units are prioritized using a sophisticated weighted priority list method. Then based on the load demand and spinning reserve requirements, the units are turned ON. The corresponding Q-individual is also set by reflecting the binary bit by weighting associated Q-bit depending on the units' status. Assuming that, on the peak load time, all units will be committed. To satisfy minimum up/down constraints, some

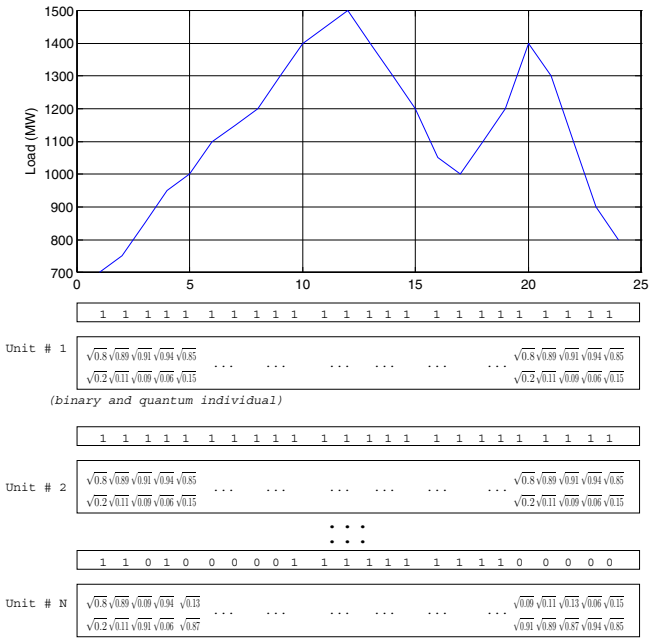

Fig. 5. Generating initial solution process.

excess units are needed to be ON. A logarithmic probability distribution function is used stochastically set such units status.

C. Fitness function

The quality of a particular individual is presented by the fitness function. In the proposed FQEA method, the fitness function is comprised with the objective function (Eq. 5), penalty function for constraints violation and aggregated fuzzy membership function to integrate the involved uncertainties. The aggregated fuzzy membership function for an individual j is defined as

$$\mu_{A_j} = min(\mu_{LD*}, \mu_{SR*}, \mu_{TC}, \mu_{LR*}) \quad (21)$$

where

$$\mu_{LD*} = min(\mu_{LD^1}, \mu_{LD^2}, \ldots, \mu_{LD^T}) \quad (22)$$
$$\mu_{SR*} = min(\mu_{SR^1}, \mu_{SR^2}, \ldots, \mu_{SR^T}) \quad (23)$$
$$\mu_{LR*} = min(\mu_{LR^1}, \mu_{LR^2}, \ldots, \mu_{LR^T}) \quad (24)$$

The penalty function needs to be defined to measure up the violation index of an individual. For the inequality constraints, a generic violation function is defined as per following equation

$$V = \sum_{k=1}^{ic} C_k |min(ULD, LLD)| \quad (25)$$

where ic is the number of inequality constraints, C_k are a constant associated with related constraints. ULD and LLD are the upper limit and lower limit constraints violations for inequality constraints respectively. The penalty function is therefore written as

$$PF = K.|D_t - \sum_{i=1}^{N} P_{i,t} - P_{w,t}| + V \quad (26)$$

TABLE I
LOOK UP TABLE FOR DETERMINING THE ROTATION ANGLE FOR QUANTUM ROTATION OPERATION.

X_j	B_j	$f(r) \geq f(global)$	$\Delta\theta_j$	$s(\alpha_j,\beta_j)$ $\alpha_j\beta_j > 0$	$\alpha_j\beta_j < 0$	$\alpha_j = 0$	$\beta_j = 0$
0	0	False	0	0	0	0	0
0	0	True	0	0	0	0	0
0	1	False	0	0	0	0	0
0	1	True	θ	-1	+1	±1	0
1	0	False	θ	-1	+1	±1	0
1	0	True	θ	+1	-1	0	±1
1	1	False	θ	+1	-1	0	±1
1	1	True	θ	+1	-1	0	±1

where K is a scaling factor. So, the evaluation function is finally defined as

$$E = \frac{10^{round(log_{10}^{F_{max}})}}{F + PF} \times \mu_{A_j}. \quad (27)$$

where F_{max} is a priori value of maximum fuel cost which is determined by several trials and errors.

D. Quantum operators

The proposed method applies several quantum operators based on the associated assigned probabilities assigned. The operators work on either single Q-bit individual or multiple Q-bit individuals.

1) Rotation gate: The rotation gate, $U(\theta)$ is employed on a singe Q-bit individual as a variation operator. $(\alpha_{i,j}, \beta_{i,j})$ of the jth Q-bit of ith individual is updated for $(t+1)$-th iteration as follows

$$\begin{bmatrix} \alpha_{i,j}(t+1) \\ \beta_{i,j}(t+1) \end{bmatrix} = U(\theta_{i,j}) \begin{bmatrix} \alpha_{i,j}(t) \\ \beta_{i,j}(t) \end{bmatrix} \quad (28)$$
$$= \begin{bmatrix} \cos(\theta_{i,j}) & -\sin(\theta_{i,j}) \\ \sin(\theta_{i,j}) & \cos(\theta_{i,j}) \end{bmatrix} . \begin{bmatrix} \alpha_{i,j}(t) \\ \beta_{i,j}(t) \end{bmatrix}.$$

where $\theta_{i,j}$ is rotation angle, $\theta_{i,j} = s(\alpha_{i,j}, \beta_{i,j})\Delta\theta_{i,j}$, where $s(\alpha_{i,j}, \beta_{i,j})$ is the sign of θ_i that determines the direction, $\Delta\theta_{i.j}$ is the magnitude of rotation angle whose lookup table is shown in Table 1. The angle θ is determined based on several trial and error considering their sensitivity towards the FQEA (explained in Section VI). In the table, B_j and X_j represents the jth quantum bit of best solution B and binary corresponding bit of Q-bit individual, X.

2) Mutation: The mutation operator on Q-individual works as follows

$$\left[\begin{array}{c|c|c|c|c} \alpha_1 & \alpha_2 & \ldots & \alpha_r & \ldots \\ \beta_1 & \beta_2 & \ldots & \beta_r & \ldots \end{array}\right] \Rightarrow \left[\begin{array}{c|c|c|c|c} \alpha_1 & \alpha_2 & \ldots & \beta_r & \ldots \\ \beta_1 & \beta_2 & \ldots & \alpha_r & \ldots \end{array}\right] \quad (29)$$

This operator is used with a probability of 0.1.

3) Crossover: The crossover operator is operated on two randomly chosen Q-individuals. The operator is analogous to genetic algorithms crossover operator. This method applies two-point crossover where the offspring will get two slices of the better fitted individual. The probability of crossover is 0.5.

4) Differential operator: A new differential operator is used in the FQEA method to provide diversified Q-bits. The trivial mutation operator does not assure a better offspring. To overcome such deficiency, the FQEA uses the information of the best Q-individual in Q-groups. Therefore, the new Q-individual, $Q_{new}(t+1)$ is defined as

$$Q_{new}(t+1) = Q_{r1}(t) + (B_{global}(t) - Q_{r2}(t)) \quad (30)$$

where Q_{r1} and Q_{r2} are two randomly chosen Q-individuals where $r1 \neq r2$, $r1 < r2$ and since the Q-individuals are in ascending order according to their fitness, $f(Q_{r1}(t)) < f(Q_{r2}(t))$. Now, the arithmetical operators on the above equation should be transformed to work with Q-individuals or the corresponding *collapsed* binary solutions. Therefore, the above equation is revisited such as follows

$$\begin{aligned} Q_{new}(t+1) \quad = \quad & Q_{r1}(t)\&\&(B_{global}(t)||Q_{r2}(t))|| \\ & (B_{global}(t)\&\&Q_{r2}(t)) \end{aligned} \quad (31)$$

The probability of this operator is set to 0.7.

E. Algorithm steps

The procedure of FQEA is stepped below.

1. Set $t = 0$ as a generation counter.

2. Initialize Q-individual as described in previous section. Divide the individuals into m groups of size n (as shown in Figure 1). Now for each group k the following steps are conducted.

a. Generate binary corresponding string $C_i(t)$ of ith Q-individual $Q_i(t)$ by *collapsing*. When a Q-bit $[\alpha\beta]^T$ is *collapsed*, its corresponding binary character c is determined by

$$c = \begin{cases} 1, & random[0,1] \ < t \ |\beta|^2 \\ 0, & otherwise \end{cases} \quad (32)$$

Thus $C_i(t)$ contains the binary strings of length of $N \times T$ (Figure 4).

b. Check for the constraint violation and repair the individual if necessary.

c. Evaluate the performance of $C_i(t)$. Determine the fuzzy membership functions for each of the imprecise constraints as stated in Section IV. The fuzzy solar-battery power output is determined by Eq. (8) and (9) using the forecasted solar radiation and considering the forecasting error. A forward dynamic programming approach is undertaken to figure out the optimal battery power output. Then calculate the ELD output for the thermal units using system lambda operation.

d. When $t = 0$, set the local attractor $A_i(t)$ to $C_i(t)$. Otherwise, compare $C_i(t)$ to $A_i(t)$ as described in Section II-A.

e. Select the best individual from the attractors list and save it as $B_{k,g}(t)$.

3. Select the best individual from m Q-groups and save it as $B_{global}(t)$.

4. Apply the operators briefed in Section V.D on Q-individual(s) based on the fuzzy probability scheme stated in Section V.E. Note that, the look up table in Table 1 is used here by replacing X to $C_i(t)$ and B to $A_i(t)$.

5. Synchronize $B_{global}(t)$ with attractors and Q-group best values using rotation gate operator.

7. Set $t = t + 1$. If t reaches to maximum, stop the process and B_{global} contains the best result. Return to Step 2(a) otherwise.

VI. Simulation

The proposed FQEA is applied on a thermal power system of 10 units with an equivalent solar power rating of 185 MW and battery-storage of 200 MW. PHP 5.0 is used to write the core program where the graphs are drawn by Matlab. The generators parameters and load data were reported on reference [4]. In order to check the scalability of FQEA, the 10 units' system is enhanced with corresponding load demand and solar power rating up to 100 units. For practical power system, FQEA is also tested on a 38-unit Taiwan power system. However solar power was not integrated in Tai-power case. Two analyses of parameters' sensitivity of FQEA are presented. First, the rotational angle θ is scrutinized. Since θ varies with the nature of applied problem domain, it should be chosen carefully. Which is why, several trials are conducted for 10-units system and the results are shown in Figure 6. The figure points out the frequency of hitting the optimal solution range ($563942-$564210) for various values of θ. θ is varied from 0.005 to 0.05 with step size of 0.0025. It can be seen that, θ is sensitive of FQEA. Among the best performed θ-values 0.03 is chosen. The second analysis is performed on the population size and maximum iteration. Table III shows the sensitivity of Q-population size ($G = m \times n$) and maximum iteration (MX_T) on 10 units system. FQEA is trialed 100 times for each of the system configurations. The solution quality of FQEA when performed under pair (G, MX_T):$(40, 150)$ is better than the other configuration. Moreover, the reported standard deviation for this pair is also not significant. The Q-population is then divided into 8-groups where each group contains 5 Q-individuals.

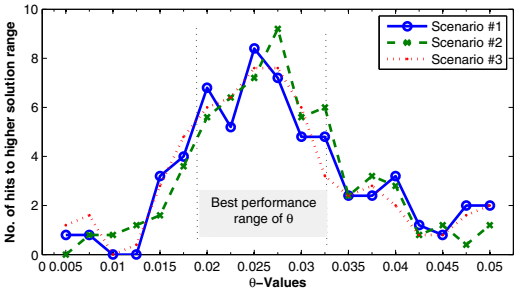

Fig. 6. Sensitivity of θ on the performance of FQEA.

Table III shows the best result achieved by FQEA by considering different combinations of the system configuration e.g. with/without solar battery system. The minimum, maximum and average cost are also reported on the table. Figure 7 shows the thermal power output with solar/battery

system and corresponding forecasted load. Table IV shows the cost comparison with established method. Note that, all of these comparing methods did not consider the solar power integration. Therefore, the comparison is limited only to the standalone thermal system. From the table, it is evident that, for high scaled power system (from 40 units to more), FQEA is capable to provide best results among comparing methods even no renewable energy sources are integrated. The fuzzy membership degrees (μ_{LD}, μ_{SR} and μ_{LR}) for different scaled power systems are reported on Table V. FQEA is able to manage the membership degrees to a higher value. The convergences of FQEA on 10-units' system for two randomly chosen runs are figured in Figure 8. The aggregated fuzzy membership function (μ_A) is also pointed in the figure from the starting point of the convergence graph to the settling cost. The μ_A also converged to 0.94 when the method reaches the optimal point.

Next simulation is conducted by applying FQEA to a 38-units' Taiwan power system[12]. Due to the unavailability of proper data on solar radiation, the simulation is run for the standalone system. The comparisons with other methods as well as the achieved result are tabled in Table VI. Like the 10 units' system, FQEA also able to produce the higher quality solutions among the established methods considering both production cost and average execution time (AET). The

two scenarios are considered here; one with ramp rate and one without ramp rate. The cost of the system becomes higher when the ramp rate is considered because this constraint restricts the power output of some units to certain capacities during rising and lowering loads. The FQEA outperforms most of the methods such as DP since it cannot reach all states of UC especially for a large power system which explains the high execution time. LR often suffers to obtain feasible solution and minimize the duality gap. As for SA, execution time is the highest among the competitors due to infeasible solution generations. CLP[13] provides good result as this approach applied problem UC specific logic while designing the algorithm. FA [12] is better performer in terms of execution time as it undertakes the similar approach as FQEA. However FQEA provides better result than FA [12]. Figure 9 shows the curves of crisp and fuzzy load demands of the optimal solution (Taiwan power system of 38 generating units) with membership degrees of fuzzy load and satisfied spinning reserve for 24 hours. The crisp load has been modified with fuzzy load by considering fuzziness of load demand. Depending on load statistics, in some hours (e.g. 9-12, 14-23) the fuzzy load is lower and the other hours it is higher than the forecasted crisp load. However the total fuzzy load is greater than total crisp load since the mean positive percentage load error is greater than the mean absolute negative percentage error. It is noticeable that, the spinning reserve membership degree is always 1 which indicates the reserve amount seems to be crisp although the fuzzy approach is taken.

VII. CONCLUSION

This paper presents a fuzzy logic based unit commitment strategy facilitating the quantum inspired evolutionary algorithm. This model comprises thermal generators, coupled with solar/battery system to provide the attention toward the global warming effects. In order to incorporate the uncertainties regarding load demand, solar radiation, spinning reserve, the formulations are modified using fuzzy logic. Trivial QEA approach is modified by applying several operators such as differential operator, crossover, and mutation to diversify the solutions. The solutions are reformed by Q-bit representation and further re-arranged into several Q-groups. Such features provide greater search space to enhance exploration as well as exploitation. The performance of the algorithm is tested in two different power systems. For the first case of 10-units system and higher, FQEA is able to produce best solutions for 40-units and above. In case of 10 and 20-units system, the cost difference is also marginal with global best. FQEA is also effective is practical power system for Taiwan 38-units since it provides the best results among comparing methods. Thus, the reported simulation results confirmed the superiority and effectiveness of FQEA. For future studies, the author will try to explore the potential of FQEA in other power system optimization problems such as ELD, optimal power flow, voltage control, optimum capacitor placement, feeder balancing etc. considering their complexity as combinatorial optimization problems involving uncertainties.

***Abstract*—An intelligent controlled doubly-fed induction generator (DFIG) system using probabilistic fuzzy neural network (PFNN) is proposed in this study. This system can be applied as a stand-alone power supply system or as the emergency power system when the electricity grid fails for all sub-synchronous, synchronous and super-synchronous conditions. The rotor side converter is controlled using the field-oriented control to produce three-phase stator voltages with constant magnitude and frequency at different rotor speeds. Moreover, the stator side converter, which is also controlled using field-oriented control, is primarily implemented to maintain the magnitude of the DC-link voltage. Furthermore, an intelligent PFNN controller is proposed for both the rotor and stator side converters to improve the transient and steady-state responses of the DFIG system for different operating conditions. The network structure, on-line learning algorithm and convergence analyses of the PFNN are introduced in detail. Finally, the feasibility of the proposed control scheme is verified using some experimental results.**

Keywords-doubly-fed induction generator; field-oriented control; probabilistic fuzzy neural network

NOMENCLATURE

v_{abs} , v_{bcs} , v_{cas}	3-Phase stator line voltage.
i_{as} , i_{bs} , i_{cs}	3-Phase stator current.
i_{al} , i_{bl} , i_{cl}	3-Phase load current.
i_{ar} , i_{br} , i_{cr}	3-Phase rotor current.

i_d , i_d^*	*d*-Axis current and command current of stator side converter.
i_q , i_q^*	*q*-Axis current and command current of stator side converter.

I. INTRODUCTION

Recently, the concept of incorporating fuzzy logic into a neural network (NN) has been grown into a popular research topic. In contrast to the pure NN or fuzzy system, the fuzzy neural network (FNN) possesses both advantages including the capability of fuzzy reasoning in handling uncertain information and the capability of artificial neural networks in learning from processes. Moreover, FNNs do not require mathematical models and have the ability to approximate nonlinear and uncertainties systems. Therefore, there were many researches which are using FNNs to represent complex plants and construct advanced controllers based on the back-propagation (BP) algorithm. Furthermore, probabilistic neural network (PNN) is a feedforward neural network, and its structure is neural network implementation of Parzen nonparametric

This work was supported in part by the National Science Council (NSC) of Taiwan, R.O.C. under Grant NSC 98-3114-E-008-001-CC2.

probability density function (PDF) estimation and Bayes classification rule [1]. The PNN can handle the uncertainties in industry applications effectively, and have been widely used in pattern classification, nonlinear mapping, and fault detection and classification. Due to the above advantages of FNN and PNN, the PFNN, which combines the characteristics of FNN (degree of truth) and PNN (probability of truth) [2], has been proposed in some applications, such as modeling and control problems [3] and stochastic modeling.

The DFIG systems have been widely used on large variable-speed fixed-frequency wind power generation systems, hydro power systems and turbine engine power generation systems. In contrast to the squirrel-cage induction generator (SCIG) system and the synchronous generator system, the power capacity of the rotor side and stator side converters of the DFIG system required only 30% of the rated power [4]. This means that the desired variable-speed range is $\pm$ 30% around the rated turbine speed. Thus, compared to the SCIG system where the converters have to handle the total power, the costs and losses in the power electronics converters can be much reduced.

There are two types of applications of a DFIG system, grid-connected type and stand-alone type. Several field-oriented control schemes for the DFIG have been proposed for the applications of both types [3], and the control strategies of the stator side and rotor side converters for the grid-connected type and stand-alone type are quite different.

The grid-connected DFIG system is quit mature and is widely used today and a lot of control schemes have been reported. However, only little attention has been paid toward the development of the control schemes of the stand-alone type DFIG system. On the other hand, satisfied transient performance can't be achieved using the traditional PID control for the DFIG system due to time-varying and nonlinear control characteristics of the DFIG system. Therefore, this study addresses the issue to develop an intelligent control scheme for the DFIG system for stand-alone application.

II. FIELD-ORIENTED CONTROL DFIG SYSTEM

A direct drive DFIG system using both the rotor side and stator side converters is shown in Fig. 1 and is consists of a doubly-fed induction machine with slip rings, and a back-to-back PWM converter between the rotor slip rings and the transformer. The stator is directly connected to the 3-phase load.

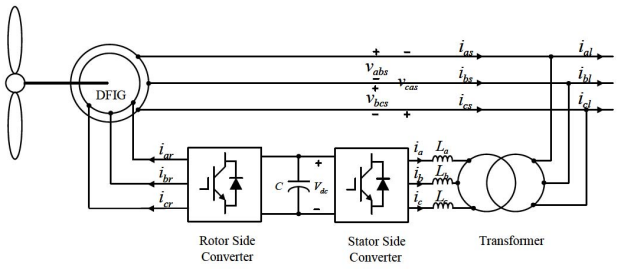

Figure 1. System block of DFIG.

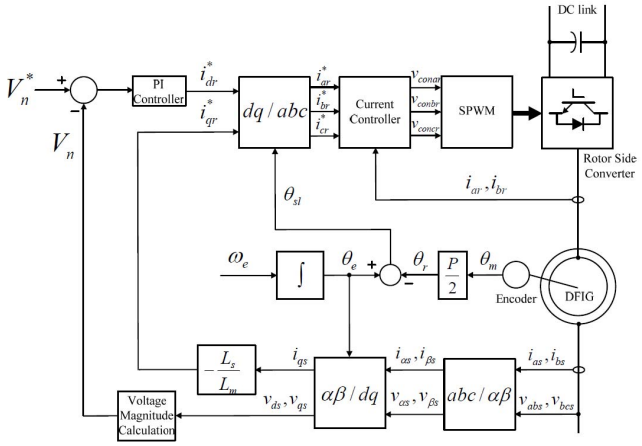

Figure 2. Control block of rotor side converter.

The control block diagram of the rotor side converter, which comprises a DFIG, a 3-phase current controlled voltage source inverter (VSI) using sinusoidal pulse-width-modulation (SPWM) and field-oriented control mechanism, is shown in Fig. 2 [5-6]. There are two control loops: one is for the regulation of the magnitude of the stator voltage; and the other one is for the field-oriented control using the command angular speed for the stator output voltage. The machine model of a DFIG can be described in the synchronous rotating reference frame as:

$$v_{ds} = R_s i_{ds} + \frac{d\lambda_{ds}}{dt} - \omega_e \lambda_{qs} \tag{1}$$

$$v_{qs} = R_s i_{qs} + \frac{d\lambda_{qs}}{dt} + \omega_e \lambda_{ds} \tag{2}$$

$$\lambda_{ds} = L_s i_{ds} + L_m i_{dr} \tag{3}$$

$$\lambda_{qs} = L_s i_{qs} + L_m i_{qr} \tag{4}$$

For the purpose of field-orientation in the synchronous rotating reference frame of the stator flux, the spatial vector of the stator flux is aligned with the *d*-axis in steady-state. That is

$$\lambda_{qs} = 0 \tag{5}$$

Substitute (5) into (4), then

$$i_{qr} = -\frac{L_s}{L_m} i_{qs} \tag{6}$$

It is possible to keep the spatial vector of the stator flux aligned to the reference frame *d*-axis despite of the load and rotor speed conditions if (6) is imposed. Moreover, the voltage control loop is used to control the magnitude of the stator voltage defined as follows:

$$V_n = \sqrt{(v_{ds})^2 + (v_{qs})^2} \tag{7}$$

Substituting (5) into (1), (2) and (3), the following equations are yielded

$$v_{ds} = R_s i_{ds} + \frac{d\lambda_{ds}}{dt} \tag{8}$$

$$v_{qs} = R_s i_{qs} + \omega_e \lambda_{ds} \tag{9}$$

$$\lambda_{ds} = L_s i_{ds} + L_m i_{dr} \tag{10}$$

Moreover, substitute (10) into (8) and (9), then

$$v_{ds} = R_s i_{ds} + L_s \frac{di_{ds}}{dt} + L_m \frac{di_{dr}}{dt} \tag{11}$$

$$v_{qs} = R_s i_{qs} + \omega_e L_s i_{ds} + \omega_e L_m i_{dr} \tag{12}$$

It can be seen from (11) and (12) that the spatial components of the stator voltage v_{ds} and v_{qs} are dependent on i_{dr} , i_{ds} and i_{qs} . However, i_{ds} and i_{qs} are load dependent perturbations. Therefore, only i_{dr} can be adopted as an independent control variable as shown in Fig. 2. Furthermore, for the sub-synchronous condition, the slip angular speed ω_{sl} is positive and the slip angular angle θ_{sl} is increasing, the direction of the power flow is from the DC-link to the rotor. On the other hand, for the super-synchronous conditions, the slip angular speed ω_{sl} is negative and the slip angular angle θ_{sl} is decreasing, the direction of the power flow is from the rotor to the DC-link.

The block diagram of the field-oriented control stator side converter with the stator voltage orientation is shown in Fig. 3. The 3-phase current controlled VSI using SPWM is also adopted in the current loop. Moreover, a voltage loop is designed for the regulation of the DC-link voltage. The active and reactive powers of the stator side converter can be described as [4,7]

$$P_s = \frac{3}{2}(v_d i_d + v_q i_q) \tag{13}$$

$$Q_s = \frac{3}{2}(v_d i_q - v_q i_d) \tag{14}$$

The *d*-axis voltage component v_d is fixed with the orientation of the stator voltage and the *q*-axis v_q voltage component is zero. Therefore, (13) and (14) can be simplified as follows:

$$P_s = \frac{3}{2} v_d i_d \tag{15}$$

$$Q_s = \frac{3}{2} v_d i_q \tag{16}$$

From (15) and (16), if i_q is set to zero, then the reactive power Q_s is zero. Thus, unit power factor of the stator side converter can be achieved. Moreover, if i_d is positive, the direction of the power flow is from the DC-link to the stator side. On the other hand, if i_d is negative, the direction of the power flow is from the stator side to the DC-link.

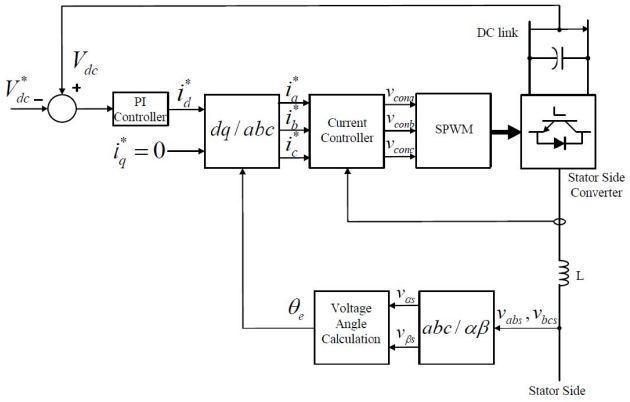

Figure 3. Control block of stator side converter.

III. PFNN CONTROLLER

In this section, the PFNN controller is proposed to replace the PI controllers shown in Figs. 2 and 3 for both the rotor side and stator side converters in order to improve the transient and steady-state responses of the DFIG system. In the proposed PFNN, not only the tracking error but also its derivative is considered as the inputs to achieve precise tracking performance in both the transient and steady-state phases to deal with instant uncertainties including system parameters variations and external disturbances. Moreover, in order to make the output of the PFNN sensitive to the history data, self-connection of the output neuron is also added. Therefore, the proposed PFNN can improve the convergence error and reduce the learning time effectively.

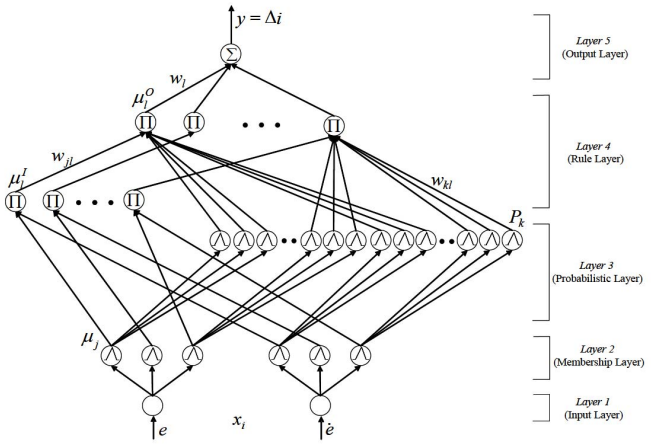

Figure 4. Network structure of PFNN.

A. Probabilistic Fuzzy Neural Network

The architecture of the PFNN including the input layer (layer 1), the membership layer (layer 2), the probabilistic layer (layer 3), the rule layer (layer 4) and the output layer (layer 5) with two inputs and one output is shown in Fig. 4. Moreover, the signal propagation and the basic function of each layer are introduced in the following:

1) Input layer(layer1): In the input layer, the node input and the node output are represented as:

$$x_i(N) = e_i(N), \quad i = 1, 2 \tag{17}$$

where x_i represents the ith input to the input layer; N represents the Nth iteration. In this study, the inputs of the PFNN are $e_1(N) = e$ and $e_2(N) = \dot{e}$, which are the tracking error and its derivative, respectively.

2) Membership layer(layer2): In the membership layer, the receptive field function is usually a Gaussian function in FNN. In order to reduce the computational requirements, a triangular function $f_m(x_i)$ is selected as the receptive field function. The equations of the triangular function $f_m(x_i)$ are in the following:

$$\mu_j(x_i) = f_m(x_i) = \begin{cases} 0 & if \quad x_i \ge m_j + \sigma_j,\ x_i \le m_j - \sigma_j \\ \dfrac{x_i - m_j + \sigma_j}{\sigma_j} & if \quad m_j - \sigma_j < x_i \le m_j \\ \dfrac{-x_i + m_j + \sigma_j}{\sigma_j} & if \quad m_j < x_i \le m_j + \sigma_j \end{cases} \tag{18}$$

$$i = 1, 2. \qquad j = 1, 2, \ldots, 6$$

where $\mu_j(x_i)$ is the output of the jth node of the ith input variable; m_j is the center of the triangle; σ_j is the center's width of the triangle.

3) Probabilistic layer(layer3): In the probabilistic layer, the receptive field function is usually a Gaussian function. For the same reason in membership layer, another triangular function $f_p(\mu_j)$ is selected as the receptive field function and its equations are as follows:

$$P_k(\mu_j) = f_p(\mu_j) = \begin{cases} 0 & if \quad \mu_j \ge m_k + \sigma_k,\ \mu_j \le m_k - \sigma_k \\ \dfrac{\mu_j - m_k + \sigma_k}{\sigma_k} & if \quad m_k - \sigma_k < \mu_j \le m_k \\ \dfrac{-\mu_j + m_k + \sigma_k}{\sigma_k} & if \quad m_k < \mu_j \le m_k + \sigma_k \end{cases} \tag{19}$$

$$k = 1, 2, \ldots, 18$$

where $P_k(\mu_j)$ is the output of the kth node of the jth input variable; m_k is the center of the triangle; σ_k is the center's width of the triangle.

4) Rule layer(layer4): In the rule layer, each node corresponds to a rule in the knowledge base. In the Mamdani inference, the node itself performs the t-norm operation (product operation) to obtain the inference set according to the rules as shown in (20). The probabilistic information is processed using the Bayes' theorem [1,3] in consideration of the group of fuzzy grade being independent variables as shown in (21). Therefore, the node input and the node output are represented as:

$$\mu_l^I = \prod_j w_{jl} \mu_j \tag{20}$$

$$P_l^I = \prod_k w_{kl} P_k \tag{21}$$

$$\mu_l^O = \mu_l^I P_l^I \qquad l = 1, 2, \ldots, 9. \tag{22}$$

where μ_l^I and P_l^I are the input of rule layer; w_{jl} is the connective weight between the membership layer and the rule layer which is set to be 1; w_{kl} is the connective weight between the probabilistic layer and the rule layer which is also set to be 1; μ_l^O is the output of the rule layer.

5) Output layer(layer5): In the output layer, the node input and the node output are represented as:

$$\Delta i = y(N) = \sum_{l=1}^{9} w_l \mu_l^O \tag{23}$$

where $\Delta i = y(N)$ is the output of the PFNN; w_l is the connective weight between the rule layer and the output layer.

B. On-Line Learning Algorithm Using Delta Adaptation Law

The central part of the learning algorithm for the PFNN

concerns how to recursively obtain a gradient vector in which each element in the learning algorithm is defined as the derivative of an energy function with respect to a parameter of the network. This is done by means of the chain rule, and the method is generally referred to as the BP learning rule. To describe the on-line learning algorithm of the PFNN using supervised gradient decent method, first the energy function E is defined as:

$$E = \frac{1}{2}(\omega_r^* - \omega_r)^2 = \frac{1}{2}e^2 \tag{24}$$

Then the learning algorithm is described as follows:

1) Layer5: The error term to be propagated is given by:

$$\delta_o = -\frac{\partial E}{\partial y(N)} = -\frac{\partial E}{\partial \omega_r}\frac{\partial \omega_r}{\partial y(N)} \tag{25}$$

and the weights are updated by the amount:

$$\Delta w_l = -\eta_1 \frac{\partial E}{\partial w_l} = -\eta_1 \frac{\partial E}{\partial y(N)}\frac{\partial y(N)}{\partial w_l} = \eta_1 \delta_o \mu_l^O \tag{26}$$

where the factor η_1 is the learning rate. The connective weight w_l is updated according to the following equation:

$$w_l(N+1) = w_l(N) + \Delta w_l \tag{27}$$

2) Layer4: In this layer, the error terms to be propagated are given by:

$$\delta_l = -\frac{\partial E}{\partial \mu_l^O} = -\frac{\partial E}{\partial y(N)}\frac{\partial y(N)}{\partial \mu_l^O} = \delta_o w_l \tag{28}$$

3) Layer2: The error terms to be propagated are given by:

$$\delta_j = -\frac{\partial E}{\partial \mu_j} = -\frac{\partial E}{\partial y(N)}\frac{\partial y(N)}{\partial \mu_l^O}\frac{\partial \mu_l^O}{\partial \mu_l^I}\frac{\partial \mu_l^I}{\partial \mu_j} = \sum_l \delta_l P_l^I \tag{29}$$

By using of the chain rule, the update laws of center and center's width of the triangle are

$$\Delta m_j = -\eta_2 \frac{\partial E}{\partial m_j} = -\eta_2 \frac{\partial E}{\partial y(N)}\frac{\partial y(N)}{\partial \mu_l^o}\frac{\partial \mu_l^o}{\partial \mu_l^I}\frac{\partial \mu_l^I}{\partial \mu_j}\frac{\partial \mu_j}{\partial m_j}$$
$$= \begin{cases} -\eta_2 \delta_j \dfrac{1}{\sigma_j} & if \quad m_j - \sigma_j < x_i \le m_j \\ \eta_2 \delta_j \dfrac{1}{\sigma_j} & if \quad m_j < x_i \le m_j + \sigma_j \end{cases} \tag{30}$$

$$\Delta \sigma_j = -\eta_3 \frac{\partial E}{\partial \sigma_j} = -\eta_3 \frac{\partial E}{\partial y(N)}\frac{\partial y(N)}{\partial \mu_l^o}\frac{\partial \mu_l^o}{\partial \mu_l^I}\frac{\partial \mu_l^I}{\partial \mu_j}\frac{\partial \mu_j}{\partial \sigma_j}$$
$$= \begin{cases} \eta_3 \delta_j \dfrac{m_j - x_i}{(\sigma_j)^2} & if \quad m_j - \sigma_j < x_i \le m_j \\ \eta_3 \delta_j \dfrac{x_i - m_j}{(\sigma_j)^2} & if \quad m_j < x_i \le m_j + \sigma_j \end{cases} \tag{31}$$

where the factors η_2 and η_3 are the learning rates. The center of the triangle m_j and center's width of the triangle σ_j are updated according to the following equation:

$$m_j(N+1) = m_j(N) + \Delta m_j \tag{32}$$

$$\sigma_j(N+1) = \sigma_j(N) + \Delta \sigma_j \tag{33}$$

In order to reduce the computation load, in layer 3, the center of the triangle m_k and the center's width of the triangle σ_k are constants where m_k is set to be 0.4 for $k = 1, 4, 7, 10, 13, 16$, 0.5 for $k = 2, 5, 8, 11, 14, 17$, and 0.6 for $k = 3, 6, 9, 12, 15, 18$; σ_k is set to be 1. Furthermore, the exact calculation of the Jacobian of the system, $\partial \omega_r / \partial y(N)$, is difficult to be determined due to the unknown dynamics of the control system. To overcome this problem, a delta adaptation law is adopted as follows [8]:

$$\delta_o \cong e(N) + \dot{e}(N) \tag{34}$$

Moreover, the on-line learning algorithm for the PFNN controller of the stator side converter is the same as PFNN controller of the rotor side converter only $V_n(N)$ is replaced by $V_{dc}(N)$ in related derivations.

IV. Design and Experimentation

A. Design

The computer controlled DFIG system is shown in Fig. 5. The block diagram of the personal computer (PC)-based control computer for the PFNN controlled DFIG system is shown in Fig. 5(a), where the inductor in the stator side converter is 3*m*H and the DC-link capacitor is 2820 μ F. The field-oriented control algorithms, synchronization algorithm and the PFNN controllers are realized in a PC. Three-phase current commands are sent to both the rotor side converter and stator side converter using digital/analog (D/A) converters. The current-controlled VSI SPWM converters are implemented using an intelligent power modules (PM30CSJ060) manufactured by Mitsubishi Co. with a switching frequency of 10kHz. Matlab & Simulink Real-Time Control package is adopted for the implementation of the proposed algorithms and

the fix-step solver in the Real-Time Control package is set to be 0.5ms. In the program, first, the v_{abs}, v_{bcs}, V_{dc}, i_{as}, i_{bs} signals are obtained via A/D converters and the θ_m signal is obtained via encoder interface. Then, both the rotor side and stator side converters are controlled using either PI controller or PFNN controller to generated i_{ar}^*, i_{br}^*, i_{cr}^* and i_a^*, i_b^*, i_c^*,

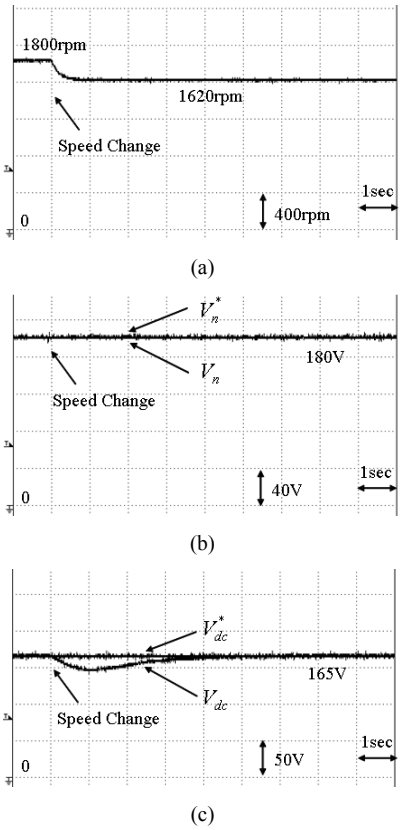

Figure 8. Experimental results of PFNN controlled DFIG system from 1800rpm to 1620rpm. (a) Speed response. (b) Magnitude response of phase *A* voltage. (c) Magnitude response of DC-link voltage.

respectively. The generated current commands are sent to the analog current controllers through D/A converters to generate the pulse-width-modulation (PWM) signals for both the converters. The initial DC-link voltage $V_{dc,initial}$ is also necessary for the stand-alone applications of the DFIG system as shown in Fig. 5(a) to provide the initial rotor excitation. Furthermore, the photo of DFIG set, resistance load and control computer is shown in Fig. 5(b). In addition, in the DFIG set, the prime mover is a field-oriented controlled permanent magnet synchronous motor (PMSM).

B. Experimentation

The adopted DFIG is a three-phase Y-connected four-pole 1Hp 220V/3.5A 1700rpm type. The parameters of the DFIG at the nominal condition are:

$$R_s = 2.85\Omega,\ R_r = 2.34\Omega,\ L_s = 0.1967H,\ L_r = 0.1970H \quad (35)$$

Moreover, the prime mover is a three-phase Y-connected four-pole 3.5kW 120V/26.4A 2000rpm type PMSM. Furthermore, sub-synchronous control 1620rpm (s=0.1), synchronous control 1800rpm (s=0) and super-synchronous control 1980rpm (s=-0.1) three operating conditions all with 484W 3-phase load are test.

To emulate the variation of the wind speed, some experimental results using both the PI and PFNN control are provided to further test the transient control performance of both the PI and PFNN controlled DFIG system. The variation of the rotor speed, the responses of the magnitude of phase *A* stator voltage V_n and DC-link voltage V_{dc} from 1800rpm to 1620rpm using the PI controller are shown in Figs. 6(a), 6(b) and 6(c). Moreover, the variation of the rotor speed, the responses of the magnitude of phase *A* stator voltage V_n and DC-link voltage V_{dc} from 1800rpm to 1980rpm using the PI controller are shown in Figs. 7(a), 7(b) and 7(c). Furthermore, the variation of the rotor speed, the responses of the magnitude of phase *A* stator voltage V_n and DC-link voltage V_{dc} from 1800rpm to 1620rpm using the PFNN controller are shown in Figs. 8(a), 8(b) and 8(c). In addition, the variation of the rotor speed, the responses of the magnitude of phase *A* stator voltage V_n and DC-link voltage V_{dc} from 1800rpm to 1980rpm using the PFNN controller are shown in Figs. 9(a), 9(b) and 9(c). From the experimental results, compared to the PI controlled DFIG system, excellent magnitudes tracking responses of the phase voltage can be obtained for the PFNN controlled DFIG system. However, the improvement of the responses of the DC-link voltage is limited due to the requirement of the stable phase voltage for the construction of the stable DC-link voltage.

V. CONCLUSION

This study has successfully demonstrated the applications of a PFNN controller on both the rotor side and stator side converters for the voltage magnitudes tacking control of an intelligent controlled DFIG system. First, the dynamic model of a field-oriented control DFIG system via the rotor side converter was introduced. Then, the control methodology of the stator side converter and the synchronization method to the stator were both introduced. Moreover, the network structure, online learning algorithm and convergence analyses of the PFNN were introduced in detail. The PFNN was proposed to control both the magnitudes of phase *A* stator voltage in the rotor side converter and DC-link voltage in the stator side converter at sub-synchronous, synchronous and super-synchronous conditions for stand-alone applications. Furthermore, the effectiveness of the proposed control scheme has been confirmed via experimentation. Form the experimental results, the control performance of the proposed PFNN controlled DFIG system is robust with regard to different operating conditions.

***Abstract*— Fingerprint identification is a well-known technique in forensic sciences. The basic idea of identifying a subject based on a set of features left by the subject actions or behavior can be applied to other domains. Identifying a web user based on a user fingerprint is one such application. This paper considers the problem of extracting fingerprints from web usage logs and matching them with those obtained from a set of known users. It presents an innovative fuzzy fingerprint algorithm based on vector valued fuzzy sets. Used sites are used as base features to create the fingerprint. The assumption is that sites accessed by each user remain approximately stable and are distinctive. The paper presents the proposed algorithm and shows some experimental results that validate the approach. The use of fast and compact algorithms is critical due to the possible huge number of users, and allows this method to be used on near real time.**

Keywords-component; fuzzy fingerprints, vector valued fuzzy sets, similarity, frequent elements, approximate algorithms, data streams

I. INTRODUCTION

In this paper, one considers the problem of extracting a fingerprint from web usage logs and then using that fingerprint to identify the user behind a distinct web session.

Identifying users based in their previously known usage is a known procedure in several areas such as telecommunications and financial fraud detection. For security and judicial purposes, identifying a user based on a specific usage behavior is also relevant. These detection methods are based on the fact that although a suspect or fraudster may present different identification credentials or simply no identification at all, its behavior and its relationships remain the same. Every individual keeps some relationships and habits, either personal or businesswise, stable for some time. Even if some of those relationships and habits change along time (the individual starts working in a different company, a distinct business, marries another person, etc.), some will remain stable (same family, some job, same interests). This provides the basis for the fingerprint as relationships and habits are translated into usage events. By using the destination number as a proxy for the individual behind a specific communication event, we can gather information out of a person's calls to its relationship network. The sites the user accesses in the web are also a clue to the user habits and interests and therefore can be used to identify him in a pool of suspected web sessions.

Within the scope of this paper, one will consider a web session as the sequence of web log records that belong to a single user, either known or unknown. For anonymous web access, one will consider that some method is available to group these records into a single session. Although out of the scope of this paper, user identity could be linked to a single fixed IP address or a single provider login.

Each web log record represents a user visit to a single web site, regardless of the used protocol. The set of known users for whom a fingerprint is available will constitute the suspects for unknown user sessions identification.

Fingerprint identification is a well-known technique in forensic sciences and widely documented. In computer sciences a fingerprint is a procedure that maps an arbitrarily large data item (such as a computer file, or author set of texts) to a much compact information block, its fingerprint, that uniquely identifies the original data for all practical purposes, just as human fingerprints uniquely identify people for practical purposes.

In computer sciences, fingerprints are typically used to avoid the comparison and transmission of bulky data. For example, a web browser or proxy server can efficiently check if a remote file has been modified simply by fetching its fingerprint and comparing it with the fingerprint of the previously fetched copy. Fingerprints are a fast and compact way to identify items.

To serve the user identification purposes, a fingerprint must be able to capture the identity of that user. In other words, the probability of a collision, i.e., two users yielding the same fingerprint, must be small. The fingerprint has also to be robust; a user should be identified even if he changes some aspects of the web use. The idea of identifying users based on a fingerprint is a very appealing one, because identification can theoretically be made on near real time.

To be useful, the fingerprint should comply with some basic criteria:

- Include a minimal set of features that describe the user (the suspect) in a compact format.
- Allow for update operations whenever new information (new logs) on the user is available.
- Allow for a fast comparison process once a new session owner needs to be identified.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

- Scalability, i.e., performance should not degrade significantly when the number of sessions and suspects in the pool increases.
- Flexibility, i.e., should allow new suspects to be included in the process, whenever information is available.

This paper proposes a new method for identifying web users given a set of possible suspects. By using the web site access frequencies as a proxy for the individual behind a specific session, one can gather information on the user and identify other unidentified sessions.

The first step in the proposed method is to gather the top-*k* site access frequencies in all known logs of each known user. An approximated algorithm is used for this purpose since classical exact top-k algorithms are inefficient and require the full list of distinct elements to be kept. The Filtered Space-Saving algorithm [1], [7] is used for this purpose since it provides a fast and compact answer to the top-*k* problem although it only gives an approximate solution. This paper defends that the algorithm approximation is not an issue, as a degree of change or randomness has to be expected and incorporated into the detection method.

Once the top-k site access frequencies are available, the fingerprint is constructed by applying a fuzzifying function to each frequency. This paper proposes the innovative method of fuzzifying the set of features based on their order on the top-*k* list instead of their frequency value.

The last part in the process is to perform the same calculations for the session being identified and then to compare this fuzzy fingerprint with all the available users fuzzy fingerprints. The most similar fingerprint is chosen and the session is assigned to the fingerprint author.

II. Relation with previous work

A. Signatures and fingerprints

Boltan and Hand [1] and Phua and al. [12] survey multiple methods for fraud detection using statistical and data-mining techniques but no mention is made of research aiming to identify individual fraudsters based on their behavior. A more common, although distinct, approach is the use of usage signatures but to detect behavior changes as in [3], [4] and [5]. Signatures are used to monitor the individual activity and detect changes in that activity, or to compare against known fraud signatures to detect similarity of patterns, not the individuals behind the fraud. In [3] and [5] signatures are created extracting relevant features out of the individual usage, such as number of local, national and international calls, etc., based on pre-defined types of traffic classifications and summarized. In [5] a list of the top-k countries and destinations called, and a count of calls that do not go to any of the top-k is used but with the purpose of detecting changes in the usage.

A recent work by Cormode et al. [1] presents the concept of signature algorithms applied to iterations between individuals and provides some signature schemes to network traffic and telecommunication calls. A generic approach and a theoretical framework for signatures communication graphs analysis are provided. The "signatures" concept has some common points to the proposed user fingerprint. However, one prefers to use the "fingerprint" designation, as the algorithm aims at extracting information about the user that he has not provided knowingly, while a "signature" usually refers to information that was created specifically to identify someone or something. In [1] the feature extraction is exact; the use of approximated algorithms is suggested and several distinct distances are proposed.

B. Fuzzy Signatures

The fuzzy fingerprint concept is a generalization of the Vector Valued Fuzzy Sets (VVFS) concept introduced by Kóczy [8]. The qualitative meaning of an object is represented by the quantities of the VVFS.

The vector valued fuzzy sets concept has also been used in [9] to introduce the fuzzy signature concept. Fuzzy signatures can model sparse and hierarchically correlated data with the help of hierarchically structured VVFS and a set of not-necessarily homogenous and hierarchically organized aggregation functions.

III. The Filtered Space-Saving Algorithm

To allow the use of user identification techniques in near real time and for a large number of potential suspects and sessions, a key issue is to be able to extract the relevant features using an efficient algorithm with reduced memory usage. In this case, features are the most frequent visited sites in the user usage. The choice was to use an approximate top-*k* algorithm capable of generating good quality estimates using a reduced memory footprint. The Filtered Space-Saving algorithm [7] was chosen. Filtered Space-Saving, originally presented in [6], is an evolution from Space-Saving algorithm presented by Metwally and al. [10].

The Filtered Space-Saving (FSS) algorithm uses a bitmap counter with h cells, each containing two values, α_i and c_i, standing for the error and the number of monitored elements in cell i. The hash function needs to be able to transform the input values (site) into an uniformly distributed integer range. The hashed value *hash(x)* is then used to increment the corresponding counter. Initially all values of α_i and c_i are set to 0.

The second storage element is a list of monitored elements A with size m. The list is initially empty. Each element contains three parts; the value itself v_j, the estimate count f_j and the associated error e_j.

The minimum required value to be included in the monitored list is always the minimum of the estimate counts, $\mu = min\ \{f_j\}$. While the list has free elements, the minimum is set to 0.

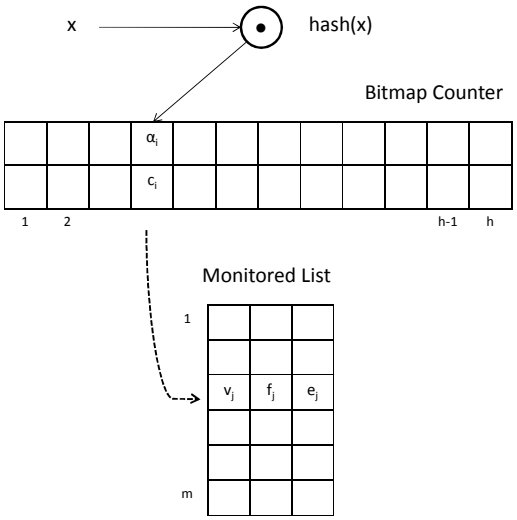

Figure 1 – FSS Algorithm Diagram.

The algorithm is quite simple. When a new element is received, its hash is calculated and the bitmap counter is checked. If there are already monitored elements with that same hash *($c_i > 0$)* the list is searched to see if this particular element is already there. If the element is in the list then the estimate count f_j is incremented. If the element is not in the list then it is checked to see if it should be added.

A new element will be inserted into the list if $\alpha_i + 1 \geq \mu$. If the element is not monitored then α_i is incremented. In fact this α_i stands for the number of elements with hash value i that have not been counted in the monitored list; it is the maximum number of times an element that is not in the list and that has this hash value could have been observed.

```
Algorithm: FSS(h cells, m counters, S stream)

begin
for each element, x, with value w, in S {
    set min to min {fj}
    let i be the hash(x) mod h
    if ci is not 0 {
        if x is monitored {
            let j be the index of x in the list
            increment fj
            continue for next x
        }
    } // this will only be executed if x is not monitored

    if  αi + 1 >= min {
        if list size equals m {
            let m be the index with lower fj
            and for same fj with higher ej
            let k be the hash(x) mod h
            decrement ck
            set αk = fi
            remove vm
        }
        include x in the list in index j
        set vj to x
        set ej to αi and fj to αi+1
        increment counter ci
    } else {
        increment αi
    }
}// end for
end
```

Figure 2 – The FSS Algorithm

IV. The Fuzzy Fingerprint Algorithm

The main concept behind this algorithm is that users have a stable enough behavior that allows a set of features to be extracted, fuzzified and then compared. The most frequent visited sites of a single user present the required stability.

User web traffic can then be analyzed as a set of site accesses generated by a stable distribution that depends only on the user. Only site visit counts are in fact relevant and used as variables.

The set of sites to consider in the fingerprint should be large enough to allow a comprehensive sample of the user behavior along time. The FSS algorithm requires two parameters, the size of the monitored list *m* and the size of the bitmap counter *h*. In all the tests the parameters were set proportional to the number of visited sites used in the fingerprint: $m = 3k$, $h = 9k$.

A. Fuzzy Fingerprint Creation

The full set of known texts are processed through the modified FSS algorithm to compute the approximated top-*k* list and frequencies for each user. Consider T_j is the set of logs by the user *j*. The result consists of a list of *k* tuplets $\{v_i, n_i\}$ where v_i is the *i*-th most frequent visited site and n_i the corresponding count estimate.

To create the actual fingerprint, the top-*k* list has to be fuzzified. The choice of the fuzzifying function is critical and the chosen approach is to assign a membership value to each site in the set based only on the order in the list. In fact, experiments have shown that the order of the frequency seems more relevant than its actual value. The more frequent sites will have a higher membership value.

Several alternative membership attribution functions for each element *i* of the top-*k* list are tested in this paper. The simplest one is:

$$\mu_{flat}(i) = \frac{k-i}{k}. \tag{1}$$

Function μ_{par}, inspired in the Pareto rule, where 80% of the membership value is assigned to first 20% elements in the ranking:

$$\mu_{par}(i) = \begin{cases} 1-(1-b)\dfrac{i}{k} & \text{if } i < a \\ a\left(1-\dfrac{i-a}{k-a}\right) & \text{if } i \geq a \end{cases} \tag{2}$$

The third function is μ_{erfc}, based on the complementary error function:

$$\mu_{erfc}(i) = 1 - erf\left(\frac{2i}{k}\right), \tag{3}$$

where *erf()* is the Gauss error function. Figure 3 presents the used functions.

The fingerprint based on the top-*k* list (size-*k* fingerprint, Φ), consists on a size-*k* fuzzy vector where each position *i*

contains a element v_i and a value μ_i representing the fuzzified value of v_i's rank (the membership of the rank).

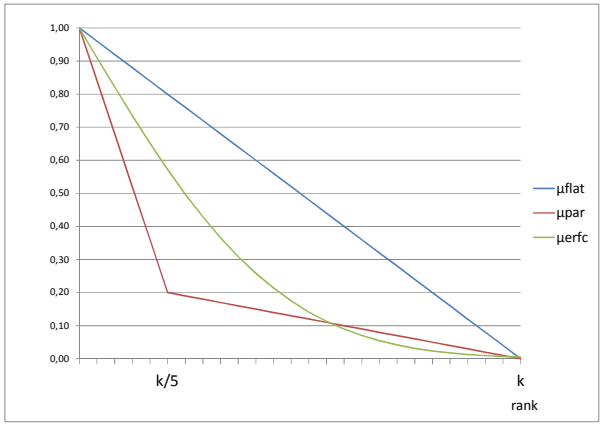

Figure 3 – Fuzzyfying functions

An user j will be represented by its fingerprint $\Phi_j = \Phi(T_j)$. Formally, fingerprint $\Phi_j = \{(v_{ji}, \mu_{ji}) | i = 1..k_j\}$ has length k_j, let $S_j = \{v_{ji} | i = 1..k_j\}$ be the set of v's in Φ_j.The set of all user fingerprints will constitute the fingerprint library.

B. *Fuzzy Fingerprint Detection*

In order to find the user of an unknown session L, one starts by computing the size-k fingerprint of L, Φ_L. Then one compares the fingerprint of L with the fingerprints Φ_j of all users present in the fingerprint library. The unknown user is identified as user j if he has the most similar fingerprint to Φ_L. Fingerprint comparision, $sim(\Phi_L, \Phi_j)$, is calculated using (4):

$$sim(\Phi_L, \Phi_j) = \sum_{v \in S_L \cup S_j} \frac{\min\left(\mu_v(\Phi_L), \mu_v(\Phi_j)\right)}{k}, \qquad (4)$$

where $\mu_v(\Phi_x)$ is the membership value associated with the rank of element v in fingerprint x. This function is based on the minimum or Gödel t-norm, but other t-norms could be used.

V. Experimental Results

A. *Experimental data set*

Experiments were performed using a data set consisting of 10 days of web logs collected from a large company (including a weekend, with much less records). The data is annonymized but every user in the web access record is identified by a unique tag. Records detailing access to .jpg, .bmp, .gif objects were filtered and are not present in the data set. Filtering the images from the web logs reduces the number records to circa 10%. Note that this company has implemented a web access policy that limits access to some sites

To create the suspect library the logs from the 8 initial days were used, constituting the training set. The sessions to be used as the test set were created with the remaining 2 days of web logs. A total of 21 669 597 records were included in the training set, and 6 621 078 records in the test set. Although both the training and test sets were created using a much reduced sample period, this may in fact be similar to real life situations where data is usually much less than ideal.

A total of 1630 users were considered for these tests, each with a minimum 750 records in the training set and 250 records in the test set. Note that this is a small number of access records; many of the users generate more than a thousand records per day (excluding images).

The site name and port part of the url were used as base features. Site name and port were prefered to the IP address because, first, many sites use multiple servers and IP addresses for load balancing, second, many sites share the same IP address as they are hosted in a single server, third, because with the emergence of cloud hosting services IP addresses are easily changed and the site name is what effectivly distinguishes one site from another. The use of the site name requires also requires some care as some services may use the name to convey some information for user or load distribution, in this case some cleaning is required to transform the site name and port to the generical format of *server.domain:port* or *server.domain*.

Although the sample period is not long it is interesting to see the site access distribution per user. Figure 4 presents the percentage of accesses for each of the most visited sites of each user. On average 90% of the users accesses are made to just 55 sites. Figure 4 also presents distribution of consecutive site accesses, and the mixture of the two distributions. Consecutive site accesses are relevant because one user may visit one site and then visit another. This path may be distinct from other users paths and helps distinguising the users.

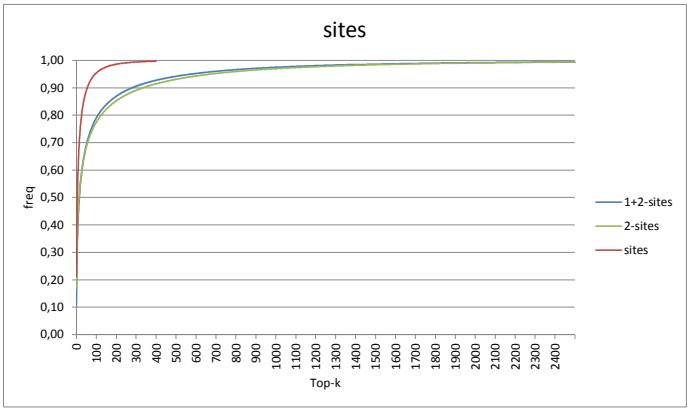

Figure 4 – Web site accesses distribution

B. *Test methodology*

The distinct fuzzifying functions were tested on each of the available users and sessions. Each test returns a ranked list of the suspects. A test is considered to be positive if the real user is returned in the first position of the ranked list. Accuracy measures the ratio of positive tests for each of the function. For each of the tested algorithms tests were performed for multiple values of k.

To evaluate the accuracy of the proposed algorithms against crisp signature algorithms one will present experimental results

obtained using equivalent methods proposed in [2]. In [2] a variety of distance functions were presented to compare signatures. They are generalized from known measures, and take into account both set overlap as well as weighted occurrence. In [2] signatures are k sized tuples with element v_i and a value w_i representing the frequency of the element. Each signature $\Omega_i = \{(v_{ij}, w_{ij}) | j = 1..k_i\}$ has length k_i, let $S_i = \{v_{ij} | j = 1..k_i\}$ be the set of v's in Ω_i. The distances considered were adapted from [2]:

$$D_{jac}(\Omega_1, \Omega_2) = 1 - \frac{S_1 \cap S_2}{S_1 \cup S_2} \quad (5)$$

$$D_{dice}(\Omega_1, \Omega_2) = 1 - \frac{\sum_{v \in S_1 \cap S_2} \min(w_1, w_2)}{\sum_{v \in S_1 \cup S_2} \max(w_1, w_2)} \quad (6)$$

$$D_{hel}(\Omega_1, \Omega_2) = 1 - \frac{\sum_{v \in S_1 \cap S_2} \sqrt{w_1 \cdot w_2}}{\sum_{v \in S_1 \cup S_2} \max(w_1, w_2)} \quad (7)$$

It is easy to verify that all these distance functions yield values in [0, 1]. D_{jac} is based on Jaccard coefficient, where the node weights are not taken into account; it is minimized when S1 = S2, and it equals 1 when their overlap is empty. D_{dice} is an scaled version of the distance based on Dice criterion, which factors in node weights; it gives an added premium if the individual weights in S_1 and S_2 are similar. D_{hel} is based on Hellinger distance .

To better characterize the classifier response ROC curves are presented for every algorithm. ROC curves are a standard measure in statistics [10]. ROC curves map the ratio of false positives against the ratio of true positives, with the false positives in the x-axis and true positives in the y-axis. ROC curves were constructed by first running every test sample against the suspect library and obtaining a ranked list. Let T be the number of tests and U the number of suspects. The total number of elements in the answer lists is TU. The total number of positive tests is T (there is always one correct user for each unknown session) and the number of incorrect tests is $T(U-1)$. The ROC curve starts at the origin (0, 0). For each rank, in ascending order, the number of positive tests p with that rank are used to draw a vertical line upwards by p/T. For the same rank a horizontal line is draw to the right by $(T-p)/(T(U-1))$.

Also a standard measure in statistics, the Area Under the ROC Curve (AUC) [10] can also be computed. AUC is an indicator of the overall accuracy of the classifier, if the AUC is 0.5, the classifier is no better than random selection; higher values indicate better precision. An AUC of 1 indicates a perfect classifier.

C. *Single site fuzzy fingerprints*

The first set of experiments use single site name and port fingerprints. Figure 5 presents the accuracy of fuzzy fingerprints using the three fuzzifying functions described and the results obtained using the three crisp distance functions. The difference between fuzzy and crisp algorithms is very significant. The fuzzy fingerprints deal better with the very sparse nature of the web accesses and significant differences of use in the training and test periods. Differences between the three proposed fuzzifying functions are not very relevant, the Pareto based function achieves the best results, followed closely by the complementary gaussian error function. These functions weight more the most frequent elements.

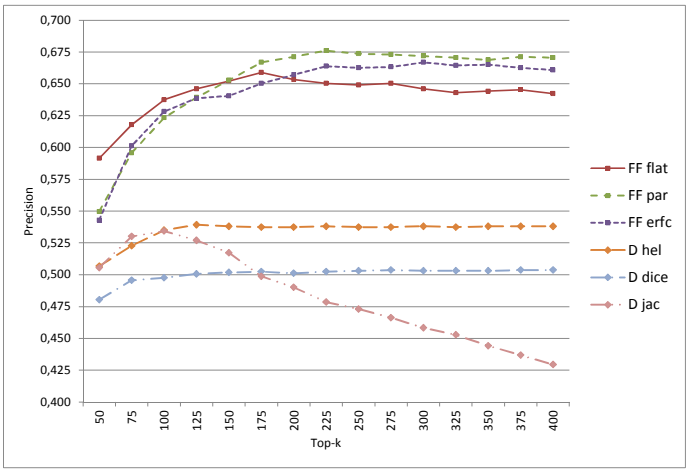

Figure 5 – Algorithms accuracy for single web site access

Figure 6 presents the ROC curve for each of the tested algorithms. To better show the differences Figure 7 presents the zoom of the most relevant area of the ROC.

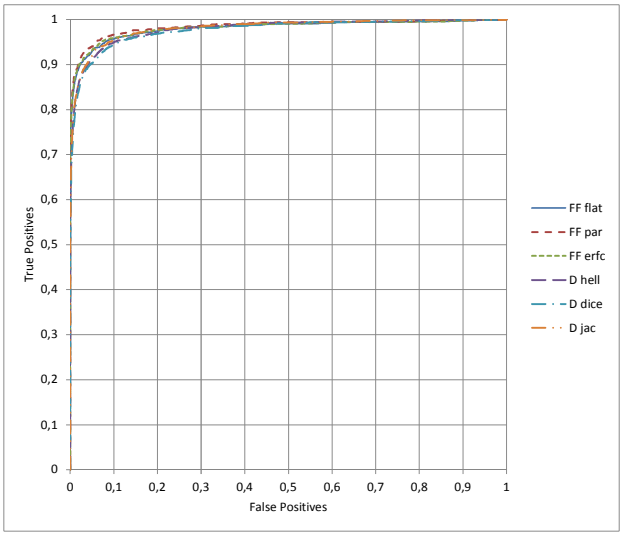

Figure 6 – Algorithms ROC for single web site access

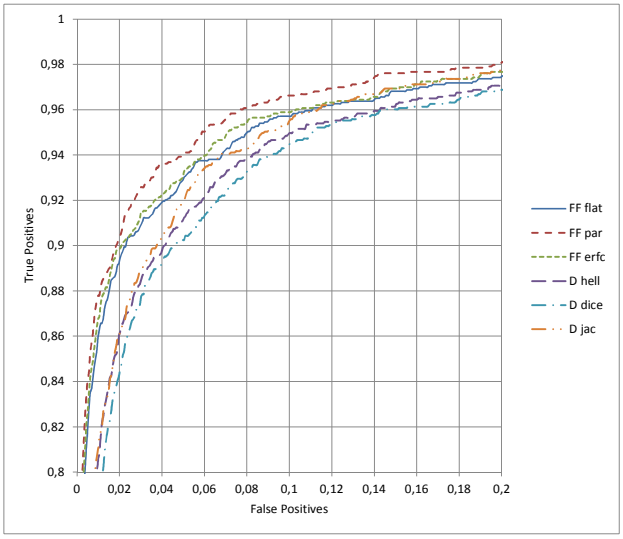

Figure 7 – Detailed ROC for single web site access

D. *Consecutive sites fuzzy fingerprints*

The second set of experiments uses pairs of consecutive site name and port fingerprints. Figure 8 presents accuracy for each of the algorithms. Both crisp and fuzzy algorithms present better results, both can use the extra information contained in the order of the accesses. But this performance increase is only achieved at the expense of much higher number of top-*k* elements. Fuzzy algorithms perform much better than crisp algorithms but is interesting to see that the worst performing algorithm in the single site tests, the Jaccard based distance performes much better with consecutive sites. Fuzzy fingerprints using the Pareto based function achieves the best results, followed closely by the complementary gaussian error function.

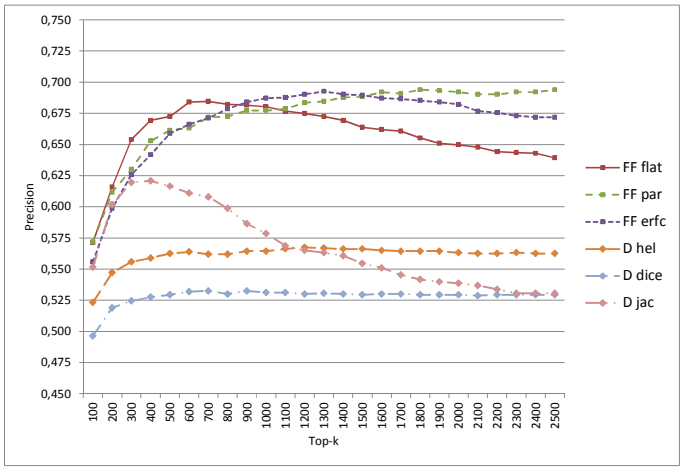

Figure 8 – Algorithms accuracy for consecutive web site accesses

Figure 9 presents the ROC curves. To better show the differences Figure 10 presents the zoom of the most relevant area of the ROC.

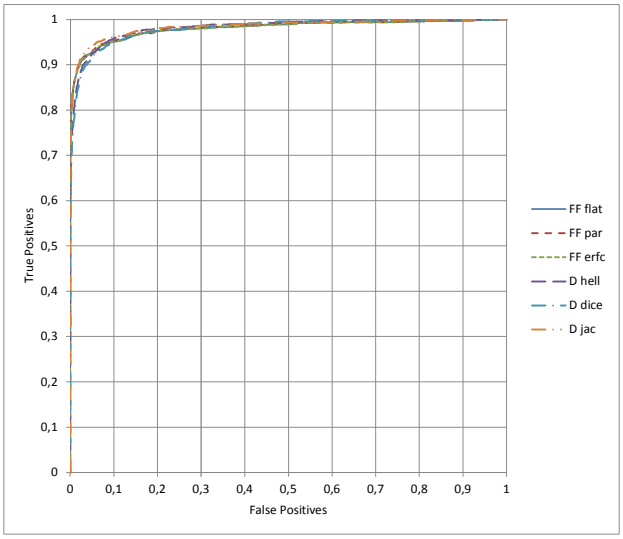

Figure 9 – Algorithms ROC for consecutive web site accesses

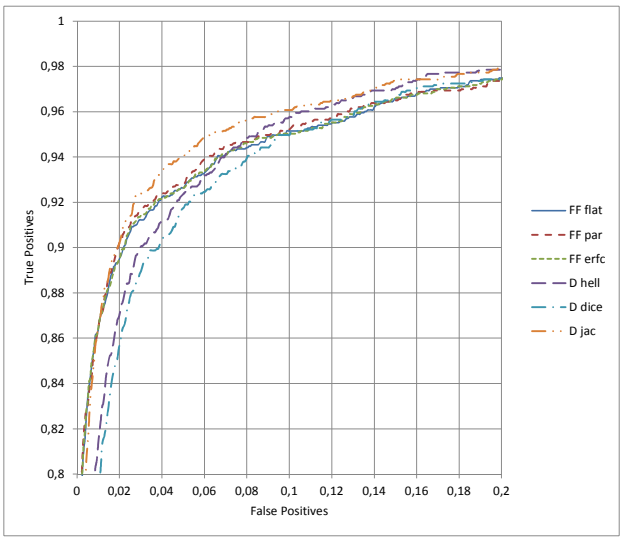

Figure 10 – Detailed ROC for consecutive web site accesses

Interestingly the ROC shows that the Jaccard based distance behaves quite well overall. Although the accuracy of the top choice is not the best of all algorithms, it generates less false positives when the list is enlarged.

E. *Mixture fuzzy fingerprints*

The final set of experiments use both the single site and pairs of consecutive site name and port fingerprints. Both elements are mixed in a single top-k list. Figure 11 presents the accuracy for each of the algorithms.

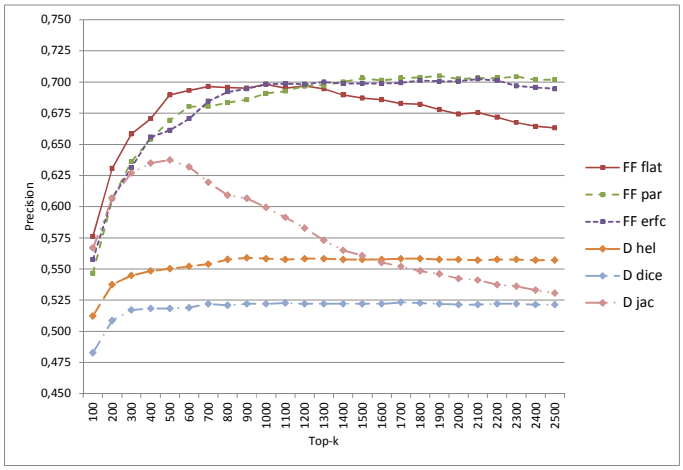

Figure 11 – Algorithms accuracy for mixture fingerprints

Figure 12 and Figure 13 present the corresponting ROC curves.

There is a slight increase in performance of all fuzzy algorithms and for the Jaccard based distance, a slight reduction for the Dice and Hellinger based distances. The most relevant benefict for the use of the mixture is that performance remains stable for a wider range of k. For Pareto and complementary gaussian error based functions the performance remains stable between k values of 1000 to 2500.

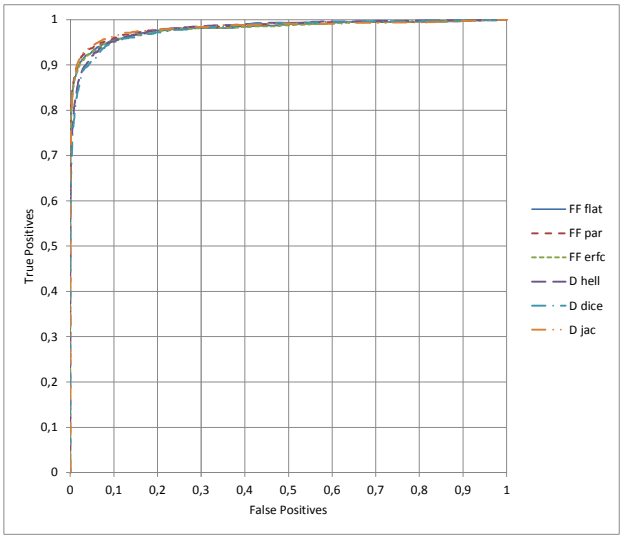

Figure 12 – Algorithms ROC for mixture fingerprints

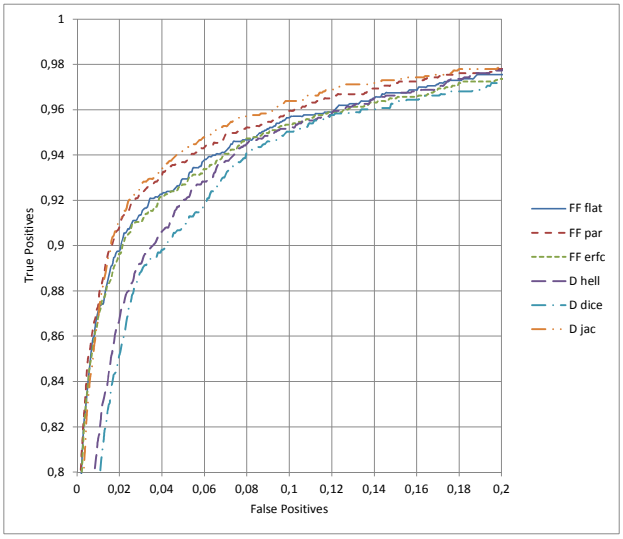

Figure 13 – Detailed ROC for mixture fingerprints

Table I presents the peak performance values for all of the experiments and algorithms. It includes the Area Under the ROC Curve (AUC) [10]. AUC is an indicator of the overall accuracy of the classifier, if the AUC is 0.5, the classifier is no better than random selection; higher values indicate better precision. An AUC of 1 indicates a perfect classifier.

TABLE I. RESULTS FOR EXPERIMENTS WITH WEB SITE ACCESSES

		Fuzzy Fingerprints			**Crisp Distances**		
		flat	***par***	***erfc***	***hell***	***dice***	***jac***
Tests		1630	1630	1630	1630	1630	1630

	AUC	0,9807	0,9829	0,9798	0,9809	0,9786	0,9826

VI. Conclusions and Future Work

This work shows how fuzzy methods may be used to identify the users behind an unidentified web session. The use of simple fuzzy techniques based on approximate algorithms leads to very interesting results.

The fact that the results remain stable for a wide range of values of *k* and for several fuzzification functions shows that the proposed method is robust.

The large number of suspects it supports and the ability to include new suspects or update existing user fuzzy fingerprints is critical to the use of the method in long-term detection processes. New fuzzy fingerprints can be created and added to the suspect's library at any time, and new session logs from known users can be added to the fuzzy fingerprint. Update to one fuzzy fingerprint does not influence all the others.

In this work the method is applied to identifying a author within a list of possible suspects but it can also be applied to the single author problem or to the one or none author within a list by considering the distance (or the inverse comparison) between fuzzy fingerprints as a distinguishing feature. One can then apply a binary classifier, such as a Bayes classifier to determine if the author is a probable one. There is however a significant risk in reducing the complexity of a very high level dimension problem to a single dimension. A candidate should only be tested in this way if all other candidates have been eliminated (i.e., it should only be applied to the top of a list of suspects).

The use of order information, by using consecutive events as base features, enriches the fingerprints, even with such as sparse data as web site names. One can expect that this approach could lead to even better improvements in domains where event order is more relevant.

The proposed method should not be seen as a specific method; it can be used in other domains to identify individual behavior based on events. The proposed method will identify individuals as long as they present a stable event distribution. Future work should also test the inclusion of additional features available in the web logs.

Abstract— **This paper presents a fuzzy multiattribute decision making (MADM) approach to evaluating airport performance in terms of the airport operator, the passenger, and the airline dimensions. Assessments for quantitative measures are represented by crisp values, and assessments for qualitative measures and attribute weights are represented by triangular fuzzy numbers, obtained via surveys using linguistic terms. An effective algorithm is developed by using the α-cut concept for incorporating the decision-maker's confidence level about respondents' fuzzy assessments on performance ratings and attribute weights. Based on the concept of the degree of optimality, the algorithm obtains a quantitative performance index for each airport evaluated, relative to other comparable airports with respect to each of three evaluation dimensions individually and all three evaluation dimensions as a whole. The performance index obtained would help individual airports understand the comparative level of their performance on measures relating to operational management, airport facilities, and passenger service quality. An empirical study of performance evaluation of 11 Asia-Pacific major international airports is conducted to illustrate how the approach works.**

Keywords-Fuzzy multiattribute decision making; Airport performance evaluation; TOPSIS

I. INTRODUCTION

The operation efficiency and service quality of international airports are critical in the modern-day context where businesses are international and people are more mobile. To help an airport identify functional areas for improvement, it is advisable to evaluate its performance relative to other comparable airports with respect to a number of manageable attributes (evaluation criteria). As the evaluation is based on a comparative process, the evaluation result can be used as a service benchmarking and management tool for airports. The most comprehensive study of comparing service performance of international airports is probably the International Air Transport Association (IATA) Global Airport Monitor. Despite a wide coverage of performance indicators for airport services, no attempt was made by IATA to develop an integrated airport performance index.

Quite a few studies on airport performance evaluation have been reported in the literature with focus on specific functional areas of airport operations, such as productivity [1]–[4], capacity and delays [5], efficiency [6]–[8], airline services [9], competitiveness [10], [11], financial performance [12], service quality [13]–[15]. Although there is no universal and exact definition for airport performance, the overall performance of airports can be measured from the viewpoints of passengers, airlines, and the airport operator [16]. The most widely used airport performance evaluation methods are perhaps the data envelopment analysis (DEA) and total factor productivity (TFP) [3], [6]–[8], [17], [18]. Although these methods are well suited for measuring the efficiency of airport operations based on resource input measures and performance output measures, they do not intend to address the effectiveness issue with respect to the overall performance of airports from the viewpoints of the airport operator, passengers, and airlines as a whole.

The evaluation of the overall performance of airports is a complex decision-making process, as it usually involves (a) multiple conflicting criteria with non-commensurable units and (b) both crisp and fuzzy data derived from precise measures of quantitative criteria and imprecise judgments of qualitative criteria resulting from human subjectivity. Multiattribute decision making (MADM) has proven to be an effective approach for ranking a finite number of alternatives characterized by multiple conflicting criteria [19]. The most widely used theory in solving MADM problems is multiattribute utility theory [20] or multiattribute value theory (MAVT) [21], with which a cardinal preference or ranking of the decision alternatives is generated. Fuzzy set theory has proven to be a powerful modeling tool for coping with the subjectiveness and imprecision of human judgments [22], [23]. In the applications of MAVT-based MADM for evaluation and selection problems involving subjective judgments of the decision maker, fuzzy MADM has demonstrated its applicability in ranking decision alternatives such as transportation systems (e.g. [10], [24]–[28]).

In this paper, we formulate the evaluation of airport performance as a fuzzy MADM problem that requires cardinal ranking. To obtain a quantitative airport performance index, we develop an algorithm based on the concept of the degree of optimality. In subsequent sections, we first discuss the performance measures suitable for evaluating the airport performance from the perspectives of the airport operator, passengers, and airlines. We then present the fuzzy MADM

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

approach to the performance evaluation problem. Finally we conduct an empirical study to measure and compare the overall performance of 11 major Asia-Pacific international airports.

II. AIRPORT PERFORMANCE MEASURES

The use of performance measures (attributes) in airport evaluation problem is crucially important because of its specific economic characteristics. In the business competitive environment optimal performance can be equated with profitability. However, the conditions under which airports operate are far from competitive. Regulatory, geographical, economic, social and political constraints all hinder direct competition between airports [29]. Various performance attributes or measures can be used to evaluate the airport performance from the perspectives of different stakeholders of the airport operation, depending on the objectives of the evaluation problem. In the case of airport performance evaluation, the airport operator (service provider) would focus more on measures concerned with the operational efficiency of the airport. Passengers are more interested in measures relating to service quality and safety. Airlines are more concerned about the facilities provided by the airport. As such, to reflect the operating characteristics of international airports, the criteria for performance evaluation should be constructed from the perspectives of the airport operator, passengers, and airlines. Fig. 1 shows the hierarchical structure of the airport evaluation problem to be addressed in the paper. The three evaluation dimensions and their associated performance measures are discussed below.

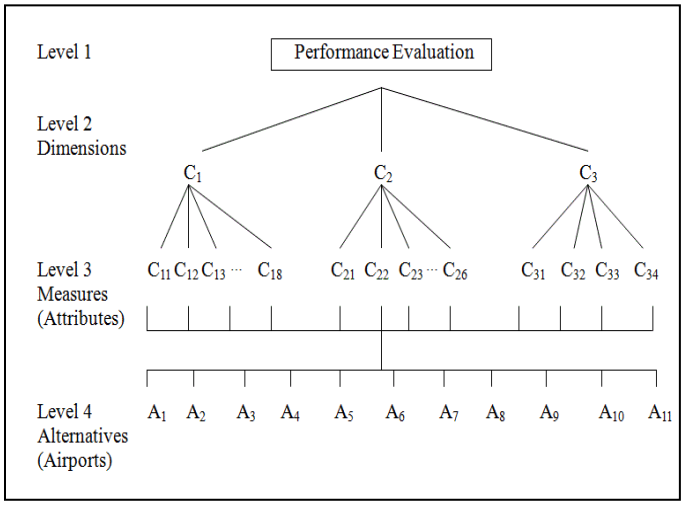

Figure 1. Hierarchy structure for airport performance evaluation.

The airport operator dimension (C_1) is mainly concerned with airport operational management and the facilities provided for the airport users. The airport operator is assessed quantitatively based on the airport operational data, including revenue (C_{11}) (total operating revenue), annual growth rate (C_{12}) (annual growth rate of total passenger volume), airport terminal size (C_{13}) (total terminal surface area of airport), navigation Aids (C_{14}) (category of the navigation aid system), ground access facilities (C_{15}) (types of ground transportation to/from city), distance to CBD (C_{16}) (distance from the airport to the central business district), car park (C_{17}) (number of parking car bays), noise pollution (C_{18}) (number of aircraft movement per day).

The passenger dimension (C_2) relates to the services provided by the airport and the quality level as perceived by the passengers. These service measures include comfort (C_{21}) (congestion level and cleanliness in the terminal building), processing time (C_{22}) (total time required during check-in, immigration inspection and customs), convenience (C_{23}) (availability and accessibility of airport facilities within the terminal building), courtesy of staff (C_{24}) (helpfulness and friendliness of airport staff), information visibility (C_{25}) (information display for flights, airport facilities, and signposting), security (C_{26}) (safety measures and security facilities). These service attributes are to be measured based on passengers' perception, which are to be assessed subjectively by a survey process using a set of linguistic terms characterized by fuzzy numbers.

The airline dimension (C_3) is mainly concerned with the facilities provided by airports such as gates, operating hours, aircraft movement and runways. Its performance measures include aircraft movement (C_{31}) (total number of aircraft movement), gates (C_{32}) (number of gates), operating hours (C_{33}) (total daily operating hours of the airport), runway (C_{34}) (number of runways).

The performance measures discussed above involve both quantitative and qualitative assessments, for which numerical data and fuzzy numbers are to be used respectively. These measures are independent of each other, thus suitable for use in an MAVT-based MADM model.

III. THE FUZZY MULTIATTRIBUTE DECISION MAKING APPROACH

A. The Evaluation Problem

In this paper, we formulate the airport performance evaluation as a fuzzy MADM problem that requires cardinal ranking. The problem involves a set of m airports (alternatives) A_i ($i = 1, 2, ..., m$), which are to be evaluated based on n evaluation dimensions C_j ($j = 1, 2, ...,n$), each of which is represented by a set of p_j performance measures (attributes) C_{jk} ($k = 1, 2, ..., p_j$). Assessments are to be given to determine (a) the weight vectors $W = (w_1, w_2, \ldots, w_j, ..., w_n)$ and $W_j = (w_{j1}, w_{j2}, ..., w_{jk}, ..., w_{jp_j})$ ($j = 1, 2, ..., n; k = 1, 2, ..., p_j$), and (b) the decision matrices $Y_{C_j} = \{y_{ki}, k = 1, 2, ..., p_j; i = 1, 2, ..., m\}$ ($j = 1, 2, ..., n$) and $X = \{x_{ij}, i = 1, 2, ..., m; j = 1, 2, ..., n\}$.

The weight vectors W and W_j represent the relative importance of n evaluation dimensions C_j ($j = 1, 2, ..., n$) and p_j performance measures C_{jk} ($k = 1, 2, ...,p_j$) for the problem and their corresponding dimension respectively. The weight vectors are to be assessed subjectively by airport experts via surveys, using the set of linguistic terms defined in Table I. Linguistic terms have been found intuitively easy to use in

expressing the subjectiveness and imprecision of the decision maker's assessments [23], [30]–[32]. To facilitate the making of qualitative assessments by respondents, a set of linguistic terms is used. Each linguistic term is characterized by a triangular fuzzy number for representing its approximate value range between 1 and 9, denoted as (a_1, a_2, a_3), where $1 \le a_1 \le a_2 \le a_3 \le 9$. a_2 is the most possible value of the term, and a_1 and a_3 are the lower and upper bounds respectively used to reflect the fuzziness of the term. As such, w_j in W and w_{jk} in W_j are the fuzzy weights of evaluation dimensions C_j (j = 1, 2, ..., m) and performance measures C_{jk} (k = 1, 2, ..., p_j), respectively.

TABLE I. LINGUISTIC TERMS USED FOR DETERMINING THE WEIGHT VECTOR

Linguistic Term	Not Important (NI)	Somewhat Important (SI)	Important (I)	Very Important (VI)	Extremely Important (EI)
Membership Function	(1,1,3)	(1,3,5)	(3,5,7)	(5,7,9)	(7,9,9)

In practical applications, the triangular form of the membership function is used most often for representing fuzzy numbers that characterize linguistic information [33], [34]. The popular use of triangular fuzzy numbers is mainly attributed to their simplicity in both concept and computation. Theoretically, the merits of using triangular fuzzy numbers in fuzzy modeling have been well justified [35]. With the simplest form of the membership function, triangular fuzzy numbers constitute an immediate solution to the optimization problems in fuzzy modeling.

The decision matrices Y_{C_j} represent the performance ratings (y_{ki}) of airport A_i with respect to each performance measure C_{jk} (k = 1, 2, ..., p_j) of the corresponding evaluation dimension C_j. These performance ratings are given based on quantitative and qualitative assessments. While the quantitative assessments are straightforward based on the data available, the qualitative assessments require subjective judgments of airport experts to reflect the degree to which each airport satisfies each qualitative safety measure. The set of linguistic terms defend in Table II is used by airport experts to assess the qualitative performance ratings via surveys.

TABLE II. LINGUISTIC TERMS USED FOR DETERMINING PERFORMANCE RATINGS

Linguistic Term	Very Poor (VP)	Poor (P)	Fair (F)	Good (G)	Very Good (VG)
Membership Function	(1,1,3)	(1,3,5)	(3,5,7)	(5,7,9)	(7,9,9)

The decision matrix $X = \{x_{ij}, i = 1, 2, ..., m; j = 1, 2, ..., n\}$ represents the performance ratings of airport A_i with respect to evaluation dimension C_j. While Y_{C_j} (j = 1, 2, ..., n) are given based on the assessments made on the airports, the decision matrix X is constructed by aggregating the weighted assessments from lower-level performance measures of each evaluation dimension C_j. Given the fuzzy weight vectors (W and W_j) and fuzzy decision matrices (X and Y_{C_j}), the objective of the problem is to rank all the airports by giving each of them an overall airport performance index with respect to all evaluation dimensions.

B. The Solution Procedure

The algorithm begins with the generation of the decision matrix X by multiplying the weight vector W_j by the decision matrix Y_{C_j}, as

$$\left(x_{1j}, x_{2j}, ..., x_{mj}\right) = W_j Y'_{C_j} \Big/ \sum_{k=1}^{p_j} w_{jk}, \; j = 1, 2, ..., n. \quad (1)$$

where Y'_{C_j} (i = 1, 2, ..., m) are the normalized decision matrices by

$$y'_{ki} = y_{ki} \Big/ \sqrt{\sum_{i=1}^{n} (y_{ki})^2}, \; i = 1, 2, ..., m; \; k = 1, 2, ..., p_j. \quad (2)$$

The normalization process is required to allow a comparable scale for all performance measures, assessed by different measurement units.

In (1), (x_{1j}, x_{2j}, …, x_{mj}) is a fuzzy decision vector in X, which is obtained from a normalized value function that multiplies the weight vector W_j for its lower-level sub-criteria C_{jk} by the corresponding normalized decision matrix Y'_{Cj}. With the use of triangular fuzzy numbers, the arithmetic operations on fuzzy numbers are based on interval arithmetic [36].

The algorithm then generates a fuzzy performance matrix by multiplying the weight vector W by the decision matrix X, as given in (3).

$$Z = \begin{bmatrix} w_1 x_{11} & w_2 x_{12} & \cdots & w_n x_{1n} \\ w_1 x_{21} & w_2 x_{22} & \cdots & w_n x_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ w_1 x_{m1} & w_2 x_{m2} & \cdots & w_n x_{mn} \end{bmatrix} \quad (3)$$

By using the concept of α-cut on the fuzzy numbers in the performance matrix, an interval performance matrix is derived as given in (4), where $0 \le \alpha \le 1$. For a given α, z_{ijl}^{α} and z_{ijr}^{α} (i = 1, 2, ..., m; j = 1, 2, ..., n) are the average of the lower bounds and upper bounds of the crisp intervals respectively, resulted from all α-cuts using the alpha values equal to or greater than the specified value of α.

$$Z_{\alpha} = \begin{bmatrix} \left[z_{11l}^{\alpha}, z_{11r}^{\alpha}\right] & \left[z_{12l}^{\alpha}, z_{12r}^{\alpha}\right] & \cdots & \left[z_{1nl}^{\alpha}, z_{1nr}^{\alpha}\right] \\ \left[z_{21l}^{\alpha}, z_{21r}^{\alpha}\right] & \left[z_{22l}^{\alpha}, z_{22r}^{\alpha}\right] & \cdots & \left[z_{2nl}^{\alpha}, z_{2nr}^{\alpha}\right] \\ \cdots & \cdots & \cdots & \cdots \\ \left[z_{m1l}^{\alpha}, z_{m1r}^{\alpha}\right] & \left[z_{m2l}^{\alpha}, z_{m2r}^{\alpha}\right] & \cdots & \left[z_{mnl}^{\alpha}, z_{mnr}^{\alpha}\right] \end{bmatrix} \quad (4)$$

The value of α represents the decision maker's degree of confidence in the fuzzy assessments, given by the respondents with respect to attribute weights and performance ratings of airports. A larger α value indicates that the decision maker is

more confident in choosing a crisp value interval to represent the corresponding fuzzy number, as the interval is smaller and has a higher possibility. This implies that a confident decision maker would not consider less possible values embedded in a fuzzy number.

To reflect the decision maker's relative preference between z_{ijl}^{α} and z_{ijr}^{α} in (4), a preference index λ in the range of 0 and 1 is incorporated in the algorithm. As a result, a crisp performance matrix is obtained as

$$Z_{\alpha}^{\lambda'} = \begin{bmatrix} z_{11\alpha}^{\lambda'} & z_{12\alpha}^{\lambda'} & \cdots & z_{1m\alpha}^{\lambda'} \\ z_{21\alpha}^{\lambda'} & z_{22\alpha}^{\lambda'} & \cdots & z_{2m\alpha}^{\lambda'} \\ \cdots & \cdots & \cdots & \cdots \\ z_{n1\alpha}^{\lambda'} & z_{n2\alpha}^{\lambda'} & \cdots & z_{nm\alpha}^{\lambda'} \end{bmatrix} \quad (5)$$

where $z_{ij\alpha}^{\lambda'} = \lambda z_{ijr}^{\alpha} + (1-\lambda) z_{ijl}^{\alpha}$, $0 \le \lambda \le 1$, *i = 1, 2, ..., m; j = 1, 2, ..., n*. The use of λ allows the algorithm to reflect the decision maker's attitude towards risk, which may be optimistic, pessimistic or somewhere in between. In actual decision settings, λ = 1, λ = 0.5, or λ = 0 can be used to indicate that the decision maker has an optimistic, moderate, or pessimistic view respectively on fuzzy assessment results. An optimistic decision maker is apt to prefer higher values of the crisp value interval derived from fuzzy assessments, while a pessimistic decision maker tends to favor lower values.

To solve the multiattribute evaluation problem characterized by the perform matrix in (5), an effective method is applied. The method is based on the concept of the degree of optimality rooted in an alternative where multiple attributes (criteria) characterize the notion of the best [37]. In the context of MADM, the concept suggests that the most preferred alternative should not only have the shortest distance from the positive ideal solution (or the best alternative), but also have the longest distance from the negative ideal solution (or the worst alternative). The positive (or negative) ideal solution consists of the best (or worst) attribute values attainable from all the alternatives if each attribute takes monotonically increasing or decreasing values [19]. This concept has been implemented by a widely used MADM method called the technique for order preference by similarity to ideal solution (TOPSIS) [19] and has been applied under different decision contexts [38]–[44]. This is mainly due to (a) its applicability in solving various practical decision problems, (b) its simplicity and comprehensibility, (c) its computational efficiency, and (d) its ability to measure the relative performance of the alternatives in a simple mathematical form.

Based on the concept presented above, the positive ideal solution $A_{\alpha}^{\lambda+}$ and the negative ideal solution $A_{\alpha}^{\lambda-}$ can be determined from (5) by selecting the maximum value and the minimum value respectively across all alternatives (airports) with respect to each service attribute, as given in (6) and (7).

$$\begin{aligned} A_{\alpha}^{\lambda+} &= \left(z_{1\alpha}^{\lambda+}, z_{2\alpha}^{\lambda+}, \ldots, z_{n\alpha}^{\lambda+}\right) \\ A_{\alpha}^{\lambda-} &= \left(z_{1\alpha}^{\lambda-}, z_{2\alpha}^{\lambda-}, \ldots, z_{n\alpha}^{\lambda-}\right) \end{aligned} \quad (6)$$

where

$$\begin{aligned} z_{j\alpha}^{\lambda+} &= \max\left(z_{1j\alpha}^{\lambda}, z_{2j\alpha}^{\lambda}, \ldots, z_{mj\alpha}^{\lambda}\right) \\ z_{j\alpha}^{\lambda-} &= \min\left(z_{1j\alpha}^{\lambda}, z_{2j\alpha}^{\lambda}, \ldots, z_{mj\alpha}^{\lambda}\right) \end{aligned}, \; j = 1, 2, \ldots, n \quad (7)$$

$A_{\alpha}^{\lambda+}$ and $A_{\alpha}^{\lambda-}$ represent the performance vectors of the best possible airport and the worst possible airport on *n* service attributes respectively.

Like the performance vectors in (6), the weighted overall performance of airport A_i on service attributes C_j (*j=1, 2,..., n*) can be expressed as a performance vector of *n* elements. Thus, we can apply the vector matching technique to measure how close a particular airport is to the best possible airport and to the worst possible airport, given respectively as

$$S_{i\alpha}^{\lambda+} = \frac{A_{i\alpha}^{\lambda} A_{\alpha}^{\lambda+}}{\max\left(A_{i\alpha}^{\lambda} A_{i\alpha}^{\lambda}, A_{\alpha}^{\lambda+} A_{\alpha}^{\lambda+}\right)} \quad (8)$$

$$S_{i\alpha}^{\lambda-} = \frac{A_{i\alpha}^{\lambda} A_{\alpha}^{\lambda-}}{\max\left(A_{i\alpha}^{\lambda} A_{i\alpha}^{\lambda}, A_{\alpha}^{\lambda-} A_{\alpha}^{\lambda-}\right)}, \; i=1, 2, \ldots, m \quad (9)$$

$A_{i\alpha}^{\lambda}$ is the i^{th} row of the performance matrix in (5), representing the corresponding performance vector of airport A_i with respect to service attribute C_j. $S_{i\alpha}^{\lambda+}$ and $S_{i\alpha}^{\lambda-}$ represent the degree of similarity between airport A_i and the positive ideal solution and the negative ideal solution respectively.

For a given decision maker's degree of confidence level (α) in fuzzy assessments and a given index of optimism (λ), an overall performance index for each airport can be determined by

$$P_{\alpha i}^{\lambda} = \frac{S_{i\alpha}^{\lambda+}}{S_{i\alpha}^{\lambda+} + S_{i\alpha}^{\lambda-}}, \; i=1, 2, \ldots, m. \quad (10)$$

The rationale behind (10) is that that a preferred alternative should have a higher degree of similarity to the positive ideal solution and a lower degree of similarity to the negative ideal solution [19]. The larger the performance index, the better the overall service performance of the airport, relative to other airports. As such, the performance index generated is a relative concept, and indicates the relative ranking of the airports evaluated in terms of service attributes.

IV. Empirical Study of 11 Asia-Pacific International Airports

To illustrate how the fuzzy MADM approach works, we conducted an empirical study on 11 major international airports in the Asia-Pacific region. Air travel demand in the Asia-Pacific region had an average annual growth rate of 10.1% during the past decade, the highest in the world. A high rate of economic growth in Asia has spurred the rapid expansion of commercial aviation industries serving the Asia-Pacific region. With 16 of the world's 25 busiest air routes, Asia's major airports are already near capacity. Asia's explosive economic growth has been accompanied by rapid expansion and the transformation of the region's aviation industry. Air transportation is expected to play a larger role in this region more than anywhere else in the world. First, the high

population and income growth rates in many Asian countries are expected to produce an astounding increase in the demand for air transportation services. The region already accounts for more than 50 per cent of the world's population. Second, vast distances separate many Asia-Pacific countries. About 60 per cent of the air routes in the region are between cities that are at least 2,000 kilometers apart, and a number of countries in the region are islands or archipelagos with few alternatives to air passenger travel [45].

The purpose of this study is to evaluate the performance of Asia-Pacific's 11 major international airports on measures relating to operational management, passenger service quality, and airport facilities. The 11 major airports selected process more than half of the region's international traffic. These airports are (A_1) Incheon International Airport - Incheon (ICN), (A_2) Chek Lap Kok International Airport - Hong Kong (HKG), (A_3) Suvarnabhumi International Airport - Bangkok (BKK), (A_4) Narita International Airport - Tokyo (NRT), (A_5) Changi International Airport - Singapore (SIN), (A_6) Kingsford Smith International Airport - Sydney (SYD), (A_7) Kansai International Airport - Osaka (KIX), (A_8) Capital International Airport - Beijing (PEK), (A_9) Taoyuan International Airport - Taipei (TPE), (A_{10}) Tullamarine International Airport - Melbourne (MEL) and (A_{11}) Pudong International Airport - Shanghai (PVG). The performance of these 11 airports is to be evaluated based on the three dimensions and their associated performance measures as shown in Fig. 1.

In this study, we use equal weights for the three evaluation dimensions, i.e. W = (1, 1, 1). The weights of performance measures within each dimension are assessed by airport experts using the linguistic terms defined in Table I. Table III shows the assessment result.

TABLE III. WEIGHT VECTOR FOR EVALUATION DIMENSIONS

Weight Vector	Fuzzy Weights for Performance Measures
W	(1, 1, 1)
W_1 (Airport operator)	(VI, EI, VI, I, I, I, VI, I)
W_2 (Passenger)	(VI, VI, VI, EI, I, VI)
W_3 (Airline)	(I, VI, VI, I)

The assessment results of the performance measures for the airport operator and the airline dimensions are obtained from the available data for 2008 as crisp data, as given in Tables IV and V respectively. The assessment for qualitative performance measures of the passenger dimension is made by surveys of 15 international tour guides using the linguistic terms defined in Table II. Table VI shows the assessment result.

With the data in Tables III - VI, the decision matrix for the three evaluation dimensions can be calculated by (1). The fuzzy performance matrix in (3) can then be obtained by multiplying this decision matrix by the weight vector W of equal weights. By applying the algorithm given as in (4)-(10) with $\alpha = 0$ and $\lambda = 0.5$, we can obtain an airport performance index for each airport with respect to each evaluation dimension individually and all the three dimensions as a whole. Table VII shows the result and the corresponding ranking order.

Airport	Overall		C_1		C_2		C_3	
	Index	*Ranking*	*Index*	*Ranking*	*Index*	*Ranking*	*Index*	*Ranking*
A_1 (Incheon)	1.414	7	0.369	8	0.512	4	0.533	4
A_2 (Hong Kong)	1.595	4	0.470	5	0.557	2	0.568	3
A_3 (Bangkok)	1.392	8	0.445	6	0.481	7	0.465	8
A_4 (Tokyo)	1.446	6	0.431	7	0.525	3	0.490	7
A_5 (Singapore)	1.681	2	0.587	2	0.570	1	0.524	5
A_6 (Sydney)	1.527	5	0.566	3	0.439	11	0.522	6
A_7 (Osaka)	1.235	10	0.354	9	0.506	5	0.374	11
A_8 (Beijing)	1.695	1	0.552	4	0.463	10	0.680	1
A_9 (Taipei)	1.122	11	0.257	11	0.485	6	0.379	10
A_{10} (Melbourne)	1.671	3	0.763	1	0.480	8	0.428	9
A_{11} (Shanghai)	1.367	9	0.329	10	0.465	9	0.572	2

The settings used for α and λ reflect that the decision maker has no particular preference for the fuzzy assessment results made by the respondents. $\alpha = 0$ implies that the mean value of a fuzzy number; that is, the average of value intervals of all α-cuts on the fuzzy number is used. $\lambda = 0.5$ indicates that the decision maker has a moderate attitude towards the respondents' assessments; that is, the decision maker weights all the values derived from fuzzy assessments equally.

In terms of the overall performance, the Beijing, Singapore, and Melbourne airports perform best, while the Taipei, Osaka and Shanghai airports have the worst performance. On the airport operator dimension, the Melbourne airport ranks first with a good performance in all measures, while the Taipei airport ranks last, mainly because of its poor performance in the areas of revenue, annual growth rate, and ground access. The Melbourne airport performs exceptionally well on this dimension as compared with its performance on other dimensions, mainly due to its highest annual growth rate among all the airports. On the passenger dimension, the Singapore, Hong Kong, and Tokyo airports perform exceptionally well based on passengers' perception of airport service quality, while the Sydney, Beijing and Shanghai airports provide relatively poor passenger service quality. On the airline dimension, the Beijing, Shanghai and Hong Kong airports have the best performance, while the Osaka and Taipei airports perform worst.

To examine whether the confidence level (the α value) and the risk attitude (the λ value) may affect the evaluation result presented in Table VII, a sensitivity analysis process was carried out by changing the values of α and λ. Table VIII shows three representative evaluation results under three typical settings of λ regardless of the settings of α. Fig. 2 shows some representative evaluation results under various settings of α and λ. As shown in Table VIII and Fig. 2, when the risk attitude is pessimistic or moderate ($\lambda = 0$ or $\lambda = 0.5$), the ranking result is not consistent. This implies that the decision maker's attitude towards the handling of the uncertainty associated with the fuzzy assessments in this case study does have significant influence on the evaluation result in terms of relative ranking. This is mainly due to the fact that these airports have relatively similar performances on the passenger service quality dimension than the other two dimensions. No airport appears to have a dominating performance in all three evaluation dimensions.

TABLE VIII. OVERALL AIRPORT PERFORMANCE INDEX AND RANKING UNDER VARIOUS RISK ATTITUDES

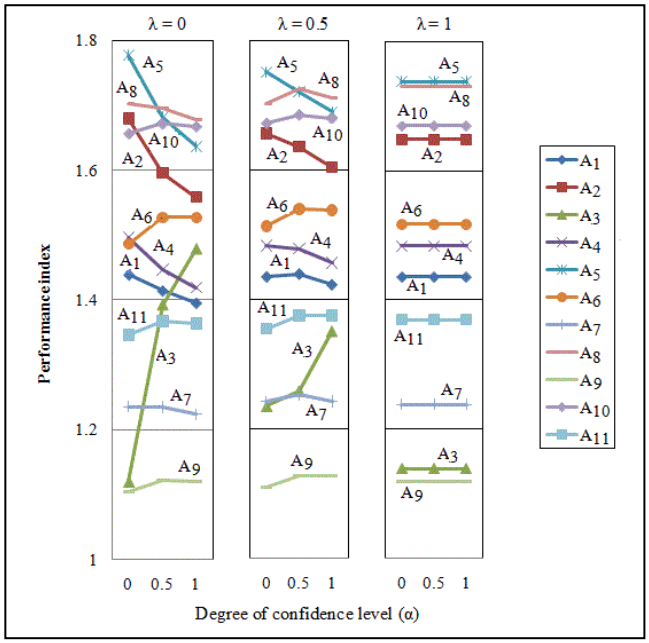

Figure 2. Overall airport performance index and ranking under various decision settings.

The performance index obtained would help airports understand the comparative level of their performance on

measures relating to operational management, airport facilities, and passenger service quality. With its relative concept, the index serves as a performance benchmarking and management tool for airports, as it can identify functional areas for performance improvement.

V. CONCLUSION

Airport performance evaluation requires considering multiple evaluation criteria structured in multi-level hierarchies. The evaluation often involves both quantitative and qualitative assessment data. In this paper, we have formulated airport performance evaluation as a fuzzy MADM problem that requires cardinal ranking of all airports. As an effective alternative to airport performance evaluation, the fuzzy MADM approach developed can effectively handle both quantitative and qualitative performance measures with a multilevel hierarchy. The empirical study of 11 Asia-Pacific international airports has demonstrated the effectiveness of the approach. The evaluation result would provide an airport with indicative information about its relative strengths and weaknesses in terms of performance measures associated with the airport operator, the passenger, and the airline. With its simplicity in concept and computation, the approach has general application in solving multiattribute evaluation problems involving both crisp assessments of quantitative attributes and fuzzy assessments of qualitative attributes.

ACKNOWLEDGMENT

This research was supported the National Science Council of Taiwan (Grant NSC100-2811-H-006-002) and the National Cheng Kung University (Grant HUA 98-21T-06-078). We are grateful to Taiwan's airport management and travel experts involved for providing assistance in problem formulation and data collection.

***Abstract* — Taking into account the need of handling hybrid information with uncertainty in human decision making, a new belief rule-base inference methodology (RIMER) has been recently proposed. RIMER approach and its relevant extensions have proved to be highly positive solving decision problems. However, for an end user it is difficult to implement the methods and algorithms from the raw equations in order to solve a specific problem. This paper presents a decision support tool based on the RIMER approach that facilitates its implementation and use to end-users. The overall structure and main functionalities of the tool are outlined, followed by an example to illustrate the use of this tool for applications.**

Keywords — knowledge-based system, belief rule base, decision making, uncertainty, decision support system.

I. INTRODUCTION

Nowadays, large amount and heterogeneous information provided by different sources is common for decision making problems, this fact implies a high complexity that is rather difficult of managing for human beings without any support. Consequently, more and more computer based decision-making support has been accepted and developed, to provide a stress-free view of the situation, joining the individuals intellectual resources with the capabilities of computers for improving the quality of decisions [1].

The use of rules is one of the most common ways in many tools for knowledge representation and inference in decision problems. Knowledge-based systems, usually constructed from human knowledge by means of if-then rules, have been one of the most visible and fastest growing branches of artificial intelligence [2]. In the design and implementation of knowledge-based systems for supporting human decision making, it is necessary and inevitable to use a scheme for representing and processing imprecise, incomplete and uncertain information in conjunction with precise data. Because of the need of handling hybrid information with uncertainty in human decision making, the belief Rule-base Inference Methodology using the Evidential Reasoning approach – RIMER was introduced in [3]. This methodology uses a belief structure for modelling hybrid rule-bases and an evidential reasoning (ER) approach [4] for making inference in the belief rule-based system by combining decision science [5], rule-based systems, and Dempster-Shafer (D-S) theory of evidence [6-7]. Therefore in RIMER a rule-base is designed with belief degrees embedded in the entire consequent terms of a rule, called belief rule-base (BRB), to capture nonlinear causal relationships as well as uncertainty. RIMER approach has been further investigated and extended in [8], denoted as RIMER$^+$, where an extended rule base is designed with belief degrees embedded in the entire consequent terms as well as in the entire antecedent terms of each rule. In addition, a simple but efficient method for automatically generating such extended belief rule-base from numerical data is proposed involving low time cost iterative learning procedure and simple rule generation mechanisms [8]. RIMER results and its relevant extensions have proved to be highly positive solving decision problems applied to different areas, such as, among others, safety and risk analysis, oil pipe leak detection and some other application in engineering systems [9-13].

This paper presents a decision support software tool which aims to facilitate the implementation and use of RIMER and RIMER$^+$ to solve complex decision making problems. This tool presents a friendly end-user interface that allows the implementation of RIMER and RIMER$^+$ in a transparent, informative and integrated way. Concretely, it offers the following functionalities: 1) A data base to store the input-output data; 2) a friendly user interface for problem structuring, information collection, and data presentation in both graphical and text formats; 3) The necessary modules for the rule-base which would be automatically generated based on the input-output sample data or assigned by domain experts and can be then represented in the interface; 4) management of heterogeneous input information in an integrated way; 5) inference algorithms to be applied once the rule-base is generated and the inputs are obtained; 6) a module to save and load solutions of a problem in both textual and graphical formats. Each functionality will be further detailed in the following sections.

This paper is organized as follows: RIMER and RIMER$^+$ are briefly overviewed in Section II. The architecture of the decision support tool and its functionalities are presented in Section III. Section IV introduces an illustrative example. This paper is concluded in Section V.

II. OUTLINING RIMER APPROACH

RIMER [3] presents a new belief rule representation scheme to extend traditional IF–THEN rules using a belief structure. The belief rule base (BRB) introduced in RIMER approach is designed with belief degrees embedded in the consequent terms. It has been then extended into a new belief rule base with belief degrees embedded in the entire consequent terms as well as in the entire antecedent terms of each rule [8].

Suppose a BRB is given by $\boldsymbol{R}=\{R_1, R_2,\ldots, R_L\}$ with the k^{th} rule represented as follows [3]:

R_k: IF $\boldsymbol{U}$ is $\boldsymbol{A^k}$ THEN D with belief degrees $\boldsymbol{\beta^k}$, with a rule weight θ_k and attribute weights $\delta_1, \delta_2,\ldots, \delta_T$ (1)

where $\boldsymbol{U}$ represents the antecedent attribute vector ($U_1,\ldots, U_T$), $\boldsymbol{A^k}$ the packet antecedents $\{A_1^k,\ldots, A_T^k\}$, and A_i^k (i=1,…, T) the referential value of the antecedent attribute U_i in the k^{th} rule; T the total number of antecedent attributes used in the rule base; $\boldsymbol{D}$ the consequent vector ($D_1,\ldots, D_N$), and $\boldsymbol{\beta^k}$ the vector of the belief degrees ($\beta_{1k},\ldots, \beta_{Nk}$) for $k\in\{1,\ldots, L\}$, and β_{sk} ($s\in\{1,\ldots, N\}$ the belief degree to which D_i is believed to be the consequent if in the k^{th} packet rule the input satisfies the packet antecedents $\boldsymbol{A^k}$. θ_k is the relative weight of the k^{th} rule and $\delta_1,\ldots, \delta_T$ are the relative weights of the T antecedent attributes. L is the number of all the packet rules in the rule-base. $\sum_{s=1}^{N}\beta_{sk}\le 1$. If $\sum_{s=1}^{N}\beta_{sk}=1$, the k^{th} packet rule is said to be complete; otherwise, it is incomplete.

Take for example the belief rule in safety analysis [10-11]:

R_k: IF the **failure rate** is *frequent* and the **consequence severity** is *critical* and the **failure consequence probability** is *unlikely,* THEN the **safety estimate** is {(*good,* 0), (*average,* 0), (*fair,* 0.7), (*poor,* 0.3)}, (2)

where the consequent is a belief distribution representation for safety consequent, stating that it is 70% sure that safety level is fair and 30% sure is poor. This kind of rule reflects another kind of uncertainty caused because an expert is unable to establish a strong correlation between premise and conclusion.

In [8], to facilitate the more general application cases and more flexible and simpler rule-base generation scheme, this belief rule is extended with belief degrees embedded in the entire possible antecedent terms of each rule as well, for example, belief rule (2) can be extended as follows:

R_k: IF the **failure rate** is {(*very low,* 0), (*low,* 0), (*reasonably low,* 0), (*average,* 0), (*reasonably frequent,* 0), (*frequent,* 0), (*highly frequent,* 1) AND the **consequence severity** is {(*negligible,* 0), (*marginal ,* 0), (*moderate ,* 0.3), (*critical,* 0.7), (*catastrophic,* 0)} AND the **failure consequence probability** is {(*highly unlikely,* 0.1), (*unlikely ,* 0.7), (*reasonably unlikely,* 0.2), (*likely ,* 0), (*reasonably likely,* 0), (*highly likely,* 0), (*definite,* 0)} THEN the **safety estimate** is {(*Good*, 0), (*Average*, 0.1), (*Fair*, 0.6), (*Poor*, 0.3)} (3)

This kind of extended belief rule is able to not only capture vagueness (with linguistic terms), uncertainty (with beliefs), incompleteness (partially known beliefs in antecedents and/or consequents) and nonlinear relationships (IF-THEN rules) between these three parameters and the safety level but also provide the flexible way to incorporate the hybrid input information as well as more efficient rule generation scheme.

Generally, rule (1) can be extended in the following form:

R_k^*: IF $\boldsymbol{U}$ is ($\boldsymbol{A}$, $\boldsymbol{\alpha^k}$) THEN $\boldsymbol{D}$ with belief degrees $\boldsymbol{\beta^k}$, with a rule weight θ_k and attribute weights $\delta_1, \delta_2,\ldots, \delta_T$ (4)

where ($\boldsymbol{A}$, $\boldsymbol{\alpha^k}$) is the packet antecedents $\{\{(A_{ij}, \alpha_{ij}^k), j=1,\ldots, J_i\}; i=1,\ldots, T\}$ (as illustrated in (3)) representing antecedent with belief structure; here A_{ij} ($j\in\{1,\ldots, J_i\}$) is the jth referential value of the i^{th} antecedent attribute U_i (i=1, …, T), α_{ij}^k the likelihood to which U_i is evaluated to be the referential value A_{ij} in the kth rule with $\alpha_{ij}^k\ge 0$ and $\sum_j^{J_i}\alpha_{ij}^k\le 1$ (i=1,… T), k=1,…, L^*, L^* is the total number of all the packet rules in the rule-base. A rule base with rules in the form of (4) is called an extended belief rule base (EBRB) compared with (1). Note that all the rules in an EBRB share the same antecedent terms and consequent terms, but have different belief distributions for each antecedent attribute and the consequent. The use of the superscript k in (4) reflects this feature.

Once given an input, the activation weight w_k which measures the degree to which the k^{th} rule is weighted and activated, will be calculated using various ways depending on the nature of an antecedent attribute as detailed in [3, 8]. Having determined the activation weight of each rule in the rule base, the ER approach can be directly applied to combine the rules and generate final conclusions. The final conclusion generated by aggregating all activated rules by the current input vector $\boldsymbol{x}=\{x_i, i=1,\ldots, T\}$ can be represented as follows:

$$f(\boldsymbol{x})=\{(D_s, \beta_s), s=1,\ldots, N\}. \quad (5)$$

The final result is still estimated a belief distribution, which gives a panoramic view about estimate for a given input [3, 8]. The inference methodology based on (1) is referred to RIMER, and the one based on (4) as RIMER$^+$. The following introduced software tool includes both methodologies, for the convenience, we use only RIMER as a representative.

III. DECISION SUPPORT SYSTEM BASED ON RIMER

This section introduces a decision support software tool that implements the RIMER method.

A. Architecture

This system has been developed under the object-oriented programming paradigm. So abstract concepts can be defined and grouped into packages. The general structure of the packages follows the classic MVC architecture [14]. Each main package – Model, View and Controller – communicate with the rest through interface classes, i.e. with non-implemented methods. The main feature of this design pattern is that permits the encapsulation of each part of the system with a minimal decoupling with the rest. The MVC architecture allows us to build the system iteratively, from the first basic window with the basic features, until the final result, which is improved due to the versioning system until all the functionalities required are achieved.

B. *Features of RIMER support system*

This section introduces the main features of the system. Firstly it presents the features related to the *problem definition* and secondly related to the *solving process.*

1) Problem definition

The system provides the flexibility to define the hierarchical decision structure which is composed of several attributes. Attributes (also referred to as parameters) are variables that represent decision sub-problems. They are organized hierarchically so the attributes in higher levels of the hierarchy depend on lower-level attributes. The system presents a clear-cut interface to define the hierarchical structure and its attributes. The interface has been designed in a way that each attribute in the structure can be directly modified. Therefore, all the elements of the problem definition can be managed directly in an integrated way, just by clicking on them. These elements are subsequently described.

The system interface is based on two main windows that show the details of every parameter and keep them visible in the window to facilitate their management. Hence, an accessible and fast way to navigate between both windows is provided. Figure 1 (a) illustrates the layout of attributes management and Figure 1 (b) shows a general hierarchical structure window (also taken as the main window).

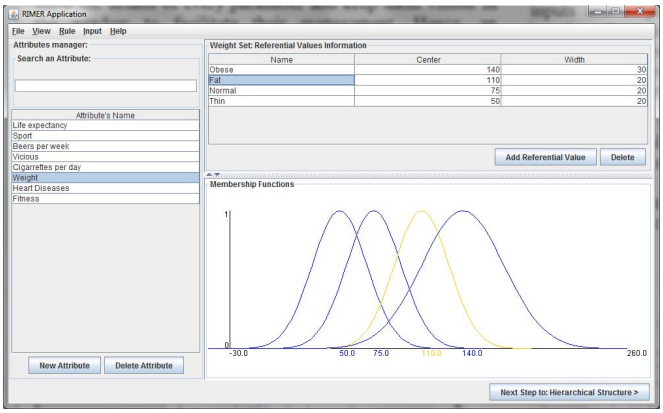

Figure 1 (a) Attribute window

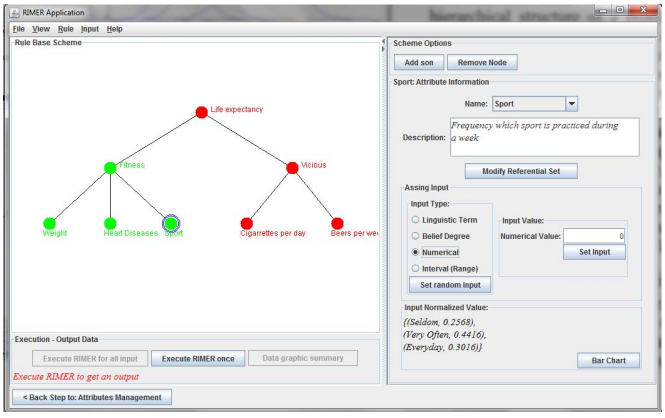

Figure 1 (b) Hierarchical structure window as main window

a) Attributes management

The attributes management window manages every aspect regarding the attributes and their referential values (a set of meaningful and distinctive evaluation standards for describing an attribute, which is commonly described by subjective linguistic terms). The definition of each attribute is essential to obtain proper results when executing RIMER, since both inputs and outputs are transformed into belief distribution based on the referential values of each attribute (see Section II). The attributes management window is divided into three parts – attributes manager (on the left), referential values manager (top-centre) and functions graph (bottom-centre).

It is possible to choose among different types of functions for the referential values when creating a new attribute in the attributes manager. Figure 2 shows examples about different functions can be graphically represented in the system– from top-left to bottom: Triangular, Trapezoidal and Gaussian fuzzy membership functions, qualitative linguistic terms and utility functions.

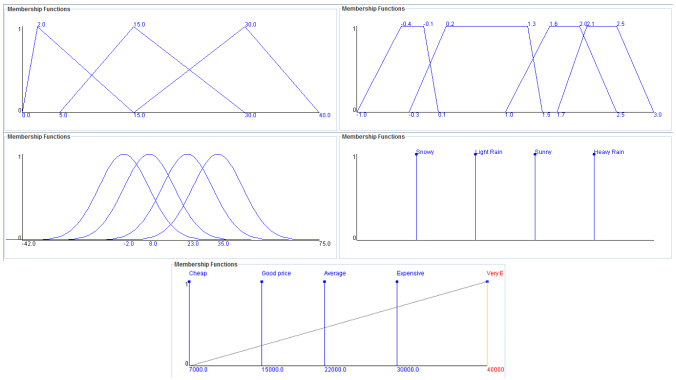

Figure 2. Possible representations in the functions graph

b) Generate hierarchal structure of the problem

From the main window, it is possible to generate a hierarchical structure of a problem by adding and removing nodes. In this case, each node of the hierarchy is associated with one of the attributes defined previously in the attributes window. By selecting a node included in the hierarchy, users will be able to modify its properties. Note that the leaf nodes have different properties from the non-leaf nodes: for a leaf node, it is possible to assign an input and for the non-leaf nodes, users can create and manage rules which form a sub-rule base in the hierarchical structure. Therefore, the content of the panel on the right side of the main window will change depending on the type of the current selected node. In Figure 1, this panel corresponds to a leaf node, since the selected node – surrounded by blue circles – is a leaf node.

c) Belief rule-bases generation and representation

Once the attributes are defined and organized into a hierarchical structure, the next step is to generate the belief rule base to model the causal relationship among the attributes. Rule based can be generated automatically from a data set, or can be manually defined and adjusted by an expert. Rules can be manually assigned in a sub rule-base by selecting one of the non-leaf nodes in the hierarchical structure. The right-side panel will shows the information related to the management of the sub rule-base correspondent to this non-leaf node. Figure 3 illustrates the appearance of the main window when a non-leaf

node (i.e. sub rule-base) is selected. Rules can be assigned automatically by selecting the option "Load Rules File" in the "Rule" menu, in the menu bar.

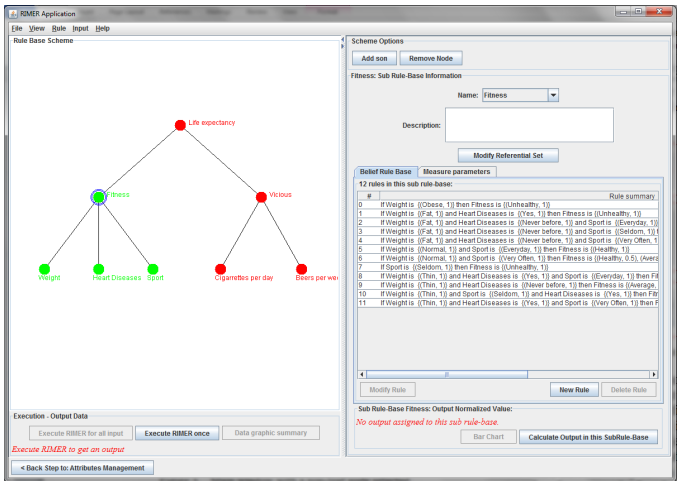

Figure 3. Main window with a non-leaf node selected

There are several options to modify the type of rules in the hierarchical structure are included. For the comparison purposes in the RIMER algorithm, the system can adopt three different types of rules:

- RIMER original rules: Rules with belief degree distributions in the antecedents of each rule. This is RIMER algorithm originally developed and executed in [3].
- RIMER^{+} extended rules: Rules with belief degree distributions not only in the antecedents of the rules, but also in each consequent. This is the extended RIMER algorithm in [8]. In the system, the rules can be automatically generated from the input-output sample data based on the simple but efficient generation proposed in [8].
- Wang-Mendel rules: Rules which do not include belief degree distributions, but linguistic terms in both antecedents and consequents. The Wang-Mendel algorithm [15] is executed when these rules are selected in the system.

In order to obtain an improved analysis of the results, the system includes data to measure the inconsistence [16] of each sub-rule base. This is an important parameter to explain the results returned by the algorithm, since it indicates the quality of the data set the system is working with.

Repeated rules are not necessary when executing the decision algorithm. Options to remove similar rules – based on a threshold – are therefore included in the system.

d) Facilate different types of inputs

Inputs can be assigned manual or automatically. To assign an input manually, click one of the leaf nodes in the hierarchical structure and select one of the options that appear in the right-side panel. Therefore, the system will ask for the required information to generate the input. Figure 4 illustrates the different types of the input format which the system could offer:

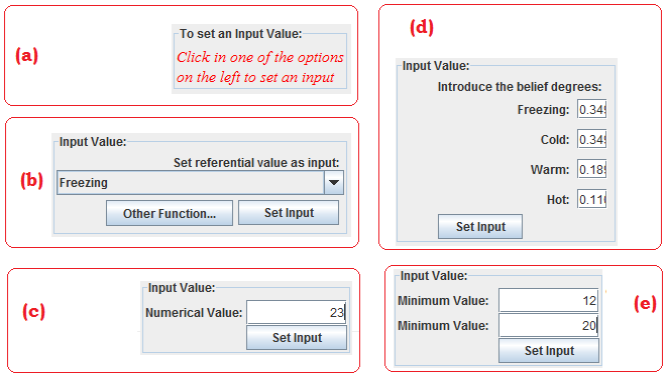

Figure 4. Different inputs that can be assigned

Fig. 4 (a) shows the initial panel, when there is no option selected; Fig. 4 (b) sets a referential value (linguistic terms) or another function that can be defined by the user as an input; Fig. 4 (c) indicates a numerical input; Fig. 4 (d) sets a belief degree distribution and Fig. 4 (e) creates an interval (range) input. Once the button "Set Input" is pressed, the input will be transformed automatically into a belief degree distribution and assigned to the current leaf node.

However, to assign inputs automatically from a properly defined input CSV file the option *Load Input File*, in the *Input* menu, included in the menu bar must be selected. In a CSV file, it is possible to specify any type of input (i.e. numerical, range, etc.). The system will automatically recognize each one of these types when loading a CSV file. Once the inputs are loaded, the system will be ready to execute the algorithm for all of them (in multi-execution mode).

Sometimes it is necessary to test a problem with random data. Thus, the system includes options to define a single random input or directly assign random values to every leaf node in the hierarchical structure.

2) Solving process

Once all the elements required for a problem definition are assigned, it is then ready to generate results by executing the RIMER approach algorithm embedded into the tool.

Depending on how the inputs have been assigned, the system could be running in different execution modes:

- If the inputs have been assigned manually, the system will be ready for single execution (with the inputs currently assigned in every leaf node). To carry out a single execution, it is just necessary to press the button so-called *Execute RIMER once* in the main window. The system will report the results of the execution through a label at the bottom part of the window. Errors during the execution process will be also specified in this label, if applicable. Users can obtain graphical representations of every input and output regarding the last single execution. The *Bar Chart* button is included in the right-side panel in the main window. It is also possible to obtain an entire graphical summary of the execution selecting the *Data Graphic Summary* included in the main window. Figure 5 shows the window where users can observe different graphical data.

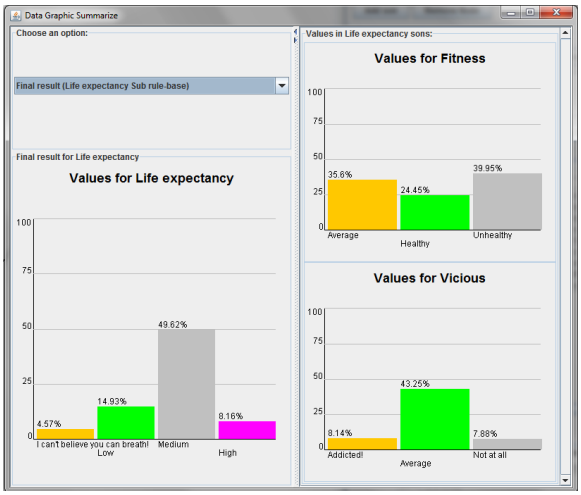

Figure 5. Data graphic summary window

- If the inputs have been loaded from a CSV file, the system will be ready for a multi-execution (one execution for each input loaded in the CSV file). For a multi-execution, the button titled "Execute RIMER for all Input" in the main window should be enabled. After this multi-execution, a log window with the results will automatically appear.

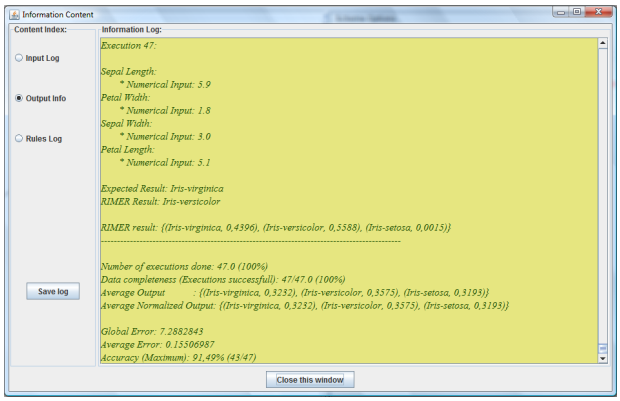

Figure 6. Statistics of the multi-execution mode for the Iris data set

Figure 6 illustrates the information log retrieved after a multi-execution process. As it can be observed, specific details are shown in this figure for the last execution (Execution 47th):

- List of original inputs used in this execution, before its transformation into belief degree distributions
- Expected result
- Result of the RIMER approach
- Result of the RIMER approach, in belief degree distribution

As aforementioned, in the multi-execution mode, general statistics about all the execution performed will be generated and showed in a log window. The statistics calculated by the system (See Figure 5) are summarized as follows:

- *Executions done*: This percentage tells us how many executions were done above the total that was supposed to be done (In case that users stop the execution, if not, this percentage always will be 100%).
- *Executions successfully done*: This percentage data acts as an indicator to show us the completeness of our rule bases. If an execution is not successfully done it is because the input data does not activate any rule. Therefore, if no rule is activated, means that a rule is not defined for this input. Thus, there is a lack of completeness in the rule-base.
- *Global and average error*: This data will show us the total and average error in RIMER predictions or classifications.
- *Accuracy*: This percentage statistic displays in how many cases RIMER predict the correct classification.
- *Average Output*: This statistic in a belief degree shape shows us which referential values of our output are more likely to be predicted. The data in the Average Normalized Output eliminates the uncertain degree and shows the average output with its values normalized.
- *T parameter*: In case that the root attribute in the hierarchical scheme has Utility functions defined within it, the system will calculate a special figure based on the distance between the output calculated and the expected one, assessing the T statistic for T=0.25, T=0.5 and T=1.

Another important feature in the system is to provide methods to load and save in external files all the information related with the application, which includes loading and saving the rules and inputs included in the current belief rule-bases and the information logs that keep information about it.

IV. Case Study

A numerical example is provided in this section to demonstrate the implementation and potential applications of the proposed system. The main focus is given on the illustration of the functionality of the developed system.

A. Problem Description

For this illustrative simulation, Iris data set for classification was chosen. Its characteristics are: 1) 150 instances (50 in each of three classes); 2) 4 attributes - Sepal length in cm, Sepal width in cm, Petal length in cm and Petal width in cm - and three possible output values - Iris Setosa, Iris Virginica and Iris Versicolor; 3) Does not contain missing values. In this example, a K-fold cross validation method by be applied, with K=5. In each test, 120 samples will be used for training and the rest 30 samples will be used for testing.

B. Implementation

Firstly, the attributes should be defined in the attributes window. In this simulation, each attribute has been assigned three linguistic terms as referential values (high, medium and low) which are defined with utility functions, so those three terms correspond the value of the maximum, average and minimum value for this attribute in the data set respectively). Figure 7 shows the attributes manager window with the definition of the five attributes for this problem (four for the input attributes and one output attribute, so called Iris).

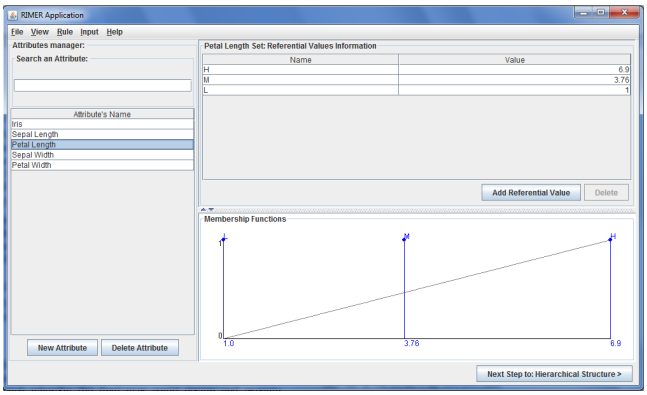

Figure 7. Attributes manager window with the Iris problem attributes

After defining all the attributes, it is needed to design the hierarchical structure for the problem. In the main window, the structure is built just by adding four son nodes to the root node, which will be the output attribute Iris.

Afterwards, the data set was downloaded and adapted into 10 CSV files, five for training and another five for testing each of the training files to apply the K-fold cross validation method. After loading one of the training files, the right-panel of the main window is updated and the rules table is filled with the rules loaded. Figure 8 shows the main window after defining the problem structure and loading one of the training files. The last element remaining to complete the definition of the problem is the input one. It is possible to assign manually inputs to the leaf nodes in the hierarchical structure. However, in this simulation one of the test CSV files that has been created before will be loaded.

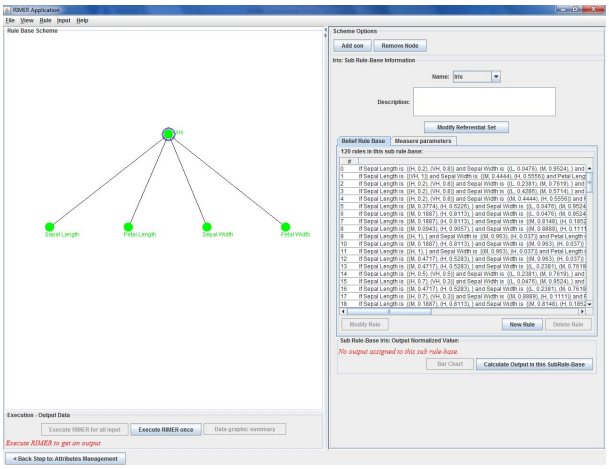

Figure 8. Main window with Iris problem structure defined

Finally, the algorithm is executed in multi-execution mode and after that the results log appears in the window, showing the results of the test executed (See Figure 6). The results for this test are 0.966 accuracy, with an average error of 0.141. For the 5 tests carried out in this simulation, the accuracy is 0.96, and the average error of 0.136.

V. CONCLUSIONS

This paper presented a decision support tool which facilitates the implementation of the recently presented RIMER approach whereby the final user could design and execute problems to obtain the decision result. The architecture and features of the system are outlined and illustrated. The system is expected to be applied for different application and we are working on further improvement about the overall presentation and functionality of the system.

***Abstract*—The paper deals with a single-item production planning problem with uncertain demands modeled by fuzzy intervals whose membership functions are possibility distributions for the values of the uncertain demands. Optimization criteria, in the setting of possibility theory, that lead to choose robust production plans under fuzzy demands are given. Algorithms for determining optimal robust production plans with respect to the proposed criteria are provided and some computational experiments are presented.**

***Index Terms*—Production Planning, Uncertain Demand, Fuzzy Optimization, Possibility Theory.**

I. Introduction

Nowadays, companies do not compete as independent entities but as a part of collaborative supply chains. The uncertainty on demands creates a risk in the supply chain as backordering, obsolete inventory due to the bullwhip effect [1]. To reduce this risk two different approaches exist: the collaboration between the customer and the supplier or the integration of the uncertainty into a planning process. In this paper, we cope with the approaches. Within these supply chains, collaborative processes are usually characterized by a set of point-to-point (customer/supplier) relationships with partial information sharing [2], [3]. More precisely, a procurement plan are built and propagated through the supply chain, moreover in stronger relationship between the customer and the supplier, the supplier can share her/him delivering capacity constraints to the customer. Another way to reduce a risk of the supply chain is to integrate the uncertainty in a planning process. Industries used the *Material requirements planning method* (MRP) [4] to plan a production. The use of *possibility theory* [5] to model the uncertainty in a production planning is due to the difficulties to access to available historical data allowing to compute a probability distribution. Different models (based on possibility theory) have been used to represent imperfections on demands to compute the gross requirements (in MRP context): [6] takes into account the imprecision on quantities with trapezoidal fuzzy intervals; [7] integrates the uncertainty on the order and the imprecision on quantities by a union of fuzzy intervals; and [8] adds to the previous model the imprecision on the date by a trapezoidal fuzzy interval. The gross requirements, in case of integration of imperfection, become fuzzy gross requirements (or a set of fuzzy gross requirements [8]) where the required quantities by period are fuzzy quantities. In the context of collaborative supply chain the customer sends a procurement plan to the supplier but this procurement plan can not be fuzzy, also the problem is to compute from the fuzzy gross requirement a procurement plan. In this communication, we are interested in computing a robust procurement plan (with and without delivering capacity of the supplier sharing). The delivering capacity are composed of two bounds: the lower one being the minimal accepted quantity that is sent to the customer and the upper bound which is due to a production capacity of the supplier. Moreover the customer accepts to have backordering but it is more penalized that inventory. This problem is equivalent to the *problem of production planning* with backordering, more precisely to a certain version of the *lot sizing problem* (see, e.g., [9], [10]), where: the procured quantities are production quantities, a *production plan*; delivering constraints are production constraints, *capacity limits on production plans*; and the gross requirements are *demands*. Thus, the problem consists in finding a production plan that fullfils capacity limits and minimizes the total cost of storage and backordering subject to the conditions of satisfying each demand. It is efficiently solvable when the demands are precisely known (see, e.g., [11], [12], [13]). However, the demands are seldom precisely known in advance and the uncertainty must be taken into account.

In this paper, we wish to investigate the above problem with uncertain demands modeled by fuzzy intervals. The membership function of a fuzzy interval is a *possibility distribution* describing, for each value of the demand, the extent to which it is a possible value. In other words, it means that the value of this demand belongs to a λ-cut of the fuzzy interval with the degree of necessity (confidence) $1-\lambda$. To evaluate a production plan, we assign to it, a *degree of necessity* that its cost does not exceed a given threshold and a degree of necessity that costs of the plan fall within a given fuzzy goal. In order to find "robust solutions" under fuzzy demands, we apply two criteria. The first one consists in choosing a production plan which maximizes the degree of necessity (certainty) that its cost does not exceed a given threshold. This criterion is similar in spirit to *threshold model* (see, e.g., [14]) in *stochastic optimization* in which we seek a solution maximizing the probability that its random value does not exceed a given threshold. The second criterion is weaker than the first one and consists in choosing

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

a plan with the maximum degree of necessity that costs of the plan fall within a given fuzzy goal. A similar criterion has been proposed in [15] for discrete optimization problems with fuzzy costs. We provide some methods for finding a robust production plan with respect to the proposed criteria under fuzzy-valued demands which heavy rely on methods for finding a robust production plan, called *optimal robust production plan*, in the problem of production planning under interval-valued demands with the *min-max* criterion. Namely, it turns out that the considered fuzzy problems can be reduced to examining a family of the interval problems with the min-max criterion.

II. The Deterministic Problem

We are given T periods. For period t, $t = 1, \ldots, T$, let d_t be the demand in period t, $d_t \geq 0$, x_t the production amount in period t, $x_t \geq 0$, l_t, u_t the production capacity limits on x_t. Let $\mathbb{X} \subseteq \mathbb{R}^T_{\geq 0}$ be the set of feasible production amounts. Two cases are distinguished, the case *with no capacity limits* $\mathbb{X} = \{(x_1, \ldots, x_T) \ : \ x_t \geq 0, t = 1, \ldots, T\}$ and the one *with capacity limits* $\mathbb{X} = \{(x_1, \ldots, x_T) \ : \ l_t \leq x_t \leq u_t, t = 1, \ldots, T\}$. Set $\mathbf{D}_t = \sum_{i=1}^{t} d_i$ and $\mathbf{X}_t = \sum_{i=1}^{t} x_i$, $\mathbf{D}_t$ and $\mathbf{X}_t$ stand for the cumulative demand up to period t and the production level up to period t, respectively. Obviously, $\mathbf{X}_{t-1} \leq \mathbf{X}_t$ and $\mathbf{D}_{t-1} \leq \mathbf{D}_t$, $t = 2, \ldots, T$.

We make the assumption: the costs of carrying one unit of inventory from period t to period $t+1$ for every $t = 1, \ldots, T$ are equal, we denote it by c_I and the costs of backordering one unit from period $t+1$ to period t for every $t = 1, \ldots, T$ are equal, we denote it by c_B. Furthermore, we assume that $c_I < c_B$. The nonnegative real function $L(u, v)$ represents either the cost of storing inventory from period t to period $t+1$ or the cost of backordering quantity from period $t+1$ to period t, namely $L(\mathbf{X}_t, \mathbf{D}_t) = c_I(\mathbf{X}_t - \mathbf{D}_t)$ if $\mathbf{X}_t \geq \mathbf{D}_t$; $c_B(\mathbf{D}_t - \mathbf{X}_t)$ otherwise. The Function has the form $L(\mathbf{X}_t, \mathbf{D}_t) = \max\{c_I(\mathbf{X}_t - \mathbf{D}_t), c_B(\mathbf{D}_t - \mathbf{X}_t)\}$.

The production planning problem consists in finding a feasible production plan $\boldsymbol{x} = (x_1, \ldots, x_T)$, $\boldsymbol{x} \in \mathbb{X}$, that minimizes the total cost of storage and backordering subject to the conditions of satisfying each demand, namely

$$\min_{\boldsymbol{x} \in \mathbb{X}} F(\boldsymbol{x}) = \min_{\boldsymbol{x} \in \mathbb{X}} \sum_{t=1}^{T} L(\mathbf{X}_t, \mathbf{D}_t). \tag{1}$$

Without loss of generality, we can assume that an initial inventory I_0 and an initial backorder B_0 are equal to zero. Otherwise, one can append period 0 and assign $x_0 = I_0$ and $d_0 = 0$ with zero inventory cost if $I_0 > 0$ or assign $x_0 = 0$ and $d_0 = B_0$ with zero backorder cost if $B_0 > 0$.

In the case with no capacity limits problem (1) has a trivial optimal solution equal to $\boldsymbol{d}$. In the case with capacity limits, (1) can be formulated as the minimum cost flow problem (see, e.g., [16]):

$$\begin{array}{lll} \min & \sum_{t=1}^{T}(c_I I_t + c_B B_t) & \\ \text{s.t.} & B_t - I_t = \sum_{j=1}^{t}(d_j - x_j), & t = 1, \ldots, T, \\ & l_t \leq x_t \leq u_t, & t = 1, \ldots, T, \\ & B_t, I_t \geq 0, & t = 1, \ldots, T. \end{array} \tag{2}$$

Problem (2) can efficiently solved, for instance, by an algorithm presented in [13] that takes into account a special structure of the underling network.

III. Robust Problem

Assume that demands d_t, $t = 1, \ldots, T$, in problem (1), are only known to belong to intervals $D_t = [d_t^-, d_t^+]$, $d_t^- \geq 0$. This means that we neither know the exact demands, nor can we set them precisely. We assume that the demands are unrelated to one another and there is no probability distribution in D_t, $t = 1, \ldots, T$. A vector $S = (d_1, \ldots, d_T)$, $d_t \in D_t$, that represents an assignment of demands d_t to periods t, $t = 1, \ldots, T$, is called a *scenario*. Thus every scenario expresses a realization of the demands. We denote by Γ the set of all the scenarios, i.e. $\Gamma = [d_1^-, d_1^+] \times \cdots \times [d_T^-, d_T^+]$. Among the scenarios of Γ *extreme scenarios* can be distinguished, that is the ones, which belong to $\{d_1^-, d_1^+\} \times \cdots \times \{d_T^-, d_T^+\}$, the set of extreme scenarios is denoted by Γ_{ext}. We denote by S^+ (resp. S^-) the extreme scenario in which all the demands are set to their upper (resp. lower) bounds. The demand and the cumulative demand in period t under scenario S are denoted by $d_t(S) \in D_t$ and $\mathbf{D}_t(S)$, respectively, $\mathbf{D}_t(S) = \sum_{i=1}^{t} d_i(S)$. Clearly, for every $S \in \Gamma$ it holds $\mathbf{D}_{t-1}(S) \leq \mathbf{D}_t(S)$, $t = 2, \ldots, T$, and $\mathbf{D}_t(S) \in [\mathbf{D}_t(S^-), \mathbf{D}_t(S^+)]$. The function $L(\mathbf{X}_t, \mathbf{D}_t(S)) = \max\{c_I(\mathbf{X}_t - \mathbf{D}_t(S)), c_B(\mathbf{D}_t(S) - \mathbf{X}_t)\}$, represents either the cost of storing inventory from period t to period $t+1$ or the cost of backordering quantity from period $t+1$ to period t under scenario S. Now $F(\boldsymbol{x}, S)$ denotes the total cost of a production plan $\boldsymbol{x} \in \mathbb{X}$ under scenario S, i.e. $F(\boldsymbol{x}, S) = \sum_{t=1}^{T} L(\mathbf{X}_t, \mathbf{D}_t(S))$.

In order to choose a robust production plan, one of robust criteria, called the *min-max* can be adopted. In the *min-max* version of problem (1), we seek a feasible production plan with the minimum the worst total cost over all scenarios, that is

$$\begin{aligned} \text{ROB}: \ \boldsymbol{x}^r &= \arg \min_{\boldsymbol{x} \in \mathbb{X}} A(\boldsymbol{x}) = \min_{\boldsymbol{x} \in \mathbb{X}} \max_{S \in \Gamma} F(\boldsymbol{x}, S) \\ &= \min_{\boldsymbol{x} \in \mathbb{X}} \max_{S \in \Gamma} \sum_{t=1}^{T} L(\mathbf{X}_t, \mathbf{D}_t(S)). \end{aligned}$$

In other words, we wish to find among all production plans the one that minimizes the maximum production plan cost over all scenarios, that minimizes $A(\boldsymbol{x})$, $A(\boldsymbol{x})$ is the *maximal cost of production plan* $\boldsymbol{x}$. An optimal solution $\boldsymbol{x}^r$ to the problem ROB is called *optimal robust production plan*. Let $\boldsymbol{x} \in \mathbb{X}$ be a given production plan. A scenario $S^w \in \Gamma$ that maximizes cost $F(\boldsymbol{x}, S)$ in problem ROB for $\boldsymbol{x}$ is called *the worst case scenario*.

Let us first study the problem of computing a worst case scenario for a given production plan $\boldsymbol{x}^* \in \mathbb{X}$, that is:

$$A(\boldsymbol{x}^*) = F(\boldsymbol{x}^*, S^w) = \max_{S \in \Gamma} F(\boldsymbol{x}^*, S). \tag{3}$$

Since $F(\boldsymbol{x}^*, S)$ is a continuous function on a bounded closed set Γ, it attains maximum for some $S \in \Gamma$. Furthermore, determining S can be restricted to the vertices of Γ, that is to the set of extreme scenarios Γ_{ext}, since $F(\boldsymbol{x}^*, S)$ is convex on Γ for any fixed production plan $\boldsymbol{x}^* \in \mathbb{X}$. The problem (3)

can be formulated as a mixed integer programming problem (MIP):

$$\begin{array}{lll} \max & \sum_{t=1}^{T}(c_I I_t + c_B B_t) & \\ \text{s.t.} & B_t - I_t = \sum_{j=1}^{t}(s_j - x_j^*), & t = 1,\ldots,T, \\ & s_t \in [d_t^-, d_t^+], & t = 1,\ldots,T, \\ & B_t, I_t \geq 0, & t = 1,\ldots,T, \\ & I_t \leq (1-\delta_t)\sum_{j=1}^{t}(x_j^* - d_j^-), & t = 1,\ldots,T, \\ & B_t \leq \delta_t \sum_{j=1}^{t}(d_j^+ - x_j^*), & t = 1,\ldots,T, \\ & \delta_t \in \{0,1\}, & t = 1,\ldots,T. \end{array} \quad (4)$$

Let s_t^w, B_t^w, I_t^w and δ_t, $t = 1,\ldots,T$, be an optimal solution to problem (4). Then $S^w = (s_1^w,\ldots,s_T^w)$ is a worst case scenario for $\boldsymbol{x}^*$ (a pessimistic realization of uncertain demands) and I_t^w is storing inventory amount from period t to period $t+1$ and B_t^w is backordering amount from period $t+1$ to period t under the worst case scenario S^w. The last two constraints model (4) and the binary variables δ_t ensure that storing inventory from period t to period $t+1$ and backordering from period $t+1$ to period t is not performed simultaneously (either $I_t > 0$ or $B_t > 0$). If $\delta_t = 1$ then backordering is performed $B_t > 0$; otherwise storing inventory is performed $I_t > 0$.

In order to assert *necessity* that the cost of a given plan $\boldsymbol{x}^* \in \mathbb{X}$ does not exceed a given threshold g under interval demands, i.e. evaluating whether $F(\boldsymbol{x}^*, S) \leq g$ for every scenario $S \in \Gamma$, we only need to determine worst case scenario S^w by solving (4) and evaluate $F(\boldsymbol{x}^*, S^w) \leq g$. Moreover, by means of worst case scenario S^w, for a given solution $\boldsymbol{x}^* \in \mathbb{X}$, one can determine the upper bound on its possible values of costs, namely $F(\boldsymbol{x}^*, S) \leq F(\boldsymbol{x}^*, S^w)$ for every scenario $S \in \Gamma$.

Let us consider the problem ROB with no capacity limits, i.e. the problem with the set $\mathbb{X} = \{(x_1,\ldots,x_T) : x_t \geq 0, t = 1,\ldots,T\}$. Note that function $F(\boldsymbol{x}, S)$ is continuous on $\mathbb{X}$ and Γ, Γ is a closed bounded set, and so $A(\boldsymbol{x})$ is well defined continuous function on $\mathbb{X}$ (see, e.g., [17, Theorem 1.4]). One can show that an optimal robust production plan $\hat{\boldsymbol{x}} = (\hat{x}_1,\ldots,\hat{x}_T)$, i.e. $\hat{\boldsymbol{x}} = \arg\ \min_{\boldsymbol{x}\in\mathbb{X}} A(\boldsymbol{x})$, can be computed by the following formulae:

$$\begin{array}{ll} \hat{\mathbf{X}}_1 := \frac{c_B \mathbf{D}_1(S^+) + c_I \mathbf{D}_1(S^-)}{c_B + c_I}, & \hat{x}_1 := \hat{\mathbf{X}}_1 \\ \hat{\mathbf{X}}_t := \frac{c_B \mathbf{D}_t(S^+) + c_I \mathbf{D}_t(S^-)}{c_B + c_I}, & \hat{x}_t := \hat{\mathbf{X}}_t - \hat{\mathbf{X}}_{t-1}, \quad t \geq 2. \end{array} \quad (5)$$

An algorithm for determining optimal robust production plan $\hat{\boldsymbol{x}}$ according to (5) can be implemented in $O(n)$ time. Note that if an initial backorder B_0 or an initial inventory I_0 are not equal to zero then one can modify the interval demand D_1 as follows: $D_1 := [d_1^- + B_0, d_1^+ + B_0]$ if $B_0 > 0$ or $D_1 := [d_1^- - I_0, d_1^+ - I_0]$ if $0 < I_0 \leq d_1^-$, and apply formulae (5) to determine an optimal robust production plan for problem ROB with the modified demand. If $I_0 > d_1^-$ then one appends period 0, as it has been described in Section II, and applies an algorithm (Algorithm 1 - presented later in this section) for the case with capacity limits, $l_t = 0$, $u_t = M$, $t = 1,\ldots,T$, where M is a large number.

Let us turn to the problem ROB with capacity limits, i.e. the problem with the set $\mathbb{X} = \{(x_1,\ldots,x_T) : l_t \leq x_t \leq u_t, t = 1,\ldots,T\}$. Notice Γ is a bounded closed set. Function $F(\boldsymbol{x}, S)$ is continuous on $\mathbb{X}$ and Γ and hence $A(\boldsymbol{x})$ is continuous function on $\mathbb{X}$ (see, e.g., [17, Theorem 1.4]). From this and the fact $\mathbb{X}$ is a bounded closed set it follows that $A(\boldsymbol{x})$ attains its minimum on $\mathbb{X}$.

We now construct an iterative algorithm for solving problem ROB based on on iterative relaxation scheme for min-max problems proposed in [18]. Similar methods were developed for min-max regret linear programming problems with an interval objective function [19], [20]. Let us consider the problem (RX-ROB) being a relaxation of problem ROB that consists in replacing a given scenario set Γ with a discrete scenario set $\Gamma_{\text{dis}} = \{S^1,\ldots,S^K\}$:

$$\begin{array}{lll} \text{RX-ROB:} & a^* = \min a & \\ & \text{s.t.} \quad a \geq F(\boldsymbol{x}, S^k) & \forall S^k \in \Gamma_{\text{dis}}, \\ & \boldsymbol{x} \in \mathbb{X}, & \end{array} \quad (6)$$

where $S^k = (s_t^k)_{t=1}^T$. The constraint $a \geq F(\boldsymbol{x}, S^k)$, called *scenario cut*, is associated with exactly one scenario $S^k \in \Gamma_{\text{dis}}$. Obviously, the maximal cost a^* of an optimal solution $\boldsymbol{x}^*$ of problem RX-ROB over discrete scenario set Γ_{dis} is a lower bound on the maximal cost of an optimal robust production plan $\boldsymbol{x}^r$ for problem ROB, i.e. $a^* \leq A(\boldsymbol{x}^r)$. Note that the scenario cut, $a \geq F(\boldsymbol{x}, S^k)$, associated with S^k is not a linear constraint. One can linearize the cut by replacing it in RX-ROB with the following $T+1$ constraints and $2T$ new decision variables:

$$\begin{array}{ll} a \geq \sum_{t=1}^{T}(c_I I_t^{S^k} + c_B B_t^{S^k}), & \\ B_t^{S^k} - I_t^{S^k} = \sum_{j=1}^{t}(s_j^k - x_j), & t = 1,\ldots,T, \\ B_t^{S^k}, I_t^{S^k} \geq 0, & t = 1,\ldots,T. \end{array}$$

Our algorithm (Algorithm 1) starts with zero lower bound on the maximal cost of an optimal robust production plan $\boldsymbol{x}^r$, $LB = 0$, a candidate $\boldsymbol{x}^* \in \mathbb{X}$ for an optimal solution for ROB and empty discrete scenario set, $\Gamma_{\text{dis}} = \emptyset$. At each iteration, a worst case scenario S^w for $\boldsymbol{x}^*$ is computed by applying the method (4) - this is the most time consuming part. Clearly, $A(\boldsymbol{x}^*) = F(\boldsymbol{x}^*, S^w)$ is an upper bound on $A(\boldsymbol{x}^r)$, $A(\boldsymbol{x}^r) \leq A(\boldsymbol{x}^*)$. If a termination criterion is fulfilled (usually $A(\boldsymbol{x}^*) \leq LB + \epsilon$, $\epsilon > 0$ is a given tolerance) then algorithm stops with production plan $\boldsymbol{x}^*$, which is an approximation of an optimal robust production plan. Otherwise the worst case scenario $S^w = (s_t^w)_{t=1}^T$ is added to Γ_{dis}, the corresponding to S^w scenario cut is appended to problem RX-ROB. Next the updated linear programming problem RX-ROB is solved to obtain a better candidate $\boldsymbol{x}^*$ for an optimal solution for ROB and new lower bound $LB = a^*$. Since set Γ_{dis} is updated during the course of the algorithm, the computed values lower bounds are nondecreasing sequence of their values. Then new iteration is started.

In order to choose a good initial production plan $\boldsymbol{x}^* \in \mathbb{X}$ in Algorithm 1, we suggest to solve the classical production planning problem (1) with capacity limits (the model (2)) under the midpoint demand scenario S^m, i.e. $d_t(S^m) = (d_t^- + d_t^+)/2$, $t = 1,\ldots,T$ and take an optimal production plan under the midpoint scenario as an initial production plan.

Algorithm 1: Finding an optimal robust production plan.

Input: Interval demands $D_t = [d_t^-, d_t^+]$, $t = 1, \dots T$, costs c_I, c_B, initial production plan $\boldsymbol{x}^* \in \mathbb{X}$, a convergence tolerance parameter $\epsilon > 0$.

Output: A production plan $\hat{\boldsymbol{x}}^r$, an approximation of an optimal robust production plan, and its worst case scenario S^w.

Step 0. $k := 0$, $LB := 0$, $\Gamma_{\text{dis}} := \emptyset$.

Step 1. $\boldsymbol{x}^k := \boldsymbol{x}^*$.

Step 2. Compute a worst case scenario S^w for $\boldsymbol{x}^k$ by applying the method (4).

Step 3. If $F(\boldsymbol{x}^k, S^w) \leq LB + \epsilon$ then output $\boldsymbol{x}^k, S^w$ and STOP.

Step 4. $k := k + 1$.

Step 5. $S^k := S^w$, $\Gamma_{\text{dis}} := \Gamma_{\text{dis}} \cup \{S^k\}$ and append scenario cut $a \geq F(\boldsymbol{x}, S^k)$ to problem RX-ROB.

Step 6. Compute an optimal solution $(\boldsymbol{x}^*, a^*)$ for RX-ROB, $LB := a^*$, and go to Step 1.

Theorem 1: Algorithm 1 terminates in a finite number of steps for any given $\epsilon > 0$.

Proof: The proof is almost the same as those given in [21, Theorem 2.5] and [18, Theorem 3]. ■

Note that if an initial inventory I_0 or an initial backorder B_0 are not equal to zero then one appends period 0, as it has been described in Section II, and applies Algorithm 1 for $T + 1$ periods.

In order to check the efficiency of Algorithm 1, we performed some computational tests. For every $T = 100, 200, \dots, 1000$, ten instances of the problem ROB with capacity limits were generated. In every instance, $c_I = 1$, $c_B = 10$, the demands and the production capacities were randomly generated intervals $[X, Y]$, where X is an integer-valued random variable uniformly distributed in $\{0, 1, \dots, 99\}$ and Y is an integer-valued random variable uniformly distributed in $\{100, 101, \dots, 199\}$. To solve the generated instances, we used IBM ILOG CPLEX 12.2 library and a computer equipped with Intel Core 2 Duo 2.5 GHz. In Table I, minimal, average and maximal computation times in seconds, required to find optimal robust production plans, are presented. All computations finished in a few iterations and about 98% of the total running time was spent on computing worst case scenarios by MIP model (4). As we can see from the obtained results, Algorithm 1 allows us to solve quite large problems having up to 1000 periods in reasonable time.

IV. FUZZY PROBLEM

In this section, we apply a more elaborate approach to model uncertain demands. Namely, the uncertain demands, in problem (1), are modeled by fuzzy intervals $\widetilde{D}_t$, $t = 1, \dots, T$. A *fuzzy interval* $\widetilde{A}$ is a fuzzy set in $\mathbb{R}$ whose membership function $\mu_{\widetilde{A}}$ is normal, quasi concave and upper semicontinuous. Usually, it is assumed that the support of a fuzzy interval is bounded. The main property of a fuzzy interval is the fact that all its λ-cuts, that is the sets $\widetilde{A}^{[\lambda]} = \{x : \mu_{\widetilde{A}}(x) \geq \lambda\}$, $\lambda \in (0, 1]$, are closed intervals. We will assume that $\widetilde{A}^{[0]}$ is the smallest closed set containing the support of $\widetilde{A}$. So, every fuzzy interval $\widetilde{A}$ can be represented as a family of closed intervals $\widetilde{A}^{[\lambda]} = [a^{-[\lambda]}, a^{+[\lambda]}]$, parametrized by the value of $\lambda \in [0, 1]$. In many applications, the class of *trapezoidal fuzzy intervals* is used. A trapezoidal fuzzy interval, denoted by a quadruple $(a^-, a^+, \alpha, \beta)$, can be represented as a family of intervals $[a^- - \alpha(1-\lambda), a^+ + \beta(1-\lambda)]$ for $\lambda \in [0, 1]$. Notice that this representation contains classical intervals ($\alpha = \beta = 0$) and real numbers (additionally $a^- = a^+$) as special cases.

Here, a membership function of $\widetilde{D}_t$ is regarded as a *possibility distribution* for the values of the unknown demand d_t (see book [5], that is entirely devoted to possibility theory). The *possibility degree* of the assignment $d_t = s$ is $\Pi(d_t = s) = \pi_{d_t}(s) = \mu_{\widetilde{D}_t}(s)$. Let $S = (s_t)_{t=1}^T$ be a scenario that represents a state of the world where $d_t = s_t$, for $t = 1, \dots, T$. It is assumed that the demands are unrelated one to each other. Hence, the possibility distributions associated with the demands induce the following possibility distribution over all scenarios in $S \in \mathbb{R}^T$ (see [22]):

$$\begin{aligned} \pi(S) &= \Pi((d_1 = s_1) \wedge \dots \wedge (d_T = s_T)) \\ &= \min_{t=1,\dots,T} \Pi(d_t = s_t) = \min_{t=1,\dots,T} \mu_{\widetilde{D}_t}(s_t). \end{aligned} \quad (7)$$

The value of $\pi(S)$ stands for the possibility of the event that scenario $S \in \mathbb{R}^T$ will occur. We have thus extended scenario set Γ given by the intervals (see Section III) to the fuzzy case and now $\widetilde{\Gamma}$ is a fuzzy set of scenarios with membership function $\mu_{\widetilde{\Gamma}}(S) = \pi(S)$, $S \in \mathbb{R}^T$. We see at once that the λ-cuts of $\widetilde{\Gamma}$ for every $\lambda \in (0, 1]$ fulfill the following equality:

$$\widetilde{\Gamma}^{[\lambda]} = \{S : \pi(S) \geq \lambda\} = [d_1^{-[\lambda]}, d_1^{+[\lambda]}] \times \dots \times [d_T^{-[\lambda]}, d_T^{+[\lambda]}],$$

which is from (7) and the definition of λ-cut. We also define $\widetilde{\Gamma}^{[0]} = [d_1^{-[0]}, d_1^{+[0]}] \times \dots \times [d_T^{-[0]}, d_T^{+[0]}]$. Notice that $\widetilde{\Gamma}^{\lambda}$, $\lambda \in [0, 1]$, is the classical scenario set containing all scenarios whose possibility of occurrence is not less than λ.

In order to choose a reasonable production plan under fuzziness, we first show how to evaluate a given production plan $\boldsymbol{x} \in \mathbb{X}$. Notice that a cost of a production plan is unknown quantity, denoted by $f_{\boldsymbol{x}}$, since demands are unknown and modeled by fuzzy intervals in the setting of possibility theory. Thus, the unknown cost $f_{\boldsymbol{x}}$ falls within fuzzy interval $\widetilde{F}_{\boldsymbol{x}}$, called *fuzzy cost*, whose membership function $\mu_{\widetilde{F}_{\boldsymbol{x}}}$ is a possibility distribution for the values of fuzzy variable $f_{\boldsymbol{x}}$, $\pi_{\widetilde{F}_{\boldsymbol{x}}} = \mu_{\widetilde{F}_{\boldsymbol{x}}}$,

defined as follows:

$$\mu_{\widetilde{F}_{\boldsymbol{x}}}(v) = \Pi(f_{\boldsymbol{x}} = v) = \sup_{\{S:\, F(\boldsymbol{x},S)=v\}} \pi(S), \quad v \in \mathbb{R}. \tag{8}$$

Making use of (8), we can define the *degree of necessity* that a cost of a given plan $\boldsymbol{x} \in \mathbb{X}$ does not exceed a given threshold g:

$$\begin{aligned} \mathrm{N}(f_{\boldsymbol{x}} \leq g) &= 1 - \Pi(f_{\boldsymbol{x}} > g) = 1 - \sup_{v>g} \pi_{\widetilde{F}_{\boldsymbol{x}}}(v) \\ &= 1 - \sup_{\{S:\, F(\boldsymbol{x},S)>g\}} \pi(S). \end{aligned} \tag{9}$$

It is easily seen that $\mathrm{N}(f_{\boldsymbol{x}} \leq g) = 1 - \lambda$ means that for all scenarios S such that $\pi(S) > \lambda$, costs of plan $\boldsymbol{x}$ under these scenarios do not exceed g.

We now propose two criteria of choosing a robust solution in the fuzzy-valued problem (1). We have a threshold g, and we would like to find a production plan which maximizes the degree of certainty (necessity) that its cost does not exceed threshold g. Thus, we would like to solve the following problem:

$$\max_{\boldsymbol{x}\in\mathbb{X}} \mathrm{N}(f_{\boldsymbol{x}} \leq g). \tag{10}$$

There are no doubts that an optimal production plan computed according to (10) is a robust one, since with the highest degree of certainty costs of the plan over scenarios will not exceed threshold g. Problem (10) is equivalent to the following mathematical programming problem:

$$\begin{array}{ll} \min & \lambda \\ \text{s.t.} & f_{\boldsymbol{x}}^{+[\lambda]} \leq g, \\ & \lambda \in [0,1], \\ & \boldsymbol{x} \in \mathbb{X}. \end{array} \tag{11}$$

If λ^* is the optimal objective and $\boldsymbol{x}^*$ is an optimal solution for problem (11) then $\mathrm{N}(f_{\boldsymbol{x}^*} \leq g) = 1 - \lambda^*$ and $\boldsymbol{x}^*$ is an optimal production plan for (10). If (11) is infeasible then $\mathrm{N}(f_{\boldsymbol{x}} \leq g) = 0$ for all $\boldsymbol{x} \in \mathbb{X}$.

We now present a more general criterion of choosing a robust production plan than (10). Namely, suppose that a decision maker knows her/his preferences about a cost of a production plan $f_{\boldsymbol{x}}$ and expresses it by a *fuzzy goal* $\widetilde{G}$, which is a fuzzy interval with a bounded support and a nonincreasing upper semicontinuous membership function $\mu_{\widetilde{G}} : \mathbb{R}_{\geq 0} \to [0,1]$, such that $\mu_{\widetilde{G}}(v) = 1$ for $v \in [0,g]$. The value of $\mu_{\widetilde{G}}(f_{\boldsymbol{x}})$ is the extent to which cost $f_{\boldsymbol{x}}$ satisfies the decision maker. Now the requirement "$f_{\boldsymbol{x}} \leq g$" is replaced softer one, i.e. "$f_{\boldsymbol{x}} \in \widetilde{G}$". So, using (8), the necessity that event "$f_{\boldsymbol{x}} \in \widetilde{G}$" holds can be expressed as follows:

$$\begin{aligned} \mathrm{N}(f_{\boldsymbol{x}} \in \widetilde{G}) &= 1 - \Pi(f_{\boldsymbol{x}} \notin \widetilde{G}) \\ &= 1 - \sup_{v\in\mathbb{R}} \min\{\pi_{f_{\boldsymbol{x}}}(v), 1 - \mu_{\widetilde{G}}(v)\} \\ &= 1 - \sup_{S} \min\{\pi(S), 1 - \mu_{\widetilde{G}}(F(\boldsymbol{x},S))\}. \end{aligned} \tag{12}$$

Thus, if $\mathrm{N}(f_{\boldsymbol{x}} \in \widetilde{G}) = 1 - \lambda$ means that for all scenarios S such that $\pi(S) > \lambda$, the degree that costs of plan $\boldsymbol{x}$ fall within fuzzy goal $\widetilde{G}$, is not less than $1 - \lambda$. Note that $\mathrm{N}(f_{\boldsymbol{x}} \in \widetilde{G})$ is more general and weaker than $\mathrm{N}(f_{\boldsymbol{x}} \leq g)$. If $\mu_{\widetilde{G}}(v) = 0$ for $v \in (g, \infty)$ then they are the same. Moreover, $\mathrm{N}(f_{\boldsymbol{x}} \leq g) \leq \mathrm{N}(f_{\boldsymbol{x}} \in \widetilde{G})$.

Let us give the second criterion of choosing a robust plan. We have a fuzzy goal $\widetilde{G}$, and we wish to find a production plan which maximizes the necessity degree that costs of the plan fall within fuzzy goal $\widetilde{G}$. Thus we need to solve the following optimization problem,

$$\max_{\boldsymbol{x}\in\mathbb{X}} \mathrm{N}(f_{\boldsymbol{x}} \in \widetilde{G}). \tag{13}$$

We check at once that problem (13) is equivalent to the following mathematical programming problem:

$$\begin{array}{ll} \min & \lambda \\ \text{s.t.} & f_{\boldsymbol{x}}^{+[\lambda]} \leq g^{+[1-\lambda]}, \\ & \lambda \in [0,1], \\ & \boldsymbol{x} \in \mathbb{X}. \end{array} \tag{14}$$

If $(\boldsymbol{x}^*, \lambda^*)$ is an optimal solution for problem (14), then $\mathrm{N}(f_{\boldsymbol{x}^*} \in \widetilde{G}) = 1 - \lambda^*$. If (14) is infeasible then $\mathrm{N}(f_{\boldsymbol{x}} \in \widetilde{G}) = 0$ for all $\boldsymbol{x} \in \mathbb{X}$.

An algorithm for solving problem (14) (resp. (11)) is based on the standard binary search technique in $[0,1]$ (the interval of possible values of λ) which follows from the fact that $f_{\boldsymbol{x}}^{+[\lambda]}$ and $g^{+[1-\lambda]}$ (resp. g) are nonincreasing and nondecreasing functions of λ, respectively. We call the algorithm the *binary search based algorithm*. To find an optimal (x^*, λ^*), $x^* \in \mathbb{X}$, $\lambda^* \in [0,1]$, with a given error tolerance $\xi > 0$, we seek at each iteration, for a fixed λ, a plan $\boldsymbol{x} \in \mathbb{X}$ satisfying $f_{\boldsymbol{x}}^{+[\lambda]} \leq g^{+[1-\lambda]}$ (resp. $f_{\boldsymbol{x}}^{+[\lambda]} \leq g$), which boils down to seeking an optimal robust production plan $\boldsymbol{x}^r$ and its worst case scenario under scenario set $\widetilde{\Gamma}^{[\lambda]}$, i.e. to solving problem ROB (see Section III). Note that $f_{\boldsymbol{x}}^{+[\lambda]} = A(\boldsymbol{x})$ and also that $f_{\boldsymbol{x}}^{+[\lambda]} \leq g^{+[1-\lambda]}$ (resp. $f_{\boldsymbol{x}}^{+[\lambda]} \leq g$) holds for some $\boldsymbol{x} \in \mathbb{X}$ if and only if it holds for an optimal robust production plan under $\widetilde{\Gamma}^{[\lambda]}$. Thus, at each iteration, we use either formulae (5) for the case without capacity limits or Algorithm 1 for the case with capacity limits. If the length of determined interval of possible values of λ is less than ξ, then an optimal robust production plan $\boldsymbol{x}^r$ for a fixed λ, $(\boldsymbol{x}^r, \lambda)$, is an approximation of an optimal solution for problem (14) (resp. (11)) with precision ξ. The running time of the above algorithm is $O(I(T)\log \xi^{-1})$ time, where $\xi > 0$ is a given error tolerance and $I(|T|)$ is time required for finding an optimal robust production plan and its worst case scenario under interval scenario set $\widetilde{\Gamma}^{[\lambda]}$ (the running time of either (5) or Algorithm 1).

In order to evaluate the efficiency of the binary search based algorithm, we show some results of computational experiments. For every $T = 100, 200, \ldots, 1000$, ten instances of the problem (13) with capacity limits were generated. In every instance, $c_I = 1$, $c_B = 10$, the production capacities were randomly generated intervals $[X, Y]$, where X is an integer-valued random variable uniformly distributed in $\{0, 1, \ldots, 99\}$ and Y is an integer-valued random variable uniformly distributed in $\{100, 101, \ldots, 199\}$, the demands are triangular fuzzy intervals with the supports equal to $[0, 199]$ and the modal values equal to Z, where Z is an integer-valued random

TABLE II

variable uniformly distributed in $\{0, 1, \ldots, 199\}$, the fuzzy goal $\widetilde{G}$ was modeled as a trapezoidal fuzzy interval $(0, g, 0, \beta)$, where g was chosen as the maximal cost of an optimal robust production plan for the problem ROB without capacity limits (an ideal supplier) and under the interval demands being the supports of the generated triangular fuzzy demands. The values of β were equal to $0.00 \cdot g, 0.25 \cdot g, 0.50 \cdot g, 0.75 \cdot g$ and $1.00 \cdot g$ and the error tolerance $\xi = 0.01$. We used IBM ILOG CPLEX 12.2 library and a computer equipped with Intel Core 2 Duo 2.5 GHz to solve the generated instances. In Table II average computation times in seconds are presented. As we can see from the obtained results, the binary search based algorithm, which calls Algorithm 1 at each iteration, can solve efficiently the problem (13) with capacity limits having up to 1000 periods.

V. CONCLUSION

In this paper, we have investigated a certain version of production planning problem with uncertain demands modeled by fuzzy intervals, whose membership functions are possibility distributions for the values of the unknown demands. We have introduced, in this setting, the degree of necessity that the cost of a plan does not exceed a given threshold and the degree of necessity that costs of a plan fall within a given fuzzy goal, which allows us to evaluate a given production plan. For finding robust production plans under fuzzy demands, we have proposed two criteria: the first one consists in choosing a production plan which maximizes the degree of necessity that its cost does not exceed a given threshold, the second criterion is softer than the first one and consists in choosing a plan with the maximum degree of necessity that costs of the plan fall within a given fuzzy goal. We have constructed the algorithms for determining optimal robust production plans with respect to the criteria and confirmed their efficiency experimentally. The criteria are a generalization, to the fuzzy case, of the known from literature the min-max criterion. Consequently, we have shown in the paper that there exists a link between interval uncertainty with the min-max criterion and possibilistic uncertainty with the necessity based criteria. Therefore, we have discussed first the interval-valued case and then we have extended the methods introduced for the interval-valued problem to the fuzzy-valued one.

***Abstract*—This paper deals with a class of combinatorial optimization problems with uncertain costs. The uncertainty is modeled by specifying a scenario set containing a finite number of possible realizations of the costs called scenarios. Additionally, a possibility distribution on the scenario set can be defined. Two robust models, namely the min-max and two-stage, for hedging against uncertainty of the costs in the possibilistic setting are considered. A general framework for solving the problems is proposed. For the linear sum objective a mixed integer programing formulation is shown. For the bottleneck objective, an algorithm is constructed which runs in polynomial time if the deterministic problem, i.e. the one with a single scenario, is polynomially solvable.**

I. Introduction

A *combinatorial optimization problem* discussed in this paper consists of a finite set of elements E and a set Φ of subsets of E, called the set of *feasible solutions*. In the deterministic case, each element in E has a precise cost and we wish to find a feasible solution whose total cost is minimal (the *linear sum* objective) or whose the largest element cost is minimal (the *bottleneck* objective). This formulation encompasses a large variety of problems. It contains, for example, the important class of *network problems*, where E is a set of the edges of a given graph G and Φ consists of some objects in G such as trees, paths or matchings (see, e.g., [1]).

The usual assumption in combinatorial optimization is that the element costs are precisely known. However, in real life this requirement is seldom satisfied and, in many optimization models, a possible uncertainty of costs must be taken into account. In general, this uncertainty can be modeled by specifying a *scenario set* which contains all possible cost realizations, called *scenarios*. This scenario set can be defined in several ways. In the *discrete scenario representation*, which is considered in this paper, we simply list all the possible scenarios. In the *interval scenario representation*, we specify for each cost a closed interval containing all its values. This means that we neither know the exact costs, nor can we set them precisely. The scenario set is then the Cartesian product of all the uncertainty intervals (see, e.g., [2]). For this representation, it is assumed that the costs are unrelated, that is the value of a cost does not depend on the values of the remaining costs. The interval scenario representation can be generalized by assuming that the scenario set is any convex set (see, e.g., [3]), which allows us to model the relationships between the costs. We can also use a combination of discrete and interval uncertainty representations (see, e.g., [4]).

A criterion of choosing a solution depends on additional information provided with the scenario set. If a probability distribution on the scenario set is specified, then the *stochastic optimization* can be used [5], where the typical goal is to optimize the expected cost of a solution built. If there is no probability distribution on the scenario set, then the *robust optimization can be* applied [2], [6]. In order to choose a solution in this setting, the *min-max* criterion can be used. Under this criterion, we seek a solution which minimizes the largest cost over all scenarios. We can consider a *single-stage model* in which a complete solution must be determined before a cost scenario is observed (see, e.g., [2]) or a *two-stage model*, where only a partial solution must be computed when the costs are precisely known and completed when a cost scenario is observed (see, e.g., [7], [8]). Finally, if a possibility distribution on the scenario set is given, then the *fuzzy optimization* is appropriate [9], [10], [11]. In the fuzzy optimization, the goal is to choose a solution optimizing a criterion based on the *possibility* or *necessity* measures.

In this paper, we consider the discrete scenario uncertainty representation. So, we assume that the scenario set contains a finite number of distinct scenarios (element cost realizations). A decision maker can additionally specify a possibility distribution on the scenario set which describes more or less plausible scenarios. Namely, she/he can assign a number from the interval [0,1] to each scenario, which is the possibility of the event that this scenario will occur. Such a more elaborate description of scenario sets is often required in practical applications, where decision makers may know likely scenarios, but the probability distributions are unknown or there is lack of statistical data validating the choice of the probability distributions. In this paper, we propose the solution concepts which generalize the single and two stage models with the min-max criterion. We thus extend the robust approach to the fuzzy one by using *possibility theory* [12] which offers

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

a framework of decision making under uncertainty and allows us to extend the robust models in a natural way.

II. Combinatorial Optimization Problem with Deterministic Costs

Let $E = \{e_1, \ldots, e_n\}$ be a finite ground set and let $\Phi \subseteq 2^E$ be a set of subsets of E called the set of the *feasible solutions*. A nonnegative cost c_e is given for each element $e \in E$. In a combinatorial optimization problem $\mathcal{P}$ with the linear sum objective, we seek a solution $X \in \Phi$ whose total cost, $f(X) = \sum_{e \in X} c_e$, is minimal. In a combinatorial optimization problem $\mathcal{BP}$ with the bottleneck objective, we wish to find a solution $X \in \Phi$ whose largest element cost, $f(X) = \max_{e \in X} c_e$, is minimal. The formulations $\mathcal{P}$ and $\mathcal{BP}$ encompass a large variety of classical combinatorial optimization problems such as the shortest path, the minimum spanning tree, the minimum cost matching, the 0-1 knapsack *etc.* (see, e.g. [13], [1], [14]). The problem $\mathcal{P}$ is often formulated as the following mathematical programming problem:

$$\begin{array}{ll} \min & \sum_{i=1}^{n} c_i x_i \\ & (x_1, \ldots, x_n) \in \Phi' \\ & x_i \in \{0,1\} \qquad\qquad i = 1, \ldots, n, \end{array} \tag{1}$$

where x_i is a binary variable equal to 1 if and only if element e_i belongs to the solution computed. Thus Φ' is the set of all characteristic vectors of Φ and the condition $(x_1, \ldots, x_n) \in \Phi'$ is specified in the form of constraints involving variables $x_1, \ldots, x_n$. It is worth pointing out that many important combinatorial problems are NP-hard (see e.g., [1]). The framework proposed in this paper can also be applied to the NP-hard problems if one can represent them in the form of (1).

III. Basic Notions of Possibility Theory

Possibility theory [12] is an approach for dealing with incomplete information and is based on two dual measures: *possibility* and *necessity*, which express plausibility and certainty of events. Both measures are built from a *possibility distribution*. Let Z be a real valued quantity whose value is not precisely known. We specify for Z a *possibility distribution* π_{Z}, which describes the set of more or less plausible, mutually exclusive values of Z. The value of $\pi_{\mathrm{Z}}(z) = \Pi(\mathrm{Z} = z)$ is a possibility of the event that Z will take the value of z. In particular, $\pi_{\mathrm{Z}}(z) = 0$ means that $\mathrm{Z} = z$ is impossible and $\pi_{\mathrm{Z}}(z) > 0$ means that $\mathrm{Z} = z$ is plausible. The possibility distribution encodes a family of probability functions and a degree of possibility can be viewed as an upper bound on a degree of probability [15]. A detailed interpretation of the possibility distribution and some methods of obtaining it from a knowledge possessed about Z are described in [12].

Let $\tilde{A}$ be a fuzzy set in $\mathbb{R}$ with membership function $\mu_{\tilde{A}}$. Then $\mathrm{Z} \in \tilde{A}$ is a *fuzzy event* and we can determine the possibility that this event will occur in the following way:

$$\Pi(\mathrm{Z} \in \tilde{A}) = \sup_{z \in \mathbb{R}} \min\{\pi_{\mathrm{Z}}(z), \mu_{\tilde{A}}(z)\}. \tag{2}$$

Thus $\Pi(\mathrm{Z} \in \tilde{A})$ evaluates the extent to which "$\mathrm{Z} \in \tilde{A}$" is possibly true. We can also determine the necessity of the event $\mathrm{Z} \in \tilde{A}$ in the following way:

$$\mathrm{N}(\mathrm{Z} \in \tilde{A}) = 1 - \Pi(\mathrm{Z} \in \tilde{A}'), \tag{3}$$

where $\tilde{A}'$ is the complement of $\tilde{A}$ with the membership function $1 - \mu_{\tilde{A}}(z)$. Hence, $\mathrm{N}(\mathrm{Z} \in \tilde{A})$ evaluates the extent to which "$\mathrm{Z} \in \tilde{A}$" is certainly true. If A is a crisp subset of $\mathbb{R}$, then it is easy to verify that $\Pi(\mathrm{Z} \in A) = \sup_{z \in A} \pi_{\mathrm{Z}}(z)$ and $\mathrm{N}(\mathrm{Z} \in A) = \inf_{z \notin A}(1 - \pi_{\mathrm{Z}}(z))$.

IV. Possibilistic Min-Max Problem

Consider a situation in which the costs of the elements $e_1, \ldots, e_n$ are uncertain. This uncertainty is modeled by specifying a scenario set Γ which is defined by explicitly listing all the possible element cost vectors. Thus $\Gamma = \{S_1, \ldots, S_K\}$ is finite and contains exactly K scenarios, where a scenario S_j, $j = 1, \ldots, K$, is a vector of the element costs $S_j = (c_{1j}, c_{2j}, \ldots, c_{nj})$. Additionally, a possibility distribution on the scenario set is specified. This possibility distribution expresses the fact that some scenarios are more plausible than others. Hence, for each scenario S_j a number $\pi(S_j) \in [0, 1]$ is given, which denotes the possibility of the event that S_j will occur. The value of $\pi(S_j)$ can also be seen as an upper bound on the probability of occurring S_j [15]. It is convenient to represent the uncertain costs in the form of Table I whose columns contain all the cost scenarios in Γ.

TABLE I
The scenario representation of the uncertain costs

	$\pi(S_1)$	$\pi(S_2)$	$\ldots$	$\pi(S_K)$
	S_1	S_2	$\ldots$	S_K

e_2	c_{21}	c_{22}	$\ldots$	c_{2K}
e_3	c_{31}	c_{32}	$\ldots$	c_{3K}
$\vdots$	$\vdots$	$\vdots$	$\ldots$	$\vdots$
e_n	c_{n1}	c_{n2}	$\ldots$	c_{nK}

A. Linear Sum Criterion

Let $f(X, S_j) = \sum_{e_i \in X} c_{ij}$ be the cost of solution X under scenario S_j. We will denote by $\mathrm{f(X)}$ the uncertain cost of X, i.e. a real variable whose value depends on scenario $S_j \in \Gamma$. The uncertain cost $\mathrm{f(X)}$ has the following possibility distribution $\pi_{\mathrm{f(X)}}$:

$$\pi_{\mathrm{f(X)}}(z) = \max_{\{j : f(X, S_j) = z\}} \pi(S_j) \tag{4}$$

and $\pi_{\mathrm{f(X)}}(z) = 0$ if $f(X, S_j) \neq z$ for all $j = 1, \ldots, K$. Hence, $\pi_{\mathrm{f(X)}}(z) = \Pi(\mathrm{f(X)} = z)$ is the possibility of the event that the cost of X will take value of z. To illustrate this idea, let us consider the example of the shortest path problem presented in Fig. 1.

In this problem $E = \{e_1, \ldots, e_5\}$ is the set of arcs of a given graph G and $\Phi = \{\{e_1, e_4\}, \{e_1, e_3, e_5\}, \{e_2, e_5\}\}$ contains all directed paths between s and t in G. There are six cost scenarios listed in the table and each scenario has some possibility of occurrence. The possibility distribution of

	0.6	0.8	0.8	0.5	1	0.3
	S_1	S_2	S_3	S_4	S_5	S_6
e_1	3	4	1	5	4	2
e_2	1	6	3	4	3	7
e_3	2	3	2	2	2	1
e_4	3	8	1	7	2	4
e_5	1	1	7	2	2	1

Fig. 1. An example of the shortest path problem with uncertain costs

the cost $\mathrm{f(X)}$ for the path $X = \{e_1, e_3, e_5\}$ is shown in Fig. 2. Observe that the path X has a cost of 8 under two scenarios S_2 and S_5 and, according to (4), $\pi_{\mathrm{f(X)}}(8) = \Pi(\mathrm{f(X)} = 8) = \max\{\pi(S_2), \pi(S_5)\} = 1$.

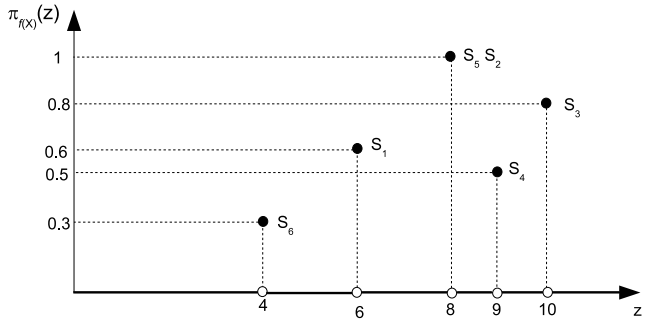

Fig. 2. The possibility distribution for $\mathrm{f}(X)$, where $X = \{e_1, e_3, e_5\}$

Now assume that a decision maker expresses her/his preferences about solution costs by means of a *fuzzy goal* $\tilde{G}$. The membership function of $\tilde{G}$ has the following form:

$$\mu_{\tilde{G}}(z) = \begin{cases} 1 & \text{if} \quad z \leq g \\ 1 - \frac{g-z}{\beta} & \text{for} \quad z \in [g, g+\beta] \\ 0 & \text{if} \quad z \geq g+\beta \end{cases} \tag{5}$$

The interpretation of $\tilde{G}$ is as follows. The solution costs less than g are totally accepted and the solution costs greater than $g + \beta$ are not at all accepted. The acceptance of the solution costs decreases linearly between g and $g + \beta$. In general, a fuzzy goal $\widetilde{G}$ can be any fuzzy set in $\mathbb{R}$ with a bounded support and the membership function $\mu_{\widetilde{G}}$ being a nonincreasing mapping from $[0, \infty)$ into $[0, 1]$ such that $\mu_{\widetilde{G}}(z) = 1$ for $z \in [0, g]$. In this paper we use the membership function (5) to simplify the presentation. We will denote by $\tilde{G}'$ the complement of $\tilde{G}$ with the membership function $1 - \mu_{\tilde{G}}(z)$.

Now, we are ready to give a criterion of choosing a robust solution in problem $\mathcal{P}$ with the uncertain costs. Having a fuzzy goal $\tilde{G}$ we would like to find a solution $X \in \Phi$, whose cost belongs to $\tilde{G}$ with the highest necessity (certainty). Thus, we would like to solve the following problem:

$$\text{POSS MIN-MAX } \mathcal{P}: \quad \max_{X \in \Phi} \mathrm{N}(\mathrm{f(X)} \in \tilde{G}). \tag{6}$$

There are no doubts that every optimal solution to (6) is robust, since the cost of such a solution falls within $\tilde{G}$ with the highest degree of certainty. Since $\mathrm{N}(\mathrm{f(X)} \in \tilde{G}) = 1 - \Pi(\mathrm{f(X)} \in \tilde{G}')$, problem (6) is equivalent to

$$\min_{X \in \Phi} \Pi(\mathrm{f(X)} \in \tilde{G}'). \tag{7}$$

By (2) and (4) we obtain

$$\begin{aligned} \Pi(\mathrm{f(X)} \in \tilde{G}') &= \sup_{z \in \mathbb{R}} \min\{\pi_{\mathrm{f(X)}}(z), \mu_{\tilde{G}'}(z)\} \\ &= \max_{j=1,\ldots,K} \min\{\pi(S_j), \mu_{\tilde{G}'}(f(X, S_j))\}, \end{aligned} \tag{8}$$

which is illustrated in Fig. 3.

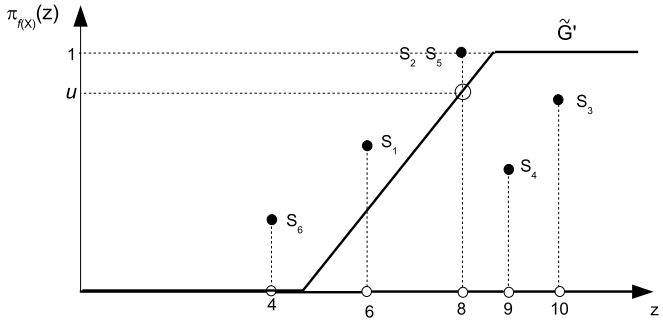

Fig. 3. $\Pi(\mathrm{f(X)} \in \tilde{G}') = u$ for the path $X = \{e_1, e_3, e_5\}$

Observe that $\mathrm{N}(\mathrm{f(X)} \in \tilde{G}) = 1$ if $\Pi(\mathrm{f(X)} \in \tilde{G}') = 0$, i.e. when the cost of X under every scenario $S_j \in \Gamma$ such that $\pi(S_j) > 0$ is totally accepted. On the other hand, $\mathrm{N}(\mathrm{f(X)} \in \tilde{G}) = 0$ if $\Pi(\mathrm{f(X)} \in \tilde{G}') = 1$, i.e. when the cost of X under some scenario S_j such that $\pi(S_j) = 1$ is not at all accepted. In the example presented in Fig. 3 an intermediate situation is shown, where $\mathrm{N}(\mathrm{f(X)} \in \tilde{G}) \in (0, 1)$. Note that the solution costs under scenarios S_3 and S_4, which are not at all accepted (i.e. belong to $\tilde{G}'$ with degree 1), occur with possibility less than 1. Using (7) and (8), we can represent POSS MIN-MAX $\mathcal{P}$ as the following mathematical programming problem:

$$\begin{array}{l} \min u \\ u \geq \min\{\pi(S_j), \mu_{\tilde{G}'}(f(X, S_j))\}, \quad 1 \leq j \leq K, \\ X \in \Phi, \\ u \geq 0 \end{array} \tag{9}$$

Let us introduce additional binary variables $\delta_j \in \{0, 1\}$, $j = 1, \ldots, K$, and a sufficiently large constant M. We then get the following equivalent formulation:

$$\begin{array}{ll} \min u & \\ u \geq \pi(S_j) - M\delta_j, & 1 \leq j \leq K, \\ u \geq \mu_{\tilde{G}'}(f(X, S_j)) - M(1 - \delta_j), & 1 \leq j \leq K, \\ X \in \Phi, & \\ \delta_j \in \{0, 1\}, & 1 \leq j \leq K, \\ u \geq 0. & \end{array} \tag{10}$$

From (5) and the equality $f(X, S_j) = \sum_{i=1}^{n} c_{ij} x_i$, we obtain:

$$\begin{array}{ll} \min u & \\ u \geq \pi(S_j) - M\delta_j, & 1 \leq j \leq K, \\ u \geq \frac{1}{\beta} \sum_{i=1}^{n} c_{ij} x_i - \frac{g}{\beta} - M(1 - \delta_j), & 1 \leq j \leq K, \\ (x_1, \ldots, x_n) \in \Phi', & \\ \delta_j \in \{0, 1\} & 1 \leq j \leq K, \\ x_i \in \{0, 1\}, & 1 \leq i \leq n, \\ u \geq 0, & \end{array} \tag{11}$$

where x_i is a binary variable equal to 1 if and only if element e_i belongs to the solution computed. For a particular problem, $(x_1, \ldots, x_n) \in \Phi'$ can be replaced with a set of linear constraints. As the result we obtain a mixed integer linear programming (MIP) model which can be solved by the available and powerful software such as CPLEX. If X^* is an optimal solution to (11) with an objective value of u^*, then $\mathrm{N}(\mathrm{f}(\mathrm{X}^*) \in \tilde{G}) = 1 - u^*$. We now illustrate the approach using two examples. In the first example the deterministic problem is polynomially solvable while in the second one it is NP-hard.

Example 1: Consider the following *shortest path problem* with imprecise costs (POSS MIN-MAX SHORTEST PATH). We are given a digraph $G = (V, A)$ with uncertain arc costs. Namely, for each arc $(k, l) \in A$ a cost $c_{(k,l)j}$ of this arc under scenario S_j, $j = 1, \ldots, K$, is specified. We distinguish two nodes s and t in G and seek a directed path X from s to t which maximizes $\mathrm{N}(\mathrm{f}(\mathrm{X}) \in \tilde{G})$. Let us introduce a binary variable $x_{(k,l)}$ for each arc $(k, l) \in A$, $x_{(k,l)}$ is equal to 1 if and only if the arc (k, l) belongs to the path computed. The set Φ' is described by the standard mass balance constraints (see e.g., [14]). Hence, we obtain the following MIP model for the problem:

$$
\begin{array}{ll}
\min u & \\
u \geq \pi(S_j) - M\delta_j, & 1 \leq j \leq K, \\
u \geq \frac{1}{\beta} \sum_{(k,l)\in A} c_{(k,l)j} x_{(k,l)} - \frac{g}{\beta} - M(1 - \delta_j), & 1 \leq j \leq K, \\
\sum_{\{l:(k,l)\in A\}} x_{(k,l)} - \sum_{\{l:(l,k)\in A\}} x_{(l,k)} = b(k), & k \in V, \\
x_{(k,l)} \in \{0, 1\}, & (k, l) \in A, \\
\delta_j \in \{0, 1\}, & 1 \leq j \leq K, \\
u \geq 0, &
\end{array}
$$

where $b(s) = 1$, $b(t) = -1$ and $b(k) = 0$ for all $k \in V \setminus \{s, t\}$.

Example 2: Consider the following *minimum cost knapsack problem* (POSS MIN-MAX MINIMUM COST KNAPSACK). We are given a set of items $E = \{e_1, \ldots, e_n\}$. Each item e_i has a precise weight w_i and imprecise cost, where c_{ij} is the cost of e_i under scenario S_j, $j = 1, \ldots, K$. We would like to find a subset X of the items of the total weight at most W which maximizes $\mathrm{N}(\mathrm{f}(\mathrm{X}) \in \tilde{G})$. Contrary to the shortest path problem discussed in the previous example, the deterministic knapsack problem with one scenario is NP-hard. Nevertheless, by introducing binary variable x_i for each item $e_i \in E$, where x_i is equal to 1 if and only if item e_i belongs to the subset computed, we can propose the following mixed integer programming model for the problem:

$$
\begin{array}{ll}
\min u & \\
u \geq \pi(S_j) - M\delta_j, & 1 \leq j \leq K, \\
u \geq \frac{1}{\beta} \sum_{i=1}^{n} c_{ij} x_i - \frac{g}{\beta} - M(1 - \delta_j), & 1 \leq j \leq K, \\
\sum_{i=1}^{n} w_i x_i \leq W, & \\
x_i \in \{0, 1\}, & 1 \leq 1 \leq n, \\
\delta_j \in \{0, 1\}, & 1 \leq j \leq K, \\
u \geq 0. &
\end{array}
$$

Examples 1 and 2 show that our approach is general and can also be applied to the problems whose deterministic versions are NP-hard. The obtained MIP model can be solved by using some standard off-the-shelf MIP solvers.

Now we show that POSS MIN-MAX $\mathcal{P}$ is a generalization of the min-max robust problem $\mathcal{P}$, i.e. the problem $\mathcal{P}$ with the min-max criterion, where no probability and possibility distributions on the scenario set are given. Suppose that $\pi(S_j) = 1$ for all scenarios $S_j \in \Gamma$, which means that a decision maker believes that all the scenarios in Γ are equally possible to occur. Let us choose a fuzzy goal $\tilde{G}$ such that $g = 0$ and β is sufficiently large, so that the inequality $\frac{1}{\beta} \sum_{i=1}^{n} c_{ij} x_i \leq 1$ always holds. We can set, for example, $\beta = \sum_{i=1}^{n} \sum_{j=1}^{K} c_{ij}$. Then the model (11) can be simplified as follows:

$$
\begin{array}{ll}
\min u & \\
u \geq \frac{1}{\beta} \sum_{i=1}^{n} c_{ij} x_i & 1 \leq j \leq K \\
(x_1, \ldots, x_n) \in \Phi' & \\
u \geq 0 &
\end{array}
\tag{12}
$$

Substituting $z = \beta u$ in (12) yields:

$$
\begin{array}{ll}
\min z & \\
z \geq \sum_{i=1}^{n} c_{ij} x_i & 1 \leq j \leq K \\
(x_1, \ldots, x_n) \in \Phi' & \\
z \geq 0 &
\end{array}
\tag{13}
$$

which is the well known min-max robust combinatorial optimization problem with scenario set Γ [2]. This implies that all the negative complexity results known for (13) hold true for POSS MIN-MAX $\mathcal{P}$. The robust min-max problems are typically NP-hard and also hard to approximate. Hence, POSS MIN-MAX $\mathcal{P}$ cannot be easier. We refer the reader to [6], [2], [16], [17] for some complexity results for the min-max versions of the classical combinatorial optimization problems.

B. Bottleneck Criterion

It turns out that the problem becomes easier to solve if we replace the linear sum criterion with the bottleneck one. Assume that the cost of solution X under scenario S_j is expressed as $f(X, S_j) = \max_{e_i \in X} c_{ij}$. The uncertain cost $\mathrm{f}(X)$ of solution X is defined exactly the same as (4) and we seek a solution X maximizing $\mathrm{N}(\mathrm{f}(\mathrm{X}) \in \tilde{G})$ (or, equivalently, minimizing $\Pi(\mathrm{f}(\mathrm{X}) \in \tilde{G}')$). From (8) we get:

$$
\Pi(\mathrm{f}(\mathrm{X}) \in \tilde{G}') = \max_{j=1,\ldots,K} \min\{\pi(S_j), \mu_{\tilde{G}'}(\max_{e_i \in X} c_{ij})\}.
$$

Function $\mu_{\tilde{G}'}$ is nondecreasing ($\mu_{\tilde{G}}$ is nonincreasing), therefore

$$
\begin{aligned}
\Pi(\mathrm{f}(\mathrm{X}) \in \tilde{G}') &= \max_{j=1,\ldots,K} \min\{\pi(S_j), \max_{e_i \in X} \mu_{\tilde{G}'}(c_{ij})\} \\
&= \max_{e_i \in X} \max_{j=1,\ldots,K} \min\{\pi(S_j), \mu_{\tilde{G}'}(c_{ij})\}
\end{aligned}
$$

Set $c_i^* = \max_{j=1,\ldots,K} \min\{\pi(S_j), \mu_{\tilde{G}'}(c_{ij})\}$, $e_i \in E$, and in consequence

$$
\min_{X \in \Phi} \Pi(\mathrm{f}(\mathrm{X}) \in \tilde{G}') = \min_{X \in \Phi} \max_{e_i \in X} c_i^*,
$$

which is a deterministic bottleneck combinatorial optimization problem. So, POSS MIN-MAX $\mathcal{BP}$ can be reduced to problem $\mathcal{BP}$ with deterministic costs c_i^*, $e_i \in E$. We have thus proved the following theorem:

Theorem 1: If problem $\mathcal{BP}$ is polynomially solvable, then problem POSS MIN-MAX $\mathcal{BP}$ is also polynomially solvable.

The above result holds true for a wide class of classical polynomially solvable bottleneck combinatorial ooptimization problems [18], [19], [20], [21].

V. Possibilistic Two-Stage Problem

Suppose that we are given first stage element costs C_i for all $e_i \in E$ and these costs are precisely known. In the second stage the costs are imprecise and all the possible cost scenarios are listed in scenario set $\Gamma = \{S_1, \ldots, S_K\}$. Additionally, a possibility distribution π is specified in Γ and its interpretation is the same as for the single-stage problem discussed in the previous section. An instance of the problem can be represented in the form of Table II.

TABLE II
The representation of costs in two stages

	stage I	stage II			
		$\pi(S_1)$	$\pi(S_2)$	$\ldots$	$\pi(S_K)$
		S_1	S_2	$\ldots$	S_K
e_1	C_1	c_{11}	c_{12}	$\ldots$	c_{1K}
e_2	C_2	c_{21}	c_{22}	$\ldots$	c_{2K}
e_3	C_3	c_{31}	c_{32}	$\ldots$	c_{3K}
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\ldots$	$\vdots$
e_n	C_n	c_{n1}	c_{n2}	$\ldots$	c_{nK}

Let $X \subseteq E$ be a part of a feasible solution determined in the first stage. The cost of X under scenario $S_j \in \Gamma$ is then

$$f(X, S_j) = \sum_{e_i \in X} C_i + \min_{\{Y_j : X \cup Y_j \in \Phi\}} \sum_{e_i \in Y_j} c_{ij}.$$

So, a decision consists of choosing a partial solution X in the first stage and augmenting it optimally to a complete feasible solution $X \cup Y_j$ after observing that scenario S_j has occurred in the second stage. The cost f(X) of a partial solution X is uncertain and its possibility distribution is defined in the same way as (4).

Consider the following example. A set of eight elements $E = \{e_1, \ldots, e_8\}$ is given and we must select exactly 5 out of them. We can select any $X \subset E$ such that $|X| \leq 5$ in the first stage and complete it, after observing which of the six scenarios in $\Gamma = \{S_1, \ldots, S_6\}$ has occurred. The representation of the costs in both stages for this problem is shown in Table III.

TABLE III
The representation of costs for the sample problem

	stage I	stage II					
		0.4	0.3	0.6	0.8	1	0.7
		S_1	S_2	S_3	S_4	S_5	S_6
e_1	5	5	1	2	1	3	2
e_2	4	5	3	2	9	3	5
e_3	2	8	1	6	1	1	9
e_4	7	4	4	7	8	3	5
e_5	4	9	1	1	8	7	7
e_6	7	6	3	1	9	8	8
e_7	5	1	1	4	6	1	5
e_8	3	1	1	1	2	1	2

Suppose that a decision maker decides to select two elements, say e_3 and e_5, in the first stage. Therefore, $X = \{e_3, e_5\}$ and the cost in the first stage is 6. The cost $f(X, S_j)$ depends now on a scenario S_j that will occur. For instance, if scenario S_1 is observed, then the subset X is completed to form a feasible solution (a five element subset of E) by choosing the elements in $Y_1 = \{e_5, e_8, e_7\}$, which gives the smallest cost $f(X, S_1)$ equal to 12. A similar reasoning can be performed for the remaining scenarios. The possibility distribution for f(X) is presented in Fig. 4.

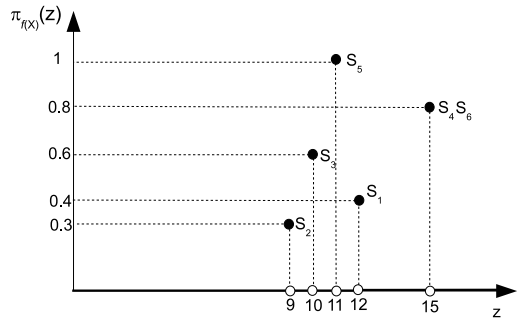

Fig. 4. The possibility distribution for f(X) where $X = \{e_3, e_5\}$

In order to choose a solution, we use exactly the same solution concept as in Section IV. Namely, a decision maker specifies a fuzzy goal $\tilde{G}$ and we seek a solution which maximizes the necessity that its costs will fall within $\tilde{G}$. Thus Poss 2-Stage is the optimization problem $\max_{X \in \Phi} \mathrm{N}(\mathrm{f(X)} \in \tilde{G})$ or equivalently $\min_{X \in \Phi} \Pi(\mathrm{f(X)} \in \tilde{G}')$. The same reasoning as in Section IV leads to a model similar to (10). Let us introduce binary variables x_i and y_{ij}, $i = 1, \ldots, n$, $j = 1, \ldots, K$. Variable x_i is equal to 1 if and only if element e_i is selected in the first stage, y_{ij} is equal to 1 if and only if element e_i is selected in the second stage if scenario S_j occurs. Then a feasible solution $X \cup Y_j$ under scenario S_j is described by variables $x_1, \ldots, x_n, y_{1j}, \ldots, y_{nj}$, which form a vector $(x_1, \ldots, x_n, y_{1j}, \ldots, y_{nj}) \in \Phi'$. The cost $f(X, S_j)$ can be then expressed as $\sum_{i=1}^{n} C_i x_i + \sum_{i=1}^{n} c_{ij} y_{ij}$. The model takes the following form:

$$\begin{array}{ll}
\min u & \\
u \geq \pi(S_j) - M\delta_j, & 1 \leq j \leq K, \\
u \geq \frac{1}{\beta}(\sum_{i=1}^{n} C_i x_i + \sum_{i=1}^{n} c_{ij} y_{ij}) - \frac{g}{\beta} - M(1 - \delta_j), & 1 \leq j \leq K, \\
(x_1, \ldots, x_n, y_{1j}, \ldots, y_{nj}) \in \Phi', & 1 \leq j \leq K, \\
\delta_j \in \{0, 1\}, & 1 \leq j \leq K, \\
u \geq 0. &
\end{array} \tag{14}$$

For a particular problem we should only replace $(x_1, \ldots, x_n, y_{1j}, \ldots, y_{nj}) \in \Phi'$ with some linear constraints involving the variables $x_1, \ldots, x_n, y_{1j}, \ldots, y_{nj}$. We now apply the above MIP approach to the following examples of combinatorial problems.

Example 3: Consider the 2-stage *minimum cost selecting items* with imprecise costs (Poss 2-Stage Minimum Cost Selecting Items). A set of items $E = \{e_1, \ldots, e_n\}$ and integer p, $1 < p < n$ are given. The set of feasible solutions consists of all the subsets of E with cardinality p. We select

some elements in the first stage, where the item costs C_i are known for each $e_i \in E$ and complete it to a feasible solution after a scenario from Γ is observed. The cost of item e_i under scenario S_j is c_{ij}. This problem can be solved by using the following MIP formulation:

$$\begin{aligned}
&\min u \\
&u \geq \pi(S_j) - M\delta_j && 1 \leq j \leq K, \\
&u \geq \frac{1}{\beta}(\sum_{i=1}^{n} C_i x_i + \sum_{i=1}^{n} c_{ij} y_{ij}) - \frac{g}{\beta} - M(1-\delta_j), && 1 \leq j \leq K, \\
&\sum_{i=1}^{n} x_i + \sum_{i=1}^{n} y_{ij} = p, && 1 \leq j \leq K, \\
&\delta_j \in \{0,1\}, && 1 \leq j \leq K, \\
&x_i \in \{0,1\}, && 1 \leq i \leq n, \\
&y_{ij} \in \{0,1\}, && 1 \leq i \leq n, \\
& && 1 \leq j \leq K, \\
&u \geq 0.
\end{aligned}$$

Example 4.: Consider the 2-stage *minimum cost matching* with imprecise costs (POSS 2-STAGE MINIMUM COST MATCHING). Let E be the set of the edges of a complete bipartite graph $G = (U \cup V, E)$, where $|U| = |V| = n$. The solution set Φ consists of all perfect matchings (assignments) in G. We can build a partial assignment in the first stage X, when the edge costs are equal to $C_{(k,l)}$ for $(k,l) \in E$ and complete it in the second stage when a cost scenario from Γ is observed. The cost of edge (k,l) under scenario S_j is equal to $c_{(k,l)j}$. This problem can be solved by using the following MIP formulation:

$$\begin{aligned}
&\min u \\
&u \geq \pi(S_j) - M\delta_j, && 1 \leq j \leq K, \\
&u \geq \frac{1}{\beta}(\sum_{(k,l)\in E} C_{(k,l)} x_{(k,l)} \\
&+ \sum_{(k,l)\in E} c_{(k,l)j} y_{(k,l)j}) - \frac{g}{\beta} - M(1-\delta_j), && 1 \leq j \leq K, \\
&\sum_{k\in U} (x_{(k,l)} + y_{(k,l)j}) = 1, && l \in V, 1 \leq j \leq K, \\
&\sum_{l\in V} (x_{(k,l)} + y_{(k,l)j}) = 1, && k \in U, 1 \leq j \leq K, \\
&x_{(k,l)} \in \{0,1\}, && (k,l) \in E, \\
&y_{(k,l)j} \in \{0,1\}, && (k,l) \in E, \\
& && 1 \leq j \leq K, \\
&\delta_j \in \{0,1\}, && 1 \leq j \leq K, \\
&u \geq 0.
\end{aligned}$$

By assuming that $\pi(S_j) = 1$ for each $S_j \in \Gamma$ and choosing a suitable fuzzy goal, we can show that POSS 2-STAGE $\mathcal{P}$ is is a generalization of the robust two-stage problem $\mathcal{P}$ known from the literature (see, e.g., [7], [8], [17]). This implies that all the negative complexity results for robust two-stage problem $\mathcal{P}$ hold true for POSS 2-STAGE $\mathcal{P}$.

VI. CONCLUSIONS

In this paper, we have proposed a general framework for dealing with possibilistic combinatorial optimization problems with uncertain costs in the single and two-stage decision models. The uncertainty has been modeled by a specified scenario set with a possibility distribution given on it. We have provided the solution concepts that lead to robust solutions in the setting of possibility theory. The concepts are consistent with popular and widely accepted robust approach to single and two stage optimization, where decision makers are interested in minimizing a solution cost in the worst case. Apart from showing the general framework, we have provided some methods based on mixed integer models for computing a solution with respect to the given solution concepts and we have illustrated them by examples.

A Fuzzy Concept for Climate Management in Preventive Conservation

An Approach to Define and Manage Climate Setpoints using Fuzzy Decision Making

***Abstract* — Especially for air conditioning tasks with applications in the area of preventive conservation, requirements can only be described by using vague and incomplete information. In this field of application a fuzzy formulation, which considers stationary, dynamical and economy demands of climate values, turned out to be appropriate. The presented paper describes an unifying approach of formulating fuzzy setpoints as well as using fuzzy decision making, in order to develop a automated climate management system for the best possible preventive conservation.**

Keywords - setpoint optimization; fuzzy decision making; process management system; preventive conservation

I. INTRODUCTION

Climate describes the state of physical values of an ambiance, mostly of the air. The automation task is to control these values in an effective way, so that they are stabilized in defined climate goals. Climate values are classified into a thermal and non-thermal group. The values concerning the non-thermal group are mainly those, which describe a local concentration of substances, for example the concentration of carbon dioxide. These values mostly represent measures of pollution. They originate from indoor sources and the goal is to reduce their concentration to an accepted limit. Usually the only way to fulfill this demand is to change air volumes with the environment using a ventilation system. [1]

As opposed to this, thermal values (we take the focus on temperature ϑ and relative humidity φ) should not be reduced to a limiting threshold, they have to reach a specified setpoint with an allowed deviation. The aim of keeping these values in a specified range is established by demands of people, caused by aspects of comfort and health.

It is an important fact that climate goals are usually formulated not crisp, but fuzzy. Looking into standards (for this ISO 7730, [2]) only vague parameters define specifications like the predicted mean vote (PMV-Index) and the predicted percentage of dissatisfied (PPD-Index). Hence, in the area of air conditioning and climate management there are only rough values of setpoints (or ranges of setpoints) available. That is why climatic requirements are often described linguistically and are provided with lack of knowledge [3]. These characteristics leads to the application of Zadeh's fuzzy theory [4], using fuzzy numbers and intervals [5] to formulate setpoints and evaluate controlled variables [6], [7] by creating a membership function (like in figure 1).

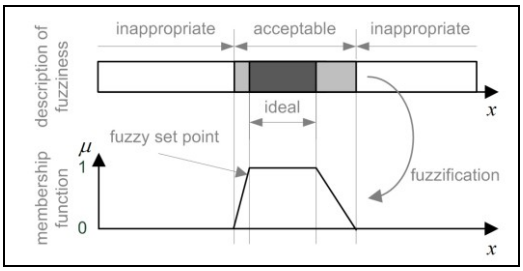

Figure 1. Fuzzification of a vaguely known setpoint

Conventional applications of air conditioning already use intervals of setpoints in order to realize energy-efficient operations and to reduce operation costs. Furthermore, state of the art concepts use theory of fuzzy decision making in order to generate setpoints and to find compromises between comfort and economical demands. These concepts to integrate requirements concerning the preventive conservation of cultural heritage, where the velocity of changes in the controlled values has to be minimized, will be enhanced in the presented paper. In this paper two concepts to calculate fuzzy setpoints are proposed: the first one will be used for an offline calculation (section V-*A*) and the second one will be used to make an online adaption of setpoints (section V-*B*).

II. CLIMATE DEMANDS IN PREVENTIVE CONSERVATION

Methods in saving cultural heritage objects may be classified into restoration and conservation. Restoration methods are treatments of the object, with a manipulation of the material substance (maybe by exchanging or repairing). In contrast, conservation methods are characterized by operations, which do not interact directly with the material. Fundamentally, the use of conservation methods is preferred for saving the original state of the object. Especially methods of preventive conservation are coming up, where (among other things) the

environment of objects should be designed in a way that material ageing and damaging get slowed and delayed. The topic of analyzing the present climate, determining reasonable setpoints for the different climate values and optimization of climate control, is in focus of many research groups, as appeared to reports and proceedings like [8].

A. Stationary demands

Except for a few applications, the significant thermal climate value is the relative humidity φ and not the temperature ϑ. This can be explained by looking at chemical and biological damaging processes: they slow down, if the temperature is low. In defining a reasonable range for the relative humidity, such a simplified rule cannot be defined. Figure 2 shows different goals for relative humidity of different materials. It is obvious to use fuzzy theory to formulate setpoints of relative humidity as fuzzy number or fuzzy interval, to utilize the range of setpoints in management systems and to define compromises in applications with different demands.

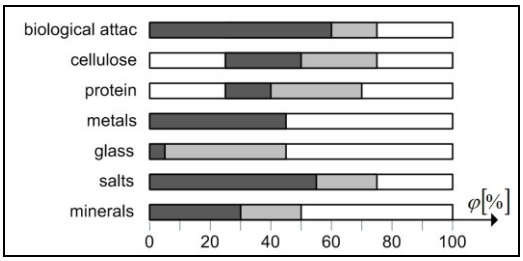

Figure 2. Stationary demands of relative humidity (modified from [9])

B. Dynamical demands

Furthermore, materials react on climate changes in their environment. In the stationary case, there is an equilibrium of environment and object climate (or the object state). If temperature in the environment changes, a heat flow at the material surface will start to reach another point of equilibrium, since the object's material serves as a heat storage. The same effect can be noticed on changes in humidity: the relation between the humidity in the air and the material states (like water content or inner stress) causes moisture flows. Based on the saturated vapor pressure of material and air, the relative humidity and not the absolute humidity should be focused. [10]

Hence, if there is a heat or moisture flow into or out of the material, the inner structure of the material has to transport energy or mass. This transport process fatigues the material, and if it is too fast, the inner structure will be damaged. But some materials are acclimatized during the transport process over the course of the years. They accustom their inner structure to historic climate cycles. [10]

C. Guidelines and standards

Some standards [11], [12] and guidelines [13] are published concerning the avoidance of such damaging processes. Also there are some quality climate classes published in [14]. Material-specific demands, the calculation of individual historical climates and the acceptable climate fluctuations in a time span can be found there. But it is not yet defined,

- how these fuzzy demands can be realized by an air conditioning system,
- how the setpoints can be calculated, if the historical climate (for all objects in a room!) is unknown,
- how to define a compromise between stationary and dynamical demands as well as to economical aspects and
- how to manage basic automation and planning setpoint trajectories in the case of an error.

III. Decision Making in Fuzzy Environment

The task of decision making is to find the best solution for a value (or multiple values) inside a decision space. So we talk about an optimization problem. For the frequent case of several objectives, we even have a multi criteria optimization problem. Searching the best solution will be more difficult, if objectives are only inexactly, imprecisely or vaguely known.

A. Basic concept of fuzzy decision making

The theory of fuzzy decision making aims primarily at finding the best solution x^* from a set of alternatives x. Objectives are formulated as fuzzy sets. Objectives are classified in a set of n goals $\mu_{Gi}(x)$ (objectives to aim requirements, with $i=1,\ldots n$) and a set of m constraints $\mu_{Cj}(x)$ (objectives to avoid damages, with $j=1,\ldots,m$). The question arises, how to aggregate all single objectives to an overall objective function for the elements of the decision space. Initially Bellman and Zadeh [15] suggest to create the intersection of all objectives and to determine the maximum of the resulting function as the best solution. Hence, we can aggregate all the goals to a new fuzzy set and all the constraints to a new fuzzy set. All goals and constraints may be combined to the set of decisions by creating the intersection [16]:

$$\mu_D(x)=\left(\bigcap_{i=1}^{n}\mu_{Gi}(x)\right)\cap\left(\bigcap_{j=1}^{m}\mu_{Cj}(x)\right) \tag{1}$$

The optimal decision x* can be determined (shown in figure 1):

$$\mu_D(x^*)=\max\{\mu_D(x)\} \tag{2}$$

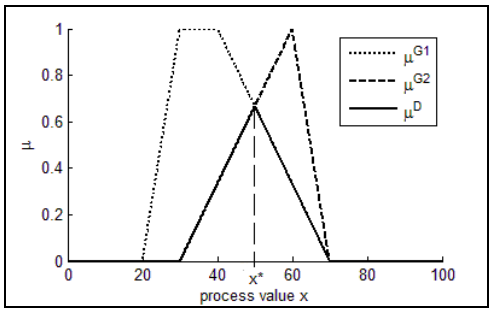

Figure 3. Fuzzy decision making of two fuzzy goals

Theoretical constraints can also be formulated as goals. For instance, if an objective is nominated to avoid a bad state, it will be possible to formulate this in a way that it will be good to reach the opposite. Hence, after reformulating the constraints it is sufficient to focus the goals [17]. Further information about fuzzy decision making can be found in [16], [18], [19] and [20]. Applying this theory in climate management, there are two major issues to be discussed: how to weight the goals and how to handle extremely contrasting demands.

B. Weighting objectives

In the concept described in section *A*, the importance of all goals in the intersection is equivalent. In some applications this is not correct, because single objectives have to be weighted. Bellman and Zadeh [16] suggest at first to weight single goals by using multiplicative factors. Instead of the aggregation using the intersection, the sum of all sets is advised:

$$\mu_D(x) = \sum_{i=i}^{n} a_i \cdot \mu_{Gi}(x) \tag{3}$$

To stay in the fuzzy world, it is necessary that the maximum of the decision set is not higher than one. For equation (3) this may be reached, if the sum of all weighting factors a_i is equal to one. As an alternative concept, exponents between zero and infinity may be used to weight single objectives. If the exponent is near infinity, the set will be equal to the kernel-function of the initial set (all elements round down to zero, except the elements with the degree of one), which means that the objective is very high weighted. In the opposite case, if the exponent is near zero, the set will be equal to the support (all elements will be round to one, except the elements with the degree of zero), which means that the objective is not very important. So, the intersection may be used for aggregation:

$$\mu_D(x) = \bigcap_{i=1}^{n} \mu_{Gi}(x)^{a_i} \tag{4}$$

This concept is also known in the area of fuzzy modifiers, where these powering operations are used as methods to describe the fuzziness in a linguistic term and to consider linguistic hedges in modeling of knowledge based systems [21], [22]. That is pretty much the same as weighting of objectives. A drawback of this concept is that the weighting process is not very obviously, because there are different ranges for dilatation (between zero and one) and concentration (between one and infinity). As an extension of this concept, we suggest to introduce an additional value λ_i by using the following mark:

$$\mu_{Gi}^{\langle\lambda_i\rangle}(x) = \mu_{Gi}(x)^{a_i} \tag{5}$$

The parameter is scaled from –1 to 1 and defined as:

$$a_i = \begin{cases} \dfrac{1}{1-\lambda_i} & for \quad 0 \le \lambda_i < 1 \\ 1+\lambda_i & for \quad -1 < \lambda_i < 0 \end{cases} \tag{6}$$

Figure 4 shows the effect of the modification using equation (6). If the weighting value λ_i moves toward –1, the shape will be deformed equal to the support-function and if the λ tends to 1, the shape will be deformed to the kernel-function.

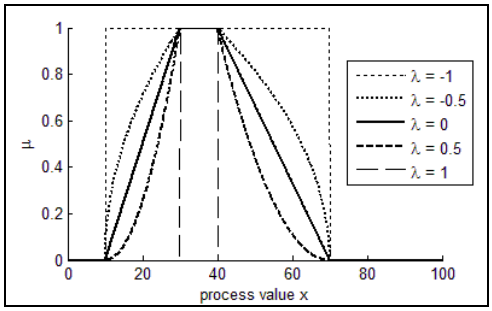

Figure 4. Effect of the weighting parameter λ_i to the membership function

C. Extremely contrasting demands

In some applications it can happen that a creation of an intersection is impossible. There will be no element in the set of alternatives where all membership functions are different to zero at once and finally an empty decision is resulting. This case occurs, if the demands are in an extreme contrast. In fuzzy decision making also values outside the appropriate area must be evaluated and it has to come to a decision about the reaction in such cases. It is necessary to distinguish those states, because a value far away from the kernel should not get the same bad rating as a value more close to it. This is why we should talk about an "inappropriate" and not about a "forbidden" area. The task before was to find the solution which satisfies all objectives equally; now the task is to find the solution where all objectives are unfulfilled in the same way.

To handle such scenarios, membership functions with degrees always higher than zero should be used. That can be done if suitable parametric membership functions (like the difference between two sigmoidal functions) are used or existing membership functions are manipulated. Remember: goals and constraints have finally been defined by human, where complicated functions may not be obviously parameterizable.

We prefer to keep the clearness of trapezoidal linear functions, because it is simple to define areas like “inappropriate” (outside the support), “appropriate” (inside the support) and “ideal” (inside the kernel), as shown in figure 1. In the classical trapezoidal function

$$\mu(x) = f_{Trap}(a,b,c,d) \tag{7}$$

the shape is defined by four parameters: a linear function increase from zero at *a* till one at *b*; another linear function

decrease from one at *c* till zero at *d*; between *b* and *c* all degrees are equal to one; all other degrees are zero. After defining this, we mitigate the crossing between the acceptable and the inappropriate zone to solve special cases as described in section *A* and we extend the conventional function by an additional parameter ε:

$$\mu(x) = f_{Trap\,\varepsilon}(a,b,c,d,\varepsilon) \tag{8}$$

The shape is defined as:

$$\mu(x) = \begin{cases} \varepsilon \cdot e^{\left(\frac{x-a}{\varepsilon\cdot(b-a)}-1\right)} & for \quad x \le a+\varepsilon\cdot(b-a) \\ \frac{x-a}{c-a} & for \quad a+\varepsilon\cdot(b-a) < x < b \\ 1 & for \quad b \le x \le c \\ \frac{d-x}{d-c} & for \quad c < x < d-\varepsilon\cdot(d-c) \\ \varepsilon \cdot e^{\left(\frac{d-x}{\varepsilon\cdot(d-c)}-1\right)} & for \quad x \ge d-\varepsilon\cdot(d-c) \end{cases} \tag{9}$$

The effect of choosing ε is shown in figure 5. We justify our approach as follows: if we look at a fuzzy objective it is possible that an ideal area (with equivalent ratings inside) could be defined by an expert; but the boundaries could not be defined clearly.

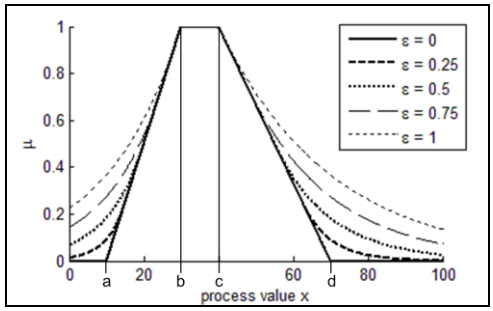

Figure 5. Effect of breaking the hard constraint

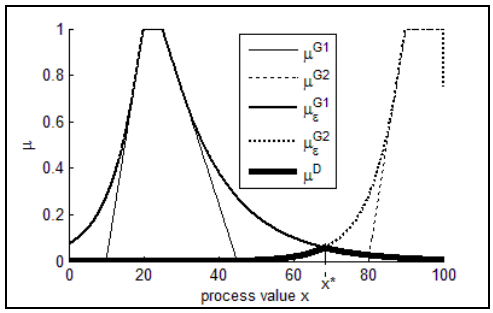

Figure 6. Decision making with controversy goals

Using this concept, it will always be possible to find a solution, also for controversial demands. An example is shown in figure 6: Two fuzzy sets defined according to equation (9) are intersected according to equation (1). The optimal process value *x** is obtained from equation (2).

D. *Manage the trajectory of setpoints*

The requirements of a controlled variable can usually be characterized by different criteria. First of all, stationary goals μ_{GS} should be reached to work in desired operating points. Generally, the necessary operations to reach the stationary goals should be done very efficient with low costs, thus aspects of economy μ_E are added. Finally, dynamical demands μ_{GD} have to be considered; these goals are dependent on past values of the controlled variable (as an example figure 7 shows a decision making process):

$$\mu_{GD}(x, x(k-1)) = f_{Trap\,\varepsilon}(x(k-1)+[a,b,c,d],\varepsilon) \tag{10}$$

All goals may be aggregated to the decision set:

$$\mu_D(x) = \mu_{GS}(x) \cap \mu_E(x) \cap \mu_{GD}(x, x(k-1)) \tag{11}$$

Hence, the question arises, how to weight the interacting of goals. It is obvious that all requirements are coupled: a higher performance may be reached by a high weighted stationary goal on the one hand and by a low weighted dynamical goal on the other. Surely, both cases will involve increasing costs. Based on the normalization, one goal may be inflexible and the other two goals may be mutually weighted .

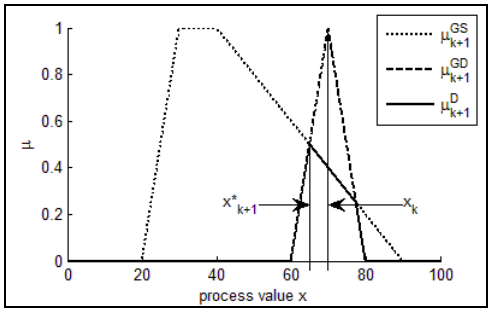

Figure 7. Decision making of stationary and dynamical demands

IV. THE AIR CONDITIONING PROCESS

Every climate value (thermal or non-thermal) can be described by a mass or energy balance. By summarizing all flows into the room, we get an universal balance equation for the indoor value σ^R, where the exchange of air with the outdoor climate is named as σ^E, buffering and storage effects are described by σ^S, transmission effects by σ^T, disturbance and non-manipulable inner loads by σ^Z and at last the manipulable inner sources named as σ^Y are added:

$$\dot{\sigma}^R(t) = \dot{\sigma}^\Sigma(t) = \dot{\sigma}^E(t) + \dot{\sigma}^S(t) + \dot{\sigma}^T(t) + \dot{\sigma}^Z(t) + \dot{\sigma}^Y(t) \tag{12}$$

A. Calculation of temperature and humidity

Taking the focus on temperature values, it is necessary to integrate the heat flows with a capacity (product of density ρ, specific capacity of air c and the room volume V_R of); using equation (12) and setting the universal value σ to the heat quantity Q:

$$\vartheta^R(t) = \frac{1}{\rho \cdot c \cdot V_R} \cdot \int \dot{Q}^{\Sigma}(t) \cdot dt \tag{13}$$

Model structures and control concepts of the temperature are well known and can be found in the corresponding literature [1], [23]. Taking the focus on the humidity, it is necessary to integrate the flows of (absolute!) humidity with a capacity (as the volume) of the room; using equation (12) and setting the universal value σ to the moisture content f:

$$f^R(t) = \frac{1}{V_R} \cdot \int \dot{f}^{\Sigma}(t) \cdot dt \tag{14}$$

As already mentioned above, the most important physical value of air conditioning is not the absolute humidity but rather the relative humidity, which is a temperature-dependent function and may be calculated by equation (15), where R^S is the specific gas constant and p^S is the saturated vapor pressure, which can be calculated by using appropriate functions (look at [24]). A structure of the process is shown in figure 8.

$$\varphi^R(t) = \frac{f^R(t) \cdot R^S \cdot \vartheta^R(t)}{p^S} \tag{15}$$

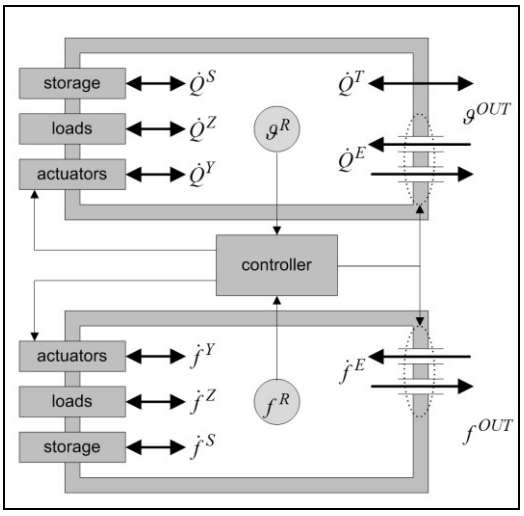

Figure 8. Control schema and influences on the indoor climate

B. Manipulating and controlling the process

It is obvious that the task of control thermal values is coupled to temperature and humidity, especially the temperature dependence of relative humidity and the influence of the ventilation rate. Additional to the manipulation of the ventilation rate, heating and cooling may be used to control the temperature. Humidifier and dehumidifier may be used to control the moisture balance. There are special requirements in the area of preventive conservation, because installations of air conditioning systems needs often a huge installation space and are also very expensive. Furthermore, it is also not allowed to damage the substance of historical buildings by additional installations. Finally, there are only a few options left to manipulate the process. Tasks of air conditioning may be divided into tasks of different time scales:

- short-term: measure process states, control of the variables in order to meet the given setpoints, aggregation of process information, time span: minutes till hours (daily fluctuations)
- medium-term: online optimization of setpoints, planning trajectories, time span: days (weather fluctuations)
- long-term: seasonal optimization, time span: weeks till month (seasonal fluctuation)

Short-term tasks are usually handled in concepts of basic automation, where standard controllers are used or manual operations (on/off switching of actuators, manual aerating) are provided to the process. Medium-term and long-term tasks can be aggregated to tasks of the process management system (PMS), which calculates the setpoints for the different control variables online (so far as online process information is available). Figure 9 shows the division of tasks and decision making in different levels of the automation structure.

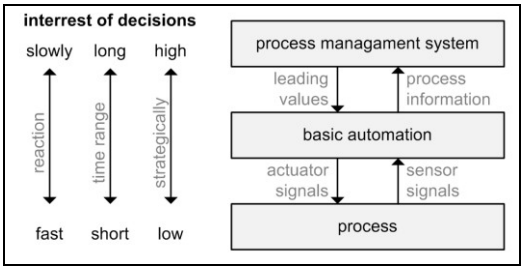

Figure 9. Levels of process automation

V. Application: Calculation of Climate Setpoints

This section describes a concept to find the optimal setpoints for the climate in applications of preventive conservation. Initially, applications where elements of basic automation are already present are considered. But this will also be a task, if the process is controlled by manual operations and the process staff is trying to reach the setpoints in that way. In this case, the PMS works as a decision support system.

A. Offline planning of fuzzy trajectories

The first approach for using fuzzy decision making is the design of a planning system. In interaction with the user, a local climate profile and stationary demands of people and cultural heritage have to be defined (maybe by using an additional configuration system). In this case there is no information about the process state, hence the system is only a

stationary offline system, dynamical aspects cannot be taken into account. Taking a priori information of the local climate in the course of the year into account, only the seasonal component is estimable, as effects of weathers and daily fluctuations are unknown.

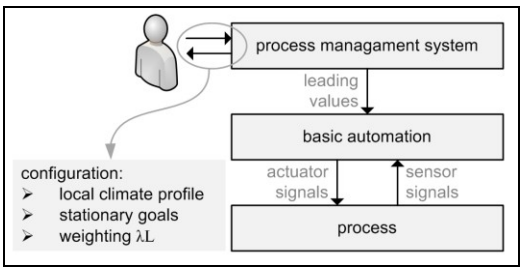

Figure 10. Structure of the planning tool

The outdoor climate of temperature and humidity can be approximated using a sine function [24]; hence, an appraisal of the economical demand to control a specific value is calculable. As an example, we plan the fuzzy setpoints of relative humidity in a room, where the indoor climate is controlled by components of the basic automation. Ignoring short-term effects, the demand of humidifying and dehumidifying may be calculated by looking at the required power in order to compensate the losses of absolute humidity by the mean of the natural air exchange $\dot{V}^E$:

$$\dot{f}^Y(t) \approx -\frac{1}{V} \cdot \left[f^{OUT}(t) - f^R(t) \right] \cdot \bar{\dot{V}}^E \tag{16}$$

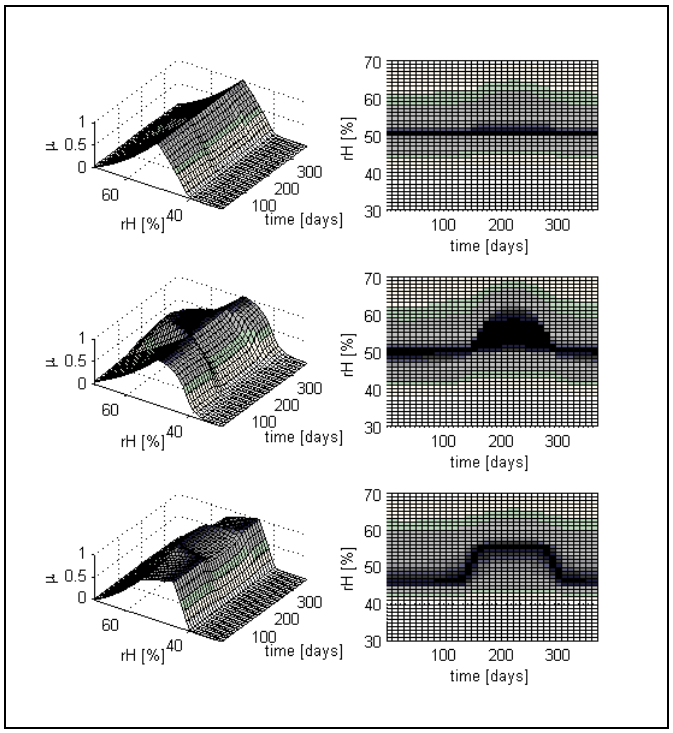

Figure 11. Fuzzy setpoints for relative humidity in the course of the year at different configurations. Left: stationary goal $f_{Trapε}$ (40, 50, 50, 70, 0.1) and λ_L =0. Middle: stationary goal $f_{Trapε}$ (40, 50, 50, 70, 0.1) and λ_L =-0.5. Right: stationary goal $f_{Trapε}$ (40, 45, 55, 70, 0.1) and λ_L =0.

Using equation (15), the economical demand may be calculated for various setpoints of relative humidity at every time step:

$$\dot{\vec{f}}^Y(t) \approx -\frac{1}{V} \cdot \left[\frac{\varphi^{OUT}(t)}{\vartheta^{OUT}(t)} - \frac{\vec{\varphi}^R(t)}{\vartheta^R(t)} \right] \cdot \frac{p^S}{R^S} \cdot \bar{\dot{V}}^E \tag{17}$$

We use the following relation to create a fuzzy membership function of the cost objective applying the result of (17):

$$\mu_{EL}\left(\varphi^R, t\right) = 1 - \frac{\left| \dot{\vec{f}}^Y(t) \right|}{\max \left| \dot{\vec{f}}^Y(t) \right|} \tag{18}$$

To reduce the complexity of configuration, we define λ_L as a weighting parameter, hence we can calculate the trajectory of fuzzy setpoints over the year. Figure 11 shows some examples for different configurations:

$$\mu_{\varphi L}\left(\varphi^R, t\right) = \mu_{GS}^{\langle \lambda_L \rangle}\left(\varphi^R\right) \cap \mu_{EL}^{\langle -\lambda_L \rangle}\left(\varphi^R, t\right) \tag{19}$$

B. *Online process management system*

Another approach for using the presented concept is an online PMS. In interaction with the user stationary and dynamical demands of people and cultural heritage have to be defined (may be using an additional configuration system again); but now there is no need of defining an outdoor climate profile (because of online measurements).

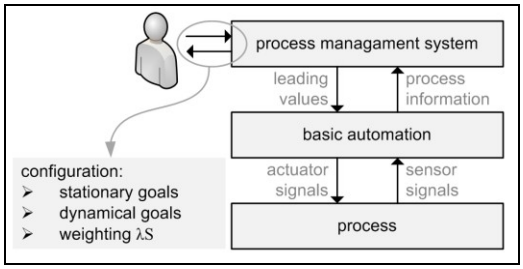

Figure 12. Structure of the process management system

Economical demands are calculated using online information of indoor and outdoor climate. We use equations like (17) and (18), but not over the course of the year (only for the present time). Furthermore, it is possible to calculate the membership function for dynamical goals, also using process information about the actual states. To reduce the configuration complexity, we do not weight the stationary demand (see above) and introduce a parameter λ_S as a weighting parameter between economical and dynamical demands, which may be justified obliviously.

$$\mu_{\varphi S}(x,t) = \mu_{GS}(x) \cap \mu_{GD}^{\langle \lambda_S \rangle}\left(x, x(k-1)\right) \cap \mu_{ES}^{\langle -\lambda_S \rangle}(x,k) \tag{20}$$

VI. Case-Study: Simulations of a the PMS

Based on simulations, in which a PMS has to generate optimal setpoints for an underlying control circuit of relative humidity, we will show the effectiveness of the proposed concept. This circuit in the basic automation level is using a feedback controller (PID) combined with a disturbance feed forward control (DFF). The structure is shown in figure 13.

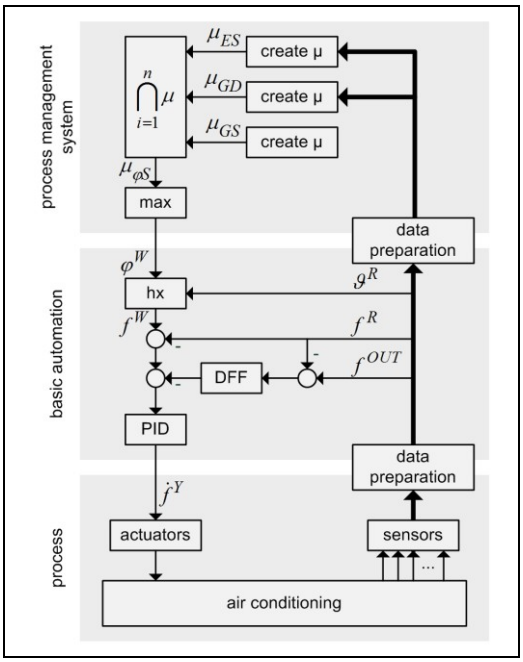

Figure 13. Structure of the controller in the case study

The PMS works dependent on the process values in medium-term range, a discrete filter (moving average of 24 hourly samples) is used to blind out short-term effects, which must be handled by basic automation. The setpoint of relative humidity gets an update every hour. Equation (20) is used for calculating the decision set. Thus the design parameter is λ_S. For the simulation we use a simulation environment of a building model in MATLAB/Simulink, which depends on first order balance equations of energy as well as additional components like storage effects for heat and moisture of the room. For details regarding to building physics and simulation look at the respective literature [25], [26] and [1].

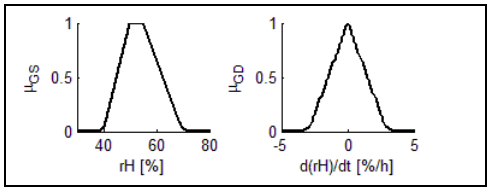

Figure 14. Stationary and dynamical goals in the case study

The goals are fuzzy values, the stationary demand is defined as appropriate in the area from 30% to 55% and in the vicinity of 35% and 50% the value is ideal. Regarding dynamical aspects, no changes would be the best solution; changes about ±3% per hour are accepted. To create a fuzzy membership function, we use equation (9) with a value ε of 0.1 for all membership functions. A scenario of outdoor climate and initial conditions is defined and simulated at different configurations of λ_S (figure 15). It is obvious that the design parameter λ_S has a significant influence on the dynamic behavior of the controlled variable. In a more detailed analysis of the simulation results, the membership of all simulation data to the stationary and the dynamical goal is determined just as the power (needed for humidification) is cumulated. The normalized and scaled values are plotted in figure 16.

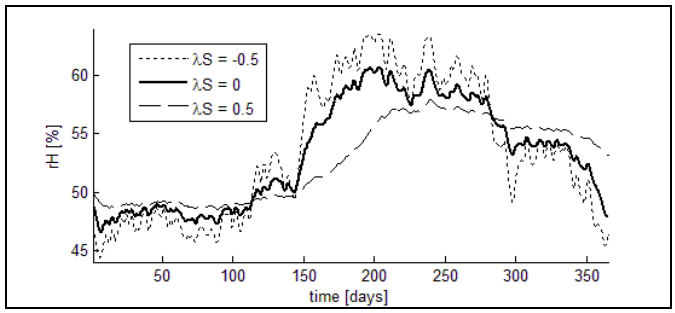

Figure 15. Simulation results: behaviour of the controlled relative humidity at various weightings.

As expected, choosing a higher λ_S (higher weighting of the prevention of high gradients) leads to lower economical effects. Considerable is the correlation of the effect of choosing λ_S to stationary and dynamical demands, which is caused at the coevally opposed weighting of economical aspects.

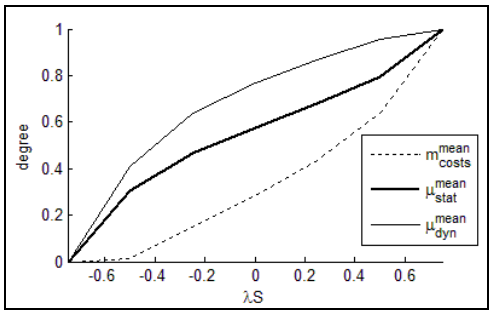

Figure 16. Simulation results (normalized and scaled): sum of power demands and means of bad ratings

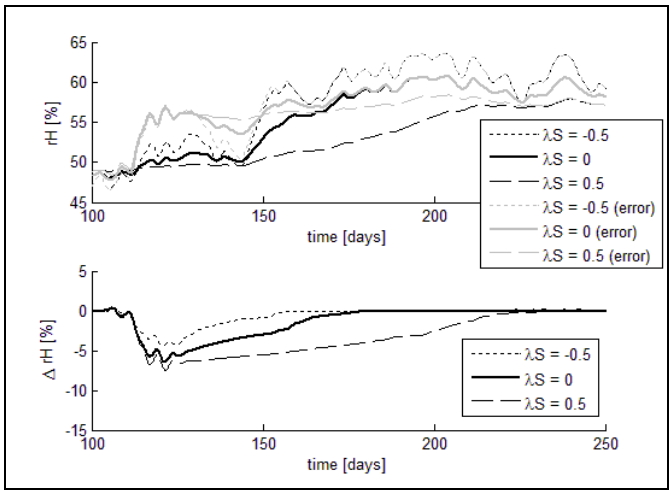

Figure 17. Dynamical behaviour of the controlled variable after an error (between the 105th and the 130th day): simulation results (above) and difference to normal behaviour (below)

Analyzing the second effect of using the PMS, an error in the technical equipment is simulated. The task of the PMS is now to guarantee the return of the process back to the optimal sequence of setpoints (depicted in figure 17). After reactivation of the equipment, the parameter λ_S defines the velocity to reach the behavior in the normal operation; the activation is also bumpless. Hence, the PMS also resumes the task of planning trajectories.

VII. Conclusion and outLook

The theory of fuzzy decision making can be used to make decisions in applications where the demands of the controlled process are only inexact, imprecise or vague known. We presented established weighting methods and suggested a simple principle for using the powering operator obviously. Furthermore, we discussed the problems of decision making in the case of controversial demands and suggested a principle to transform hard constraints in trapezoidal membership functions.

Applications of air conditioning, especially in the area of preventive conservation are complex tasks, where the demands to avoid climate damages are only roughly known. There are some goals defined in norms, but no method how to find a compromise between the different demands, for instance how to weight stationary and dynamical demands. The presented approach and the simulations of a process management system were presented in this paper. Especially for the use in preventive conservation such a system may be used to find compromises between stationary and dynamical goals as well as to economical aspects.

In following work, we will use the concept of the process management system to generate future fuzzy setpoints and to optimize future manipulating operations in cooperation with the theory of multistage fuzzy control [26], maybe for planning an optimal ventilation sequence. Furthermore, we will expand the theory for MIMO processes, especially to combine the generation of setpoints for relative humidity and temperature.

***Abstract*—This paper proposes a fuzzy controller design using group-crossover particle swarm optimization (GCPSO) algorithm. The GCPSO uses a group-based framework for defining particle neighborhood topology and incorporating crossover operation into particle swarm optimization. The GCPSO dynamically forms different groups for selecting parents in crossover operations, particle updates and replacements. The objective of GCPSO is to improve fuzzy control accuracy. Comparisons with different population-based optimizations on truck reversing control problem demonstrate the performance of GCPSO algorithm.**

Keywords- fuzzy controller, particle swarm optimization, genetic algorithms.

I. INTRODUCTION

Fuzzy controllers (FCs) have been successfully applied to many optimum control problems, like robots and power systems. Evolutionary fuzzy control (EFC) concerns automatic design of FC using evolutionary computation techniques. Two popular EFC approaches are genetic algorithms (GAs) [1,2] and particle swarm optimization (PSO) [3]. The PSO algorithm studies collective behavior in decentralized systems [4]. Its development was based on mimicking the social behavior of animals or insects models in an effort to find the optima in the problem space. Original PSO models are initialized with a population of random solutions. Each individual in PSO is assigned with a randomized velocity according to its own and its companions' flying experiences, and the individuals, called particles, are the flown through hyperspace.

Many modified PSO have been proposed and successfully applied to different optimization problems [5-12], such as a hybrid of GA and PSO (HGAPSO) [5], self-organizing hierarchical PSO with time-varying acceleration coefficients (HPSO-TVAC) [6], PSO with controller random exploration velocity (PSO-CREV) [7], a species-based PSO (SPSO) [8], and a hierarchical cluster-based multi-species particle swarm optimization (HCMSPSO) [12]. In HGAPOS and several latter studies [9-11], the idea of crossover in GA is incorporated into PSO. In SPSO and HCMSPO, a swarm population is divided into species subpopulations, and the dominating particle in each species is used as a best neighborhood for particles within the same species. This paper proposes a new framework for incorporating crossover operation and species formation into PSO.

This paper proposes a group-crossover PSO, called as GCPSO. According to the adaptively formed groups in a swarm, a new group-based crossover operation (GCRO) is proposed. Unlike the SPSO and HCMSPSO, the formation of the group is used not only for particle velocity update but also for particle crossover in the EGPSO. The EGPSO uses the name "group" because individuals in different species do not perform crossovers in nature. This paper applies the GCPSO algorithm to design a fuzzy controller for a truck reversing control problem. In the simulation, this paper demonstrates the performance of GCPSO via comparisons with various advanced GA and PSO algorithms.

This paper is organized as follows: Section II introduces the FC designed by the GCPSO. Section III introduces the GCPSO. Section IV conducts the truck reversing control problem. Finally, Section V presents conclusion.

II. FUZZY CONTROLLER(FC)

This paper designs a fuzzy controller (FC) using the GCPSO. The i th rule, denoted as R_i, in the FC is represented in the formula :

$$\begin{aligned} R_i:\ &\text{If } x_1(k) \text{ is } A_{i1} \text{ And ... And } x_n(k) \text{ is } A_{in} \\ &\text{Then } u(k) \text{ is } a_i \end{aligned} \tag{1}$$

where k is time step, $x_1(k)$, …, $x_n(k)$ are the input variables, $A_{i1},\ldots,A_{in}$ are fuzzy sets, and a_i is a crisp value. The fuzzy set A_{ij} uses a Gaussian membership function

$$M_{ij}(x_j) = \exp\{-(\frac{x_j - m_{ij}}{\sigma_{ij}})^2\}, \tag{2}$$

This work was supported by the National Science Council, Taiwan, under Grants NSC-99-2221-E-005-064-MY2 and NSC 99-2221-E-010 -013.

where m_{ij} and σ_{ij} represent the center and width of the fuzzy set A_{ij}, respectively. The fuzzy AND operation in the inference engine implemented by the algebraic product in the fuzzy theory. Therefore, given an input data set $\vec{x}(k) = (x_1(k), \ldots, x_n(k))$, the firing strength $\phi_i(\vec{x}(k))$ is calculated by

$$\phi_i(\vec{x}(k)) = \prod_{j=1}^{n} M_{ij}(x_j(k)). \quad (3)$$

If there are r rules in the fuzzy controller, then the output of the controller computed by the weighted average defuzzification method and is shown

$$u(k) = \frac{\sum_{i=1}^{r} \phi_i(\vec{x}(k)) a_i}{\sum_{i=1}^{r} \phi_i(\vec{x}(k))}. \quad (4)$$

The designed of an FC training data consists of the determination of fuzzy rules and the optimization of all free parameters in each fuzzy rule. For the FC in (1) that consists of n inputs variables and r rules. Therefore, all of ties free parameters can be described by the following vector

$$\vec{s} = m_{11}, \sigma_{11}, \cdots, m_{1n}, \sigma_{1n}, a_1, \cdots, m_{r1}, \sigma_{r1}, \cdots, m_{rn}, \sigma_{rn}, a_r] \in \Re^{r(2n+1)} \quad (5)$$

In GCPSO-designed FC, the number of rules r is assigned in advance. The number of fuzzy sets in each input variable is simply equal to the number of rules. The solution vector in (5) functions as a particle. The GCPSO-designed FC optimizes all of the free parameters in an FC with the number of rules being fixed.

III. GROUP-CROSSOVER PARTICLE SWARM OPTIMIZATION (GCPSO)

In basic PSO, the initial P_s (which is the swarm size) particles forming the swarm are randomly generated. However, there are too many search points before locating the global optimum. To improve the search ability, this paper applies the idea of swarm speciation proposed in species-based PSO (SPSO) [8] for particle velocity update. Unlike the SPSO, the formation of groups is used not only for particle velocity update but also for particle crossover in GCPSO. Figure 1 shows the block diagram of the group formation, particle update, particle generation, and replacement operations in the GCPSO. Details of these operations are introduced as follows.

A. Group formation

Initially, the particles are sorted from best performance to worst performance. The first particle is the best-performing one in the sorted swarm. This particle forms the first group and functions as first group leader (denoted as $\vec{p}_1^{\,L}$). For the leader $\vec{p}_z^{\,L}$ of group z, positions of the particles ranked after $\vec{p}_z^{\,L}$ are checked one by one against $\vec{p}_z^{\,L}$ until a particle whose

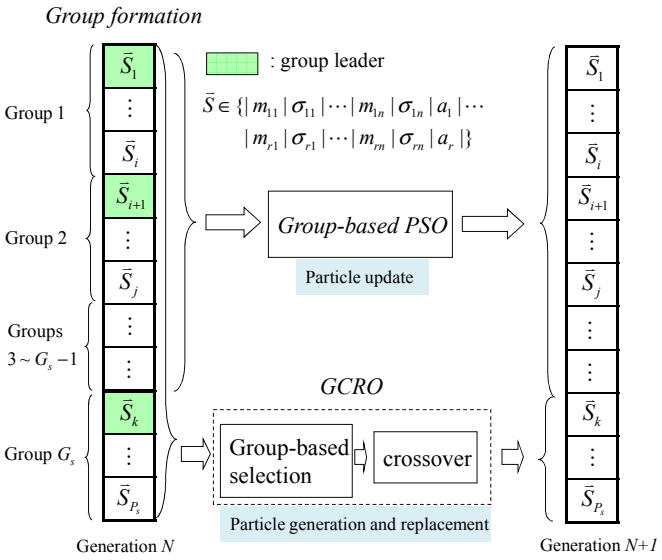

Fig. 1. The Block diagram of the GCPSO.

similarity degree with respect to $\vec{p}_z^{\,L}$ is larger than a predefined threshold ρ_{th}. The similarity degree, ρ, between a particle $\vec{s}_i$ and a group leader $\vec{p}_z^{\,L}$ is given by

$$\rho(\vec{p}_z^{\,L}, \vec{s}_i) = \sqrt{\frac{\| \vec{p}_z^{\,L} - \vec{s}_i \|_2^2}{D}}, \quad (6)$$

where D is the length of a particle vector. The ρ value can be regarded as the root-mean-squared error between twovectors. The particles with $\rho(\vec{p}_z^{\,i}, \vec{s}_i)$ being smaller than the threshold ρ_{th} are categorized into group z. The first particle with $\rho(\vec{p}_z^{\,i}, \vec{s}_i)$ being larger than the threshold ρ_{th} functions as a new leader $\vec{p}_{z+1}^{\,L}$ and forms a new group $z+1$. This paper sets the threshold ρ_{th} to be 1.5.

B. Particle Update

Suppose that there are G_S groups in the GCPSO, where G_S changes with learning iterations. The GCPSO updates particles in groups $1, \ldots, (G_S - 1)$. In the GCPSO, grouping is used for neighborhood topology definition in a swarm. That is, the neighbors of a particle are defined as the particles within the same group. Therefore, the neighborhood best position is the leader $\vec{p}_z^{\,L}$ for particles within group z. The velocity $\vec{v}_i$ of each particle i in group z is updated using its individual best position, $\vec{p}_i$, and the neighborhood best position, $\vec{p}_z^{\,L}$. The following equation with a constriction coefficient is used for velocity updating [4]:

$$v_i^j(t+1) = \chi(v_i^j(t) + c_1\varphi_1^j \cdot (p_i^j(t) - s_i^j(t)) + c_2\varphi_2^j \cdot (p_z^{Lj}(t) - s_i^j(t))), \quad j = 1,...,D \tag{7}$$

where χ is a constriction factor controls the magnitude of $\vec{v}_i^j$, c_1 and c_2 are positive acceleration coefficients, and φ_i^j is uniform random number [0, 1]. The particles in different groups are attracted by the different group leaders, which causes different groups to locate different optima. This method helps to reduce the chance of getting stuck in a local solution. Each particle changes its position according to the following velocity-dependent formula:

$$\vec{s}_i(t+1) = \vec{s}_i(t) + \vec{v}_i(t+1). \tag{8}$$

C. *Particle Generation and Replacement*

The GCPSO generates new particles by using a new group-based crossover operation (GCRO), which is inspired by the crossover operation in the GAs. The GCRO-generated particles are used to replace the worst-performing group in each iteration. In the GCRO, parents for crossover are selected from different groups except for the worst-performing group in order to avoid inbreeding. Therefore, this operation is applied only when the number of groups G_S is larger than two. To select parents for the GCRO, the group-based tournament selection scheme is used. To select one parent, $G_S/2$ groups are first randomly and uniformly selected regardless of group performance. For these $G_S/2$ groups, the one with the best performance is selected. A particle within the selected group is then randomly and uniformly selected regardless of particle performance. This selected particle is designated as one parent $\vec{s}_{p1}$. The other parent $\vec{s}_{p2}$ is selected by the same way. Two new particles, $\vec{s}_{n1}$ and $\vec{s}_{n2}$, are created by performing crossover on the two selected parents. Two crossover sites are randomly selected and are denoted by t_1 and t_2. The GCRO creates each element in the two new particle vectors using the following operations:

$$s_{n1}^j = \begin{cases} \gamma_1 s_{p1}^j + (1-\gamma_1)s_{p2}^j, & j = 1,\dots,t_1 \\ \gamma_2 s_{p1}^j + (1-\gamma_2)s_{p2}^j, & j = t_1+1,\dots,t_2 \\ \gamma_3 s_{p1}^j + (1-\gamma_3)s_{p2}^j, & j = t_2+1,\dots,D \end{cases} \tag{9}$$

and

$$s_{n2}^j = \begin{cases} (1-\gamma_1) s_{p1}^j + \gamma_1 s_{p2}^j, & j = 1,\dots,t_1 \\ (1-\gamma_2) s_{p1}^j + \gamma_2 s_{p2}^j, & j = t_1+1,\dots,t_2 \\ (1-\gamma_3) s_{p1}^j + \gamma_3 s_{p2}^j, & j = t_2+1,\dots,D \end{cases} \tag{10}$$

where γ_i is a uniform random number in [0,1]. Each crossover operation creates two new particles. For worst-group replacement, the number of crossover operations is equal to $\lceil N_w/2 \rceil$, where N_w denotes the number of particles in the worst-performing group.

Table 1. The SAE of GCPSO and Different Population-based Algorithms in for The Truck Reversing Control Problem.

Methods	EGA [1]	C-PSO [4]	HGAPSO [5]	HPSO-TVAC [6]	PSO-CREV [7]	GCPSO
Average	0.525	0.5438	0.141	0.3252	1.29	0.1204
STD	0.564	1.0643	0.176	0.257	0.67	0.1531

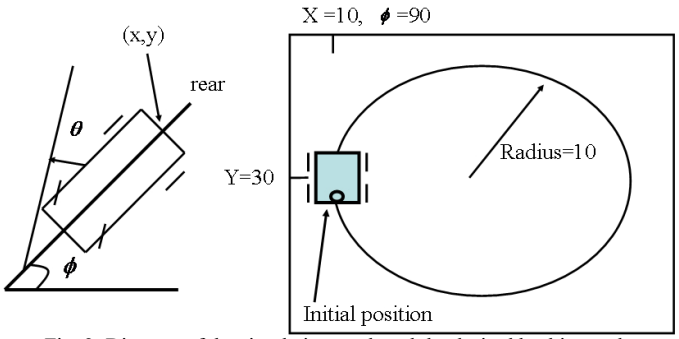

Fig. 2. Diagram of the simulation truck and the desired backing path.

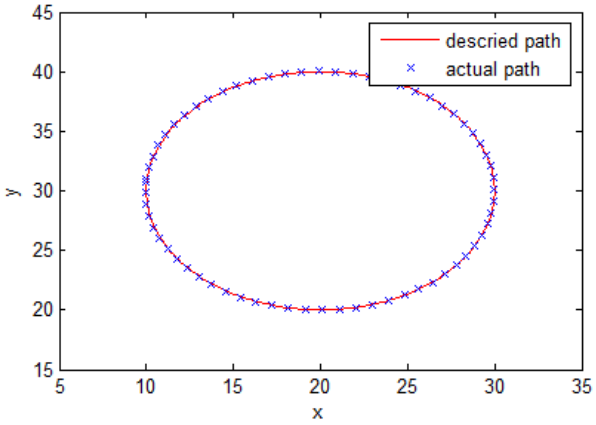

Fig. 3. The control results using GCPSO, where the desired and actual paths are denoted by solid line and "×", respectively.

For each new particle $\vec{s}_n$, its initial velocity $\vec{v}_n$ should be assigned accordingly, which is introduced as follows. The similarity degree between $\vec{s}_n$ and each of the left $G_S - 1$ group-leaders $\vec{p}_z^L$ are computed, and the leader with the minimum degree is found. That is, find

$$\hat{z} = \arg \min_{1 \le z \le G_S - 1} \rho(\vec{p}_z^L, \vec{s}_n) \tag{11}$$

The particle $\vec{s}_n$ is categorized into group $\hat{z}$. The initial velocity vector is assigned by the following formula:

$$v_n^j = \gamma_4^j \cdot (p_{\hat{z}}^{Lj} - s_n^j) + \gamma_5^j \cdot (s_{p1}^j - s_n^j) + \gamma_6^j \cdot (s_{p2}^j - s_n^j), \quad j = 1,...,D \tag{12}$$

This initial velocity is assigned according to the positions of the two parents and the group leader to which the new particle $\bar{s}_n$ belongs.

IV. SIMULATION

This paper simulates a truck reversing control problem. The FC is designed using GCPSO. Figure 2 shows the simulated truck. The truck position is precisely determined by the three state variables ϕ, x, and y, where ϕ is the angle of the truck with the horizon as shown in Fig. 2. The control signal to the truck is steering angle θ, where $\theta \in [-20°, 20°]$. Only reversing is considered. The truck moves backward by a fixed unit distance every stage. The model of the truck reversing system is [13]

$$x(k+1) = x(k) + \cos[\phi(k) + \theta(k)] + \sin[\theta(k)]\sin[\phi(k)] \quad (13)$$

$$y(k+1) = y(k) + \sin[\phi(k) + \theta(k)] - \sin[\theta(k)]\cos[\phi(k)] \quad (14)$$

$$\phi(k+1) = \phi(k) - \sin^{-1}[\frac{2\sin(\theta(k))}{b}] \quad (15)$$

where b is the length of the truck and b =4 in this simulation. Equations (13) to (15) generate the next state when the present state and control are given. The task here is to design a fuzzy controller to reverse the truck following the desired circular path

$$(x-20)^2 + (y-30)^2 = 10^2 \quad (16)$$

with an initial state of $(x, y, \phi) = (10, 30, 90^\circ)$. Figure 3 shows the initial state and the desired driving path. There are a total of 65 control steps, and control error is defined as

$$SAE = \sum_{k=1}^{65} |e(k)|, e(k) = (((x(k)-20)^2 + (y(k)-30)^2)^{1/2} - 10)^2 \quad (17)$$

FC inputs are $x(k)$, $y(k)$, and $\phi(k)$, and the input output is θ. The number of fuzzy rules is set to be four. In the GCPSO-designed FC, the particle size is set to be 40. This paper sets the parameters in (7) as follows: $\chi = 0.9$, $C1 = C2 = 1$, and the $\rho_{th} = 1.5$. The number of iterations is 1000. For statistical analysis, learning is performed for 50 runs. Table 1 shows the average SAE and standard deviation (STD) over 50 runs.

For the sake of comparisons, this paper compares the GCPSO performance with different advanced GA and PSO, including: an elite GA (EGA)[1], constriction PSO (C-PSO) [4], a hybrid of GA and PSO (HGAPSO) [5], self-organizing hierarchical PSO with time-varying acceleration coefficients (HPSO-TVAC) [6], and PSO with controller random exploration velocity (PSO-CREV) [7]. The number of rules in these methods is also set to be four *a priori*. Table 1 shows the learning average SAE and STDs of these population-based optimization algorithms used for comparison. The result shows that the GCPSO achieves the smallest control error.

V. CONCLUSION

This paper proposes a new optimization algorithm, GCPSO, for truck reversing control problem. The GCPSO generates a new swarm by using not only group-based particle update but also group-based crossover operation. The group-based crossover operation (GCRO) is incorporated into PSO for performance improvement. Effectiveness and efficiency of the GCPSO have been demonstrated through comparisons with different population-based optimization algorithms in the FC design problem. In the future, the GCPSO-designed FC will be applied to other control problems to verify its performance.

***Abstract*—This paper presents an online learning-based neuro-fuzzy system called evolving Fuzzy Ensemble (eFE). The hierarchical computational structure of eFE is progressively adapted to autonomously support fuzzy data associations in accordance with neurophysiological studies. Activity-dependent synapse with global decay learning rule is incorporated to simulate the retention and active forgetting mechanisms that are involved in memory persistence. Such features incorporated in eFE model make it suitable to address the nonstationary characteristics of real-world problems. This work demonstrates the use of simple mechanisms to accomplish complex form of associative learning, an idea that has been suggested by psychologists for many years but has only recently been verified at the cellular level. The proposed eFE model is evaluated and compared with other modelling techniques in two benchmark time series experiments. The experimental results demonstrate the capabilities, and illustrate the viability of the proposed modelling technique.**

I. Introduction

Soft computing has been a significant and influential computing paradigm in drawing complementary methodologies to exploit the tolerance for uncertainty, so as to achieve cost-effective intelligent solutions [1]. A typical approach is the integration of neural network and fuzzy system to create a hybrid structure called *neuro-fuzzy system* (NFS) [2]. The application of NFS has been demonstrated in a number of fields, including time-varying signal detection [3], adaptive nonlinear control [4], forecasting [5], knowledge extraction [6], decision support [7], fault detection [8], and robotics [9]. This neural-fuzzy synthesis provides flexible information processing capability, in a human comprehensible neural construct, for handling real life complex and uncertain situations [2].

A. Incremental Adaptation

Existing NFSs (see, e.g., [10], [5], [11], [12], for instance) generally employ all the training data samples multiple times either during network structure identification or network parameter adaptation. These systems generally require the representative data samples of the problem domain to be collected in advance. Hence, such batch learning models are not suitable for modelling of complex time-varying processes in dynamically changing environments. In addition, the ever increasing flow of data makes batch learning models unfeasible because these models generally make use of time consuming complex optimization with the objective of deriving a globally optimized solution that is representative of the training data. In order to use these models in online applications, it is only possible for the price of re-training the whole model structure and parameters with iterative and time-consuming procedures [13], [14].

In fact, a situation is likely to be encountered where it is not easy to collect a complete set of training samples to build a classification or forecasting system. For instance, it is almost impossible to construct a human face database without taking into consideration all the various factors that can affect an image quality. Thus, it is usually the case that an imperfect system is constructed to work well with some limited conditions, and only to revise it when more information is acquired. Therefore, in many practical situations, the presentation of training samples becomes sequential and adaptation to the system and forecasting by the system have to be alternatively carried out. In other practical applications (e.g. stock price forecasting), a static forecasting system is rendered ineffective by the changing property of the data source. Thus, a system is required to be incrementally adaptable to new information.

Progressive adaptation refers to the incremental modification of the network structure and parameters. The objective of progressive adaptation is to bring the network to produce a model close to a desired process through a gradual and progressive change of the network computational capability. In this paper, the progressive adaptation of a NFS is concerned with online learning of a data stream. The training exemplars from the data stream are assumed to arrive one at a time, and that the online learning algorithm adapts the structure and network parameters of the model based on the current training exemplar in an incremental manner. Online learning algorithms encompass the following four distinguishing features from *sequential learning algorithms* [15]: *1)* All the training observations are sequentially (one-by-one) presented to the learning system; *2)* At any time, only one training observation is seen and learned; *3)* A training observation is discarded as soon as the learning procedure for that particular observation is completed; *4)* The learning system has no prior knowledge as to how many total training observations will be presented. In addition, the following additional features are specifically considered for online learning algorithms: *1)* There is no knowledge of the lower and upper bound of the training

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

observations; *2)* The system should account for time-varying data characteristics (i.e. knowledge about data should change).

B. Focus and Structure of Paper

This paper focuses on the structure and learning aspects of a NFS [2] called *evolving Fuzzy Ensemble* (eFE). The proposed eFE network is organised into a modular and hierarchical network of neurons. Starting with zero neuron, eFE adopts a single-pass progressive learning approach that is inspired from the neurobiological learning theories of synaptic plasticity. This paper is organised as follows. Section II presents the architecture of the eFE network. Section III provides an overview of the proposed progressive biologically inspired learning algorithm for eFE network. In Sect. IV, two experiments are conducted to demonstrate the modelling and tracking capabilities of the proposed eFE model. Section V summarises and concludes this paper.

II. Network Architecture

The proposed eFE is a feed-forward network comprising of five layers of neurons. Other than layer I and V, the neurons in the other layers of eFE network are organised into a modular and hierarchical structure with H levels. Figure 1 shows the hierarchical structure of eFE network with two input variable nodes, one output variable node, and H hierarchical levels of nodes in layer II, III, and IV. The symbols used in this paper denotes the following:

I	number of input features;
M	number of output features;
K_h	number of rule nodes at hth hierarchical level;
IV_i	input linguistic node for input feature x_i ($1 \leq i \leq I$);
OV_m	output linguistic node for output feature y_m ($1 \leq m \leq M$);
$J_{h,i}$	number of linguistic term node/membership functions (MFs) for input feature x_i at hth hierarchical level;
$L_{h,m}$	number of MFs for output feature y_m at hth hierarchical level;
$IL_{h,i,j}$	jth MF for input feature x_i at hth hierarchical level ($1 \leq j \leq J_{h,i}$);
$OL_{h,m,\ell}$	ℓth MF for output feature y_m at hth hierarchical level ($1 \leq \ell \leq L_{h,m}$);
$R_{h,k}$	kth rule node at hth hierarchical level ($1 \leq k \leq K_h$);
$C_{h,m,\ell,k}$	fuzzy rule connection between $R_{h,k}$ and $OL_{h,m,\ell}$.

The hierarchical organisation of eFE network corresponds to the structure of the neocortex [16]. A hierarchical level of eFE corresponds to a cortical layer. The differences in the sensory function among the cortical layers are simulated using different hierarchical levels of linguistic term/label nodes with different receptive fields (supports of fuzzy MFs). A layer of nodes in eFE network corresponds to a vertical cortical column. Every layer of neurons in the proposed eFE network is a functional module of a *fuzzy inference system* (FIS). Each layer of the eFE network performs specific fuzzy operations to realize an extended-Mamdani fuzzy reasoning model that handles *mutual inclusivity* [17]. A fuzzy rule at the hth hierarchical level of eFE network is encoded as follows:

IF x_1 is $IL_{h,1,j}$ $\ldots \wedge \ldots$ x_i is $IL_{h,i,j}$ $\ldots \wedge \ldots$ x_I is $IL_{h,I,j}$ THEN y_1 is $OL_{h,1}$, …, y_m is $OL_{h,m}$, …, y_M is $OL_{h,M}$

where $OL_{h,m}$ represents a fuzzy partition that is shaped by the output MFs ($OL_{h,m,1}, \ldots, OL_{h,m,L_{h,m}}$) of different degrees [18].

The input and output signals at any time t are respectively represented as crisp vectors $\mathbf{x}(t) = [x_1, \ldots, x_I]^T$ and $\mathbf{y}(t) = [y_1, \ldots, y_M]^T$. Every node in the first layer of the network takes in a single element from the input vector $\mathbf{x}(t)$. Every output node computes a single output element of the output vector $\mathbf{y}(t)$ with respect to the input stimulus vector $\mathbf{x}(t)$. The forward reasoning with signal propagation through each layer of the network as shown in Fig. 1 is described as follows.

A. Layer I: Input Linguistic Nodes

A node IV_i simply receives signal from the input stimulus x_i, and propagates it to the next layer nodes for processing. The output o_i^I of IV_i is defined in (1).

$$o_i^I = x_i \ . \tag{1}$$

B. Layer II: Input Linguistic Term Nodes

A neuron $IL_{h,i,j}$ denotes the jth fuzzy MF of the ith input feature at the hth hierarchical level and constitutes an antecedent of a fuzzy rule. Every node $IL_{h,i,j}$ defines a triangular fuzzy MF and its output $o_{h,i,j}^{II}$ is computed using *singleton fuzzification* operation in (2).

$$\begin{aligned} o_{h,i,j}^{II} &= \mu_{h,i,j}^{II}(o_i^I; a_{h,i,j}^{II}, b_{h,i,j}^{II}, c_{h,i,j}^{II}) \\ &= \max\left(\min\left(\frac{o_i^I - a_{h,i,j}^{II}}{b_{h,i,j}^{II} - a_{h,i,j}^{II}}, \frac{c_{h,i,j}^{II} - o_i^I}{c_{h,i,j}^{II} - b_{h,i,j}^{II}}\right), 0\right) \ , \end{aligned} \tag{2}$$

where parameters $a_{h,i,j}^{II}$ and $c_{h,i,j}^{II}$ are the minimum and maximum support, and $b_{h,i,j}^{II}$ is the kernel of the MF for $IL_{h,i,j}$ respectively. In addition, the following conditions are satisfied for the input fuzzy MFs.

$$o_{h,i,1}^{II} = \begin{cases} 1, & o_i^I \leq b_{h,i,1}^{II}; \\ \mu_{h,i,1}^{II} \text{ defined in (2)}, & \text{otherwise.} \end{cases} \tag{3}$$

$$o_{h,i,J_{h,i}}^{II} = \begin{cases} 1, & o_i^I \geq b_{h,i,J_{h,i}}^{II}; \\ \mu_{h,i,J_{h,i}}^{II} \text{ defined in (2)}, & \text{otherwise.} \end{cases} \tag{4}$$

$$\sum_{j=1}^{J_{h,i}} \mu_{h,i,j}^{II} = 1 \ ; \ b_{h,i,j}^{II} < b_{h,i,j+1}^{II} \ . \tag{5}$$

Equation (3) and (4) respectively defines the first and the last MF in $x_i \subset \mathbb{R}$, and (5) specifies the overlap level of 0.5 between any two successive MFs. The eFE network consists of H sets (each set belonging to a level of eFE) of input linguistic labels, with each of them characterized by a scale parameter $\sigma_{h,i}^{II}$ defined in (6),

$$\sigma_{h,i}^{II} = b_{h,i,j}^{II} - a_{h,i,j}^{II} = c_{h,i,j}^{II} - b_{h,i,j}^{II} \ , \tag{6}$$

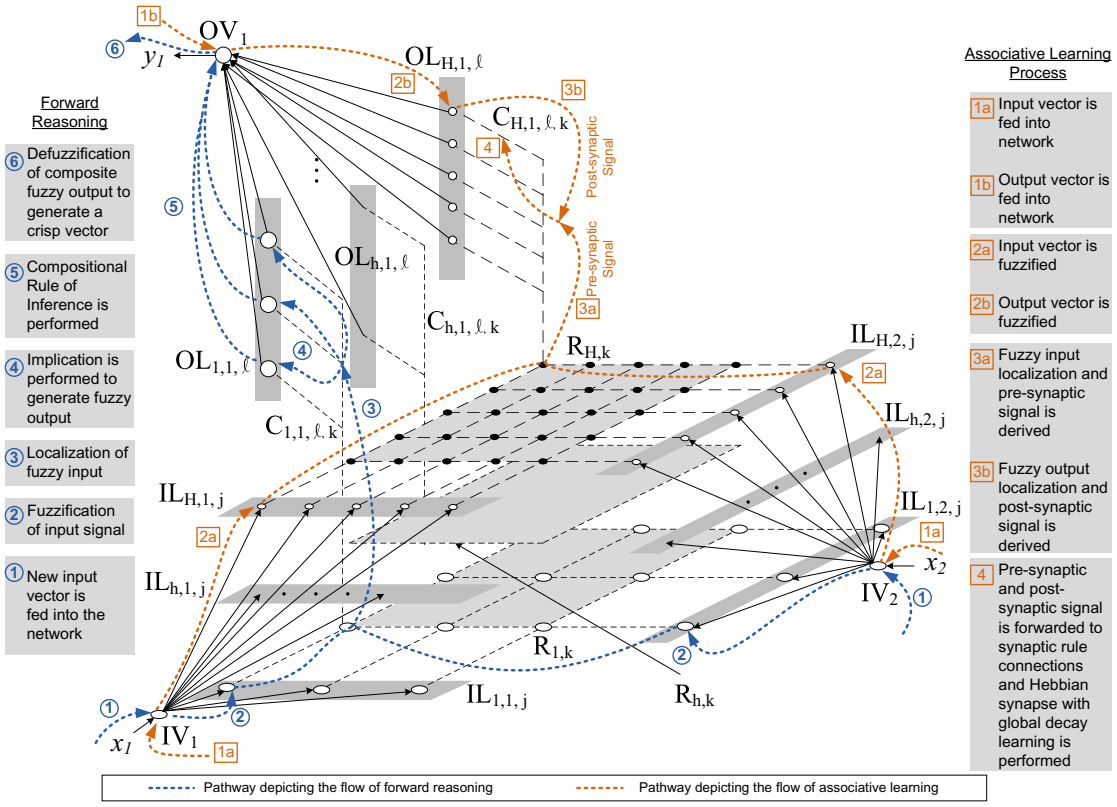

Fig. 1. Structure of eFE network.

and $\sigma^{II}_{h,i} > \sigma^{II}_{h+1,i}$. Each higher hierarchical level composes of MFs with smaller uniform entropies than the ones at the lower hierarchical level [19].

C. Layer III: Rule Nodes

A neuron $R_{h,k}$ represents the kth fuzzy rule node at the hth hierarchical level with output $o^{III}_{h,k}$ computed using a conjunctive fuzzy set operation (minimum t-norm operation) [20] defined in (7).

$$o^{III}_{h,k} = \min_{(h,i,j)\in A^{II}_{h,k}} o^{II}_{h,i,j} \ , \tag{7}$$

where $A^{II}_{h,k}$ is the set of input linguistic term nodes in layer II (antecedent) that are connected to $R_{h,k}$.

D. Layer IV: Output Linguistic Term Nodes

A neuron $OL_{h,m,\ell}$ represents the ℓth output linguistic term node of the mth output linguistic node at the hth hierarchical level. Each node implements the *Compositional Rule of Inference* (CRI) [21] scheme. The output $o^{IV}_{h,m,\ell}$ of $OL_{h,m,\ell}$ is defined in (8).

$$o^{IV}_{h,m,\ell} = \max_{k\in R^{III}_{h,m,\ell}} \left(\min(o^{III}_{h,k}, C^{f}_{h,m,\ell,k})\right) \ , \tag{8}$$

where $R^{III}_{h,m,\ell}$ is the set of rule nodes in layer III that are connected to $OL_{h,m,\ell}$, and $C^{f}_{h,m,\ell,k}$ (refer to (13)) is the certainty factor (normalized weight) of the rule node connection $C_{h,m,\ell,k}$ between $R_{h,k}$ and $OL_{h,m,\ell}$.

The eFE network consists of H sets of output linguistic labels. These labels also satisfy the same conditions ((3), (4), (5)) that are specified for the input linguistic labels. Each output linguistic label is characterized by a scale parameter $\sigma^{IV}_{h,m}$ defined in (9),

$$\sigma^{IV}_{h,m} = b^{IV}_{h,m,\ell} - a^{IV}_{h,m,\ell} = c^{IV}_{h,m,\ell} - b^{IV}_{h,m,\ell} \ , \tag{9}$$

and $\sigma^{IV}_{h,m} > \sigma^{IV}_{h+1,m}$. At each hierarchical level, the overlap of 0.5 between any two successive output MFs implies no reconstruction error in the linguistic-numerical transformation [19].

E. Layer V: Output Linguistic Nodes

The neuron or defuzzification node OV_m defuzzifies the fuzzy composite output generated in layer IV into a crisp value. The output o^{V}_{m} of OV_m is computed using the *height defuzzification* method [20] defined in (10).

$$o^{V}_{m} = y_m = \frac{\sum_{h=1}^{H}\sum_{\ell=1}^{L_{h,m}} o^{IV}_{h,m,\ell} b^{IV}_{h,m,\ell}}{\sum_{h=1}^{H}\sum_{\ell=1}^{L_{h,m}} o^{IV}_{h,m,\ell}} \ , \tag{10}$$

where $b^{IV}_{h,m,\ell}$ represents the kernel of the MF that is employed to describe $OL_{h,m,\ell}$.

III. Progressive Learning Algorithm

Figure 2 depicts the overview of the progressive learning procedure. The learning algorithm consists of three modules; namely: *network expansion*, *associative learning*, and *network*

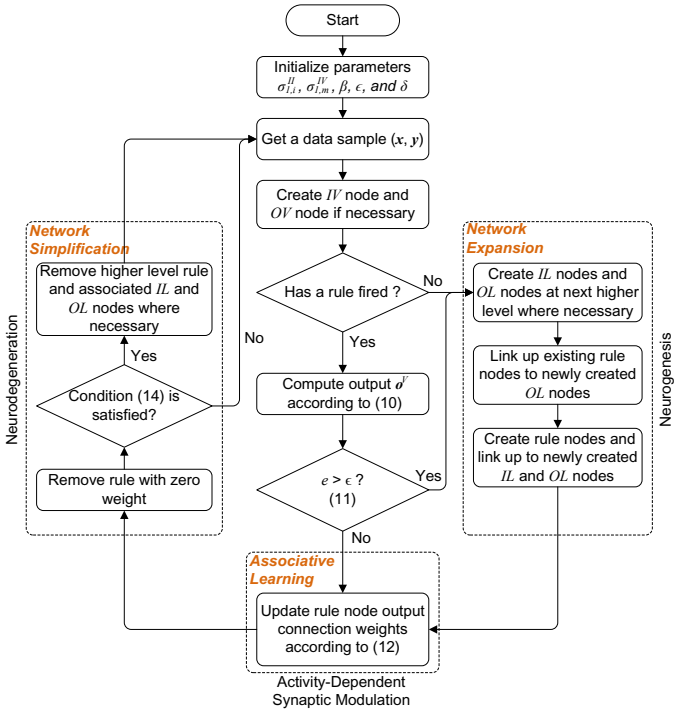

Fig. 2. Progressive learning procedure.

simplification. The learning procedure for each of the module is outlined as follows.

A. Network Expansion Module

The biological network structure plasticity is partially due to *neurogenesis* [22], [23], [24]. The function of neurogenesis was hypothesized to avoid prediction error due to *catastrophic interference* [24] by extending the encoding of new pattern with new neuron. In addition, microscopic examination of a coronal section through the neocortex shows that the neuronal cell bodies are arranged in different layers [25]. Birth dating studies showed that cortical neurons generated earlier reside in deeper layers while later-born neurons migrates past existing layers to form superficial layers [25].

First, to account and model the neurogenesis process and development in neocortex, new higher level rule node and its associated linguistic label nodes (IL and OL nodes) are added to the proposed eFE network whenever the network has a forecast error $e(t)$ exceeding a maximum acceptable error threshold ϵ defined in (11).

$$e(t) = \|\mathbf{o}^V(t) - \mathbf{y}^d(t)\|/M > \epsilon \ , \tag{11}$$

where $\mathbf{o}^V(t)$ is the output vector produced by eFE, and $\mathbf{y}^d(t)$ represents the desirable response the network should produce at time t.

The incremental insertion of new level neurons corresponds to the sequence of neurogenesis process in neocortex, in which neurons that are generated earlier reside in the deeper cortical layers (lower levels of eFE network). In addition, new neurons are added to avoid catastrophic interference and reduce prediction error according to the function of neurogenesis [24].

Second, new input and output linguistic label nodes are added with smaller fuzzy membership "width" (smaller support) at each higher level. Every new higher level linguistic label node is created with receptive field half the size of the immediate lower level linguistic label node. This creates linguistic label nodes in a hierarchical organisation with different receptive fields to simulate the laminar differences in the sensory function among the different cortical layers [16].

As a result, linguistic label nodes with smaller scales (receptive fields) will be present in those regions where the most subtle details are located. Nodes are adaptively allocated with adequate scale in the different regions of the input and output data space to form a sparse approximation of the data. The differences in the sensory function encoded by the different level of linguistic label nodes also allow the proposed network to describe the input and output feature across different scales. The lower level neurons could encode knowledge on more general information, and the higher level neurons to describe knowledge in finer detail.

Third, neurons created earlier (having wider receptive fields in lower levels) will be activated more frequently than higher level neurons. Consistent with physiological findings, in which older neurons are relatively more stable than newer neurons [26], this mechanism allows the lower and older neurons less likelihood from being removed (cf. Sect. III-C). In addition, this mechanism is also consistent with memory retention behaviour in human. Human normally remember more general than specific fact/knowledge.

Fourth, individually adding node as required limit the network complexity by preventing network to memorize training patterns and generalize poorly (large variance case). The network is also adapted according to changing pattern statistics to prevent the network being too simple that it can not even be able to represent training patterns well (large bias case) [27].

B. Associative Learning Module

Numerous evidences have suggested that rehearsal is required to support the consolidation of memories [28], [29], [30]. At the molecular level, the formation and consolidation of *long-term memory* are thought to be ultimately expressed in the form of structural changes at the synapses [31]. At the same time, other studies suggested that the decay of memory traces is the result of an active forgetting mechanism which opposes the strengthening mechanism involved in memory persistence [32], [33]. The progressive learning algorithm (cf. the associative learning process depicted in Fig. 1) captures these two key features; namely: retention and forgetting of memory traces, as follows.

- *Retention Mechanism*: First, to model the involvement of retention mechanism in long-term memory formation, the dynamics of the Hebbian learning rule [34] is incorporated to mediate the synapses between rule nodes and output linguistic term nodes. Synapse is strengthened by the retention term in (12) during correlated activation (firing) between rule node (pre-synaptic neuron) and output linguistic term node (post-synaptic neuron).

- *Forgetting Mechanism*: Second, the forgetting mechanism is interpreted as having a destabilizing effect on the existing stored memories. To account for such a process, a global synaptic decay term is included in (12) to weaken the synaptic strength.

The overall changes in the synaptic strength (Step 4 of the associative learning process depicted in Fig. 1) is simulated in (12),

$$\begin{aligned}\Delta C^{w}_{h,m,\ell,k}(t) &= C^{w}_{h,m,\ell,k}(t) - C^{w}_{h,m,\ell,k}(t-1) \\ &= \underbrace{\min(o^{III}_{h,k}(t), \mu^{IV}_{h,m,\ell}(y^{d}_{m}(t)))}_{\text{retention term}} - \underbrace{\beta \cdot C^{w}_{h,m,\ell,k}(t-1)}_{\text{forgetting term}},\end{aligned} \tag{12}$$

where $C^{w}_{h,m,\ell,k}$ denotes the synapse strength of rule node connection $C_{h,m,\ell,k}$, $\mu^{IV}_{h,m,\ell}(y^{d}_{m}(t))$ represents the membership grade of $OL_{h,m,\ell}$ for output variable node OV_m (Step 2b of associative learning process in Fig. 1), $y^{d}_{m}(t)$ denotes the mth element of the desired output vector $\mathbf{y}^{d}(t)$ at time instance t, and β represents the forgetting rate.

To prevent saturation and loss of input selectivity, the weights of the connections between rule nodes and output linguistic term nodes are normalized according to (13).

$$C^{f}_{h,m,\ell,k}(t) = \frac{C^{w}_{h,m,\ell,k}(t)}{\sum_{\ell=1}^{L_{h,m}} C^{w}_{h,m,\ell,k}(t)} \ , \tag{13}$$

where $C^{f}_{h,m,\ell,k}$ is the normalized weight of rule node connection $C_{h,m,\ell,k}$. $C^{f}_{h,m,\ell,k}$ is the degree (certainty factor) of the output MF $OL_{h,m,\ell}$ associated with $R_{h,k}$. Different certainty factors to the output MFs are used to shape an alternative output fuzzy answer space [18].

The computational model demonstrates the effect of active forgetting and retention memory processes. Only in the presence of sufficient and repeated synaptic reinforcements, either triggered by multiple repetitive training events or reactivation/recollection of such events, can memories be maintained and strengthened. This is consistent with evidence, in which the more frequently an event is recalled, the better and longer it will be remembered [28].

C. Network Simplification Module

Even though higher level rules and associated linguistic label nodes are adaptively added, the consolidated rules will be updated according to changing pattern statistics. Some rule nodes that represent the different localized regions of the data space may at a later stage of adaptation make to produce similar forecast as those rules activated at a lower level.

At each presentation of a data sample, the highest level activated rule $R^{f}_{H_f,k}$ is removed if the following condition (14) is satisfied.

$$\|\mathbf{o}^{R}_{H_f,k} - \mathbf{o}^{R}_{H_f-1,a}\|/M < \delta \ ; \ \exists a \in R^{f}_{H_f-1}, H_f \neq 1 \ , \tag{14}$$

where δ represents the output forecast similarity threshold, H_f represents the highest level of the rules that are activated, $R^{f}_{H_f-1}$ represents the set of lower immediate level rules that are activated, and $\mathbf{o}^{R}_{H_f,k}$ represents the inferred crisp output vector of $R^{f}_{H_f,k}$ using CRI scheme defined in (15) with $h = H_f$.

$$\begin{aligned}\mathbf{o}^{R}_{h,k} &= [o^{R}_{h,k,1}, \ldots, o^{R}_{h,k,m}, \ldots, o^{R}_{h,k,M}]^{T} \ ; \\ o^{R}_{h,k,m} &= \frac{\sum_{\ell=1}^{L_{h,m}} \min(o^{III}_{h,k}, C^{f}_{h,m,\ell,k}) \cdot b^{IV}_{h,m,\ell}}{\sum_{\ell=1}^{L_{h,m}} \min(o^{III}_{h,k}, C^{f}_{h,m,\ell,k})}.\end{aligned} \tag{15}$$

Such higher level rule with smaller receptive field can safely be removed as it describes the localized fuzzy region that is also enclosed by a lower immediate level rule.

In addition, if a rule node $R_{h,k}$ has all its rule node connection weights $C^{w}_{h,m,\ell,k}$ ($1 \leq \ell \leq L_{h,m}$; $1 \leq m \leq M$) reduced to zero then $R_{h,k}$ is removed from the rule base. This is because the rule node is not frequently activated to make it relevant for the present data events. Thus, the network structure is simplified in this process. This step corresponds to structure plasticity related to the removal of neurons and synapses that contributes to the loss of memory (see, e.g., [35], for instance).

IV. Experiments: Simulations

In this section, two experiments are conducted to demonstrate the quality features of the proposed eFE model.

A. Online System Identification of a Nonlinear System

The objective of this experiment is to evaluate the proposed eFE network in one-pass identification of a nonlinear system defined by (16).

$$y_d(t+1) = \frac{y_d(t)}{1 + y^{2}_{d}(t)} + u^{3}(t) \ , \tag{16}$$

where $u(t) \in$ [-1.0, 1.0] is given by $\sin(2\pi t/100)$, and $y_d(t) \in$ [-1.5, 1.5] and $y_d(0) = 0$. The proposed eFE model is benchmarked with existing works; namely, MRAN [36], RANEKF [37], SONFIN [38], SAFIS [14], Simpl_eTS [39], eTS [13], DENFIS [40], FALCON-ART [41], and EFuNN [42] under the same experimental set-up in [14].

Table I lists the consolidated generalization result achieved by the various modelling techniques. The result shows that neural network and TSK modelling techniques deliver better generalization accuracies than the proposed eFE model. The following are the reasons to explain this result.

- TSK-based fuzzy models [43], [44] are used for *precise fuzzy modelling* (PFM) in place of *linguistic fuzzy modelling* (LFM) [45]. The proposed eFE model is based on Mamdani fuzzy model used for LFM.
- The benchmark modelling techniques (MRAN, RANEKF, SONFIN, SAFIS, Simpl_eTS, eTS, DENFIS, FALCON-ART, and EFuNN[1]) utilize a clustering-based prototyping to partition the data space. In contrast, eFE makes use of the more restrictive grid based type of data space partitioning [46]. Clustering-based prototyping poses less

[1]The second layer nodes in EFuNN are fully connected to a rule node in the third layer via a set of connection weights. These connection weights represent the coordinates of the center of the hypersphere in the fuzzy input space for a rule node.

constraint as this methodology provides direct modelling of data distribution in the data space. Hence, clustering-based partitioning of data space usually requires lesser number of prototypes (rule nodes). However, systems based on clustering-based prototyping usually have opaque computing structure. For example, the input fuzzy sets derived by SAFIS have large overlaps that obstruct the understandings of the underlying data structure (refer to [14]).

- The other benchmark systems employ complex operations and perform fine tuning of network parameters. The proposed eFE model does not require such time consuming complex operations. For example, RANEKF and MRAN networks are evolving radial basis neural networks based on the principle of the Resource Allocation Network (RAN) [47]. RANEKF extends the RAN by employing the Extended Kalman Filter (EKF) algorithm in place of the Least Mean Squares (LMS) algorithm. MRAN extends RAN (and RANEKF) by combining the growth criterion of the RAN with a pruning strategy based on the relative contribution of each hidden unit to the overall network output. SAFIS computes the statistical contribution of every rule to the system output and the parameters are tuned with EKF algorithm. eTS has to recursively update its TSK model structure based on the potential of the input data. This is defined based on its distances to all other data points that have been received. As for the DENFIS online model, a weighted recursive Least-Square Estimator (LSE) is used. In SONFIN, the consequent parameters of its TSK rules are tuned either by LMS or Recursive Least Squares (RLS) algorithms and the precondition parameters are tuned by back-propagation algorithm. FALCON-ART tunes the parameters of the MFs using the back-propagation algorithm. Unconstraint accuracy-oriented parameter optimization is also one of the other reasons that will produce significant overlapping of the fuzzy MFs. This obstructs the understandings of the underlying data structure.
- The training and testing data are generated from the same difference equation (16). An accuracy-oriented modelling technique with enough training cycles to tune its network structure and parameters would definitely perform better in this case. On the other hand, the eFE learning algorithm does not try to reduce the error to zero. Under soft computing paradigm, the proposed eFE aims to contain the error between the computed output and desirable values within an acceptable threshold. Hence, the learning error is not asymptotically reduced to zero. It is seldom the case in reality that the unseen events replicate exactly the same as past events. Hence, optimization done at the present time instance has no guarantee in providing an optimal solution that will also generalize well for future unseen events. For one obvious reason, current optimization may produce a solution that over fits to the current set of training data. Section IV-B illustrates this point by evaluating EFuNN, DENFIS and eFE to track a time-varying nonlinear system.

TABLE I
FORECAST RESULTS ON ONLINE NONLINEAR SYSTEM IDENTIFICATION

Reasoning Model	Type	# Rules	Testing RMSE
MRAN[a]	NN	10*	0.0129

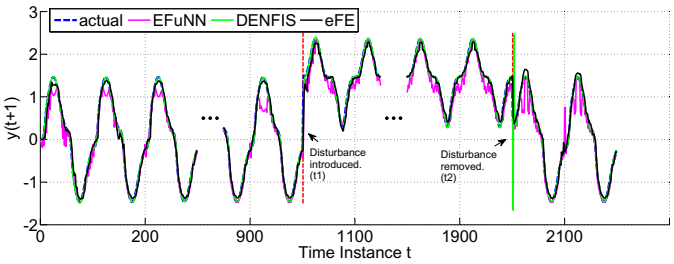

Fig. 3. Forecast of time-varying nonlinear system.

B. Online System Identification of a Time-Varying Nonlinear System

The previous nonlinear dynamic system (16) is modified as shown in (17).

$$y_d(t+1) = \frac{y_d(t)}{1+y_d^2(t)} + u^3(t) + f(t) \ , \qquad (17)$$

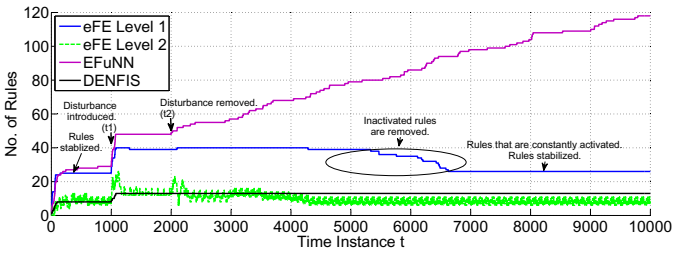
where $f(t)$ simulates the disturbance to be introduced, and is defined in (18),

$$f(t) = \begin{cases} 0, & 0 \le t \le 1000 \text{ and } t \ge 2001; \\ 1, & 1001 \le t \le 2000. \end{cases} \qquad (18)$$

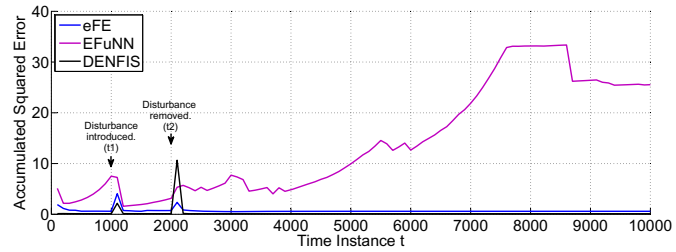
Similar to [48], the eFE model is employed to progressively identify the characteristics of the modified nonlinear dynamic system.

Figure 3 shows the tracking capability of eFE, EFuNN, and DENFIS. The eFE model is able to track the underlying system characteristics right from the initial stage. The proposed eFE model is also able to track new system characteristics when the disturbance $f(t)$ is introduced at time t1 ($t = 1001$) and when it is removed at time t2 ($t = 2001$). EFuNN has large tracking error towards the end of the simulation. DENFIS exhibits large tracking error at time t2.

Figure 4(a) illustrates the corresponding changes to the structure of the three models. For eFE, rule nodes are progres-



(a) Number of rule nodes.



(b) Online learning error.

Fig. 4. Online learning of the time-varying nonlinear system.

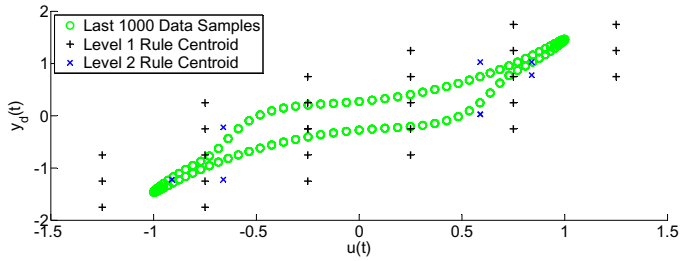


Fig. 5. Rules identified by eFE at the end of simulation ($t = 10000$).

sively added and removed. After the disturbance is removed at t2, the fuzzy rules that describe the disturbance are subsequently removed. This is because these rules are not activated frequently enough to make it relevant for the present data events. For EFuNN, rule nodes are progressively added even when disturbance has been removed at t2. The structure of DENFIS is fixed after the introduction of disturbance at time t1.

Figure 4(b) illustrates the accumulated squared error computed over 100 adjacent time steps. Spikes in the eFE learning error are observed at three instances; namely, during the initial stage at time $t = 0$, when the disturbance is introduced at time t1, and when the disturbance is removed at t2. The increase in learning error at these three instances corresponds to the time when there are changes in the underlying properties of the nonlinear system model. When the disturbance $f(t)$ is removed at t2 only a smaller increase in eFE learning error has been observed. In contrast, EFuNN performs unacceptably. The online learning error of EFuNN generally becomes larger at each time instance. On the other hand, DENFIS has overly learnt and fitted the data. This is because the online learning error accumulated by DENFIS just after the disturbance was removed, is higher than the amount of error accumulated when the disturbance was introduced. The information learnt by DENFIS before the disturbance was introduced is lost even though the number of rules has not reduced. This experiment illustrates that DENFIS accuracy-oriented optimization on the given information causes the network to quickly skew towards current information and forget the information learnt in the past.

Figure 5 plots the distribution of the last 1000 input data samples, and the centroids of the rules identified by eFE. The figure shows more rules are identified near the lower left and upper right region of the input data space. These regions correspond to the input data samples that are more closely located. The lower level eFE rules coarsely describe these regions and higher level rules are added to describe these regions in finer detail.

V. Conclusion

This paper presents an online learning-based hierarchical NFS called, eFE (evolving Fuzzy Ensemble). A progressive learning algorithm is proposed to incrementally modify the hierarchical structure of eFE in accordance with neurophysiological studies. With continuous exposure to external stimuli, the eFE network adapts its structure by allocating nodes and creating links to autonomously support fuzzy data associations. Activity-dependent synapse with global decay learning rule is incorporated such that fuzzy rules that are relevant to the observed training data are reinforced while rules that are inconsistent are weakened. This technique simulates the two opposite mechanisms that are involved in memory persistence [32], [33], [28]. At the same time, the eFE network structure is simplified by removing similar and irrelevant fuzzy knowledge. This is accomplished by removing rules that have similar forecast output, and irrelevant rules that are no longer reinforced by the external stimuli. This technique corresponds to structure plasticity related to the removal of neurons and synapses that contributes to the loss of memory (see, e.g., [35], for instance).

The learning algorithm employed by eFE possesses the distinguishing features of online learning algorithms as outlined in Sect. I. The experimental results are concluded as follows.

- The experimental result showed that the proposed eFE model is able to adequately model the underlying data characteristics of a nonlinear system compared to other benchmarked modelling techniques.
- The tracking capability of eFE model was demonstrated by learning the underlying data characteristics of a time-varying system. Without prior knowledge of the data distribution, the eFE multi-resolution hierarchy structure allows both good generalization and fine detail to be captured. Unlike other benchmark modelling techniques, the experiment also showed the capability of the proposed eFE in removing irrelevant fuzzy knowledge. The experiment also demonstrated that optimization can cause a model to quickly skew towards current information and forget the information learnt in the past.

In conclusion, most batch learning methodologies are computationally intensive with the objective of deriving a global

solution by optimizing certain criterion (e.g. parameter adaptation to minimize prediction error under supervised learning). The extension of offline learning paradigms to online learning mode questions the need for such intensive computation given that only limited information is available at a given time. After all, such form of *limited-knowledge optimization* in time-varying environment would likely not produce a globally optimized solution which directly contradicts the initial idea for optimization in a global sense. Instead, this paper presents a simple fuzzy associative learning algorithm that does not rely on computationally intensive accuracy-oriented optimization to incrementally adapt an ensemble of fuzzy models.

***Abstract*- machine learning algorithms, which have been considered as robust methods in different computational fields, assume that the training and test data are drawn from the same distribution. This assumption may be violated in many real world applications like bank failure prediction because training and test data may come from different time periods or domains. An efficient novel algorithm known as Fuzzy Refinement (FR) is proposed in this paper to solve this problem and improve the performance. The algorithm utilizes the fuzzy system and similarity concept to modify the instances' labels in target domain which was initially predicted by shift-unaware Fuzzy Neural Network (FNN) proposed by [1]. The experiments are performed using bank failure financial data of United States to evaluate the algorithm performance. The results address a significant improvement in the predictive accuracy of FNN due to applying the proposed algorithm.**

Keywords-Transfer Learning; Fuzzy Neural Network; Fuzzy Sets; Long Term Prediction; Bank Failure Prediction

1. INTRODUCTION

Although machine learning technologies have gained remarkable attention among researches in different computational fields including classification, clustering and prediction, most of them work very well under a common assumption that the training data and test data has the same future space and same distribution. So once the distribution or feature space changes, the models need to be rebuild and retrained from the scratch using new collected training data. In many real world applications, particularly finance business, recollecting new training data and retraining the model is very expensive or practically impossible. For example, more and more labeled financial data become out of date and may not follow the same distribution as time goes by and thus past labeled data cannot be used to reliably predict financial situation of an organization. It would be so useful if the necessary of the recollecting labeled data can be reduced and the data from different time periods or domains can be utilized to assist the current learning task such as failure prediction. In this situation a new field of study has been emerged recently which is called *Transfer Learning*.

Transfer learning, which is different from the traditional machine learning and semi-supervised algorithms [2-4], considers that the domains and tasks of training and testing data can be different [5]. The study of transfer learning has been inspired by this fact that human beings can utilize the knowledge, which learned previously, to solve upcoming similar but not identical problems much faster and even better. The study of Transfer learning has begun since 1995 in different names: learning to learn, life-long learning, meta learning, multi-task learning [6]. According to the definition of Transfer learning which will be explained in the next Section, this techniques can be categorized into different settings.

However there are many researches in this field, most of them have used statistical models and there are a few studies have used soft computing techniques. In this paper a novel Transductive Transfer learning algorithm is proposed for fuzzy neural network using fuzzy sets concept which has been proved to be a successful soft computing techniques in machine learning. Likewise most of existence methods aim to refine decision boundary and models while the proposed algorithm has developed a method namely bridge refinement [7] to modify the prediction labels in target domain and focus on currently given test data. This ability makes the algorithm more practical and independent from the prediction method.

The rest of paper is organized as follow. In Section 2, some preliminaries concepts including the definition of Transductive Transfer learning and related works are given. Section 3 proposes the Fuzzy Refinement (FR) algorithm and Section 4 describes the experimental illustration and results comparing Fuzzy Neural Network (FNN) with FNN-FR (FNN using Fuzzy Refinement). Section 5 concludes this paper and discusses future researches.

2. PRELIMINARIES AND RELATED WORKS

In this section the definition of transfer learning and particularly Transductive Transfer learning is introduced and then the related works are presented. Also the FNN, which is proposed by [1], is briefly explained at the end.

A. Definition 1 (Domain)

A domain consists of two components: 1) feature space X and 2) marginal probability distribution $P(X)\ where\ X = \{x_1, \dots, x_n\}$, Domain is denoted by $D = \{X, P(X)\}$.

B. *Definition 2 (Task)*

A task consists of two components: 1) a label space $Y = \{y_1, \dots, y_m\}$ and an objective predictive function $f(.)$ which is not observed and to be learned by pairs$\{x_i, y_i\}$, Task is denoted by $T = \{Y, f(.)\}$.

C. *Definition 3 (Transfer learning)*

Given a source domain D_s and learning task T_s, a target domain D_t and learning task T_t, transfer learning aims to help improve the learning of the target predictive function $f_t(.) in\ D_t$ using the knowledge in $D_s\ and\ T_s, where\ D_s \neq D_t\ or\ T_s \neq T_t$.

D. *Definition 4 (Transdutive Transfer learning)*

A category of transfer learning in which $T_s = T_t$ and $D_s \neq D_t$ which implies that either $X_t \neq X_s\ or\ P_t(x) \neq P_s(x)$, in this situation no labeled data is available in the target domain while a lot of labeled data in the source domain are available.

E. *Related works*

Transductive Transfer learning was first proposed by [8]. It mentioned that the source and target tasks are the same, although the domains are different due to their distribution. Almost all studies in Transductive Transfer learning can be categorized into two groups[6]:

1) *Transferring the knowledge of instances:* this approach is motivated by the importance of samples and it tries to find an optimum weight for each instance to learn a precise model for target domain. There are some papers in this category which can be found in a recently published book [9] by Quionero-Candela et al.

2) *Transferring the knowledge of feature representation:* this approach focuses on feature space and attempts to extract and/or convert some relevant features which reduce the difference between the domains. Blitzer et al [10-12] proposed SCL algorithm to define a pivot features on the target domain from both domains and then uses unlabeled instances from target do create the classification model. Dai et al. [13] proposed a co-clustering based algorithm to propagate the label information across domains. In [7] Xing et al. introduced a novel algorithm known as bridge refinement to modify the predicted labels of instances from target domain. This study, which is the base idea of this paper, utilizes mixture distribution of the training and test data as a bridge to transfer feature distribution from source domain to target one. Xue et al. [14] presented a cross-domain text classification known as TPLSA to integrate target instances and source instances into a unified probabilistic model.

F. *Fuzzy Neural Network*

Assume that $X = [x_1, x_2, \dots, x_n]$ and $Y = [y_1, y_2, \dots, y_m]$ represent the vector of inputs and outputs respectively to and from the network. In addition, assume the vector $D = [d_1, d_2, \dots, d_m]$ represents the desired (actual) outputs required during the learning phase.

The proposed network has five layers of nodes: (1) Input layer consisting of input nodes $It_i, i \in \{1,2, \dots, n\}$, which have a single input x_i. (2) Input cluster layer including cluster nodes $ITerm_{ij}, i \in \{1,2, \dots, n\}\ \&\ j \in \{1, \dots, k_i\}$ which represent linguistic terms for each input. For instance, $ITerm_{23}$ represents the third linguistic term of input x_2. (3) Rule layer consisting of rule nodes $R_h, h \in \{1,2, \dots, l; l = \sum_{i=1}^{n} k_i \times \sum_{i=1}^{m} k_i\}$,which are representative of each rule and connect only one labels of each input ($x_i\ ; i \in \{1,2, \dots, n\}$) to one labels of each output ($y_i; i \in \{1,2, \dots, m\}$) . (4) Output cluster layer including cluster nodes $OTerm_{ij}, i \in \{1,2, \dots, m\}\ \&\ j \in \{1, \dots, k_i\}$ which represent linguistic terms for each output. For instance, $OTerm_{35}$ represents the fifth linguistic term of output y_3. (5) Output layer consisting of output nodes $Ot_i, i \in \{1,2, \dots, m\}$, which have single output y_i. Figure 1 shows the structure of the proposed FNN.

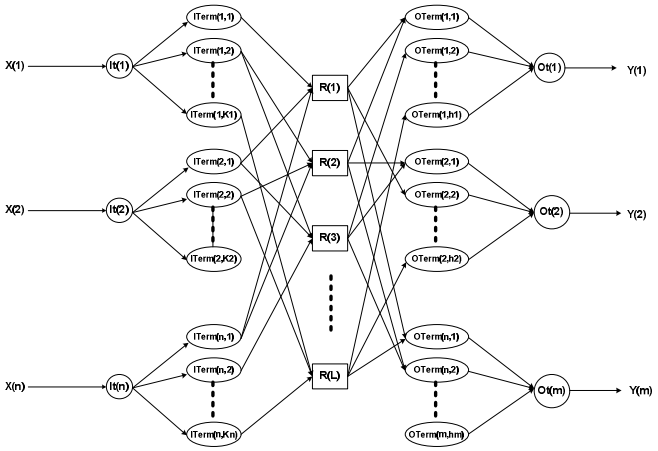

Fig1. FNN structure

The rule generation algorithm is developed by formulating an algorithm which is based on the structure of our proposed FNN. In this algorithm, ISP_h is the terms for all input linguistic terms (layer 2 nodes) that contribute to antecedent of rule node R_h and OSP_h refers to all output linguistic terms (layer 4 nodes) that form the consequent of rule node R_h:

$$ISP_h = \{ITerm_{1P_1}, ITerm_{2P_2}, \dots, ITerm_{nP_n}\} \quad and$$
$$OSP_h = \{OTerm_{1Q_1}, OTerm_{2Q_2}, \dots, OTerm_{mQ_m}\}$$

if and only if

$$R_h: \ \boldsymbol{If}\ x_1 is\ ITerm_{1P_1}\ and\ x_2\ is\ ITerm_{2P_2} and \dots and\ x_n\ is\ ITerm_{nP_n} \boldsymbol{then}\ y_1\ is\ OTerm_{1Q_1} and\ y_2\ is\ OTerm_{2Q_2}\ and \dots and\ y_m\ is\ OTerm_{mQ_m}) \quad (1)$$

The rule generation algorithm has three main steps as follows: Algorithm 1:

Step 1: Firing input and desired vectors

The input vector $X(T) = [x_1(T), \dots, x_n(T)]$ and the desired vector $D(T) = [d_1(T), \dots, d_m(T)]$ are feed to the network through layer 1 and layer 5 respectively at T-th

epoch. According input and output linguistic terms (fuzzy sets) membership function, the membership value of inputs and outputs in each term is evaluated and then the linguistic terms of each input and output with maximum membership value is selected:

$$MITerm(T) = \{ITerm_{1b_1}, ITerm_{2b_2}, \dots, ITerm_{nb_n} \mid \mu_{ITerm_{ib_i}}(x_i(T)) = Max\left\{\mu_{ITerm_{ij}}\ (x_i(T)), j \in \{1, \dots, k_i\}\right\}\} \quad (2)$$

$$MOTerm(T) = \{OTerm_{1b_1}, OTerm_{2b_2}, \dots, OTerm_{mb_m} \mid \mu_{OTerm_{ib_i}}(d_i(T)) = Max\left\{\mu_{OTerm_{ij}}\ (d_i(T)), j \in \{1, \dots, k_i\}\right\}\} \quad (3)$$

Step 2: Indicating nominated rule

In this step, the rule which has to be nominated for updating is selected in each epoch. The rule which satisfies (4) in epoch T-th is qualified for an update:

$$ISP_h = MITerm(T)\ and\ OSP_h = MOTerm(T)$$
$$h \in \{1,2, \dots, l\},\ \ l = \sum_{i=1}^{n} k_i \times \sum_{i=1}^{m} k_i \} \quad (4)$$

Step 3: Rule updating

To update the rule weight in epoch T-th, equation (5) is applied:

$$W_h(T) = W_h(T-1) + \left(M_{ISP_h}(T) \times M_{OSP_h}(T)\right),$$
$$W_h(0) = 0, h \in \{1,2, \dots, l\} \quad (5)$$

where $M_{ISP_h}(T) = \mu_{ITerm_{1b_1}} \times \mu_{ITerm_{2b_2}} \times \dots \times \mu_{ITerm_{nb_n}}$ and $M_{OSP_h}(T) = \mu_{OTerm_{1b_1}} \times \mu_{OTerm_{2b_2}} \times \dots \times \mu_{OTerm_{mb_m}}$.

To prune the weak rules at the end of the rule generation phase, a predefined threshold parameter $Thresh$ is considered and then each rule satisfying (6) will be pruned at the end of the training step.

$$l \times \left(\frac{W_h}{\sum_{k=1}^{l} w_k}\right) < Thresh \quad (6)$$

Through using this algorithm we can obtain an initial consistent and compact fuzzy rule base which needs to be modified and updated to gain more accurate results. In the next section, a learning algorithm is proposed to optimize the rule base.

The adaptive inference-based learning algorithm aims to update the fuzzy rule base, which is obtained by rule generation algorithm, to improve the prediction accuracy. This algorithm tries to adapt the parametric t-norm of inference system to reduce the significance of rules causing errors and consequently augment accuracy.

Assume that $X(T) = [x_1(T), \dots, x_n(T)]$ and $D(T) = [d_1(T), \dots, d_m(T)]$ are input and desired output vectors in T-th epoch of training respectively and there is a fuzzy rule base that includes l rules and each rule, R_i ($i^{th}\ rule$) has the form as shown in (7).

$$R_i: If\ x_1\ is\ ITerm_{1j_1} \dots and\ x_n\ is\ ITerm_{nj_n}$$
$$Then\ \ y_1\ is\ OTerm_{1h_1} \dots and\ y_m\ is\ OTerm_{mh_m} \quad (7)$$

The proposed **adaptive inference-based learning algorithm** has seven steps as follows:

Algorithm 2:

Step 1: Fuzzyfying

Input nodes act as singleton fuzzifier that fuzzyfy the crisp-valued inputs. So, the activation function of each node in layer 1 is defined as:

$$Z_i^{(1)}(T) = f^{(1)}(x_i(T)) = \mu_{\tilde{X}_i}(\tilde{x}_i(T)) = \begin{cases} 1, & if\ \tilde{x}_i(T) = x_i(T) \\ 0, & Otherwise \end{cases} \quad i \in \{1,2, \dots, n\} \quad (8)$$

where $\tilde{x}_i(T)$ is the fuzzyfied equivalent of crisp input $x_i(T)$ and $Z_i^{(1)}(T)$ is the output of node $It_i, i \in \{1,2, \dots, n\}$ at T-th epoch.

Step 2: Antecedent matching

To perform antecedent matching of fuzzyfied inputs against linguistic terms, input cluster nodes compute the similarity measure which is the input membership value in each term. The activation function of each node in layer 2 is defined as:

$$Z_{ij}^{(2)}(T) = f^{(2)}\left(Z_i^{(1)}(T)\right) = \mu_{ITerm_{ij}}(x_i(T)) = \begin{cases} 0, & if \quad x_i(T) \le l_{ij} \\ \frac{x_i - l_{ij}}{u_{ij} - l_{ij}}, & if \quad l_{ij} \le x_i \le u_{ij} \\ 1, & if \quad u_{ij} \le x_i \le v_{ij} \\ \frac{r_{ij} - x_i}{r_{ij} - u_{ij}} & if \quad v_{ij} \le x_i \le r_{ij} \end{cases}$$
$$i \in \{1,2, \dots, n\} \quad j \in \{1,2, \dots, k_i\} \quad (9)$$

where $Z_{ij}^{(2)}(T)$ is the output of node $ITerm_{ij}$ at T-th epoch.

Step 3: Rule fulfillment

To calculate the strength of activation of an antecedent for all rules with input vector $X(T)$, rule nodes compute the degree of rule fulfillment as their outputs. The higher the degree of fulfillment, the greater is the compatibility of the input to the antecedent of the rule. Hence, the activation function of each node, R_h ; $h \in \{1,2, \dots, l\}$, in layer 3 is defined as:

$$Z_{R_h}^{(3)}(T) = f^{(3)}\left(Z_{(ij)_h}^{(2)}(T), i \in \{1,2, \dots, n\}\right) =$$

$$T\left(Z_{(ij)_h}^{(2)}(T),\ i \in \{1,2,\dots,n\}\right) \quad (10)$$

where $Z_{(ij)_h}^{(2)}(T)$ is the output of the j-th term of the i-th input that is connected to the rule R_h and T is the conjunction operator. In order to adapt the inference system, this operator is considered as parameterized t-norm. Some researchers [15, 16] have shown that a tuning parameter can significantly improve the accuracy of linguistic fuzzy systems. Therefore, Dubios t-norm shown in (13) is used as conjunction operator in this step because it provides better accuracy than other parametric t-norms [15].

$$T_{Dubios}(x,y,\alpha) = \frac{x \times y}{\max(x,y,\alpha)} \quad (11)$$

Dubios t-norm operates as the minimum and an algebraic product with $\alpha = 0\ and\ \alpha = 1$ repectively. The activation function is represented as:

$$Z_{R_h}^{(3)}(T) = f^{(3)}\left(Z_{(ij)_h}^{(2)}(T), i \in \{1,2,\dots,n\}\right) = T_{Dubios}\left(Z_{(ij)_h}^{(2)}(T), i \in \{1,2,\dots,n\}, \alpha_h(T)\right) = \left(\prod_{i=1}^{n} Z_{(ij)_h}^{(2)}(T)\right)/Max\{Z_{(ij)_h}^{(2)}(T), i \in \{1,2,\dots,n\}\}, \alpha_h(T)\Big) \quad (12)$$

where $Z_{R_h}^{(3)}(T)$ is the output of node R_h at T-th epoch. In addition,$\alpha(0) = (\alpha_1(0), \alpha_2(0), \dots, \alpha_l(0))$ is initialized as 0 at the beginning of the learning algorithm, and then, during the feedback learning phase, each α_h may be increased separately.

Step 4: Consequent derivation

In this step, an aggregator operator is used to derive the consequent of fuzzy rules. Max operator which is considered as s-norm uses rule weights and rule outputs to compute the inferred output according to each rule in the rule base. Therefore, the activation function for each node in layer 4 becomes:

$$Z_{ij}^{(4)}(T) = f_{ij}^{(4)}\left(Z_{R_h}^{(3)}(T), h \in \{1,\dots,l\}, W_h\right) = Max\left(\prod_{h=1}^{l} W_h \times Z_{R_h}^{(3)}(T)\right) \quad (13)$$

where $Z_{R_h}^{(3)}(T)$ is the output of the h-th rule node in layer 3 that is connected to $OTerm_{ij}$ as its consequent.

Step 5: Deffuzyfying

To deffuzify the derived fuzzy outputs, the weighted center of averaging (COA) technique [17] is used. So, the activation function in layer 5 is as follows:

$$y_i(T) = Z_i^{(5)}(t) = f_i^{(5)}\left(z_{ij}^{(4)}(T), j = (1,2,\dots,h_j)\right) = \frac{\sum_{j=1}^{h_j}(Z_{ij}^{(4)}(T) \times \tilde{m}_{ij})}{\sum_{j=1}^{h_j} Z_{ij}^{(4)}(T)} \quad (14)$$

where $\tilde{m}_{ij} = \frac{u_{ij}+v_{ij}}{2}$ and $y_i(T)$ is the output of i-th node Ot_i in layer 5.

Step 6: Error evaluation

During the feed forward phase, the input vector $X(T)$ is presented to the network and the output vector $Y(T)$ results in T-th epoch. At the beginning of the feed backward pass, $Y(T)$ is compared against the desired output vector D(T) and the error is used to modify the vector $\alpha(T)$ in T-th epoch. Regarding the framework of imbalanced data-sets, the geometric mean presented in (2) should be used to calculate the error for all outputs. The following equation denotes the error in the t-th epoch.

$$Error(T) = \left(1 - G(T)\right) = \left(1 - \sqrt{\frac{TP(T)}{TP(T) \times FN(T)} \times \frac{TN(T)}{FP(T) \times TN(T)}}\right) \quad (15)$$

where $G(T)$ is the accuracy of model till T-th epoch of training.

Step 7: Modifying t-norm

All links in the proposed network do not have a particular weight which affects the error in the feed backward phase. The first issue to be taken into consideration in order to achieve better accuracy is the significance of antecedents that make inaccuracy should be reduced. Dobius t-norm performs like minimum t-norm if the following equation (15) becomes satisfied and Dobius t-norm approaches to product t-norm, which reduces the significance of the antecedent causing inaccuracy, by increasing $\alpha_h(T)$. Hence, better prediction can be achieved by increasing $\alpha_h(T)$ of ruleR_h which participates in producing $Error(T)$.

$$Z_{(ij)_h}^{(2)}(T) \geq \alpha_h(T) \quad (16)$$

To modify the parameter $\alpha_h(T)$ in each iteration (17) is used.

$$\alpha_h(T+1) = \alpha_h(T) - \sigma \times (Error(T) \times W_h) \quad (17)$$

where σ is a positive experimental consistent less than 1.

3. FUZZY REFINEMENT ALGORITHM

The bridge refinement algorithm[7] is motivated by PageRank algorithm [18] and it assumes that the conditional probability of a specified label C given an instance$d$, does not vary among different distributions: $P_{D_s}(C|d) = P_{D_{sUt}}(C|d) = P_{D_t}(C|d)$ although the marginal probability of instance d, $P(d)$, varies. The reason is based on the fact that if an identical instance appears in the target and source domain, the predicted label should be the same. In further, the more similar instances are in the target domain, the more the probability is they have the same label. This situation forms a mutual reinforcement relationship between instances in target domain

and source domain and can be used to correct the predicted labels. Not only is this assumption considered in our research but also a complementary idea of that is applied. We assume that more different instances in the target domain, the less the probability is they have the same label.

Given $\widetilde{F^s} = \{\widetilde{f^s}_1, \dots, \widetilde{f^s}_m\}$ and $\widetilde{F^t} = \{\widetilde{f^t}_1, \dots, \widetilde{f^t}_m\}$ are the fuzzy feature sets for source and target domain respectively. The number of these features is the same for both target and source domains but the membership function of these fuzzy sets are different. This assumption implies a Transductive Transfer learning problem in which the feature space is the same but the distribution is different. Given $X^s = \{x_1^s, \dots, x_{n_s}^s\}$ and $X^t = \{x_1^t, \dots, x_{n_t}^t\}$ are the instances of source and target domain respectively. Given $\tilde{Y} = \{\tilde{y}_1, \dots, \tilde{y}_l\}$ is the predictive fuzzy label set which is the same for both domains. Given $G(.)$ is a predictive model, which is fuzzy neural network (FNN) proposed by [1], such that $G(x_i) = \{\mu_{\tilde{y}_1}(x_i), \dots, \mu_{\tilde{y}_l}(x_i)\}$ is the vector of membership value of x_i that belongs to each label. The parameter k is the number of the most and least similar instances which is applied to refine the predicted labels and α is used to specify the degree of refinement in each iteration. The steps of Fuzzy Refinement (FR) algorithm are described as follow.

[Fuzzy Refinement algorithm]

Input: F^s , F^t , X^s, X^t, $\tilde{Y}$, $G(.)$, k and $\propto$.

Output: Label matrix for instances of target domain, MR.

[Begin]

Step 1: At the first step the singleton fuzzifier is used as follow to fuzzyfy the crisp-valued of instances from both domains.

$$\mu_{\tilde{X}_i}(\tilde{x}_i(T)) = \begin{cases} 1, & if\ \tilde{x}_i(T) = x_i \\ 0, & Otherwise \end{cases} \quad i \in \{1,2,\dots,n\} \qquad (18)$$

where $\tilde{x}_i$ is the fuzzyfied equivalent of crisp input x_i , $i \in \{1,2,\dots,n\}$.

Step 2: In this step the similarity matrix is calculated by following equation:

$$M_{n_s \times n_t} = \{m_{(i,j)} | m_{(i,j)} = 1 - \sqrt{\sum_{k=1}^{m}((\mu_{\widetilde{f_k^s}}(x_i^s) - \mu_{\widetilde{f_k^t}}(x_i^t))^2}\} \qquad (19)$$

Step 3: In this step the pseudo label matrix for target domain instances and label matrix for source domain instances are calculated by FNN as follow.

$$G_{n_s \times l}^s = \{g_{(i,j)}^s | g_{(i,j)}^s = FNN(x_i^s) = \mu_{\widetilde{y_j}}(x_i^s)\} \qquad (20)$$

$$G_{n_t \times l}^t = \{g_{(i,j)}^t | g_{(i,j)}^t = FNN(x_i^t) = \mu_{\widetilde{y_j}}(x_i^t)\} \qquad (21)$$

Step 4: In this step for each target instance, k most similar and k least similar instances from source domain are found. N^i and V^i includes the k most similar and k least similar instances from source domain to target instance i.

$for\ i = 1\ to\ n_t$

$$N_{1\times k}^i = \{n_1^i, \dots, n_k^i\} = \{n_j^i = x_p^s | m(p,i) = Max\{M(.,i)\}, j = 1, \dots, k\} \qquad (22)$$

$$V_{1\times k}^i = \{v_1^i, \dots, v_k^i\} = \{v_j^i = x_p^s | m(p,i) = Min\{M(.,i)\}, j = 1, \dots, k\} \qquad (23)$$

$Next\ i$

Step 5: The pseudo label for each instance from target domain is refined in this step according to the following equation. $\widetilde{MR}_{n_t \times l}$ is the fuzzy label matrix for instances of target domain.

$For\ i = 1\ to\ n_t$

  $For\ j = 1\ to\ l$

    Do

$$MR_{(i,j)}(t) = (1-\propto) g_{(i,j)}^t + \propto \left(\frac{(\sum_{p=1}^{k} \mu_{\widetilde{y_j}}(n_p^i) - \sum_{p=1}^{k} \mu_{\widetilde{y_j}}(v_p^i))}{k}\right)(MR_{(i,j)}(t-1)) \qquad (24)$$

    Until MR converges

  Next j

Next i

[End]

As can be seen from the equation (24) the refinement is based on the fact that the label of most similar and least similar instances to the target instance is used to modify the pseudo label of target instance which was initialized by FNN. As result of this algorithm a fuzzy label matrix for all instances of target domain is achieved. Each row of this matrix indicates the membership value of one instance to all label classes. To find the final label for each instance namely x_i^t , the following equation can be used.

$$\text{MR} = \arg max_j \{\widetilde{MR}_{i,j} | j = 1, \dots, l\} \qquad (25)$$

It should be mentioned that the above algorithm is implemented by Matlab which has the ability of matrix language programming.

4. EXPERIMENTS

In this section we would like to validate the proposed algorithm using real world financial data considering different scenarios. The task in this experiment is bank failure prediction and the prediction label has two classes: Failed; Survived. We perform the experiments to examine the algorithm whether it can transfer knowledge from different time periods.

A. Data Sets

The data set and financial variables are extracted from Call Report Data, which is downloaded from the website of Federal Reserve Bank of Chicago (http://www.chicagofed.org) and the status of each bank is identified according Federal Financial Institutions Examination Council (http://www.ffiec.gov/nicpubweb/nicweb/NicHome.aspx). The dataset, which is showed in Table 1, includes the observation period of the Survived banks of 21 years from Jun 1980 to Dec 2000 and based on the history of each bank in FFIEC.

There are 548 Failed banks and 2555 Survived ones which are presented by [19, 20] . Although, Tung et al. [19] used nine financial features, according to their statistical significance and correlation, it is observed that the model with three features has less created rules, less computational load and more prediction accuracy. Each feature is ranked based on the importance of a feature as a result of a future selection process and three features with the highest grade are selected [20]. The definition of all features and their expected impacts on bank failure are described in Table 2. The proposed approach is run by nine inputs and three inputs separately and the results are then compared.

TABLE 1
DATA SETS

Year	Total Number banks	Number of Survived banks	Number of Failed banks
1990	2156	1843(85.48%)	313 (14.52%)
1995	2539	2192(86.34%)	347(13.66%)
1998	2943	2585(87.84%)	358(12.16%)
2000	3103	2555(82.34%)	548(17.66%)

Number of available records in second data set for each scenario

TABLE 2
VARIABLES

Financial Variable
1) *CAPADE: average total equity capital /average total assets
2) OLAQLY: average (accumulated)loan loss allowance/average total loans and leases, gross
3) PROBLO: Loans 90+days late/average total loans & leases, gross
4) *PLAQLY: Loan loss provision /average total loans and leases, gross
5) NIEOIN: noninterest expense/operating income
6) NINMAR: (total interest income – interest expense)/average total asset
7) *ROE: (net income after tax +applicable income taxes)/average total equity capital
8) LIQUID: (average cash + average federal funds sold)/ (average total deposit + average fed funds purchased + average banks' liability on acceptance + average other liabilities)
9) GROWLA: (total loans & leases (t) – total loans & leases (t-1))/ total loans & leases (t-1)

Definition of variables (three selected variables are marked with *).

B. Research design and preprocessing

The domain instances (training data) are selected from data until year 1990 and the target instances (test data) are selected from records of year 1995, 1998 and 2000, 5, 8 and 10 years after 1990 (see Table 1). We compare the results of FNN using proposed algorithm denoted as FNN-FR with FNN to find out the improvement gained due to fuzzy refinement. Likewise the evaluation is performed using two categories of feature sets: nine variables; three variables. In conclusion the experiments have been performed based on 12 scenarios.

To reduce the influence of imbalance data-sets problem, the SMOTE technique is applied to train data sets. The number of Failed banks increases to the number of Survived ones to achieve balanced data set which improves the accuracy of prediction without losing important information.

In each scenario, the training data set splits into two pools: (1) Failed banks denoted with output 1; (2) Survived banks denoted with output 0. There are five cross-validation groups which include instances of both pools randomly to form the training set. The training set of the five groups are mutually exclusive. The FNN and FNN-FR are trained using training data sets and then evaluated by the testing data sets. The accuracy of the each experiment, which is the mean value of cross-validation groups' accuracy, is calculated using following equation.

$$GM = \sqrt{\frac{TP}{TP+FN} \times \frac{TN}{FP+TN}} \tag{9}$$

where $\frac{TP}{TP+FN}$ is called *sensitivity* and $\frac{TN}{FP+TN}$ is called *specificity,* measure the effectiveness of the prediction algorithm in any class. The proposed metric (9) is a geometric mean of *sensitivity* and *specificity,* because both of them are expected to be high simultaneously

C. Experiment results analysis

In this section the results which are gained from the experiment is reported. To ensure that the Fuzzy Refinement (FR) algorithm for Transfer learning makes significant improvement, the performance of FNN applying FR (FNN-FR) is compared with FNN which generates unrefined results.

As a result of this comparison, the Figure 2 represents the difference of FNN and FNN-FR performance using three financial features. In all data sets the FNN-FR outperforms the FNN. The relative increase is achieved by 10%, 14% and 15% on 1995, 1998 and 2000 data sets. Surprisingly it shows that the influence of proposed algorithm become more significant once the period of prediction become farther and so the difference between target domain and source domain become greater. Figure 3 shows the results of FNN and FNN-FR using nine financial features. The relative growth is 10%, 20% and 25% on 1995, 1998 and 2000 data sets. This growth in accuracy, which is gained due to applying proposed algorithm, is more than previous experiments. The reason may be that the proposed algorithm works better on larger feature space and more number of features. The summary of all 12 scenarios results are shown in the Table 3.

To clarify this improvement clearly the t-test is applied on the level of confidence of 0.05 on 12 scenarios. As it is showed in Table 4, the null hypothesis of the equality of average accuracy is rejected for FNN-FR. So it can be concluded that the proposed algorithm can significantly improve the predictive accuracy of FNN for long term prediction.

FNN_FR	87.3950				

The t-test result for comparison of FNN and FNN-FR

D. Parameter sensitivity

The proposed algorithm has two parameters, *k and* ∝, which need to be set in performing experiments. In this section we investigate the influence of these parameters on the performance of the Fuzzy refinement algorithm. To do this the performance of the algorithm is examined using different value of these parameters on 6 scenarios. The accuracy of the algorithm for different value of *k* is shown in the Figure 4. It shows that the performance is not greatly sensitive to *k* as long as *k* is large enough. According to this figure the value of 80 is the best value for *k* which is chosen in this research. Figure 5 shows the accuracy by applying different values of ∝. It shows that 0.66 is the best value for ∝ which is selected in this paper.

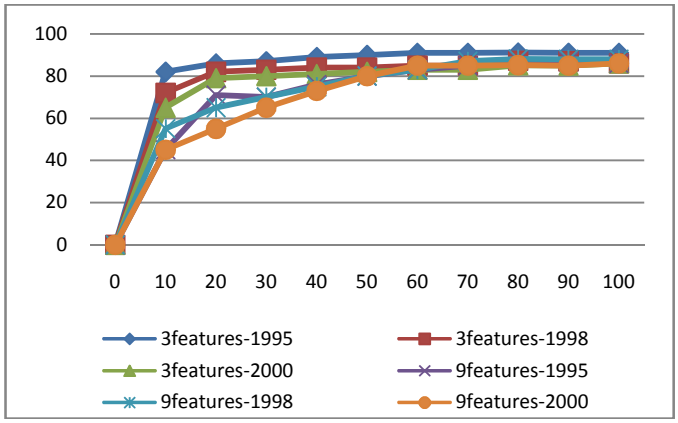

Figure 4. The accuracy of FNN-RF using different value of K

5. CONCLUSION AND FUTURE STUDY

In this paper Fuzzy Refinement algorithm is proposed to solve the Transductive Transfer Learning problem. The algorithm concentrates on the modification the instances' labels in target domain and uses the fuzzy concepts to improve the predictive accuracy. The FNN which is proposed by [1] is considered as prediction model to determine the initial labels for target instances. According to the empirical results, the proposed algorithm brings about remarkable improvement in performance. It demonstrates a

significant increase in predictive accuracy when the algorithm is applied particularly for farther time period ahead prediction

The approach which is mentioned in [7] to apply two refinement steps can be applied in the algorithm as future research. Also developing an algorithm based the proposed algorithm which can extract the relevant features to reduce the difference between domains is desirable for future work. Finally evaluating the proposed algorithm in the situation that there are some labeled data in target domain can be an interesting study for future as well.

***Abstract*—Most of existing search engines retrieve web pages by means of finding exact keywords. Traditional keyword-based search engines suffer several problems. First, synonyms and terms similar to keywords are not taken into consideration to search web pages. Users may need to input several similar keywords individually to complete a search. Second, traditional search engines treat all keywords as the same importance and cannot differentiate the importance of one keyword from that of another. Third, traditional search engines lack an applicable classification mechanism to reduce the search space and improve the search results. In this paper, we develop a fuzzy search engine, called Fuzzy-Go. First, a fuzzy ontology is constructed by using fuzzy logic to capture the similarities of terms in the ontology, which offering appropriate semantic distances between terms to accomplish the semantic search of keywords. The Fuzzy-Go search engine can thus automatically retrieve web pages that contain synonyms or terms similar to keywords. Second, users can input multiple keywords with different degrees of importance based on their needs. The totally satisfactory degree of keywords can be aggregated based on their degrees of importance and degrees of satisfaction. Third, the domain classification of web pages offers users to select the appropriate domain for searching web pages, which excludes web pages in the inappropriate domains to reduce the search space and to improve the search results.**

Keywords- Fuzzy Search Engine; Fuzzy Ontology; Semantic Search

I. INTRODUCTION

As the massive data on the internet is increasing rapidly, internet search engines have become the essential ways to find information. Most of existing search engines, such as Google, Yahoo, MSN, ASK, Baidu, and Bing, retrieve web pages by means of finding exact keywords. These keyword-based search engines collect and analyze web pages through web crawlers. While users input keywords to search web pages, web pages that contain exact keywords are retrieved and ranked. For example, the Google search engine sorts the search results by their Page-rank scores, Relevance scores and Local scores. However, traditional keyword-based search engines suffer several problems:

- Synonyms and terms similar to keywords are not taken into consideration to search web pages. Users may need to input several similar keywords individually to complete a search. The restriction of exact keywords makes it inconvenient for users to search web pages. Many valuable web pages would be omitted if users did not search for several similar keywords individually.
- While users input several keywords to search web pages, different keywords may have different degrees of importance in their opinions. Traditional search engines treat all keywords as the same importance and cannot differentiate the importance of one keyword from that of another.
- The problem of information overload makes it difficult for users to find really useful information from a large amount of search results. Traditional search engines lack an applicable classification mechanism to reduce the search space and improve the search results.

To alleviate the mentioned problems, we have applied the fuzzy logic theory and the semantic search techniques to develop a fuzzy search engine, called Fuzzy-Go. First, a fuzzy ontology is constructed by using fuzzy logic [15] to capture the similarities of terms in the ontology, which offering appropriate semantic distances between terms to accomplish the semantic search of keywords. The Fuzzy-Go search engine can thus automatically search web pages that contain synonyms or terms similar to keywords. Second, users can input multiple keywords with different degrees of importance based on their needs. The totally satisfactory degree of keywords can be aggregated based on their degrees of importance and degrees of satisfaction. Third, the domain classification of web pages offer users to select the appropriate domain for searching web pages, which excludes web pages in the inappropriate domains to reduce the search space and to improve the search results.

An overview of the Fuzzy-Go search engine is shown in Figure 1. The Web Crawler is developed to gather and classify web pages. Web pages are classified and stored based on their domains. The characteristic information of web pages is recorded in the Web Document. The Ontology Manager constructs and maintains a Fuzzy Ontology. A data mining approach is applied on the Web Document to calculate the fuzzy similarity between terms in the Fuzzy Ontology. The User Interface provides users to select an appropriate domain and to input multiple keywords with different degrees of

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

importance based on their needs. The Fuzzy Search Mechanism would exclude web pages in the inappropriate domains to reduce the search space and to improve the search results. The keywords are expanded by the Fuzzy Ontology to find out synonyms and terms similar to keywords. The search results are ordering based on several fuzzy factors including the satisfaction degrees of keywords, the importance degrees of keywords, the relevance of domains, the page ranks [3], the page in-links [2], titles, and last modified dates.

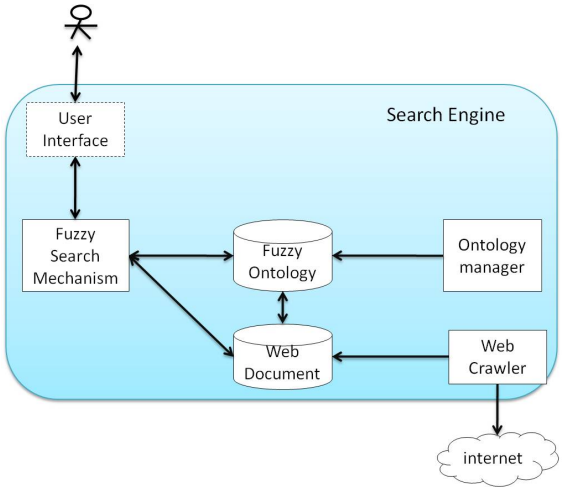

Figure 1. An overview of the Fuzzy-Go search engine

II. CONSTRUCTING THE FUZZY ONTOLOGY

Domain dependency is an important character of knowledge: the meaning of a term may be different in different domains. We construct a two-layered fuzzy ontology to organize terms that are elicited from WordNet [6]. WordNet is a large lexical database of English, built by Princeton University. Nouns, verbs, adjectives and adverbs are grouped into sets of cognitive synonyms, each expressing a distinct concept. In the two-layered fuzzy ontology, the first layer forms a domain hierarchy (see Figure 2). We adopt the Suggested Upper Merged Ontology (SUMO) [5] to classify domains. SUMO is owned by the IEEE and defines a group of domain ontologies which have been mapped to the WordNet domains. In our approach, the domain hierarchy is treated as gen-spec relationships. The upper level in the domain hierarchy

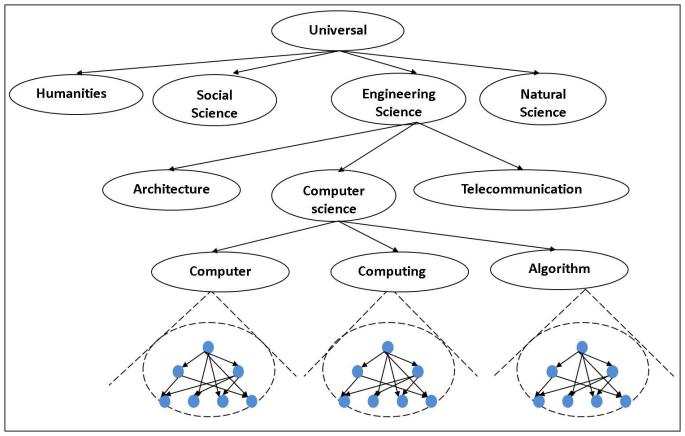

Figure 2. The domain hierarchy in the two-layered fuzzy ontology

maintains terms in a more general domain, while the lower level maintains terms in a more specific domain. Each domain contains a term lattice in the second layer (see Figure 3). A sub-domain can inherit the term lattice from its super-domain, add new terms specific to the sub-domain itself, and override (i.e., redefine) fuzzy similarity between terms in the super-domain.

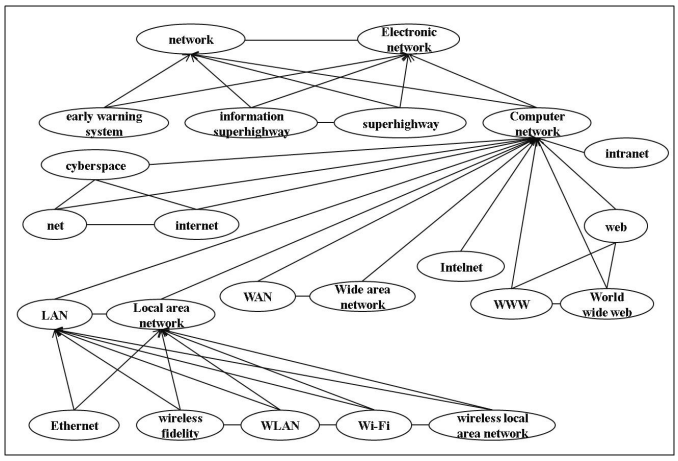

Figure 3. The term lattice in a domain

Church et al. [9] had extended the word association in psycholinguistics to provide the basis for a statistical description of the semantic relationship between words through the co-occurrence of words. To determine the similarity degree between terms, we use the data mining method to find out the degree of co-occurrence for two terms in web pages. The measure of mutual information [9] is adopted to calculate the degree of a children node conforming to a parent node in the term lattice. For any two terms x and y, the mutual information $I(x,y)$ is defined as

$$I(x,y) \equiv \log_2 \frac{P(x,y)}{P(x)P(y)} \quad (1)$$

Where $P(x)$ and $P(y)$ is the probabilities of observing x and y independently in web pages, and $P(x,y)$ is the probabilities of observing x and y together in web pages. The higher the semantic relationship between x and y, the larger the co-occurrence degree (i.e. $P(x,y)$ is larger), and consequently the larger the mutual Information $I(x,y)$.

To normalize the mutual information into a similarity degree in interval $[0,1]$, we adopt the maximizing set [16] to assign the fuzzy similarity degree between terms. For all mutual Information $x \in X$, let f be a real-valued function in X. The maximizing set $\tilde{M} = \{(x, \mu_{\tilde{M}}(x))\}, x \in X$ assigns the degrees of membership $\mu_{\tilde{M}}(x)$ for all $x \in X$ with

$$\mu_{\tilde{M}}(x) = \frac{f(x) - \inf(f)}{\sup(f) - \inf(f)} \quad (2)$$

Where $inf(x)$ is the minimum of f and $sup(x)$ is the maximum of f.

The Ontology Manager is responsible to apply the data mining approach to give the similarity degrees between terms in all term lattices based on the Web Document. Figure 4 shows a term lattice with the similarity degrees. Note that the similarity degree between two synonyms defined by WordNet is assigned 1.0 directly.

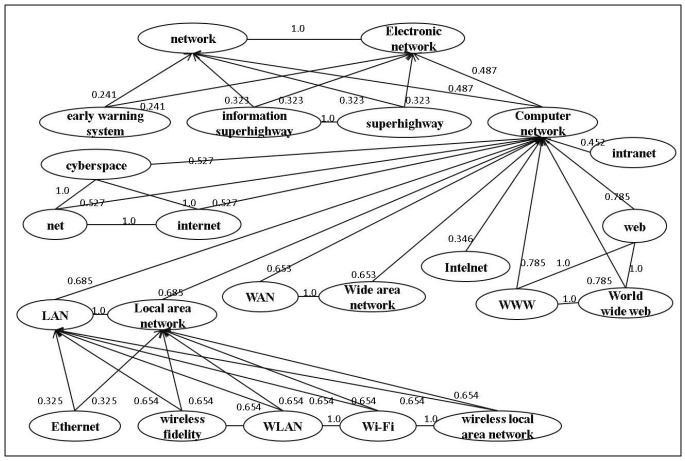

Figure 4. A term lattice with similarity degrees

III. THE WEB CRAWLER

We develop a crawler agent to automatically extract web pages and inventory them by finding out keywords and characteristic values. While the Web Crawler retrieves web pages, some important information of web pages is analyzed and stored, including titles, keywords, the page ranks of web pages, the last modified dates etc. Figure 5 shows the work flow of the Web Crawler.

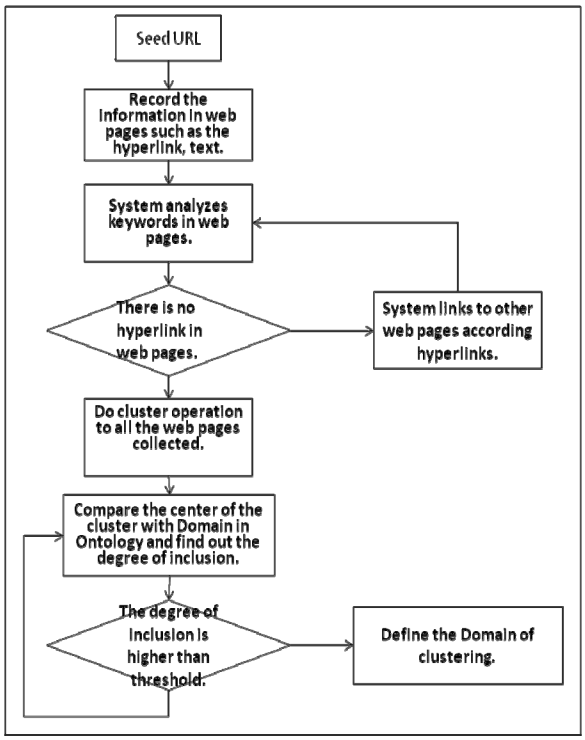

Figure 5. The work flow of the Web Crawler

The Web Crawler is also responsible to classify retrieved web pages by determining their domains. Since the amount of retrieved web pages is huge, we adopt the notions of Fuzzy C-Mean (FCM) [7] to cluster web pages based on their keywords. In our approach, each web page is translated into a vector of keywords. Each vector doesn't belong to only one cluster but belongs to several clusters with different degrees. By comparing to the terms within domains in the Fuzzy Ontology, the keywords in the center of a cluster are useful to determine what domain the cluster belongs to.

Keywords in web pages are regarded as the characteristic values and each web page is translated into a vector of keywords in the web page. Assume that all web pages in the Web Document are gathered into k clusters. The Euler distance between two web pages x_i and x_j would be

$$dist(x_i, x_j) = \left(\sum_{d=1}^{k} \left| x_{id} - x_{jd} \right|^2 \right)^{\frac{1}{2}} \quad (3)$$

The center of a cluster will be changed after iteration. In each iteration, we calculate the total deviation for changing the center of the cluster. In the case of k clusters, the total deviation E can be obtained by $E = \sum_{i=1}^{k} \sum_{x \in S_i} \left\| x - C_i \right\|^2$, where C_i is the center of each cluster S_i and x is the web page in cluster S_i. If the total deviation for the m+1's iteration is smaller than the m's, the center of the cluster would be changed into m+1's iteration -- otherwise the center would remain unchanged (see Figure 6).

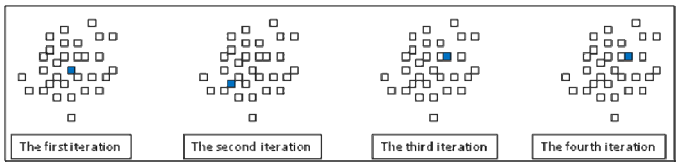

Figure 6. Changing of the FCM center of the clustering

Since the centers of clusters will be changed again and again, we use an objective function J to check if the result of clustering is stable.

$$J = \sum_{i=1}^{k} J_i = \sum_{i=1}^{k} \sum_{j=1}^{n} w_{ji}^m \left\| x_j - C_i \right\|^2 \quad (4)$$

Where w_{ji} is the degree of the web page x_j belongs to the cluster S_i with $w_{ji} = \frac{1}{\sum_{s=1}^{k} \left(\frac{\left\| X_j - C_i \right\|}{\left\| X_j - C_s \right\|} \right)^{\frac{2}{m-1}}}$, $\sum_{i=1}^{k} w_{ji} = 1$, w_{ji}^m forms a weighting matrix, and C_i is the center of each cluster S_i with $C_i = \frac{\sum_{j=1}^{n} w_{ji}^m x_j}{\sum_{j=1}^{n} w_{ji}^m}$. If the value of the objective function J is stable, the result of clustering is stable.

Finally, the characteristic values set of the center of the cluster is captured to compare with terms of domains. We applied N-Gram [4] to find out the degree of match between a cluster and a domain. Assume that C_K is the keywords set extracted from a cluster K and C_D is the keywords set of a domain D. The degree of match between a cluster K and a domain D is

$$Sim(C_K, C_D) = \frac{|C_K \cap C_D|}{|C_K|}, \{C_K\} \neq \phi \qquad (5)$$

A web page may belong to several domains. While the degree of match between a cluster and a domain is above the threshold, we assign all web pages in the cluster into the domain. The domain classification mechanism can reduce the search space and improve the search results.

IV. THE FUZZY SEARCH MECHANISM

The User Interface of the fuzzy search engine provides users to select an appropriate domain and to input multiple keywords with different degrees of importance based on their needs (see Figure 7). On the one hand, web pages in the inappropriate domains can be excluded to reduce the search space and to improve the search results, since all web pages are already classified by domains. On the other hand, a better search result can be obtained by differentiating between keywords according to the degrees of importance. We use linguistic degrees of importance [13] (i.e. don't care, unimportant, rather unimportant, moderately important, rather important, very important, and most important) to make it easier for users to grade relative importance. Each linguistic degree of importance can be mapped to a triangular fuzzy number as shown in Figure 8.

Figure 7. The user interface of the fuzzy search engine

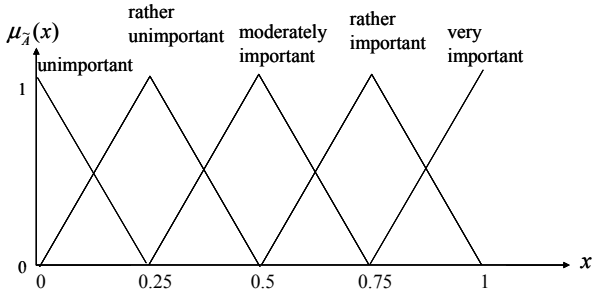

Figure 8. Membership functions for degrees of importance

It is inconvenient for users to be restricted to input precise keywords. Users may need to input several similar keywords individually to complete a search. To alleviate the problem, we use the term expansion to find out synonyms and terms similar to keywords based on the semantics inherited from the selected domain. While the user selects an appropriate domain and inputs keywords to search web pages, the Fuzzy Search Mechanism would expand keywords to synonyms and terms similar to keywords based on the term lattice of the selected domain. For the example in Figure 9, when the keyword is 'Computer Network' and the α-cut is set to 0.475, we would acquire 12 terms whose similarity degrees to 'Computer Network' are greater than 0.475.

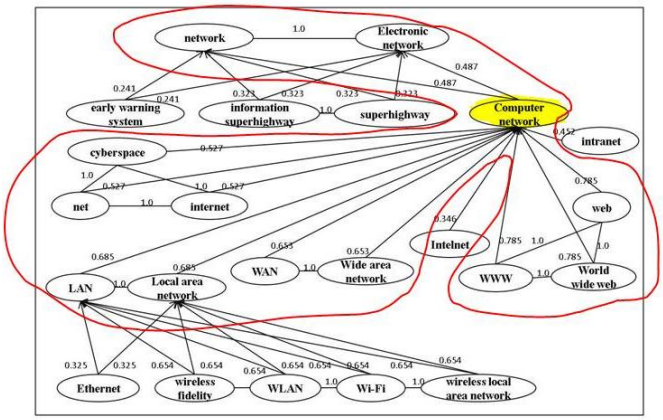

Figure 9. The term expansion of keywords in the term lattice

The fuzzy similarity between two non-adjacent terms T_A and T_B can be calculated by the multiplication principle for a path from T_A to T_B. That is, we can obtain the fuzzy similarity between T_A and T_B via another term T_C in the term lattice of the domain D.

$$Sim(T_A, T_B) = \underset{\forall\, Tc \in D}{Max}\{Sim(T_A, T_C) \times Sim(T_C, T_B)\} \qquad (6)$$

Therefore, the terms similar to a keyword with degree $\geqq$ α-cut could be found through the term lattice of the selected domain. All synonyms and terms similar to keywords are taken into account while we calculate the degree of satisfaction between the keyword and a web page. In our approach, the keyword density is used to determine the degrees of satisfaction between keywords and web pages. The keyword density is the percentage of times a keyword appears on a web page compared to the total number of words on the web page. Many SEO (Search Engine Optimization) experts consider the optimum keyword density to be 1 to 3 percent [1]. Others claim that the optimum keyword density would be 3%, 4% even as high as 2%~8%. We add the density of the keyword and all similar terms together, and adopt the largest range (i.e. 2 to 8 percent), S functions and Z functions [16] to establish the membership function of the optimum keyword density (see Figure 10). If the keyword density falls within 2% to 8%, the degree of satisfaction between the keyword and the web page would be set to 1. In the case of 0% to 2%, the S function is applied to set the degree value; whereas in the case of 8% to 12%, the Z function is applied to set the degree value.

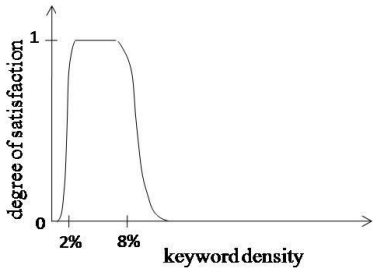

Figure 10. The membership function of the optimum keyword density

Since users may input multiple keywords with different degrees of importance to search web pages, the totally satisfactory degree of multiple keywords should be aggregated based on their degrees of importance and degrees of satisfaction. The fuzzy weighted average (FWA) [8,11] is applied to calculate the totally satisfactory degree of multiple keywords using triangular fuzzy numbers. In our approach, the degree of satisfaction between a keyword and a web page is the indicator (x_i), and the degrees of importance are weights (w_i) that act upon indicators. Therefore, the fuzzy weighted average y can be defined as

$$y = f(x_i,...,x_n,w_1,...,w_n) = \frac{\sum_{i=1}^{n} w_i x_i}{\sum_{i=1}^{n} w_i} \qquad (7)$$

Where there is n keywords, the degree of satisfaction x_i, $1 \le i \le n$ is a crisp value, and the degree of importance w_i, $1 \le i \le n$ is represented by a triangular fuzzy number. We adopt the approximate expressions on $\oplus$ and $\otimes$ operators for the computation of L-R fuzzy numbers, which is suggested by Dubois and Prade [10]. For example, a user may input two keywords to search web pages: 'expert systems' with moderately important and 'soft computing' with very important. In the term lattice, the term 'expert systems' links to a similar term 'knowledge-based systems' with the similarity degree 0.786, and 'soft computing' links to 'fuzzy logic' with 0.623. Assume that the keyword densities of 'expert systems', 'knowledge-based systems', 'soft computing' and 'fuzzy logic' for the web page *P* are 1.5%, 1.2%, 0% and 2.1% respectively. The expanded keyword density of 'expert systems' would be $1.5\%+1.2\%\times 0.786=2.4432\%$, and the degree of satisfaction between 'expert systems' and *P* would be 1. The expanded keyword density of 'soft computing' would be $0\%+2.1\%\times 0.623=1.3083\%$, and the degree of satisfaction between 'soft computing' and *P* would be $S(1.3083)=1-2\left(\frac{2-1.3083}{2-0}\right)^2 \cong 0.76$. FWA is applied to calculate *P*'s totally satisfactory degree of keywords as

$$y = \frac{(0.25,0.5,0.75)\otimes 1.0 \oplus (0.75,1,1)\otimes 0.76}{(0.25,\ 0.5,\ 0.75)\oplus(0.75,\ 1,\ 1)} = \frac{(0.82,1.26,1.51)}{(1,\ 1.5,\ 1.75)}$$

$$\cong \frac{1.1517}{1.3536} = 0.8508$$

Applying the mathematical operations on fuzzy numbers [10,16], we get two fuzzy numbers (0.82, 1.26, 1.51) and (1, 1.5, 1.75). The center of gravity is adopted to defuzzify a fuzzy number [14], which is achieved by mathematical integral. Therefore, *P*'s totally satisfactory degree of keywords is 0.8508 .

The search results are ordering based on several fuzzy factors including the totally satisfactory degrees of keywords, the page ranks, the page in-links, titles, and last modified dates. Through the mutual compensation of all fuzzy factors, an ordering of search results which is considered in every respect can be generated. The fuzzy weighted average [8,11] is utilized to aggregate all fuzzy factors based on their degrees of importance and degrees of satisfaction. The users can manually select appropriate fuzzy factors with different importance degrees to meet their specific requirements (see Figure 11) -- otherwise the importance degrees of fuzzy factors would be default values. Figure 12 shows the ordering of search results which the grade is generated by aggregating all fuzzy factors.

Figure 11. The selection of fuzzy factors with different importance degrees

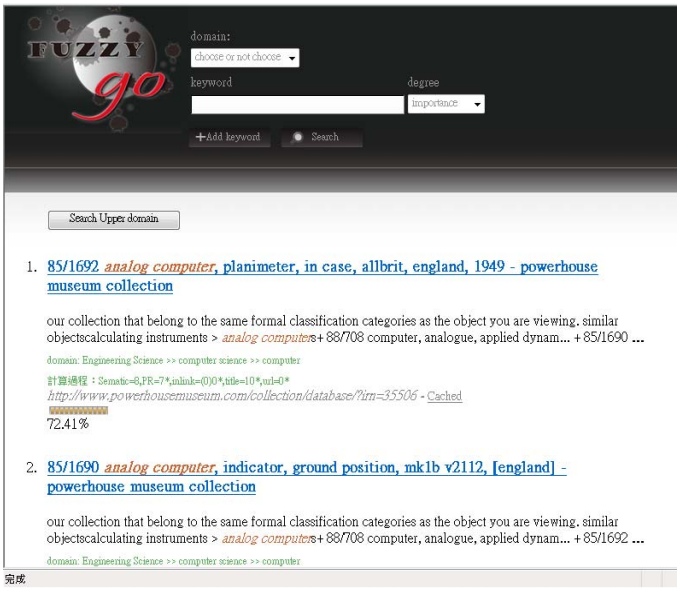

Figure 12. The ordering of search results

However, the original setting is not optimal, and it needs continuous learning and adaptation to fit users' expectations gradually. We have applied the genetic algorithm to propose a self-adaptation approach to Fuzzy-Go search engine [12]. For each search, the fuzzy search engine records the difference between the ordering of search results and user's real behavior on clicking web pages. This feedback is gathered and analyzed to adjust the fuzzy similarities between terms in the fuzzy ontology, the domain classification of web pages, and the default importance degrees of fuzzy factors. The ordering of search results can thus be improved gradually by continuous learning and adaptation.

V. CONCLUSION

In this paper, we develop a fuzzy search engine, called Fuzzy-Go. First, the Ontology Manager constructs and maintains a Fuzzy Ontology. A data mining approach is applied on the Web Document to calculate the fuzzy similarity between terms in the Fuzzy Ontology. The Fuzzy Ontology is constructed by using fuzzy logic to capture the similarities of terms in the ontology, which offering appropriate semantic distances between terms to accomplish the semantic search of keywords. The Fuzzy-Go search engine can thus automatically retrieve web pages that contain synonyms or terms similar to keywords. Second, the Web Crawler is developed to gather and classify web pages. Web pages are classified and stored based on their domains. To deal with the huge amount of retrieved web pages, we propose a data mining approach to cluster web pages based on their keywords. Third, the User Interface provides users to select an appropriate domain and to input multiple keywords with different degrees of importance based on their needs. The totally satisfactory degree of keywords can be aggregated based on their degrees of importance and degrees of satisfaction. Finally, the Fuzzy Search Mechanism would exclude web pages in the inappropriate domains to reduce the search space and to improve the search results. The keywords are expanded by the Fuzzy Ontology to find out synonyms and terms similar to keywords. The search results are ordering based on several fuzzy factors including the totally satisfactory degrees of keywords, the page ranks, the page in-links, titles, and last modified dates. The advantages of the proposed approach are as follows.

- Using fuzzy logic to capture the similarities of terms in the ontology, which offers appropriate semantic distances between terms to accomplish the semantic search of keywords. The domain classification of web pages offers users the selection of the appropriate domain to search web pages, which excludes web pages in the inappropriate domains to reduce the search space and to improve the search results.
- Users can input multiple keywords with different degrees of importance based on their needs, and all fuzzy factors are aggregated based on their degrees of importance and degrees of satisfaction. Through the mutual compensation of all fuzzy factors, the ordering of search results which is considered in every respect can be generated.

***Abstract*—this paper proposes an argumentation and negotiation mechanism for multi-agent systems. Through argumentations and negotiations, agents obtain more information on the topics of common interests or on those they have odds with. At the inception of the negotiation, agents can hardly understand completely the goals and beliefs other agents have toward related issues. Through argumentations and negotiations, the beliefs evolve, and agents will have better understanding about each other's target needs and preferences. During negotiations, agents can select the proposal that better suits other agents, further improving the chances for the agents to reach a consensus. Lastly, this paper illustrates our proposed methods through a simple course-scheduling negotiating system.**

Keywords-agent; Negotiation; argumentation

I. INTRODUCTION

In a multi-agent system, agents, in order to complete tasks with others through various forms of interaction, negotiation is the most commonly used method. Negotiation is a form of interaction in which a group of agents, with conflicting interests and a desire to cooperate try to come to a mutually acceptable agreement on the division of scarce resources. Resources are scarce in the sense that not all demands can be simultaneously satisfied [7][8]. For the information in the surroundings, agents can hardly obtain complete information about them. Therefore, agents often have to make decisions based on incomplete information, or to use a different way trying to obtain more information on the subject in order to make the decision making more precise. In traditional negotiations, an agent can only refute or submit another proposal when it doesn't agree with it. Recently, it has been proposed that argumentation mechanisms can be used to facilitate negotiation among computational agents. These mechanisms attempt to overcome some of the limitations of bargaining-based frameworks by allowing agents to exchange additional information or to argue about their beliefs and other internal characteristics during the negotiation process. This process of argumentation allows an agent to justify its negotiation stance and/or influence that of another agent [10][14][15]. Adding in the argumentation mechanism allows agents to understand the reasons and considerations behind these rejections of other's. In the end of the Negotiation and Argumentation System [1][13], agents can understand the reason behind other agents' decisions in favor of or against the proposal.

In a general course scheduling problem, a set of courses need to be arranged into a certain number of time slot under a set of constraints. This often makes the problem very hard to solve in real world circumstances [5]. It consists of efficiently arranging a set of courses into class periods. Scheduling consists of assigning offered courses to available time periods so that the teachers' satisfaction factor is maximized while preserving the unbreakable academic rules such as two distinct courses cannot be scheduled during the same period of time.

It is practically impossible to exhaustively consider and evaluate all possible schedules. The number of such schedules is exponential in the number of courses and time periods. Many papers proposed different approaches to solve this tough problem, such as genetic algorithm, case-based reasoning and fuzzy reasoning [4][6][9]. The present work applied negotiation and argumentation approaches for the courses scheduling problem. Each teacher is regarded as an agent called *course negotiation agent*. Through the negotiation and argumentation process of multi-agent, a suitable course timetable is scheduled. The paper is organized as follows. In the next section, we provide a conceptual framework of the negotiation and argumentation mechanism. Section 3 presents the processes of the negotiation and argumentation. Section 4 shows the results of the experiment. Section 5 is the conclusions of this work.

II. THE FRAMEWORK OF NEGOTIATION AND ARGUMENTATION

The work was supported by the National Science Council of Taiwan, Republic of China under research contract NSC 99-2220-E-027-009.

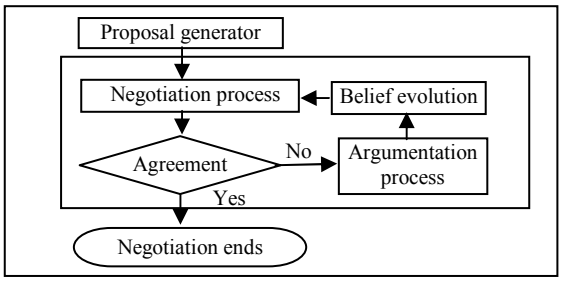

Figure 1 the System Pocess

The System Process is shown in Figure 1. The System obtains the User Belief from each agent, then generates numbers of different proposals through the Proposal Generator according to agents' various preferences and enters the Negotiation Process phase. During the negotiation process, each agent will select the acceptable proposal from all the proposals. The agents then submit this proposal and make efforts to reach a consensus with other agents. If there is a consensus among all the agents on a specific proposal, this proposal becomes the final agreement proposal and the Negotiation ends. If the attempt to reach a consensus has been unsuccessful, the System goes to Argumentation process where agents create arguments according to their own beliefs, and proceed with Argumentation with other agents. After the Argumentation phase comes the Belief Evolution, where beliefs are updated and intensified according to the outcome of Argumentation. The system then goes back to the start and proceeds with the next negotiation, re-evaluating proposals until a general consensus is reached.

A. Negotiation Mechanism

TABLE 1 DEFINITION OF NEGOTIATION SYMBOL

Symbol	Definition
bp_i	The most suitable proposal for $agent_i$.
bp_i'	The most personally effective proposal for $agent_i$.
P	Negotiation proposal.
NS (Negotiation set)	The set of available proposals.
T_i	The proposed proposal by agent.
$Utility_i$	The utility of the agent for the proposal.
$Risk_i$	The risk of the agent.

The so called Negotiation is a series of interactions performed by a group of conflicting agents when they need to work together, finding a way they all agree to allocate limited resources within an environment. The complete definition of Negotiation Symbol is shown in Table 1. During the process of Negotiation, agents select a proposal for the agent negotiation from existing proposals through a specific evaluating method. The purpose of Negotiation is to reach a consensus, and different negotiating proposal may have different value for the objects within the negotiation. The entire agent proposal can be defined by the equation (1).

$$P = \{(issue.name, issue.value) \mid issue, issue \in NO\} \quad (1)$$

The NO represents the entire Negotiation object; where issue is an issue within the Negotiation object. Agents select the best proposal by evaluating the best utility as a whole from those that have the highest utility. The expression for evaluating the utility of a proposal is presented in expression (2).

$$Utility_k(P) = \frac{\sum_{i=1}^{N}\sum_{j=1}^{M} f_j(issue_i)}{max(LevelPriority_k \mid K \in M) * N} \quad (2)$$

The system obtains the agent's preference on $issue_i$ based on $f_j(issue_i)$. $issue_i$ represents the *ith* issues of the agent; where fj represents the level of *jth* preference time of the $issue_i$. In the equation (2), *k, N, M*, and *LevelPriority* are used to represent the agent number, the number of issues agent *k* has, the number of time level of the agent *k's* preference and assign weighting values according to its Level respectively. *max* and *Σ* are used to present the maximum value within a group and its summation. Evaluating with equation (2), the agent can then evaluate which proposal has the highest utility for itself.

The raising of a proposal is based on an agent's individual preference. The utility degree the agent evaluates on in this proposal is the preference this proposal has for this agent. We can divide the level of preference into different levels according to how strong it is, and average them evenly as a general utility of the proposal.

$$bpi = \{P \mid P \in bpi' \text{ and } Utility(P) = max\{ Utility(P') \mid P' \in bpi'\}\} \quad (3)$$

Equation (3) evaluates the proposal that is most suitable for agent *i*. Agents decide whether to join bp_i based on the utility of each proposal. The proposal of bp_i will be submitted as a negotiating proposal during the negotiation and then be joined into T_i, which records every proposal agent submitted. The Negotiation Set is a set of all the available proposals. If the set is not empty, it means there is at least one proposal on which there exists a general consensus among all the agents.

To select which agent to concede during the negotiation, it is often decided by figuring out which agent has the lowest risk value. The risk value is evaluated by how much utility an agent will lose during the concession, as shown in equation (4). The equation calculates the maximum cost of giving in to other agent's proposal and the utility of its own proposal in order to obtain how much the agent will lose. This is the risk value for concession.

$$Risk_k = \frac{(Utility_k(SP_k) - min(Utilit\ y_k(SP_j) \mid K \in N)}{Utility_k(SP_k)} \quad (4)$$

The *priority* is the calculation of *priority* value according to the teacher's teaching years and its job title; *N* is the number of selected proposals submitted by other agents. SP_k*(Selected Proposal)* is the negotiation proposal submitted by the *k*th agent during this round of negotiation. If there are many agents that share the same lowest risk value, the selection of which agent to concede will take turns in fair. In that case, the agent that has conceded for the least times in history will be selected.

B. Argumentation Mechanism

In order to pass on additional information between agents, the Negotiation system relies on the argumentation system to generate arguments and to evaluate them. [1][2][3][11][12].

For the architecture in this paper, the purpose behind the agents submitting argument contents is to persuade others in the negotiation. The content of the submitted argument by the agent is a series of reasoning principles intended to praise the benefits of its own argument. The argumentation content A is represented by formula (5).

$$A = (H, h) \quad (5)$$

The purpose of the argumentation system is to provide agents with the ability to evaluate and generate arguments. Our research extended the argumentation system in [3] to generate suitable arguments using reasoning principles according to agents' beliefs, and to provide conflicts between beliefs in order for the agents' beliefs to evolve after argumentation. It also assigns priorities to beliefs that help the agents to compare them more easily.

A represents the argument content. H is the knowledge set that the reasoning is based on. h is the reasoning-formed conclusion. The knowledge includes the reasoning principle knowledge base available for the agents; the argumentation content is the set of used reasoning principles. When the arguments submitted by different agents in the system clash with each other, use *Undercut* to resolve the conflict, as shown in equation (6) and (7). Assume *(H1, h1)*, *(H2, h2)* to be two arguments.

(H1, h1) undercuts *(H2, h2):*

(1) If $h1 \equiv h2$ or If $\exists h \in H2$ *such that* $h \equiv h1$, *Using Rule of* Inference. (6)

(2) Undercut $= \{(A_i, A_j) \mid A_i, A_j \in Arguments\}$ (7)

For example, A_i and A_j represents two arguments respectively, where A_i *undercuts* A_j as in equation (7). A_i is *(H1, h1)*, and A_j is *(H2, h2)*. The two arguments, based on (6):

$h1 \wedge h2 \Rightarrow False$, *If* $h \in H2$, $h \wedge h1 \Rightarrow False$, *(H1, h1)* can then refute *(H2, h2)*.

For example, in equation (7), A_i and A_j represents proposal by agent i and j, respectively. The A_i submitted by agent i is P. By using the *Modus ponens:* $\{P, PQ\} \vdash Q\}$ in (6), agent j can submit A_i as Q, and A_i *undercuts* A_j.

This ordering is considered the priority of *Knowledge_Preference*. The definition of argumentation symbol is shown in Table 2.

TABLE 2 DEFINITION OF ARGUMENTATION SYMBOL

<A(∑), Undercut, Knowledge_Preference>	
∑	The knowledge base.
A(∑)	Output the suitable arguments for the agent according to the given ∑.
Undercut	Describes the conflicts between arguments.
Knowledge_Preference	Divide the available knowledge into several prioritized levels.

During the process of argumentation, agents can submit, query, and accept proposal by other agents. Agent submits a new proposal P by *assert(p)*; query other agents' proposal by *question(p)*, and accept other's proposal using *accept(p)*.

In the agent argumentation process, each argumentation is preceded with two agents, submitting proposal in turns. For those conflicting items, both agents are required to explain the reason of their own once. The proposal of both agents and other's that passes the argumentation wins. For the agent that loses, its belief needs to be updated and intensified.

III. NEGOTIATION AND ARGUMENTATION PROCESS

Negotiation process uses the conceding policy shown in Figure 2. If the negotiation fails, the system will enter argumentation process shown in Figure 3. Upon the completion of the argumentation, the beliefs are updated and the next round of negotiation begins.

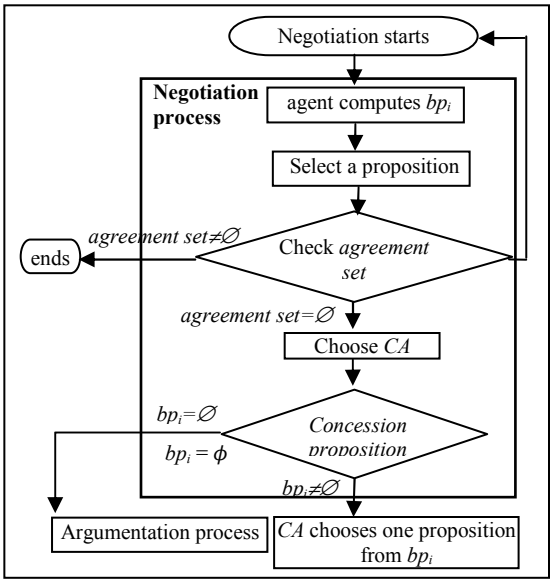

Figure 2 Negotiation process

A. Negotiation Process

This research proposes the negotiation process as follows:

- The agent calculates the utility value of the proposal. Select the proposal that best meets the agent requirement standards based on the utility value to form bp_i.
- Each agent chooses a proposal from bp_i to submit. The submitted proposal is then removed from bp_i and added to T_i.
- Evaluate whether the Negotiation Set is empty; if it is not empty, then at least one consensus has been reached, and the negotiation ends.
- Calculate the risk value of each agent. The agent with the least risk value will concede in the next turn. If numerous agents share the same minimum risk value,

the system chooses the agent who has conceded for the least times in the past to concede.

- The conceding agent then checks if bp_i is empty. If it is, which means that the agent does not have any other proposals that meet the requirements during this negotiation, it enters the argumentation process.
- On the other hand, if bp_i is not empty, choose a proposal from it. The chosen one should be the proposal that hasn't been submitted before, and goes back to step 1 to continue the negotiation.

B. Argumentation Process

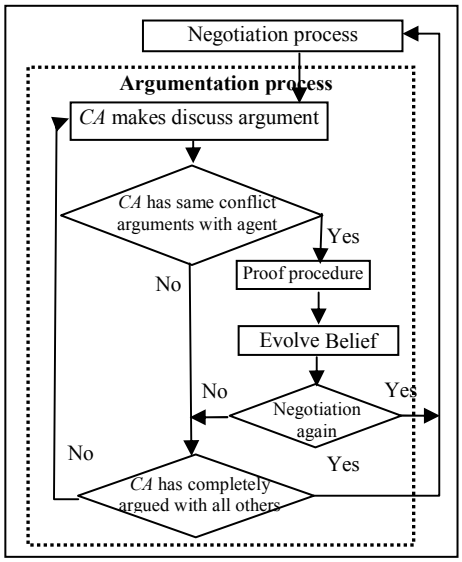

Figure 3 Argumentation process

The proposed argumentation process is specified as follows: (1) The conceding agent picks $agent_i$ who has the minimum risk value during negotiations, and compare the value for any conflicting issues. (2) The two agents search for any conflicting issue between them. If there is a conflicting issue, proceed with argumentation on this conflicting issue; if there is not, the conceding agent checks whether it has completed argumentations with all the other agents. (3) If the arguments conflict each other, use the argumentation reasoning. (4) The agents that fail the argumentation must evolve their beliefs. (5) After evolving, the failed agents re-check whether the negotiation can be carried on again. (6) Checking whether the conceding agents have completed argumentations with all the others. If they all have, the process goes back to the negotiation process and proceeds with the next negotiation; otherwise, it goes back to negotiation process step 1 and continues with argumentations.

C. Belief Evolvement

During the argumentation process, the agents pass on the argument to each other. The failed agents in the argumentation process get persuaded, and their beliefs must be evolved. The process includes: (1) Acquire the conflicting relations between beliefs through argumentation system. (2) Evolve the agent's belief according to the conflicting relations and the obtained results. (3) Remove the conflicting relation from the agent's belief. (4) Adjust and evolve the agent's belief.

IV. CASE STUDY

This paper uses a simple course-scheduling system to illustrate our negotiation and argumentation architecture written by Java and Jade (Java Agent Development Framework). A teacher represents the equivalence of a negotiation agent in this system, and each teacher obtains a suitable school timetable scheduling through negotiations.

A central coordinator obtains the preference time of each teacher agent, and with the help of the general school timetable generator, it submits a general school timetable proposal. For each teacher agent involved in the negotiation, according to this general timetable, each of them forms their own set of proposals. Based on the timetable set, the teacher agent submits proposal to the central coordinator, who then checks if any consensus can be reached within all the submitted proposals submitted by fellow agents. If there is no consensus, the conceding generator will decide which agent to concede. The conceding agent will carry on with the next round of negotiation later on, until a consensus has been reached.

A. Agent Belief

In this paper, agent's preference, and their thoughts on the available proposals affect how agents choose the negotiating proposal. We classify agent's preference into their beliefs. The agent can provide others with how it thinks about each proposal, making others' proposals more suitable to itself. The teacher agents' beliefs can be set by themselves; the beliefs are represented in XML, which includes the following elements: (1) Course: The courses name. (2) Degree: Agent's preference over the course timetable scheduling. Smaller value means higher preference; Degree = 1 represents the favorite time schedule. (3) Time_Preference: The preferred time schedule of the teacher. Each Time_Preference includes the ArgumentDep of the related arguments. (4) ArgumentDep: The arguments related to teachers' preferred time schedule, associated with the arguments in argumentation. (5) Argumentation: The argument that the agent (teacher) holds, which is classified into "Arguments" and "Counter-Arguments". (6) Arguments: The argument of the agent (teacher) its own. (7) Counter-Argument: Refute the argument of other agents.

TABLE 3 CANDIDATES PROPOSALS

Course Name \ Proposal Number	1	2	3	4	5
Web 2.0	Monday, afternoon	Tuesday, afternoon	Thursday, morning	Monday, afternoon	Monday, afternoon
Network Fundamental	Tuesday, afternoon	Friday, morning	Friday, afternoon	Thursday, morning	Friday, morning
Algorithm	Monday, morning	Monday, morning	Monday, morning	Monday, morning	Monday, morning
Linear Algebra	Wednesday, morning	Thursday, morning	Friday, morning	Friday, afternoon	Tuesday, afternoon
Java	Thursday, afternoon	Thursday, afternoon	Thursday, afternoon	Tuesday, morning	Thursday, afternoon
AI	Tuesday, morning	Wednesday, morning	Monday, afternoon	Wednesday, morning	Friday, afternoon

The agent belief includes its preffered time and the school timetable. The time format includes the day of the week and whether it's in the morning or afternoon. The purpose of negotiation is to arrange the course timetable for each teacher agent, therefore the issue contained in the proposal of the agent is the course schedule. The complete proposal candidates are listed in Table 3, where five course schedules are designated with the day of the week, and the time during the day.

The argumentation system allows the agents to generate suitable arguments. With specific information, agents can predict the arguments, conflicting knowledge relations, and knowledge usage level. The course schedule is the focus of argumentation among teacher agents in this experiment, which begins after negotiation fails to reach consensuses. If two teachers have same preference over certain schedules, they must provide with the reasons behind their choices. This paper designs the possible reasons behind teacher's preference over the schedule and assigns priority according to these reasons' characteristics. This priority is the *Knowledge_Prederence*. The process of assigning priorities can be discussed in public, or be decided by an unbiased third-party. Next we design possible preference reasons and their *Knowledge_Preference*. The reasons why having lower *Knowledge_Preference* value is better are: (1) Having regular executive meetings: ExecutiveCouncil (Agent, Time), Knowledge_Preference: 1. (2) Agent having courses from other department: HasCourse(Agent, Time), Knowledge_Preference: 2. (3) Single family: SingleFamily (Agent), Knowledge_Preference: 3. (4) Picking up kids from and to school: SendChildToSchool(Agent, Status), Knowledge_Preference: 4. (5) Preference over a schedule: Prefer(AgentName, (day, time)). (day, time) is the time the agent wishes others to concede, Knowledge_Preference: 5. (6) How intense the agent wishes the schedule to be: DaysOfCourse(Agent, Density), Knowledge_Preference: 6.

B. Negotiation and Argumentation Process

During the negotiation process, agent needs first to select the target proposal and then proceed with the argumentation in order to evolve its beliefs. Finally, it obtains the negotiation-argumentation result. Using the utility equation below, we can calculate the utility value that each agent can obtain for all the proposals in this round. They are listed in Table 12. We assume that the agent will set the proposal with the highest utility value as the most suitable proposal (bp_i), as Table 13 illustrates.

In round 1, teacher A chooses proposal 2, teacher B chooses proposal 1, 2, and teacher C chooses proposal 1. Obviously, in the first round, there are no proposals that can satisfy all the agents. Risk values of agents in round 1 are A: 0.17, B: 0 and C: 0.17. B has the lowest risk of all, so B has to concede in the first round. B submits another proposal for the next round, and other agents propose the same proposal on the next round. There is still no consensus in this round. Risk values of agents on round 2 are A: 0.17, B: 0 and C: 0.17. B has the lowest risk of all, and B has to concede in the second round. B's bp_i is empty, which means there is no proposal, so the negotiation process enters the argumentation process. B in the argumentation continues to concede. B argues with A. Based on the teacher's beliefs, both of them prefer Monday morning. B cast out reasons why it loves this particular time.

- B asserts SendChildToSchool(B, AfterClass).
- A asserts ¬SendChildToSchool(B, AfterClass)).
- B Supposes P=SendChildToSchool(B,AfterClass). P asserted by A, P=¬SendChildToSchool(B, AfterClass). Teacher B according to Modus ponens {{¬P, P∨Q} ⊢ Q}, inference Q=SingleFamily (B), then asserts SingleFamily (B).
- A accepts SingleFamily (B).

TABLE 4 THE EFFECTIVENESS OF AN AGENT TO RE-CALCULATE THE VALUE OBTAINED

Teacher \ Proposal Number	1	2	3	4	5
A	1	1	0.67	0.83	0.83
B	1	1	0.83	0.83	0.83
C	1	0.83	0.83	0.83	0.67

Finally, agent A won the argumentation. B evolves its beliefs, and makes a concession on the Monday morning time and removes it from its belief. Next, B selectes from the preference of session degree two which is the closest to Monday. After teacher B updated its beliefs, the perceptions of the environment are changed, and the assessment of the proposal on the curriculum will be different. All agents re-calculate *Utility* value and the bp_i for the curriculum proposal in Table 4, and check whether to continue with the negotiations.

Return to the negotiation process. During round 3, teacher A chooses proposal 1, teacher B chooses proposal 1 and teacher C chooses proposal 1. The negotiation focuses on a proposal to find an agreement, and the agent concludes the negotiations. Proposal is a schedule that can be used as a school curriculum and is acceptable to all the teachers. All agents make their own proposals for the most desired curriculum at the beginning of the negotiation. After a few concessions, if it is still unable to reach consensus on the proposal, the negotiations breaks down. So that agents can use the argument mutual understanding of each other's needs and then update the agent's beliefs. The proposals will close other agent's demands in next round of consultations.

We compared method [15] with this study. In research [15], if the proposal set is empty, the agent withdraws from negotiation. Because conventional trading negotiation will not change agent's beliefs, an agent will not interact with other agents of change in spite of understanding the environment. In our method, agents interact with other agents. This allows a better understanding of the needs of others, further changing the perceptions of the environment and updates their beliefs. For example, after the teacher argumentation, B is persuaded by A, and B will change its beliefs. The curriculum for the proposal in Table 1 candidate proposals will have a different assessment.

TABLE 5 THE FINAL PROPOSALS

Approach / Teacher	Negotiation	Negotiation and Argumentation
A	1	1
B	1	1
C	0.83	1

Table 5 shows the argumentation and negotiation of the final proposal with their values for comparison. In the traditional negotiation method, if there is no more proposal that can be chosen, the negotiation process would be withdrew. In this experiment, the final outcome of the negotiations is proposal 2. However, C is not very satisfied with proposal 2. A evolves its beliefs through argumentation; the proposal 2 may be accepted. Proposal 1, which satisfies all the agents, is the best result of the negotiation. After adding the argumentation method in negotiation, agents can interact with other agents and obtain more information and evolve their beliefs and then cause the perceptions of the environment to change. The agent who withdraws from the negotiation can re-evaluate the proposal, and goes back to the negotiation process once again to put forward a new proposal. Conceding agents can put forward new proposals more in line with all the agents.

V. CONCLUSION

Many research papers have addressed to the problem of agents' decision making accuracy being affected by the incomplete environment information in multi-agent systems. Through negotiation and argumentation, this paper makes agents understand others in the environment better, further achieving the evolvement of their beliefs.

***Abstract*—This paper proposed an approach to extract fuzzy candlestick patterns from financial time series and select a set of patterns for investment decision making. The candlestick chart in stock market is a widely used technical analysis model. The investor observes the candlestick chart and makes investment decisions by identifying patterns in the chart. We use fuzzy linguistic variables to model candlestick chart and extract patterns from the chart. A Genetic algorithm based approach is used to select a set of extracted pattern as the background knowledge in the system for investment decision making. The advantage of the proposed approach is the investment knowledge is comprehensible, editable, and visible. The user can set different range of historical financial time series to extract and select different set of patterns. The experimental results shows that the investment decisions based on selected fuzzy patterns have better investment performance than using original non-fuzzy patterns.**

Keywords-component; fuzzy candlestick pattern; time series; genetic algorithm

I. INTRODUCTION

How to modeling and implementing domain knowledge is an important part when design and implement an intelligent decision supporting system. For example, if an intelligent investment expert system has rich background knowledge from human expert, the system can give more precise suggestions to the user [1].

There are a lot of fundamental and technical analysis concepts and techniques have been established in financial investment domain such as Relative Strength Index (RSI), Moving Average Convergence Divergence (MACD), and Fast and Slow Stochastic (KD-line), etc. These technical analysis tools are the basis when design some investment decision supporting systems [2].

However, the set of data used to calculate RSI, MACD, and KD indicators is the closing price in a time point. There is rich information which exists in the financial time series database, but most of the traditional approaches only scratch the surface of the wealth of knowledge buried in the data. Many financial time series prediction approaches only use daily closing price as raw data to construct the forecasting model.

Figure 1 shows three general ways to represent the stock trading price during a time period. Figure 1(a) indicates a single closing price. Figure 1(b) represents the bar line which contains richer information than 1(a). The data required to produce a standard bar chart consists of the open, high, low, and close prices for the time period under study. A bar chart consists of vertical lines representing the high to low range in prices for that trading time period. The high price refers to the highest price that the issue traded during that trading time period. Likewise, the low price refers to the lowest price traded that trading time period. Figure 1(c) illustrates the candlestick line which is similar to the bar line but using a box to makes up the difference between the open and close price.

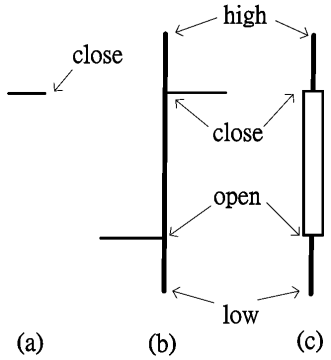

Figure 1. Different represention of financial data.

The candlestick chart in stock market is a widely used empirical model for investment decision making [3]. The investor observes the candlestick chart and makes investment decisions by identifying patterns in the chart. Figure 2 shows two examples of the daily candlestick chart in a stock market. Daily opening, closing, highest, and lowest prices are recorded in the candlestick lines for days d1, d2, d3, and d4. On d1, the stock opens in a higher price, but close at a lower price. On the next day d2, the opening price is lower than previous closing price, but closes at the highest price and is much higher than the lowest price. This situation might be interpreted by an experienced investor as the candlestick line on the day d1 reflecting a downtrend of the stock price, because there are many investors want to sell their stock and make the closing price much lower than the opening price. However, the downtrend might reverse itself on the day d2, because there are investors to buy the stock in the trading period that makes

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the price close at the highest price and much higher than the lowest price. In other word, the candlestick lines at d1 and d2 might represent a bouncing back. At d3, the closing price is higher than the opening price, and at d4, the opening price is much higher than the previous closing price, but closes at lowest price. The lines at d3 and d4 might be interpreted by the investor that the trend is returned, because the uptrend is broken at d4. It is obvious that the interpretation between the lines at d1, d2 and d3, d4 is very different, but the closing prices of d1, d2 and d3, d4 are the same.

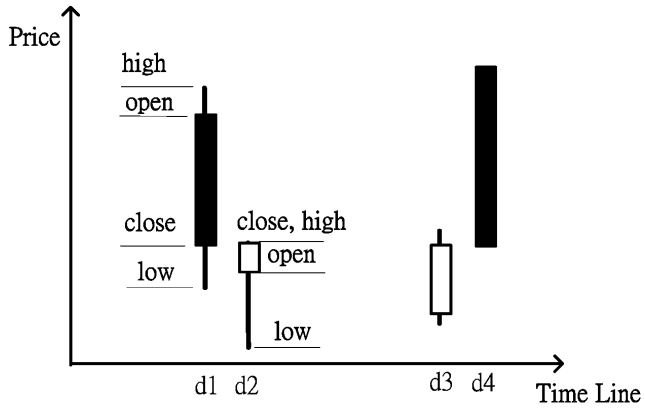

Figure 2. A candlestick chart.

Candlestick patterns which exist in the candlestick chart are empirical models of investment decision. The experienced investors can make their investment decision based on the observation of some specific candlestick patterns such as Bullish Engulfing, Hanging Man, Hammer, etc which are defined by the pioneer investors. However, to a human investor, to identify an effective pattern from a lot of imprecise and vague candlestick patterns needs years of investment experience and expertise. In addition, to retrieve the candlestick patterns from a large amount of financial trading data is time consuming.

In this paper, we propose a fuzzy candlestick pattern based financial decision supporting system to acquire the stock trading data in the Taiwan stock market (TAIEX) [4] from the Internet, provide an interface for the users to edit their own fuzzy candlestick patterns which are represented by fuzzy linguistic variables, extract fuzzy candlestick patterns from financial time series, and use a Genetic Algorithm (GA) based approach to select a set of extracted pattern as the background knowledge in the system for investment decision making. The advantage of the proposed approach is the investment knowledge is comprehensible, editable, and visible. The user can use different range of historical financial time series as basis for candlestick patterns construction.

This paper is organized as follows. In Section 2, the fuzzy-based candlestick pattern representation method is introduced. Section 3 describes the Genetic algorithm (GA) based fuzzy candlestick pattern extraction approach and the experimental results. Finally, Section 4 concludes this paper.

II. MODELING CANDLESTICK CHART

By the trading experience, the investor tries to identify the candlestick patterns to help themselves to make the investment decisions such as to buy, sell, or hold the stock. There are many existing defined candlestick patterns which are widely used by the investors. Figure 3(a) shows a hierarchy to represent the relationships among the candlestick pattern, candlestick line, and the prices. A visual candlestick pattern which called Bearish Engulfing is demonstrated in Figure 3(b).

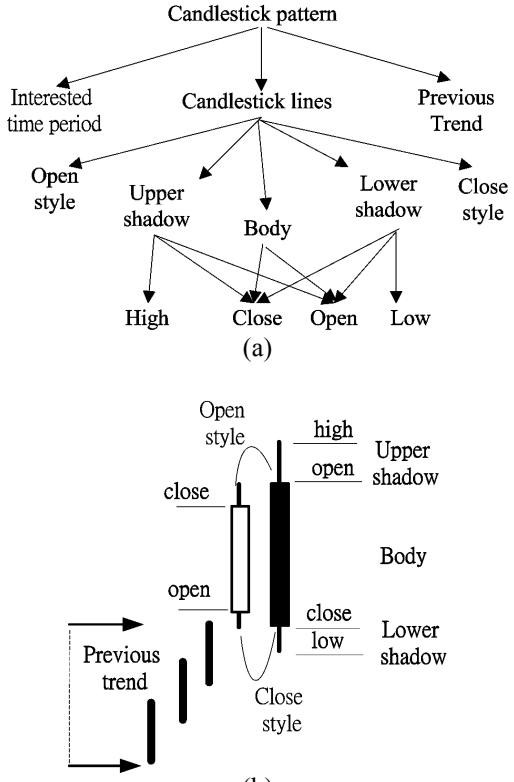

Figure 3. An example of the candlestick pattern.

The advantage of candlestick chart to investors is that the candlestick chart is visual, and a reversal or continuation candlestick pattern can be easily identified by an experienced investor. However, identifying the candlestick pattern from a large amount of trading data is time consuming, and there are no crisp and standard definitions to the candlestick patterns. The imprecise and vague definitions of the candlestick patterns make the automated searching, mining, and processing the candlestick patterns with computer software difficult. In this paper, we adapted the approach proposed in [5] to solve this problem.

A. Modeling Candlestic Patterns

A candlestick chart is composed by a series of continual candlestick lines. The lines consist of the open, high, low, and close prices in a time period under study. The time period can be of any duration, such as five minute, fifty minute, one hour, one day, one week, or one month. The first trading price in the interested trading time period is called open price; the last

trading price is called close price; the highest price is called high price, and the lowest price is called low price. These four prices compose a candlestick line. A candlestick pattern is composed by several serial candlestick lines.

The box that makes up the difference between the open and close is called the real body of a candlestick line. The height of the body is the range between a trading day's open price and the day's close price. When the body is black, it means that the closing price was lower than the opening price. When the closing price is higher than the opening, the body is white.

Four fuzzy linguistic variables EQUAL, SHORT, MIDDLE, and LONG are defined to indicate the fuzzy sets of the shadows and body length. Figure 4 shows the fuzzy membership function $\mu(x)$ of the linguistic variables.

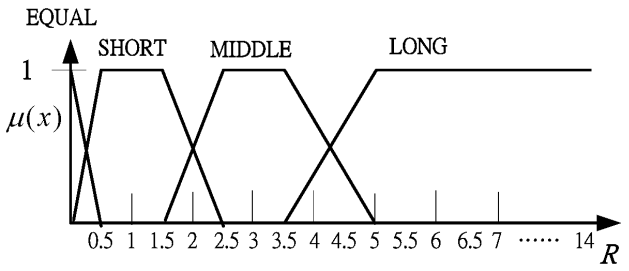

Figure 4. The membership functions of the length of the body and shadows.

The time period used in this paper is one day and the range of body and shadow length are set to 0 to 14 percent of the fluctuation of stock price, because the varying percentage of the stock prices are limited to 14 percent in TAIEX. Although we limit the fluctuation of body and shadow length in 14 percent in this paper, it is up to the system designer to change the range of the lengths to fit the needs of other applications.

In Figure 4, the unit of X axis is the percentage of price change in a stock and it indicates the lengths of body or shadows. The crisp input value of the membership function can be calculated by the following equations.

$$L_{upper} = [high - \max(open, close)]/open$$
$$L_{lower} = [\min(open, close) - low]/open$$
$$L_{body} = [\max(open, close) - \min(open, close)]/open \quad (1)$$

The character "*L*" of the equation indicates the length of the upper shadow, lower shadow, and body. The terms of open, close, high, and low are the prices in an interested time period. The function of **max** is used to calculate the greater value between the open price and the close price while and the function **min** is for the smaller value between them.

A right linear membership function is used to model the EQUAL fuzzy set and is defined by the following formula. The parameters (a, b) are equal to (0, 0.5) in this paper.

$$right_linear(x:a,b) = \begin{cases} 1 & x < a \\ (b-x)/(b-a) & a \le x \le b \\ 0 & x > b \end{cases} \quad (2)$$

The LONG fuzzy set is defined by the following left linear membership function. The parameters (a, b) are equal to (3.5, 5).

$$left_linear(x:a,b) = \begin{cases} 0 & x < a \\ (x-a)/(b-a) & a \le x \le b \\ 1 & x > b \end{cases} \quad (3)$$

The membership function of SHORT and MIDDLE is a trapezoid function and the following formula is used.

$$trapezoid(x:a,b,c,d) = \begin{cases} 0 & x < a \\ (x-a)/(b-a) & a \le x < b \\ 1 & b \le x < c \\ (d-x)/(d-c) & c \le x < d \\ 0 & x \ge d \end{cases} \quad (4)$$

Four parameters (a, b, c, d) of this function to describe the linguistic variables SHORT and MIDDLE are (0, 0.5, 1.5, 2.5) and (1, 2.5, 3.5, 5).

The body color is also an import feature of a candlestick line and can be simply defined by three terms BLACK, WHITE, and CROSS. The situation where open price equals close price has specific meaning in the candlestick pattern, so a "CROSS" term is defined to describe this situation. In this case, the height of the body is 0, and the shape is represented with a horizontal bar. The definition of body color is defined as follows.

If open - close > 0 then the body color is BLACK.

If open - close < 0 then the body color is WHITE. (5)

If open - close = 0 then the body color is CROSS.

Figure 5 shows the membership function of the linguistic variables of the open style and close style. The candlestick line in the bottom of Figure 5 is the candlestick line of previous trading time. The unit of X axis is the trading prices of previous day and the unit of Y axis is the possibility values of the membership function.

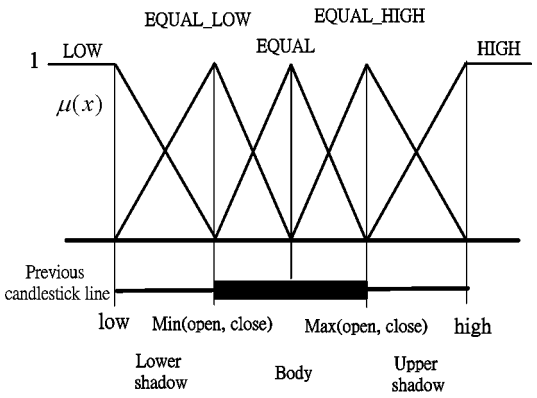

Figure 5. The membership function of the open and close style.

Five linguistic variables are defined to represent the open style relationships: OPEN LOW, OPEN EQUAL_LOW, OPEN EQUAL, OPEN EQUAL_HIGH, and OPEN HIGH, and five linguistic variables are defined to represent the close style relationships: CLOSE LOW, CLOSE EQUAL_LOW, CLOSE EQUAL, CLOSE EQUAL_HIGH, and CLOSE HIGH.

The function used to represent OPEN LOW and CLOSE LOW is the right linear function in (2), and (3) is also used to represent the fuzzy sets of OPEN HIGH and CLOSE HIGH. The other fuzzy sets are described by the triangle function in (6).

$$triangle(x:a,b,c)=\begin{cases}0 & x<a\\ (x-a)/(b-a) & a\le x\le b\\ (c-x)/(c-b) & b<x\le c\\ 0 & x>c\end{cases} \quad (6)$$

The parameters for the linguistic variables of open and close style are determined by the prices of previous candlestick line. For example, if the open price in a interested time period is equal to the price of min(*open,close*), then the open style is OPEN EQUAL_LOW and if the close price is equal to the price max(*open,close*), then the close style is CLOSE EQUAL_HIGH.

B. Modeling the Investment Knowledge

The description of a fuzzy candlestick pattern stored in the system consists of two parts: the pattern description part and the pattern information part. The description part is composed by the name of the candlestick pattern, a previous trend of the pattern, candle lines which composed the pattern, and the time period information. The information part records the candlestick pattern related information such as the pattern identification rules and the meaning of the pattern, etc. The information part is optional and is defined by the investors if the investor is interested in the pattern. If a candlestick pattern is described with the description information, it becomes more comprehensible to the other investors.

Table 1 shows a fuzzy candlestick pattern example which demonstrates a possible way to represent the Bearish Engulfing candlestick pattern and other candlestick patterns can be defined in the same way. The previous trend defined here is a crisp rule such as "down 15% in recent 10 days" to represent a downtrend or "up 15% in recent 10 days" to represent an uptrend. It should be noted that, for implementation convenience, we define the candlestick line which appear at the day *t* line 0, and the line appear in previous trading day *t-1* line 1.

Assume that the pattern appears at day *t*, the close price of day *t* is denoted *close(t)*, the highest close price in recent *k* days is denoted *highest(k)*, and the lowest close price in recent *k* days is denoted *lowest(k)*. The rules to determine the downtrend and uptrend can be defined as follows.

If $\frac{highest(k)-close(t)}{close(t)} > p$ then the stock price is in a downtrend.

If $\frac{close(t)-lowest(k)}{close(t)} > q$ then the stock price is in an uptrend,

where *p* and *q* are the thresholds to determine the trend of stock price is in uptrend or downtrend, and the unit of *p* and *q* is percentage of the fluctuation of stock prices.

Table 1
An example of the fuzzy candlestick pattern.

Pattern description part	**Pattern information part**
Pattern name: Bearish Engulfing	***Confirmation suggest:*** Suggest
Previous trend: Uptrend	***Confirmation information:*** The open price after the pattern should not be higher than the open price of candle line 0.
Candle lines: ***Candle line 0:*** ***Open style:*** OPEN HIGH ***Close style:*** CLOSE LOW ***Upper shadow:*** null ***Body:*** ABOVE MIDDLE ***Body color:*** BLACK ***Lower shadow:*** null ***Candle line 1:*** ***Open style:*** ABOVE OPEN EQUAL_LOW ***Close style:*** CLOSE HIGH ***Upper shadow:*** null ***Body:*** ABOVE SHORT ***Body color:*** WHITE ***Lower shadow:*** null	***Recognition rule:*** 1. A definite downtrend must be underway. 2. The second day's body must completely engulf the prior day's body. 3. The first day's color should reflect the trend: black for a downtrend and white …
Interested time period: DAY	***Pattern explanation:*** The first day of the Engulfing pattern has a small body and the second day has a long real body. Because the second day's move. ….

C. Pattern recognition

Since the patterns have been defined by the investor, the defined patterns can be easily transferred into fuzzy rules. For example, the Bearish Engulfing pattern can be transferred as following fuzzy rule.

IF trend = UP_TREND
AND line0.open_style = OPEN HIGH
AND line0.close_style = CLOSE LOW
AND line0.body = ABOVE MIDDLE
AND line0.body_color = BLACK
AND line1.open_style = ABOVE OPEN EQUAL_LOW
AND line1.close_style = CLOSE HIGH
AND line1.body = ABOVE SHORT
AND line1.body_color = WHITE
THEN the pattern = BEARISH ENGULFING.

A pattern recognition rule consists of the crisp part and the fuzzy part. The crisp part includes the previous trend of the pattern and the body color. The others of the rule are the fuzzy part such as the body and shadow length and the open and close style. From observation, well arranged identification rule will reduce the pattern recognition processing time.

Comparing with the processing time of the fuzzy part, the crisp part takes less processing time. For example, the body

Identify applicable sponsor/s here. *(sponsors)*

color includes three possibilities: BLACK, WHITE, and CROSS. For judging the value of the body color, the pattern recognition module only needs to compare the value of open price and close price. The pattern identifying time can be reduced if the judgment of the crisp part is placed before the process of the fuzzy part.

The concept of Hamming distance [6] is used to measure the similarity among fuzzy candlestick patterns. Assume that A and B represent two different fuzzy candlestick patterns which described by n linguistic variables, the similarity is defined as:

$$S(A,B)=\frac{1}{n}\sum_{i=1}^{n}\left|\mu_A(x_i)-\mu_B(x_i)\right|,\qquad 0<S(A,B)\le 1. \tag{7}$$

The user can set a threshold T to determine a pattern is recognized or not. If $S(A,B)\ge T$ then the pattern is identified.

III. Investment Knowledge Extracting

When using the candlestick chart, the investment decision is based on a set of candlestick patterns rather than only use a single pattern. In other word, how to select a set of patterns becomes an important problem.

Using fuzzy candlestick pattern to make investment decisions has several steps.

1. Transfer a range of financial time series into candlestick chart for pattern extraction.
2. Extracting original fuzzy candlestick patterns by using predefined heuristic rules.
3. Selecting patterns from extracted patterns by GA.
4. Using the selected patterns as the investment knowledge for decision making.

Step 1 fellows the method introduced in section 2 to transfer financial time series into candlestick chart. Three heuristic rules are defined for pattern extraction in step 2.

1. Bullish pattern recognition rule: if the previous trend is downtrend and the up_index of following N days up $P\%$ then the pattern is a bullish pattern.
2. Bearish pattern recognition rule: if the previous trend is uptrend and the down_index of following N days down $P\%$ then the pattern is a bearish pattern.
3. Other patterns: don't care.

The up and down indexes are used to indicate the maximum and minimum variation of the stock price after a specific pattern has happened. The calculation of up and down indexes is similar to previous trend of the candlestick pattern. Assume that the pattern appears on day t, the close price of day t is denoted *close(t)*, the highest close price in recent k days is denoted as *highest(k)*, and the lowest close price in recent k days is denoted as *lowest(k)*. The up and down index are defined in (8).

$$up_index=\frac{highest(k)-close(t)}{close(t)}\times 100$$
$$down_index=\frac{close(t)-lowest(k)}{close(t)}\times 100 \tag{8}$$

The *total_up_down* index is used to indicate the possibility investment result when using a specified pattern in an assigned time period, and the *mean_fluctuation* index is used to reflect the mean fluctuation of the stock prices when the pattern appears. To a reversal pattern, these two parameters should as large as possible. The total up times and total down times are also calculated. If the up index is higher than the down index, the total up times are increased by 1, and if the up index is lower than the down index, the total down times are increased by 1. The total up and down index and mean fluctuation are calculated as follows.

$$total_up_down=\sum(up_index-down_index)$$
$$mean_fluctuation=\frac{1}{T}\sum_{i=1}^{T}(up_index+down_index) \tag{9}$$
$$T=total_up_times+total_down_times$$

Figure 6 shows a reversal pattern called "Hanging Man" testing results. The selected stock number is 2409 (AUO), and the validation range is 1000 trading days before 2004-12-10. The maximum and minimum close prices from trading day t to t - 5 are selected to calculate the up and down index. In the selected range of trading days, the pattern appeared 10 times. In other words, the frequency of this pattern is 0.01. The *total_up_down* index is equal to about 20 percent, and *mean_fluctuation* index is equal to about 11 percent.

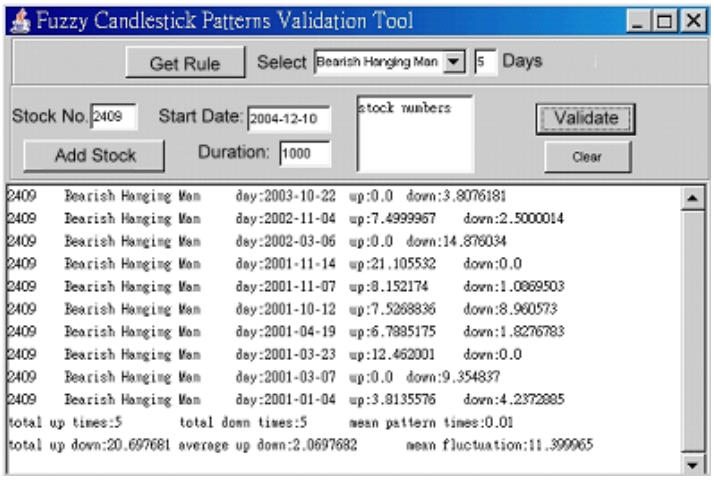

Figure 6. A pattern validation results.

In step 3, we use the extracted patterns as gene to consist a chromosome for GA. The relationship of pattern rules and chromosomes is shown in Figure 7.

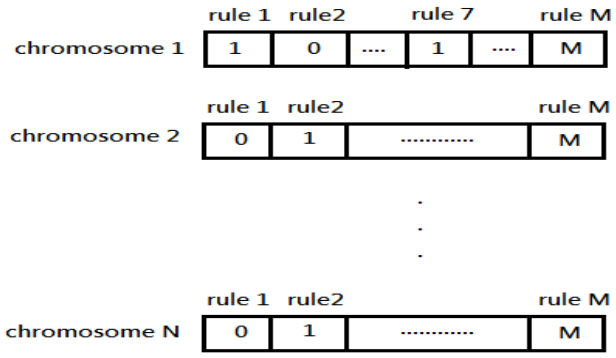

Figure 7: The chromosome used in GA.

If the pattern extracted in step 2 is 576 the *M* will be 576. In chromosome, bit 1 indicate the rule is used for investment decision making, bit 0 indicate this rule do not be used. In the beginning of GA, we set bits in chromosome randomly.

The fitness function is define as:

$$f(x_n) = \frac{x+m}{\sum_{i=1\sim N}(x_i+m)} \qquad (10)$$

Where x is the earned or lost point when using patterns indicated in chromosome and m is the stop value if earned point reached this value. We use Taiwan Stock Exchange Capitalization Weighted Stock Index (TAIEX) from 2001 to 2005 for patterns selection. The experimental results by running GA are shown in Figure 8.

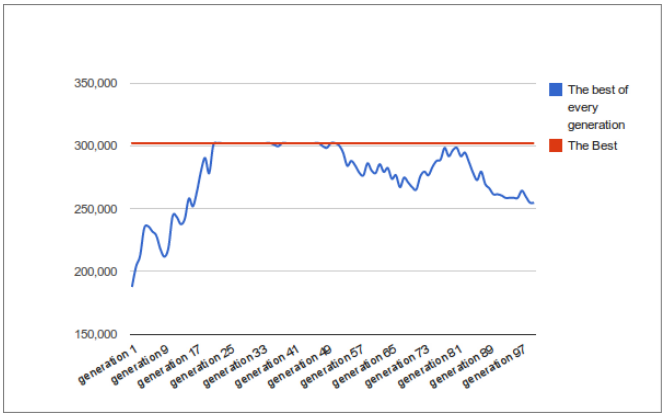

Figure 8: A comparison of different GA generation.

Finally we compared the performance by using different pattern sets. First results use extracted fuzzy candlestick pattern as background knowledge, second use user defined patterns, and third use GA to get better pattern set. The experimental results in Table 2 show fuzzy candlestick patterns with GA have best performance.

Table 2: a comparison among using different pattern set.

	Time series for pattern extraction	Evaluation Time series	Results
Extracted patterns	2001~2005	2006~2009	5027
Predefined patterns	No	2006~2009	6114
Selected patterns	2001~2005	2006~2009	8452

IV. CONCLUSION

In this paper, we proposed a knowledge based method to represent the financial time series. The variance of the stock price is represented in fuzzy candlestick patterns which make the imprecise and vague investment knowledge comprehensible, computable, visual, and editable. We also propose a GA based approach for patterns selection. The system can give investment suggestion to the investor by using these patterns as background knowledge.

The fuzzy candlestick patterns carry rich information and also can be used to increase the efficiency of the data mining, machine learning, and pattern recognition models. Pattern construction and recognition approach is introduced and implemented in a system prototype to illustrate the usage of the fuzzy candlestick patterns. Moreover, investors can save and share their investment experience. By reusing and modifying the stored candlestick pattern information, the investor can also increase the efficiency of their investing strategies. We believe that the fuzzy candlestick pattern representation method can still be used in other areas in which the time series has some properties like the stock price.

***Abstract*—Project estimation based on function point or use case point (UCP) methods provide only fixed complexity grades which can not deal with the uncertain and imprecise conditions. This study, therefore, provides a fuzzy size estimation procedure for goal-driven use case model based on UCP using fuzzy theory. We propose a metric to calculate the unadjusted use case points of goal-driven use cases based on the relations between each use cases and goals with the fuzzy membership functions and the fuzzy rules. Furthermore, the technical and environmental factors are considered to calculate the use case points which can be used to estimate the implementation time and effort of the system under development. The proposed approach is illustrated by a benchmark problem domain of a meeting scheduler systems.**

***Index Terms*—function point analysis, use case point, goal-driven use cases, fuzzy theory.**

I. Introduction

Software estimation is an important and difficult activity in project planning and management process. Several estimation models have been proposed to estimate the software size [3], [5], [14] based on function point (FP) [1]. In object oriented development process, use case analysis is a crucial activity to develop software system. Therefore, the use case points method, a software sizing and estimation method based on use case counts called use case points (UCP) [6], [12], [13] is provided to estimate functional size of software in early stage of a project. The use case point method can be divided into five parts: Weighting actors by indicating the three actor types, simple, average and complex to generate unadjusted actor weights (UAW); Weighting use cases by indicating the three use case types based on transactions or classes to generate unadjusted use case weights (UUCW); Weighting technical complexity factors (TCF) to indicate the expectations of the users for the delivered software; Weighting environment factor (EF) to indicate the experience level of people on project; Finally, calculate use case points (UCP) by the formula UCP = (UAW + UUCW) $\times$ TCF $\times$ EF.

Nevertheless, FP and UCP methods provides only fixed complexity grades which can not deal with the uncertain and imprecise conditions. Therefore, some studies have been proposed to estimate the software size using fuzzy set theory. Xia et al [15] provide a neuro-fuzzy FP calibration model that integrate fuzzy logic, statistical regression and neuro network techniques to improve the accuracy of software effort estimation. Braz and Vergilio [2] present two metrics, use case size points (USP) which considers the internal structure of the use case and fuzzy use case size point (FUSP) which uses fuzzy set theory for gradual change of complexity. Rodrigo et al [11] propose a task fuzzy estimator based on the UCP techniques with three inputs: complexity to modify the modules, experience of developers and the size of the alteration. The inference result is the effort in days for software development.

However, those studies do not consider the relationships between use cases and goals that would affect the complexity and implementation effort of each use cases. In this work, we propose a fuzzy software sizing and estimation method that considers the relationships between use cases and goals based on our previous work on goal-driven use case (GDUC) [7]–[10], in which use cases are derived based on the analysis of goals interactions. The meeting scheduler problem [4], a widely used benchmark problem domain in requirements engineering community, is adopted throughout this work as an example to illustrate the proposed approach.

The paper is organized as follows. Section 2 describes the concept of goal-driven use cases. Section 3 introduces the proposed method. Section 4 shows the results of the application of the introduced method. Section 5 concludes the paper.

II. Goal-Driven Use Cases (GDUC)

A brief summary of our goal-driven use case model [8] to construct a use case model with goals is outlined below for the readers' reference. To identify goals from domain descriptions and system requirements, we propose a faceted classification scheme so that each goal can be classified with three facets: *competence*, *view*, and *content*. The *competence* describes whether a requirement is satisfied completely or only to a degree. A *rigid* type of goal describes a minimum requirement that a target system must satisfy utterly. A *soft* goal describes properties or concerns that stakeholder care about for a target system, and can be satisfied to a degree. The *view* facet concerns whether a goal is *actor-specific* or *system-specific*. Actor-specific goals are actor's objectives in using a system; system-specific goals are requirements on services that the system provides. A goal can be further distinguished based

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

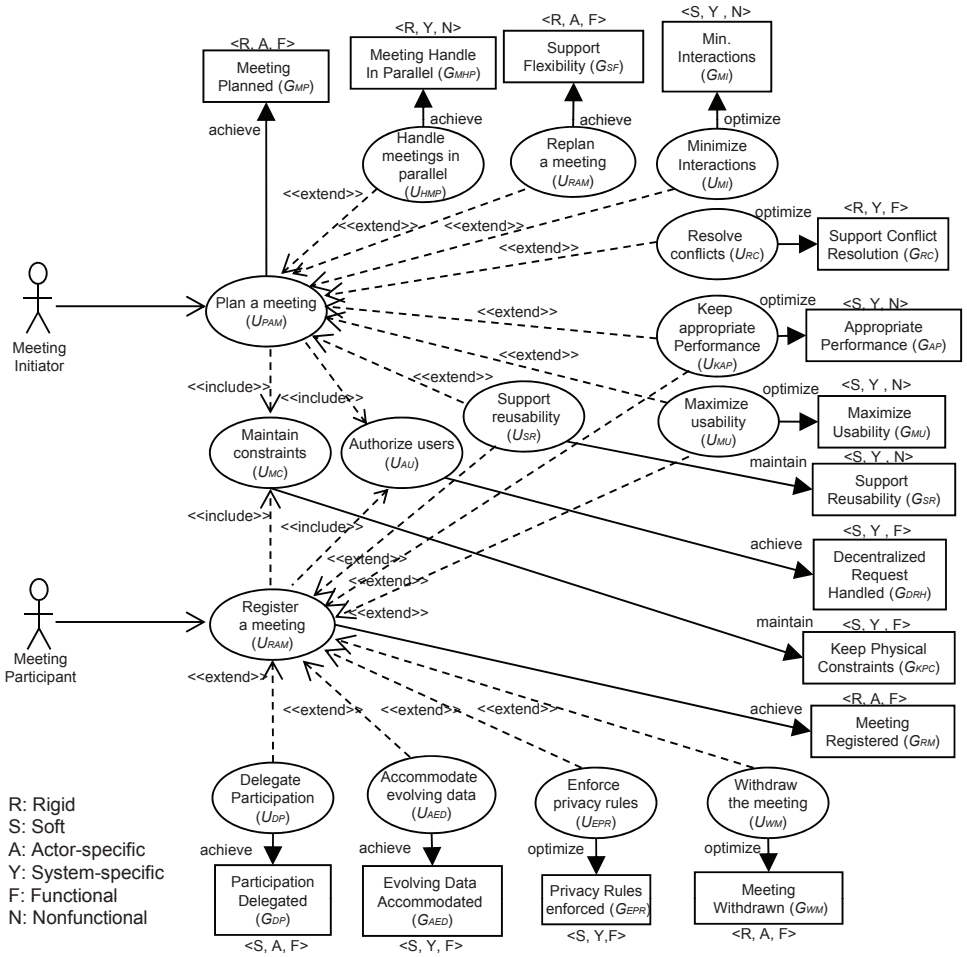

Fig. 1. Use Case Model for Meeting Scheduler System

on its *content* and can be either related to a system's *functional* aspects or associated with the system's *nonfunctional* aspect.

A goal can be achieved, optimized or maintained by its associated use case. The use cases of the meeting scheduler system are established for actors *meeting initiator* and *meeting participant* (see Figure 1). For the actor *meeting initiator*, the use case *plan a meeting* covers the scenario for an initiator to achieve an original goal *MeetingPlanned*, which is a goal of rigid, actor-specific, and functional. Meanwhile, in the case of the actor *meeting participant*, the use case *register a meeting* covers the case for a participant to achieve an original goal *MeetingRegistered*, which is a goal that is rigid, actor-specific, and functional.

To achieve a system-specific goal, an extension use case may be created. Referring to our example, the original use case *plan a meeting* describes the process to create a meeting from the view of the actor *initiator*. The extension use cases *Handle meetings in parallel* and *Resolve conflicts* extends it to take all initiators into account, that is, to achieve the system-specific goals *MeetingHandleInParallel* and *SupportConflictResolution*. The extension use cases *Accommodate evolving data* and *Enforce privacy rules* extends the original use case *Register a meeting* to achieve the soft, system-specific and functional goals *EvolvingDataAccommondated* and *PrivacyRulesEnforced*, respectively.

To achieve a nonfunctional goal, an extension use case serves as a constraint to qualify its original use case. In our example, several constraints (may be rigid or soft) on a meeting are considered as extension use cases to extend or constrain the behavior of the original use case *Plan a meeting* which is a direct course to create a meeting, including *Minimize Interactions, Keep Appropriate Performance, Support Reusability and Maximize Usability*. To enhance reusability, the use case models are further elaborated by extracting the common fragments among various use cases into an included use case by using "include" relationships. For example, the use cases *Maintain constraints* and *Authorize users*, are included by the use case *Plan a meeting* and use case *Register a meeting*.

A. Evaluate Relation from Use Case to Goal

To analyze the satisfaction values from use cases to goals, we examine the relationships among goals and use cases in a pairwise manner, which results in the satisfaction values in Use Case to Goal *U2G* matrix (see *U2G* Matrix in Figure 2).

	U_{PAM}	U_{RAM}	U_{RC}	U_{MI}	U_{HMP}	U_{AU}	U_{MC}	U_{KAP}	U_{RM}	U_{DP}	U_{AED}	U_{WM}	U_{EPR}	U_{SR}	U_{MU}
G_{MP}	5	3	1	1	1	1	1	0	0	0	0	0	0	0	0

G_{MU}	1	0	0	0	0	0	0	-1	1	0	0	0	0	-1	5

Fig. 2. Satisfaction Values of Use Case to Goal (U2G) Matrix

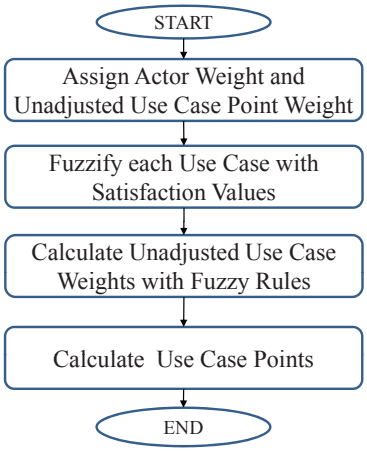

Fig. 3. Fuzzy Size Estimation Method

The gauge of satisfaction values is from 5 to -5. 5/-5 means that the goal is fully satisfied/fully denied after the use case is performed. 1/-1 means that the goal is partially satisfied/partially denied after the use case is performed. 0 means that the goal is not affected after the use cases is performed. Others represent the degrees between scores listed above. Detail explanation of the rating of satisfaction degree can be found in Table I.

TABLE I
RATINGS DEFINITION OF SATISFACTION VALUES

Score	Explanation
5	The goal is fully satisfied after the use case is performed
4	Represent the degrees between scores 5 and 3
3	The goal is largely satisfied after the use case is performed
2	Represent the degrees between scores 3 and 1
1	The goal is partially satisfied after the use case is performed
0	The goal is not affected after the use cases is performed
-1	The goal is partially denied after the use case is performed
-2	Represent the degrees between scores -1 and -3
-3	The goal is largely denied after the use case is performed
-4	Represent the degrees between scores -3 and -5
-5	The goal is fully denied after the use case is performed

For example, the effect of performing use case U_{PAM} is evaluated with respect to all goals in the system. G_{MP} is rated as 5 since performing U_{PAM} can fully satisfy the goal. G_{SF} is rated as 3 to indicate that performing U_{PAM} can largely satisfy the goal. The effect of performing use case U_{RC} with respect to goal G_{MI} is rated as -2 to show that performing U_{RC} can partially to largely deny the goal.

III. FUZZY SIZE ESTIMATION METHOD

In order to estimate the size and analyze the complexity of the goal-driven use case model, there are four steps involved in our fuzzy size estimation method (see Figure 3 for an overview). The method extends UCP method by considering the relations between use cases and goals with fuzzy theory. The details are explained below:

A. Assign Actor Weight and Unadjusted Use Case Point Weight

The unadjusted actor weights (UAW) and unadjusted use case weights (UUCW) are assigned base on UCP method with table II, III and IV [13]. Table II indicates the three actor types in UCP method. Table III and IV indicate the three use case types which are used to weight use cases based on transaction or class, respectively. The unadjusted use case weights (UUCW) is calculated by summing the weights of each use case.

TABLE II
ACTOR WEIGHTING FACTORS [13]

Actor Type	Description	Factor
Simple	Program interface	1
Average	Interactive, or protocol-driven, interface	2
Complex	Graphical interface	3

TABLE III
TRANSACTION-BASED WEIGHTING FACTORS [13]

Use Case Type	Description	Factor
Simple	3 or fewer transactions	5
Average	4 to 7 transactions	10
Complex	More than 7 transactions	15

TABLE IV
ANALYSIS CLASS-BASED WEIGHTING FACTORS [13]

Use Case Type	Description	Factor
Simple	Fewer than 5 analysis classes	5
Average	5 to 10 analysis classes	10
Complex	More than 10 analysis classes	15

B. Fuzzify each use case with satisfaction values

Since each use case satisfies each goals in different degree, *rValue*, represents the relevance from a use case to the goals of the system, can be calculated using equation 1 according to the satisfaction values in *U2G* matrix (see figure I).

U_iG_j, the satisfaction values in column i of *U2G* matrix, represents the relationships between use case U_i and the goals of the system. Equation 1 generates *rValue* of use case U_i by finding the maximum value of U_iG_j except the satisfaction value of use case U_i to its goal G_i and adding the average of the rest satisfaction values of U_iG_j where $U_iG_j \neq 0$. That is, except goal G_i of use case U_i, the satisfaction value of most complex goal of use case U_i should achieve is regarded and the average of the sum of the rest satisfaction values which are not zero is added to indicate the degree that the use case should satisfy the goals. The result generated in equation 1 denotes the relevance between use case U_i and the goals of the system.

$$rValue_i = max(|U_iG_j|) + avg(\sum |U_iG_j| - max(|U_iG_j|)) \quad \text{where } n = \#\text{ of goals}, i = 1...n, j = 1...n, i \neq j, U_iG_j \neq 0 \tag{1}$$

To allow a gradual change from one complexity category to another, we define the fuzzy input membership function *F(x)* that classify *rValue* which is between $0 \sim 10$ into five linguistic terms. (see figure 4).

$$F(x) = \begin{cases} \frac{2.5 - x}{2.5} & 0 \le x < 2.5 \quad \text{Simple} \\ \frac{x}{2.5} & 0 \le x < 2.5 \quad \text{Average} \\ \frac{5 - x}{2.5} & 2.5 \le x < 5 \quad \text{Average} \\ \frac{x - 2.5}{2.5} & 2.5 \le x < 5 \quad \text{Complex} \\ \frac{7.5 - x}{2.5} & 5 \le x < 7.5 \quad \text{Complex} \\ \frac{x - 5}{2.5} & 5 \le x < 7.5 \quad \text{Very Complex} \\ \frac{10 - x}{2.5} & 7.5 \le x < 10 \quad \text{Very Complex} \\ \frac{x - 7.5}{2.5} & 7.5 \le x < 10 \quad \text{Most Complex} \end{cases}$$

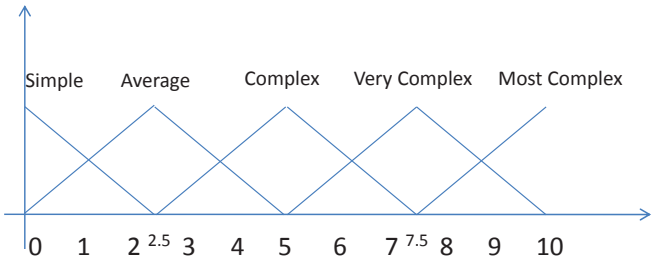

Fig. 4. The Membership Function *F(x) of* rValue

C. Calculate Unadjusted Use Case Weights with Fuzzy Rules

Table V defines the fuzzy rules with the use case types and the membership function *F(x)*. For each use case, we use min-max fuzzy inference method to match the rules with its use case types and the result of *F(rValue)*. The center of gravity defuzzification is made through the application of the rules matched with the output membership function. (see figure 5). After this, the fuzzy unadjusted use case weight (FUUCW) of each use case can be calculated.

TABLE V
FUZZY RULES

use case type / F(x)	**Simple**	**Average**	**Complex**	**Very Complex**	**Most Complex**
Simple	Simplest	Very Simple	Simple	Average	Complex
Average	Very Simple	Simple	Average	Complex	Very Complex
Complex	Simple	Average	Complex	Very Complex	Most Complex

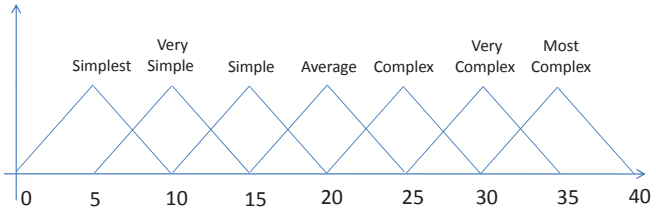

Fig. 5. The Membership Function of Fuzzy Rules

D. Calculate Use Case Points

We adopt the technical complexity factors (TCF) and environment factors (EF) [13] to take the characteristics of the system-to-be into count to generate use case points. Table VI shows the technical complexity factors which indicate the characteristics of the delivered software. The TFactor is calculated by adding all the numbers resulting from multiplying the value of each technical factors (T1-T13) by its weight.
TFactor = $\sum_i$ (*Ti* $\times$ Weight) , where i = 1,...,13
The following formula is then applied to get the TCF value:
TCF = 0.6 + (0.01 $\times$ TFactor)

TABLE VI
WEIGHTING TECHNICAL COMPLEXITY FACTORS (TCF) [13]

Factor number	Factor Description	Weight
T1	Distributed system	2
T2	Response or throughput	1
T3	End-user efficient	1
T4	Complex internal processing	1
T5	Code must be reusable	1
T6	Easy to install	0.5
T7	Easy to use	0.5
T8	Portable	2
T9	Easy to change	1
T10	Concurrent	1
T11	Includes special security feature	1
T12	Access for third parties	1
T13	Special user training facilities required	1

Table VII [13] shows the 8 environment factors which indicate the experience level of people on project. The EFactor is calculated by adding all the numbers resulting from multiplying the value of each environment factors (F1-F8) by its weight.
EFactor = $\sum_i$ (F*i* $\times$ Weight) , where i = 1,...,8

The following formula is then applied to get the EF value: EF = 1.4 + (-0.03 × EFactor).

TABLE VII
WEIGHTING ENVIRONMENT FACTOR (EF) [13]

Factor number	Factor Description	Weight
F1	Familiar with RUP	1.5
F2	Application experience	0.5
F3	OO experience	1
F4	Lead analyst capability	0.5
F5	Motivation	1
F6	Stable requirements	2
F7	Part-time workers	-1
F8	Difficult programming language	-1

The value of unadjusted use case points (UUCP) is calculated by adding unadjusted actor weights (UAW) and unadjusted use case weights (UUCW) in UCP method. In this study, we use fuzzy unadjusted use case weights (FUUCW) to replace UUCW (see equation 2).

$$UUCP = UAW + FUUCW \tag{2}$$

The use case points of the system-to-be is generated by considering the technical complexity factors and environment factors using equation 3.

$$\text{Use Case Points} = UUCP \times TCF \times EF \tag{3}$$

IV. CASE STUDY

The meeting scheduler system is used to explain how our fuzzy size estimation method be applied. The detail steps are illustrated below.

A. Step 1: Assign Actor Weight and Unadjusted Use Case Point Weight

TABLE VIII
ACTOR WEIGHTS OF MEETING SCHEDULER SYSTEM

Actor	Actor Type	UAW
Meeting Initiator	complex	3
Meeting Participant	complex	3

Table VIII represents the unadjusted actor weights (UAW) of meeting scheduler system. The total UAW is calculated as: Total UAW = 2 complex = 2 × 3 = 6

Table IX represents the unadjusted use case weights (UUCW) of meeting scheduler system. The total UUCW is calculated as:
Total UUCW = 6 simple + 6 average + 3 complex = 6 × 5 + 6 × 10 + 3 × 15 = 30 + 60 + 45 = 135

B. Step 2: Fuzzify each Use Case with satisfaction value

Taking U_{PAM} as an example, we use the satisfaction values in the first column of table 2 to calculate *rValue* of U_{PAM} below.
$rValue = max(|U_{PAM}G_j|) + avg(\sum |U_{PAM}G_j| - max(|U_{PAM}G_j|))$ where n = # of goals, j= 1...n
$= 3 + 1.5 = 4.5$

The fuzzy input membership function then takes 4.5 as input to classify the relevance of U_{PAM} to the goals of meeting scheduler system into 0.2 average and 0.8 complex (see figure 6)

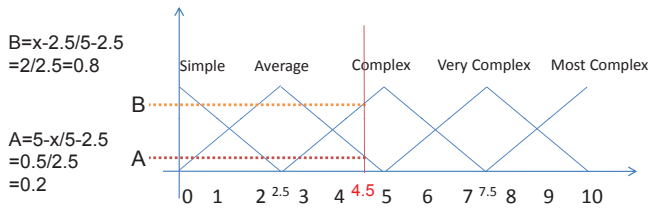

Fig. 6. U_{PAM} Example of Fuzzy Input Membership Function

C. Step 3: Calculate Unadjusted Use Case Weights with Fuzzy Rules

The fuzzy unadjusted use case weight (FUUCW) can be calculated by using center of gravity defuzzification with the output membership function of fuzzy rules. Since the complexity of U_{PAM} is complex and the results of the input membership function of *rValue* are 0.2 average and 0.8 complex, the rules matched is 0.2 complex and 0.8 very complex. We use the output membership function of fuzzy rules and center of gravity defuzzification to calculate the FUUCW which is 23.79 (see figure 7).

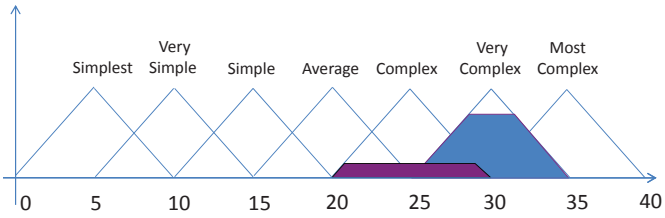

Fig. 7. U_{PAM} Example of Fuzzy Output Membership Function

Table IX represents the unadjusted use case points of meeting scheduler system.

TABLE IX
UNADJUSTED USE CASE POINTS OF MEETING SCHEDULER SYSTEM

Use Case	Use Case Type	UUCW	*rValue*	FUUCW
U_{PAM}	complex	15	4.5	23.79
U_{RAM}	simple	5	4.5	13.79
U_{RC}	complex	15	3.5	22.10
U_{MI}	average	10	3.0	16.21
U_{HMP}	simple	5	1.0	7.10
U_{AU}	average	10	3.0	16.21
U_{MC}	average	10	3.0	16.21
U_{KAP}	simple	10	3.0	16.21
U_{RM}	complex	15	3.5	22.10
U_{DP}	average	10	2.0	13.79
U_{AED}	average	10	2.0	13.79
U_{WM}	simple	5	1.0	7.10
U_{EPR}	simple	5	1.0	7.10
U_{SR}	simple	5	3.0	11.21
U_{MU}	simple	5	2.0	8.79
Total		135	40.0	215.50

D. Step 4: Calculate Use Case Points

To calculate the use case points of meeting scheduler system, we should consider TCF and EF of the system-to-be to adjust the overall complexity. Table X represents the technical complexity weights of meeting scheduler system. The TFactor is calculated as:
TFactor = 0+3+3+3+3+0.5+2.5+0+3+3+1+0+3 = 25
The TCF value is calculated as:
TCF = 0.6 + (0.01 $\times$ TFactor) = 0.6 + (0.01 $\times$ 25) = 0.85

TABLE X
TECHNICAL COMPLEXITY FACTORS OF MEETING SCHEDULER SYSTEM

Factor number	Weight	Assigned Value	Extended Value	Reason
T1	2	0	0	Not at first release
T2	1	3	3	Time response is one of the important criteria
T3	1	3	3	Needs to be efficient
T4	1	3	3	Needs to resolve conflicts
T5	1	3	3	Some code should be reused
T6	0.5	1	0.5	End users can use it through browser
T7	0.5	5	2.5	Needs to be easy for non-technical people
T8	2	0	0	Not at this time
T9	1	3	3	Yes
T10	1	3	3	Handle meeting in parallel
T11	1	1	1	Simple security
T12	1	0	0	No
T13	1	3	3	Require some training

Table XI represents the environment complexity weights of meeting scheduler system. The EFactor is calculated as:
EFactor = 3+1.5+3+2.5+5+6+0+(-1) = 20
The EF value is calculated as:
EF = 1.4 + (-0.03 $\times$ EFactor) = 1.4 + (-0.03 $\times$ 20) = 0.8

TABLE XI
ENVIRONMENT FACTORS OF MEETING SCHEDULER SYSTEM

Factor number	Weight	Assigned Value	Extended Value	Reason
F1	1.5	2	3	Some of team familiar
F2	0.5	3	1.5	Some of team familiar
F3	1	3	3	Some of team familiar
F4	0.5	5	2.5	Team is really good
F5	1	5	5	Team is really eager
F6	2	3	6	Changes may occur
F7	-1	0	0	No part-timers

Calculated by the equation 3, the total use case points of meeting scheduler system = (6+215.5) $\times$ 0.85 $\times$ 0.8 = 150.62

V. CONCLUSION

This article proposes a fuzzy size estimation method of goal-driven use cases using fuzzy theory by extending the use case point analysis method with the relations between use cases and goals. We evaluate and analyze the relations from use cases to goals to generate the relevance value which can be used as inputs of the fuzzy input membership function. The fuzzy unadjusted use case weight (FUUCW) can be calculated using center of gravity defuzzification with the matched fuzzy rules and output membership function. FUUCW not only considers the internal functionality of a use case but also its relations with other use cases and goals, which indicates the complexity of each use case. The total use case points shows the overall system size by considering the technical complexity factors and environment factors of the system under consideration.

Our future research plan will focus on applying our fuzzy size estimation method in more case studies and collecting historical data in the historical database for regression analysis.

***Abstract*—A fuzzy lymphedema clinical and functional assessment for classifying the risk of developing and its severity is proposed in this paper. Different from the previous approach where reversibility, skin infection, and skin changes were the input variables, this new fuzzy lymphedema clinical assessment takes into account the elements that compose the Brazilian Society of Lymphology (SBL). Such a SBL-based metric not only takes into account pre-clinical cases with risk of worsening and infective-degenerative local complications but also points out functional data of limb edema with the involvement of articular joints. The proposed approach includes both clinical (Pitting, Skin Changes, Stemmer Signal and Reversibility) and functional criteria (Joint Involvement). The fuzzy lymphedema assessment based on clinical and functional criteria allows establishing therapeutic global rehabilitative programs, degree of assistance necessity of patients, and reduction of the daily living activities.**

***Index Terms*—Lymphedema, Classification, Decision Support System, Fuzzy Logic, Artificial Intelligence, Computational Intelligence**

I. Introduction

Lymphedema is a condition of localized fluid retention and tissue swelling caused by compromised lymphatic systems. Often found in the extremities of the body, lymphedema is a sort of protein-rich edema that does not cause pain to the patient. Nevertheless, it is a syndrome with high prevalence in the worldwide population. In later stages, lymphedema can be a social disease that disqualify patients in their daily functional and labor activities [1].

If, for one side, lymphedema definition and characteristics are well established, on the other side, its classification is a question that remains open. The importance of classifying lymphedema concerns recognizing such a syndrome when presenting higher chance of evolving to health complications. Further, an adequate classification allows assigning appropriate treatment and, thus, reducing the morbidity risk [2].

Most of the cases of lymphedema are diagnosed by clinical findings such as reversibility, pitting, stemmer signal, among others. Lymphedema can also be classified according to its cause as primary (congenital, precocious or late presentation) or secondary (mainly associated to inflammatory processes, cancer, neoplasy, and trauma).

The etiological classification mechanisms of lymphedema present adhesion among experts in daily practice. Classifying them, however, according to their etiological aspects can be restrained. Existing etiological–based classifications not always takes into account the severity of their clinical or functional impairment [3], [4], [5].

The severity classification mechanisms of lymphedema, on the other hand, often take into account the clinical and functional characteristics. They are recommended because play a relevant role in the elaboration of criteria for measuring the risk and the development level of lymphedema. These classifications, however, present the inconvenient of not always being accessible to all experts. They or use expensive methods such as imaging tests either are too complex in its applicability due to subjective variables that depend on the observer's viewpoint. The later aspect concerns vague, imprecise, and uncertain qualification [6].

An alternative to represent the inherent subjectivity concerning the human decision to quantify the severity of lymphedema is to use fuzzy set theory and fuzzy logic. They present great appeal in the real world, being of special interest to biosciences as confirmed by the considerable increase of medical studies related to the fuzzy logic in last decades. The literature has shown that the application of fuzzy sets has a great capacity for application to biomedical problems, due to the type of uncertainty involved in medical, biological, and epidemiological procedures. Fuzzy sets associate degrees of membership values in a subset instead a rigid yes or no decision. It also uses the partiality concept by a computationally effective way while fuzzy logic allows inference in approximate reasoning [7], [8].

The proposed approach uses the Mamdani method for representing the heuristic knowledge of experts to build the

TABLE I
LYMPHEDEMA CLINICAL AND FUNCTIONAL SEVERITY ASSESSMENT ACCORDING TO THE BRAZILIAN SOCIETY OF LYMPHOLOGY (SBL).

Stage	Clinics
0	No edema in a risk patient
1	Edema which reduces spontaneously with anti–gravitation position, Pitting ++, Stemmer +, Involvement of at least two joints
2	Edema which do not reduce spontaneously but only with treatment, Pitting +, Stemmer +, Involvement of at least two joints
3	Edema which do not reduce spontaneously but partially only after treatment, Pitting +, Stemmer +, Involvement of at least three joints
4	Edema which do not reduce spontaneously but partially only after treatment, Pitting +, Stemmer +, Involvement of at least three joints, with skin changes

rule base of a Fuzzy Decision Support System (FDSS) to assess the clinical and functional severity of lymphedema. The proposed fuzzy system is based on the expertise obtained in the design of a previous lymphedema fuzzy system which is based on the classification adopted by World Health Organization (WHO) [9], [10]. This paper extends previous approach to the Lymphedema classification mechanism adopted by the Brazilian Society of Lymphology since it includes both clinical and functional criteria.

II. LYMPHEDEMA FUZZY DECISION SUPPORT SYSTEM

Current classification mechanisms for measuring the risk and the development level of lymphedema are accomplished by using classic (Aristotelian) set theory. According to it, the patient belongs to a set (class), or not, as exemplified in Table I. Therein are exposed the variables and criteria of classification for lymphedema clinical and functional severity assessment according to the Brazilian Society of Lymphology (SBL – Sociedade Brasileira de Linfedema). Nevertheless, it does not seem appropriate to attribute a Boolean classification for lymphedema severity since pitting, stemmer signal, reversibility (edema reduction) variables and terms as "partially" are inherently subjective, arbitrary, and dependent on the observer's viewpoint and expertise. Further, a patient can simultaneously belong to grade 1 because it has a good reversibility, but presents 3 involvement joints that characterize grade 3 or 4.

Building a decision support system as a grading system for clinical and functional lymphedema assessment by using fuzzy logic can be an interactive and flexible alternative that represents the approximate reasoning or experts in supporting and improving the process of decision making.

Note that all the figures herein are normalized in the range from 0 to 1.

A. Input Linguistic Variable

The proposed FDSS for fuzzy lymphedema assessment based on clinical and functional criteria is based on the lymphedema evaluation method as recommended by the Brazilian Society of Lymphology as presented in Table I.

Clinical signals evaluated by experts in the diagnosis of the severity of lymphedema forms the input variables of the proposed model. These are: Pitting (P), Skin Changes (C), Stemmer Signal (S), Reversibility (R), and Articular Joint, forming the Fuzzy (Skin)–Changes–Stemmer–Pitting–Reversibility–Articular–Joint Lymphedema Assessment.

1) Pitting (P):

Pitting refers to the consistency of the symptom of swelling in lymphedema. The consistency is evaluated by the palpation (touching) of the area presenting fluid retention and/or Godet signal, which consists of compression of the swollen area with the thumb. After removal of the thumb, it must be noticed the pitting. In hypertrophic, lipid, or spongy tissues, the depression caused by digital pressure disappears immediately (+++), which can characterize a soft or elastic type of swelling, for example, being defined as depressible edema. When the digital signal in the skin disappears in less than 1 minute, i.e., quickly (++); it is characterized a soft, malleable type of swelling being defined as partially depressing. Finally, but not less important, when the depression slowly disappears (+), or disappear in the range of 5 minutes or persists (0), the edema is defined as being non–depressing, also classified as hard or non-elastic type [11]. Additionally, it is important to emphasize that the soft swelling concerns better prognosis by charactering the liquid present in this type of edema as being easier treated and by associating this sort of signal as presenting a tissue of less fibrosis [5]. The pitting variable and the partition of the universe of discourse in depicted in Fig. 1. The linguistic terms are Immediately, Quickly, and Slowly, characterizing the speed in which the swelling due to the pitting is reduced.

2) Skin Changes (C):

Skin changes are factors associated to progression or regression concerning developmental stages of lymphedema. Examples are surgical or burns scars, signs of venous stasis, fissures, bumps, dermatofibrosclerosis, dermatitis, and skin ulcers and warty lesions that can be considered as gateways

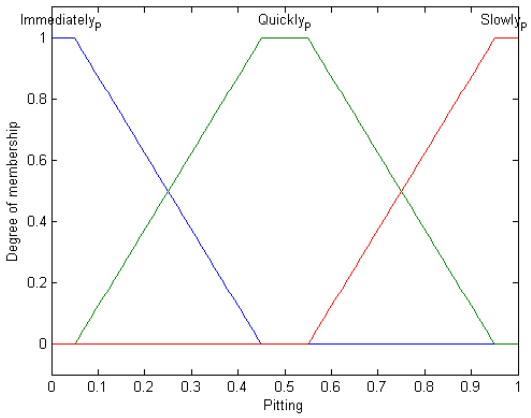

Fig. 1. Input Linguistic Variable: Pitting.

to infections. Some lesions are present and definitive while others (such as ulcers) may be transitory, making their classification still more difficult [2]. The classification of the Brazilian Society of Lymphology uses this variable to indicate greater severity, using only in the Grade 4. Clinically, it is a variable largely used for the assessment and grading the severity of lymphedema. Nevertheless, because it is a signal frequently discussed and presenting no consensus, it is difficult to determine a standard when taking into account all the current lymphedema classifications. Consequently, it brings forward a dangerous situation. The same classification term of skin changes employed by an expert can represent a complete different classification and meaning for another expert, resulting to erroneous problems in analysis, diagnosis, and treatment according to each reviewer. Further, this variable of classifications sometimes is used to quantify while others is employed to qualify the skin modifications. Due to that, this variable is also inherently subjective, arbitrary, and depends on the observer's viewpoint and expertise being able to be represented by employing fuzzy sets. The skin change variable and the partition of the universe of discourse in presented in Fig. 2 such that the linguistic terms comprise three classes of occurrence: Low, Moderate, and Intense.

3) Stemmer Signal (S):

This signal consists on skin thickening of the second toe and is obtained by the examiner when trying to do a grip of the skin from this region. In patients with lymphedema, it can be seen that there is an infiltration of the tissues, restricting an adequate grip of the skin [11]. Totally subjective and expert dependent, the universe of discourse and the fuzzy sets are shown in Fig. 3. Due to the nature of stemmer signal it is assigned only two linguistic fuzzy sets whose linguistic terms are None and Total.

4) Reversibility (R):

Reversibility is the input variable that refers to the property of edema be reverted to its previous state. Such a capacity can occur spontaneously and natural, spontaneously when elevated, or after being subjected to treatment. Some classifications only admit the possibility of edema, regardless being reversible, or not, while others stratify it based on the speed rating that lymphedema can reverse [3], [6], [10], [12], [13]. The classification recommended by the Brazilian Society of Lymphology uses the last two modes of reversibility. Moreover, the SBL classification is the only one that takes into account the treatment as a factor that boosts the reversibility speed [10] as presented in Table I. From the perspective of the variable reversibility, this classification comprises edemas that can reverse spontaneously but when in anti–gravitation position – i.e., the member put in elevate position –, featuring as Grade 1; edemas in which the swelling does not reduce spontaneously but reduces with treatment, being classified as Grade 2; and edemas in which the swelling does not reduce spontaneously but reduces partially with treatment, encompassing the Grades 3 and 4. It is worth pointing out that this classification does not contemplate the possibility of an edema does not revert. The reversibility variable and the partition of the universe of discourse in illustrated in Fig. 4 and the fuzzy sets are assigned in order to encompass the SBL requirements:

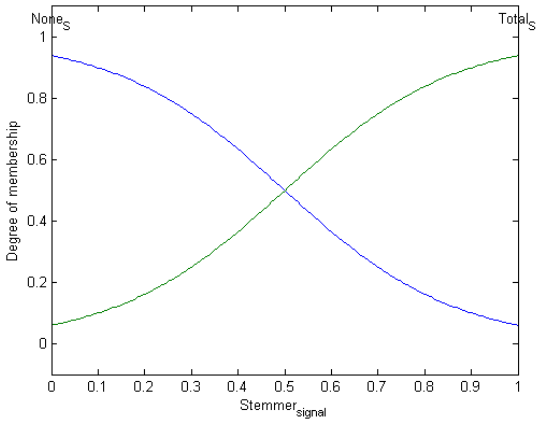

Fig. 3. Input Linguistic Variable: Stemmer Signal.

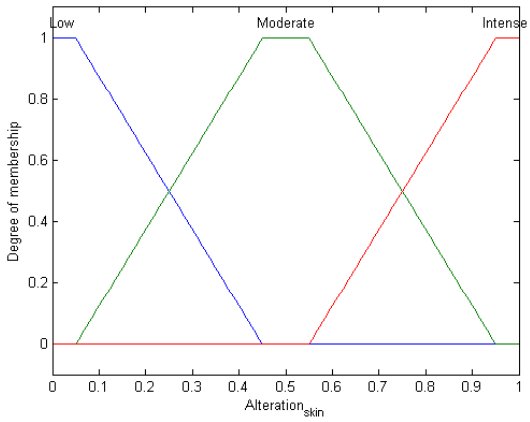

Fig. 2. Input Linguistic Variable: Skin Changes.

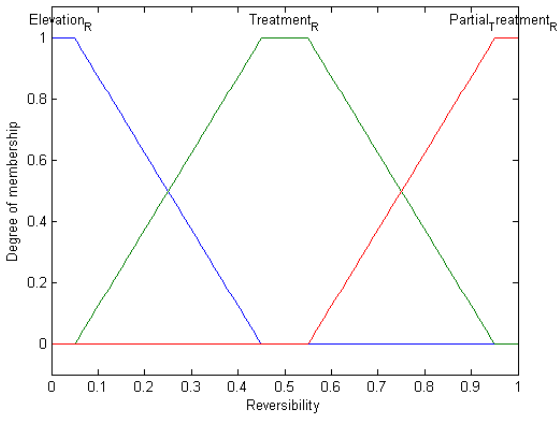

Fig. 4. Input Linguistic Variable: Reversibility.

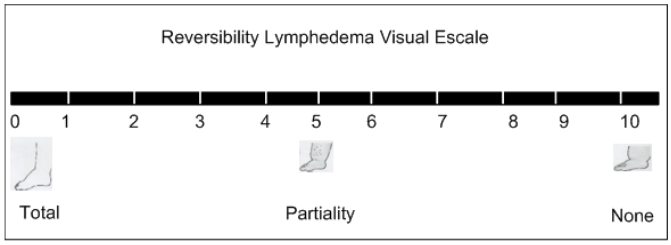

Fig. 5. Reversibility Lymphedema Visual Scale.

Elevation, Treatment, and Partial Treatment. Observe that it is considered that in all conditions the reversibility takes place. Additionally, the proposed fuzzy assessment innovate in presenting a qualitative reversibility assessment where the healthcare professional ask the patient to mark on a scale from 0 to 10 how the signal representing edema reverts (Fig. 5) according to previous approach suggested in [14]. Inspired on pain intensity scales, the proposed lymphedema reversibility scale (LRS) can deal with both singleton and fuzzy measurement following the same mechanism and understanding as presented for the fuzzy pain intensity scale in [15].

5) Articular Joint Involvement (AJI):

Articular joint involvement is a functional criterion used for evaluating the severity of Lymphedema. The articular joint involvement analysis points out functional data of limb edema when interested in dealing with big articular joint problems. According to this criterion it can evaluate only one big joint of the limb, two or the all three big articular joints. This aspect allows establishing the therapeutic global rehabilitative program, the degree of necessity of assistance of the patient, and the reduction of the daily living activities. Likewise stemmer signal, due to the nature of articular joint involvement analysis it is assigned only two linguistic fuzzy sets whose linguistic terms are Low and Total (Fig. 6).

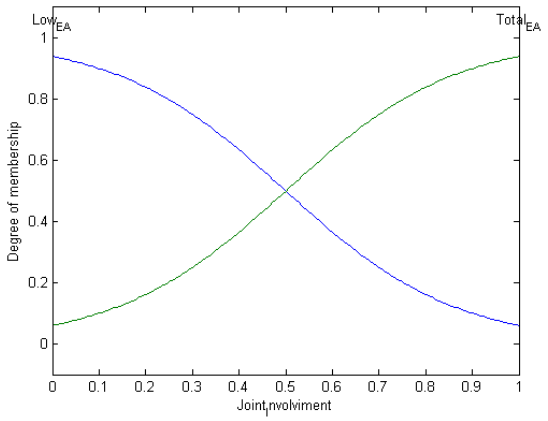

Fig. 6. Input Linguistic Variable: Articular Joint.

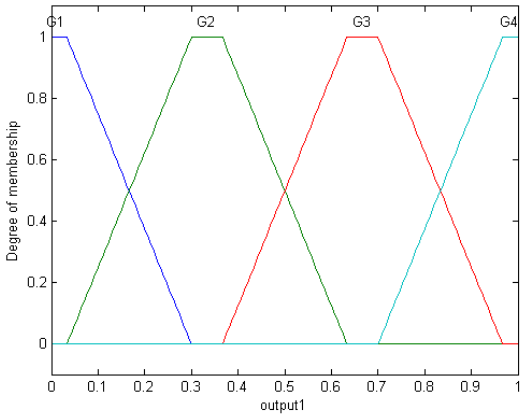

Fig. 7. Output Linguistic Variable: Lymphedema Severity.

B. Output Linguistic Variable

The outcome assessment of clinical and functional lymphedema is the severity linguistic variable. The linguistic terms that characterize the output variable are: $G1$, $G2$, $G3$ and $G4$, where $G(\cdot)$ means the grade of lymphedema severity in a discourse universe which ranges from 0 to 10 (Fig. 7). The classification of the Brazilian Society of Lymphology also uses the possibility of lymphedema presenting grade 0 that means the risk of developing lymphedema. When using the Fuzzy Lymphedema System the risk of developing lymphedema is imbedded since it can also compute the null value according to the inputs furnished to it. Further, the proposed system is able to grade the risk of developing lymphedema when the syndrome is in its initial stages.

C. Fuzzy Rules

The Mamdani fuzzy system presents its structure as a nonlinear mapping based on IF-THEN rules. Based on a review of the literature and internationally, worldwide valid classifications, the set of 3–3–3–2–2 linguistic terms that part the input universes of discourse, respectively, pitting, skin changes, stemmer signal, reversibility, and articular joint, yield a set of 89 valid fuzzy regions in a five-dimensional input space. Despite a complete 3–3–3–2–2 rule base contains 108 rules, there are rules not valid at all due to human health conditions as stated by the standard of clinical and functional criteria recommended by the Brazilian Society of Lymphology. Further, although rules could be merged in some circumstances, here they are formally separated to help enhancing transparency, mainly because there would be healthcare professionals not able to handle mathematical, logical languages.

The Fuzzy Lymphedema assessment based on clinical and functional criteria recommended by the Brazilian Society of Lymphology is, thus, represented as IF-THEN *fuzzy rules* in

the form:

$$
\begin{aligned}
\mathrm{R}_1 : \text{IF } &\langle \textit{Pitting} \text{ reduces Immediately} \rangle \text{ AND } \ldots \\
&\langle \textit{Stemmer} \text{ is None} \rangle \text{ AND } \ldots \\
&\langle \textit{Skin Changes} \text{ is Low} \rangle \text{ AND } \ldots \\
&\langle \textit{Reversibility} \text{ is Elevation} \rangle \text{ AND} \\
&\langle \textit{Articular Joint} \text{ is Low} \rangle \ldots \\
\text{THEN } &\langle \textit{Lymphedema Severity} \text{ is G1} \rangle \ , \\
\mathrm{R}_2 : \text{IF } &\langle \textit{Pitting} \text{ reduces Quickly} \rangle \text{ AND } \ldots \\
&\langle \textit{Stemmer} \text{ is None} \rangle \text{ AND } \ldots \\
&\langle \textit{Skin Changes} \text{ is Low} \rangle \text{ AND } \ldots \\
&\langle \textit{Reversibility} \text{ is Elevation} \rangle \text{ AND} \\
&\langle \textit{Articular Joint} \text{ is Low} \rangle \ldots \\
\text{THEN } &\langle \textit{Lymphedema Severity} \text{ is G1} \rangle \ , \\
&\ldots \\
\mathrm{R}_{88} : \text{IF } &\langle \textit{Pitting} \text{ reduces Quickly} \rangle \text{ AND } \ldots \\
&\langle \textit{Stemmer} \text{ is None} \rangle \text{ AND } \ldots \\
&\langle \textit{Skin Changes} \text{ is Intense} \rangle \text{ AND } \ldots \\
&\langle \textit{Reversibility} \text{ is Partial} \rangle \text{ AND} \\
&\langle \textit{Articular Joint} \text{ is Total} \rangle \ldots \\
\text{THEN } &\langle \textit{Lymphedema Severity} \text{ is G4} \rangle \ , \\
\mathrm{R}_{89} : \text{IF } &\langle \textit{Pitting} \text{ reduces Slowly} \rangle \text{ AND } \ldots \\
&\langle \textit{Stemmer} \text{ is None} \rangle \text{ AND } \ldots \\
&\langle \textit{Skin Changes} \text{ is Intense} \rangle \text{ AND } \ldots \\
&\langle \textit{Reversibility} \text{ is Partial} \rangle \text{ AND} \\
&\langle \textit{Articular Joint} \text{ is Total} \rangle \ldots \\
\text{THEN } &\langle \textit{Lymphedema Severity} \text{ is G4} \rangle \ ,
\end{aligned}
\tag{1}
$$

such that linguistic terms part the respective universes of discourse, X_k and Y and the input vector of the premise is given by $x = [x_1, x_2, x_3]^T$, while the output is associated to y.

III. Results and Discussion

At the XX International Congress of Lymphology, in a special session concerning consensus on lymphedema staging, the Brazilian Society of Lymphology proposed a classification mechanism for lymphedema [10]. This classification is, here, chosen to design a Fuzzy Decision Support System to classify the lymphedema clinical and functional severity as a comparative metric. This choice is carried out because such a SBS-based lymphedema assessment is the classification that best represents the intermediate states of the clinical and functional signals assessed by healthcare professionals.

The proposed fuzzy classification, however, advantages upon the inspired classification method by the fact that depressibility (pitting) can be graded as immediately, quickly and slowly reduced, instead of, depressing or not. Contrary to the inspired model that does not achieve the real demand in diagnosing patients porting the two concomitant intermediate possibilities, the fuzzy lymphedema assessment satisfy this demand when employing fuzzy set theory. This aspect makes fuzzy set theory effectively applied; it allows the quantitative mapping of membership degree of evaluated clinical signs and the overlapping of classes. The SBL classification allows yet that the functionality assessment be evaluated when associated to the linguistic variable articular joint involvement.

In order to demonstrate the effectiveness of the proposed fuzzy decision support system for classifying the lymphedema severity, data from literature and experts are employed. Results obtained by the comparison between the proposed method of lymphedema classification and the SBL approach is shown in Table II. Seven patients presenting diverse severity levels of lymphedema are distributed therein.

In daily practice, experts hardly face patient with lymphedema presenting the same clinical conditions. Subtle or large differences are present and the severity assessment mechanism must be able to capture these variations. For instance, when using the traditional method for classifying lymphedema, the patient can present reversibility only after treatment, thus characterizing it as grade 3 or 4, but not more than two articular joints are involved, which characterizes a grade 1. Pitting, skin changes, stemmer sign are healthcare

TABLE II
Results comparison between the Brazilian Society of Lymphology classification and the proposed model.

Pitting		Skin Changes		Stemmer Signal		Reversibility		Joint Involvement		SBL Classification	PASRIJ Classification	Severity Value
0.1	Immediately	0.1	Low	0.1	None	0.1	Limb Elevat	0.1	Low	Grade 1	Grade 1	0.15
0.1	Immediately	0.2	Low	0.3	None	0.1	Limb Elevat	0.3	Low	Grade 1	Grade 1 & 2	0.39
0.1	Immediately	0.2	Low	0.3	None	0.5	Treatment	0.3	Low	Grade 2	Grade 2	0.43
0.5	Quickly	0.9	Intense	0,6	Total	0.5	Treatment	0.5	Total	Grade 3	Grade 2 & 3	0.51
0.7	Slowly	0.6	Low	0.7	Total	0.6	Treatment	0.4	Low	Grade 3	Grade 3	0,63
0.8	Slowly	0.7	Intense	0.7	Total	0.6	Treatment	0.7	Total	Grade 3	Grade 3 & 4	0,74
0.8	Slowly	0.6	Intense	0.8	Total	0.8	Partial Treatm	0.8	Total	Grade 4	Grade 4	0,87

professional dependent. Such an inherent subjectivity in the process of staging the severity of lymphedema demonstrates vagueness and uncertainty which hampers the standardization of a classification that can be easy, simple, and widely applied. The seven patients presented in Table II feature subtle differences among the input parameters of evaluation. Observe that when the objective is to analyze classes, the results obtained with the fuzzy lymphedema system are quite similar to the method of classification used by the SBL. They barely differ except when the patient presents clinical characteristics simultaneously belonging to two classes when using the proposed fuzzy assessment. The fuzzy system allows this possibility because the classes accept the relevance of severity in different degrees being an advantage, more than a problem, mainly because the final result of evaluation can cope not only with qualitative but quantitative results.

Due to that, the proposed fuzzy lymphedema clinical and functional severity assessment not only is compatible to SBL-inspired model but carries two other important features. First, not only a class of severity is presented but there is a value, score associate to the classification allowing the value be used for objective comparative analysis and for being employed as the factor for determining the medication. Second, both qualitative and quantitative values are able to be determined by using computers or any of now–a–day available electronic devices.

It is noteworthy that this paper is a result of activities in research and development at the Hospital Municipal Dr. José de Carvalho Florense (HMJCF) and Universidade Federal de São Paulo (UNIFESP), and approved by two Committees for Research Ethics.

IV. Conclusion

The use of Fuzzy Logic becomes an alternative to stage the clinical and functional severity of lymphedema. Diagnosing and grading the diverse levels of severity of lymphedema requires dealing with diverse subjective parameters and variables that depends on the observer's viewpoint and expertise. The proposed approach turns out to be an effective tool of classification method that may cooperate with the standardization of therapeutic management of lymphedema and its classification, which is essential for the systematization of health care and decreasing morbidity in patients with high developed lymphedema.

The clinical parameters comprise pitting, skin changes, stemmer signal and reversibility whereas the functional criterion is the articular joint Involvement. The fuzzy lymphedema assessment based on clinical and functional criteria allows establishing therapeutic global rehabilitative programs, degree of assistance necessity of patients, and reduction of the daily living activities.

***Abstract*—In this paper, we propose a decision making method based on reinforcement learning and emotion learning (DRE) for inducing social behaviors of robots. Emotion of animals has an important role in their social interactions. We attempt to incorporate emotion into decision making of robots. To make a social decision making, the DRE combines a decision based on intrinsic fear emotion with a strategic decision obtained by reinforcement learning. Agents with the DRE learn state values by reinforcement learning and learn emotion values by fear emotion learning. In simulation experiments, the effectiveness of the DRE is verified concerning the emergence of social behaviors and the adaptability to an environmental change through an unmoving target search problem.**

I. Introduction

Robot technologies have been under rapid development during recent years. Robots are expected as a new labor force in the coming aging society with fewer children and are expected to work with humans in our daily life. Nursing-care and medical robots have been developed and some of them have already worked instead of humans [1]. In this situation, robots are required to coexist and cooperate with humans.

Emotion of animals determines whether or not their feelings are pleasure from their own experience and situation at the time. This ability is very important for animals to decide their actions such as approaching or avoidance action. Furthermore, emotion has an important role in social interaction between animals which have the sociality like humans. The influence of emotion on decision making has been investigated in neuro-physiological and neuropsychological studies [2], [3]. Emotion is now attracting attention as the ability to enhance robots' sociality [4], [5]. Currently, most of robotics studies regarding emotion employ emotion for expressing the internal states of robots when the robots interact with humans (e.g., [6]). To realize robots with sociality, we consider that emotion should be incorporated into decision making of robots.

In this paper, we propose a Decision making method based on Reinforcement learning and Emotion learning (DRE) for inducing social behaviors and for realizing robots with sociality. The DRE combines a decision based on intrinsic fear emotion with a strategic decision obtained by reinforcement learning. Reinforcement learning has been successfully used as an action learning method in the field of robotics to make decision and take actions based on the experience of robots [7]. Fear emotions are involved with avoidance behaviors of animals. In simulation experiments, the effectiveness of the DRE is investigated through an unmoving target search problem. We confirm the emergence of social behaviors and the adaptability of agents with DRE to an environmental change.

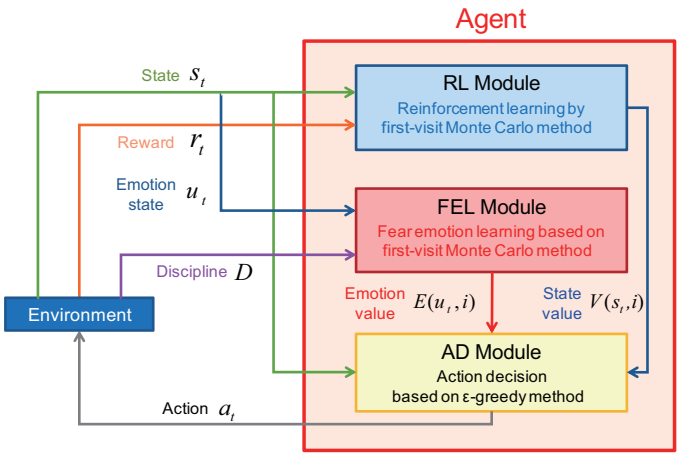

Fig. 1. Agent with DRE. The DRE comprises three modules: reinforcement learning (RL) module, fear emotion learning (FEL) module and action decision (AD) module.

II. DRE

In this research, an unmoving target search problem is considered. The task of agents is to reach one of the targets first within a limit of time steps. In addition to this task, the agents are disciplined when some conditions are met. However, they do not know this condition, that is, why they are disciplined. This is considered as fear emotional experience for the agents. The agents need to take in account not only achieving the task but also avoiding disciplines. In this paper, the condition of disciplines is that the agents do not perform social behaviors. Under this situation, the emergence of social behaviors is investigated. Social behaviors defined in this research are described in the next section.

The architecture of an agent with DRE is shown in Fig. 1. The DRE consists of three modules: reinforcement learning (RL) module, fear emotion learning (FEL) module and action decision (AD) module. Agents with DRE learn state values by

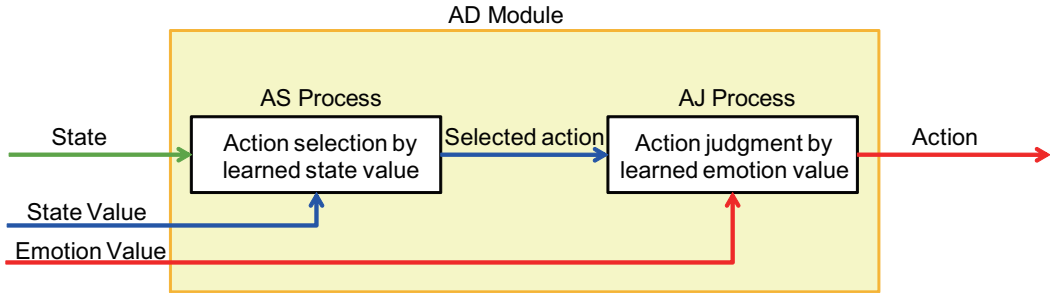

Fig. 2. Action decision (AD) module. The AD module has two processes: action-selection (AS) process and action-judgment (AJ) process.

reinforcement learning in the RL module and learn emotion values by fear emotion learning in the FEL module. In the AD module, the agents decide their actions based on both state and emotion values. These modules are described in detail below.

A. RL module

Reinforcement learning is an unsupervised learning method of machine learning. In reinforcement learning, agents can learn adequate actions to complete tasks by trial and error in interaction with an environment [7]. This learning is achieved by maximizing the cumulative rewards from the environment.

In the DRE, a basic Monte Carlo method is used for learning actions of agents to complete tasks. Actions are selected by using state values. In the RL module, the first-visit MC method is employed, that is, a state value in the position of an agent is updated only once even if the agent visits the position twice.

If an agent can reach the targets at time step t' in the i-th episode, a return R (a positive constant) is given to the agent and state values $V(s_t, i)(t = 1, 2, \ldots, t')$ are updated by

$$V(s_t, i+1) = V(s_t, i) + \alpha \cdot (r_t - V(s_t, i)), \qquad (1)$$

where t, s_t and α are time step, state and learning rate, respectively.

The discount return r_t for the state s_t is given by

$$r_t = \gamma^{t'-t} \cdot R, \qquad (2)$$

where γ is a discount rate. On the other hand, if the agents cannot reach the targets in the i-th episode, all the state values decay with a decay rate η as follows.

$$V(s, i+1) = \eta \cdot V(s, i) \quad \forall\ s. \qquad (3)$$

B. FEL module

Emotion of animals induces their feelings and affects their action selection. Recent researches in brain science show that the amygdala of cerebral limbic system processes fear emotions and plays an important role for the survival of animals [8]. Fear emotions are involved with avoidance behaviors of animals such as avoiding natural enemies and areas where they previously suffered fear experience. The concept of fear emotion is used as emotion in this paper.

The agents decide their actions based not only on the strategic judgment obtained by reinforcement learning but also on their intrinsic fear emotion. Namely, the agents select their behaviors using both state and emotion values. An emotion value is defined for an emotion state u_t. Th emotion state u_t represents the situation inducing disciplines (e.g., the combination of the agents' positions). In the FEL module, the first-visit MC method is also employed. If the agents are disciplined at time step t^* in the i-th episode, the emotion values $E(u_t, i)$ $(t = 1, 2, \ldots, t^*)$ are updated by the following equation.

$$E(u_t, i+1) = \zeta^{t^*-t} \cdot \{E(u_t, i) + \alpha' \cdot (D - E(u_t, i))\}, \qquad (4)$$

where ζ, α' and D are a discount rate, learning rate and discipline value (a negative constant) given at time step t^*, respectively. To enhance the latest emotion experience, the emotion values of the emotion states that are not updated in this episode decay with a decay rate β as follows.

$$E(u, i+1) = \beta \cdot E(u, i) \quad \text{for} \quad u \notin U_i, \qquad (5)$$

where U_i is a set of the emotion states experienced in the ith episode. If the agents are not disciplined in ith episode, the emotion values $E(u, i)$ are updated by

$$E(u, i+1) = E(u, i) \quad \forall\ u. \qquad (6)$$

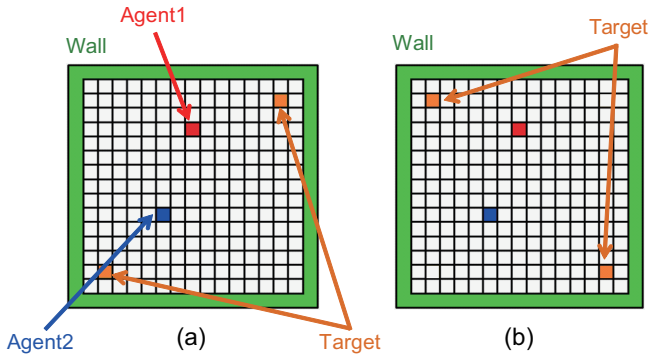

Fig. 3. Discrete grid field (15×15 cells). Each cell corresponds to a state in the DRE. (a) Target positions in the first experiment. (b) Target position after 1000th episode in the second experiment.

C. AD module

Fig. 2 shows the action decision process of the agents. The AD module has two processes: action-selection (AS) process

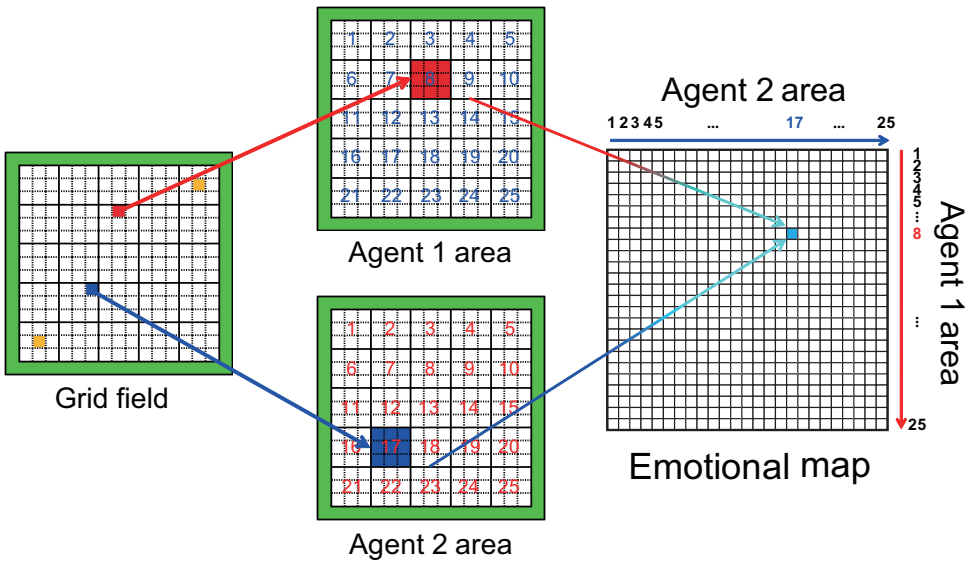

Fig. 4. Agent areas and emotion states. The grid field is separated into 25 (5×5) areas. An emotion state in the DRE corresponds to a combination of one agent area and the other agent area.

and action-judgment (AJ) process. The ε-greedy strategy is employed in the both processes. In the AS process, an action is randomly selected at probability ε_s (random selection) and is selected based on the state values at probability $1-\varepsilon_s$ (greedy selection). In the greedy selection, the agent selects an action to move to a state with the highest state value around them. In the AJ process, the action selected in the AS process is decided as the next action at probability ε_e (state-value judgment) and the next action is decided based on the emotion values at probability $1-\varepsilon_e$ (emotion-value judgment). In the emotion-value judgment, the agents select an action that the agents can approach a state with the highest emotion value around them. In other words, an action is randomly selected at probability $\varepsilon_s \cdot \varepsilon_e$, greedily at probability $(1-\varepsilon_s)\cdot\varepsilon_e$ and emotionally at probability $1-\varepsilon_e$.

III. Simulation Experiments

We conducted simulation experiments to verify the effectiveness of the DRE concerning the emergence of social behaviors and the adaptability to an environmental change.

Experimental setting

Two agents and two unmoving targets in a discrete grid field (15×15 cells) were used as shown in Fig. 3(a). The agents can observe and reach the targets if the targets are in the cells next to the agents. The task of the agents is to reach one of the targets first within a limit of time steps T_L. If the agent completes this task, a return R is given to the agent. A state s used in the RL module corresponds to a cell.

In this paper, "cooperative behaviors" that the agents reach the different targets, were defined as social behaviors. The agents were disciplined if they did not achieve the cooperative behaviors within the time limit T_L. Furthermore, if the agents collided with each other at an episode, they were disciplined and the episode was terminated. To achieve the cooperative behaviors, the agents need to take in account not only achieving the task but also avoiding disciplines.

An emotion state u used in the FEL module was defined as a combination of one agent area and the other agent area. An agent area was comprised of 3×3 cells. Thus, the grid field was separated into 25 (5×5) areas as shown in Fig. 4. Each agent can sense the area where the other agent is. Emotion map was comprised of 625 (25×25) emotion states that were all possible combinations of the agent areas (Fig. 4). The reason of using not the cells but the areas is that animals may avoid not a point but a rough area around the point if they previously suffered fear experience at the point.

The agents can move in the field by selecting one of actions: up, down, right and left. In the greedy selection of the AS process, the agents select an action that the agents can move to a cell with the highest state value around them. In the emotion-value judgment of the AJ process, the agents select an action that the agents can approach an area with the highest emotion value around them.

In the following experiments, agents with DRE were compared with agents with RL and agents with cooperative behavior learning (CL). In the rest of this section, we represent agent with DRE, agent with RL and agent with CL as DRE agent, RL agent and CL agent, respectively.

The RL agents have the RL and AD modules. State values of the RL agents were learned by the first-visit MC method. Only the parameter ε_s was used in the AD module of the RL agents. The RL agent was identical to the DRE agent with $\varepsilon_e = 1$. If the agents collided with each other at an episode, the episode was terminated. The effectiveness of the emotion-value judgment was investigated by the comparison between the DRE agents and RL agents.

The CL agents have the RL and AD modules. State values

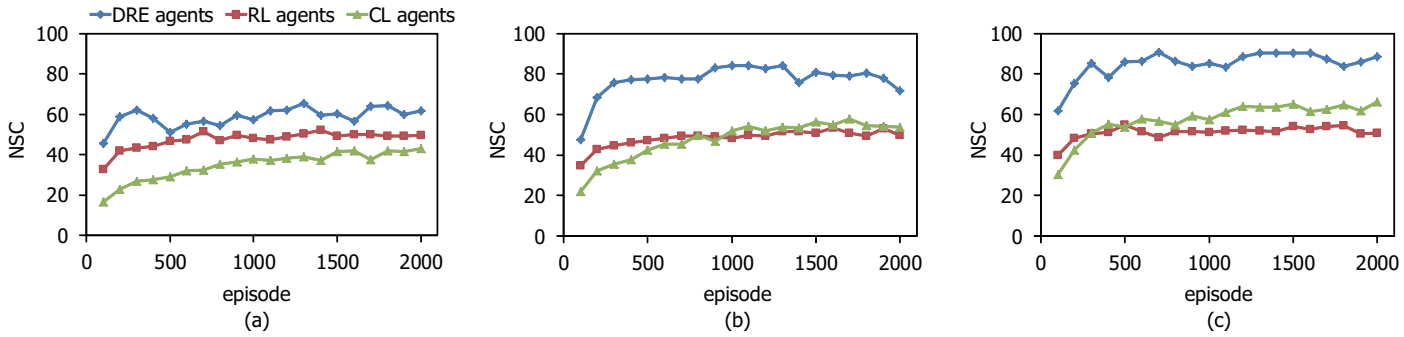

Fig. 5. Number of successful cooperative behaviors (NSC) in the first experiment. The limits of time steps T_L were (a) 30, (b) 40, and (c) 50 steps, respectively.

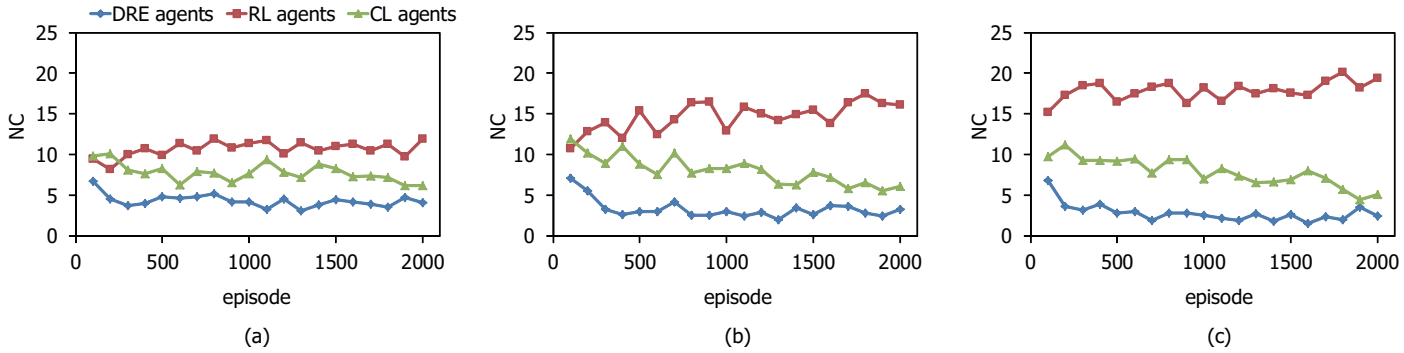

Fig. 6. Number of collisions (NC) in the first experiment. The limits of time steps T_L were (a) 30, (b) 40, and (c) 50 steps, respectively.

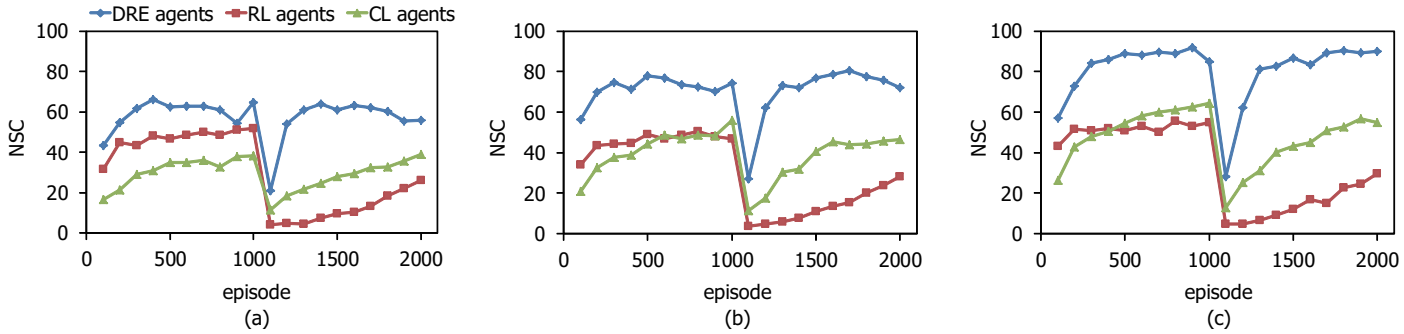

Fig. 7. The number of successful cooperative behaviors (NSC) in the second experiment. The positions of targets were changed after the 1000th episode. The limits of time steps T_L were (a) 30, (b) 40, and (c) 50 steps, respectively.

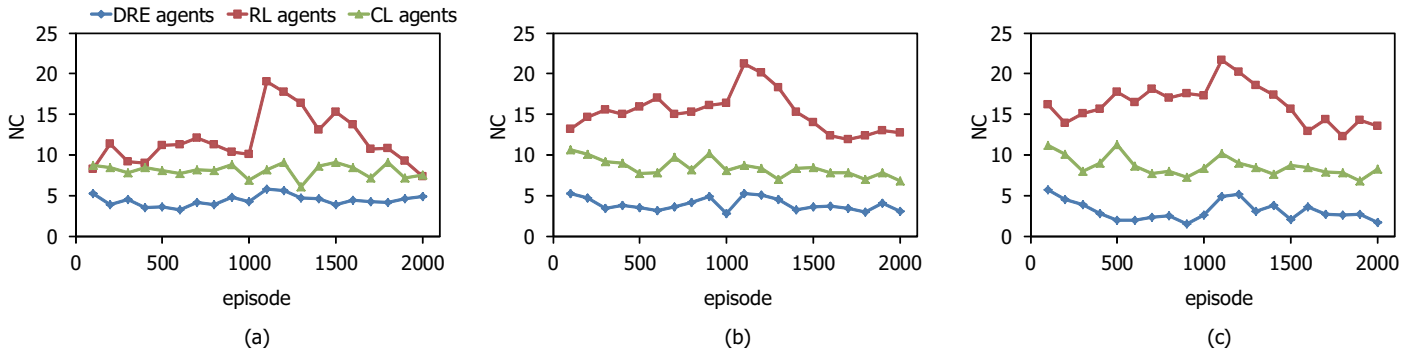

Fig. 8. The number of collisions (NC) in the second experiment. The positions of targets were changed after the 1000th episode. The limits of time steps T_L were (a) 30, (b) 40, and (c) 50 steps, respectively.

of the CL agents were learned by the first-visit MC method. Unlike the DRE and RL agents, a state of the CL agents was defined as a combination of one agent's cell and the other agent's cell. A positive return R was given to the CL agents if they achieved the cooperative behaviors and a negative return D if they did not. Therefore, the task of the CL agents is to achieve the cooperative behaviors. Only the parameter ε_s was used in the AD module of the CL agents. If the agents collided with each other at an episode, the negative return D was given to the CL agents and the episode was terminated. The effectiveness of the separation of RL and FEL was investigated by the comparison between the DRE agents and CL agents.

In the experiments, the parameters were set as follows; $\varepsilon_s = 0.1, \varepsilon_e = 0.1, R = 10, \alpha = 0.1, \gamma = 0.95, \eta = 0.99, D = -10, \alpha' = 0.9, \beta = 0.9$ and $\zeta = 0.5$. At the beginning of each episode, the positions of the agents were randomly assigned. The state and emotion values were set to zero at the beginning of the first episode. Two thousand episodes were defined as one trial. During trial, the number of successful cooperative behaviors (NSC) and the number of collisions (NC) were counted every 100 steps.

Experiment 1: Emergence of cooperative behavior

The first experiment was conducted to confirm the emergence of cooperative behaviors by using the emotion values. Figs. 5(a), (b) and (c) show the NSCs when T_L was 30, 40 and 50, respectively. The results presented in Fig. 5 are the average values of the NSC over ten trials. The NSC of the DRE agents increased with episodes and was more than those of the RL and CL agents. The NSC of the DRE and CL agents increased as T_L increased. The NSC of the RL agents converged around fifty. The RL agents approached the nearest target from their initial positions and the cooperative behaviors occurred by chance since the RL agents were not intended for the cooperative behavior. The NSC of the CL agent increased with episodes but was less than that of the DRE agents. This was because the number of the states of the CL agents was 50,625 (225×225) and was more than that of the DRE agents. The number of episodes may be insufficient to learn the whole of the state values of the CL agents although the CL agents were intended for the cooperative behavior. The DRE agents were not directly intended for the cooperative behavior. However, the first priority was given to the emotional judgment in the AJ process and this resulted in the emergence of the cooperative behavior.

Figs. 6(a), (b) and (c) show the NCs when T_L was 30, 40 and 50, respectively. The results presented in Fig. 6 are the average values of the NC over ten trials. The NC of the DRE agents was less than that of the RL agents. This was because the DRE agents were disciplined and the RL agents were not when the agents collided with each other. The NC of the CL agents was more than that of the DRE agents due to the enormous number of states although the CL agents were also disciplined when the collision occurred.

We confirmed that the cooperative behaviors (social behaviors) emerged in the DRE agents through this experiment.

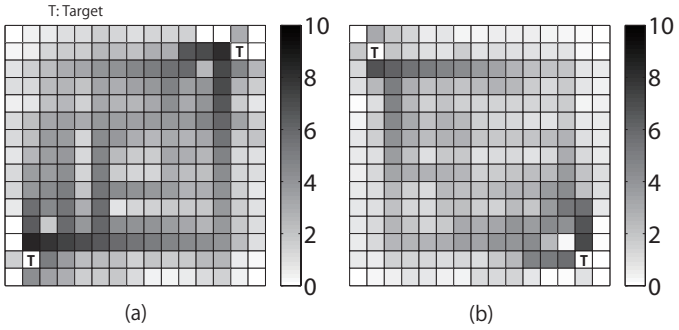

Fig. 9. State values of one of the DRE agents in a run of the second experiment with $T_L = 40$. (a) After 1000th episode. (b) After 2000th episode.

Experiment 2: Adaptation to environmental change

The second experiment was conducted to examine the adaptability of the DRE agents to an environmental change. As an environmental change, the positions of target were changed from those shown in Fig. 3(a) to those shown in Fig. 3(b) after the 1000th episode.

Figs. 7(a), (b) and (c) show the NSCs in the second experiment when T_L was 30, 40 and 50, respectively. Figs. 8(a), (b) and (c) show the NCs in the second experiment when T_L was 30, 40 and 50, respectively. The results presented in Fig. 7 an Fig. 8 are the average values over ten trials. The NSCs of all the agents remarkably decreased just after the environmental change. The NSC of the DRE agents rapidly rose with episodes even after the environmental change. Figs. 9(a) and (b) show the state values of one of the DRE agents after the 1000th episode and the 2000th episode in a run of the second experiment with $T_L = 40$, respectively. As can be seen from Fig. 9, the state values were high around the targets. Figs. 10(a) and (b) show the emotion values of the DRE agents after the 1000th episode and the 2000th episode in a run of the second experiment with $T_L = 40$, respectively. Each panel shows the emotion values on the agent 2 areas (5×5) where the number and star symbol indicate the agent 1 area. Each panel corresponds to one row in the emotion map shown in Fig. 4. From the panel 16 in Figs. 10(a) and (b), it is seen that the DRE agents were frequently disciplined due to the collisions when the both agents were in area 16 before and after the environmental change. On the other hand, from the panel 20 in in Figs. 10(a) and (b), it is considered that the DRE agents were disciplined due to the unsuccessful cooperative behaviors. The emotion values were less dependent on the positions of targets than the state values. Therefore, the DRE agents could utilize some of the emotional values learned before the environmental change. The NSC of the RL agents slowly increased with episodes after the environmental change since the state values have a high dependency on the positions of the targets. Thus, the RL agents needed to learn the state values again. The NSC of the CL agents gradually rose with episodes after the environmental change but was less than that of the DRE agents due to the enormous number of states.

The NC of the RL agents rapidly increased just after the

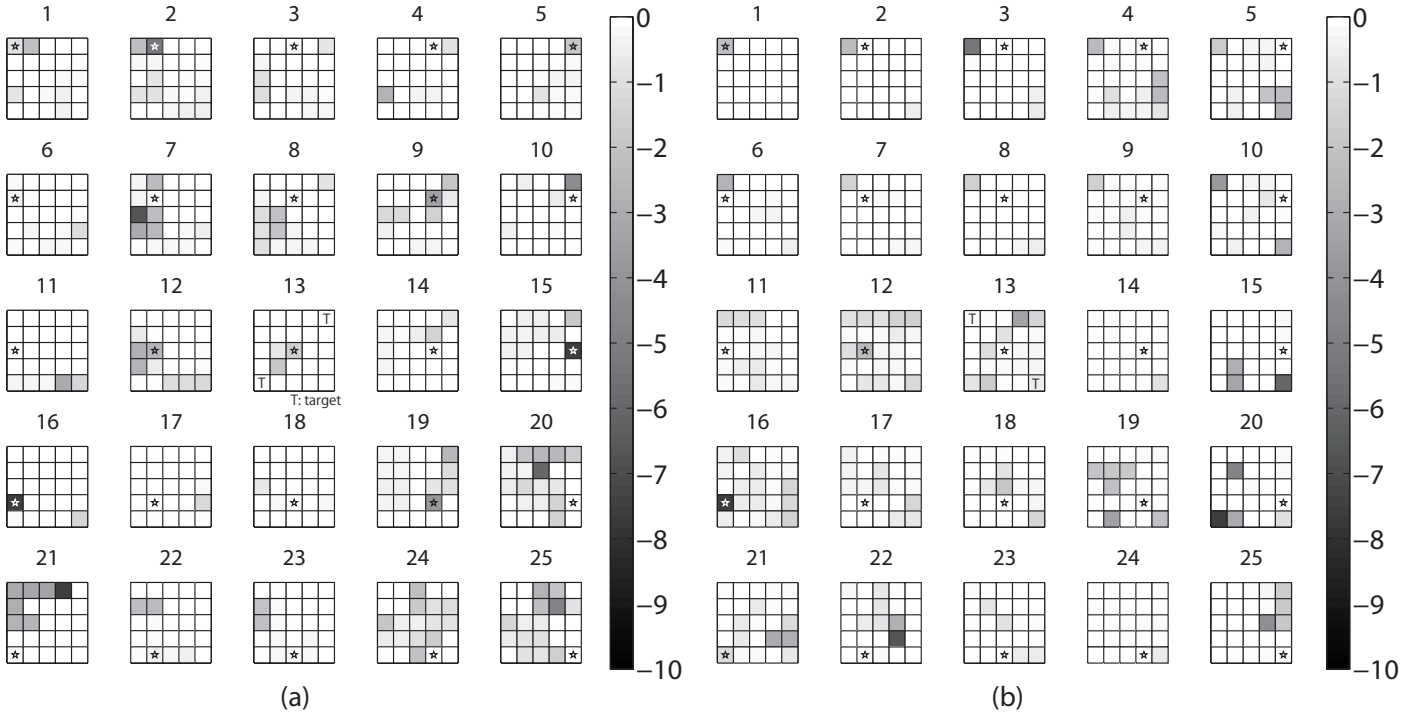

Fig. 10. Emotion values of the DRE agents in a run of the second experiment $T_L = 40$. (a) After 1000th episode. (b) After 2000th episode. Each panel shows the emotion values on the agent 2 areas (5×5) where the number and star symbol indicate the agent 1 area. The areas where the targets exit are shown as T in the panel 13.

environmental change. The state values of the RL agents were in the transition from those for the previous environment to those for the current environment at that time. This led to the increase of the NC. The NCs of the DRE and CL agents slightly increased after the environmental change.

The results of the NSC and NC suggest that the DRE agents have a high adaptability to the environmental change.

IV. Conclusion

In this paper, we proposed the DRE for inducing social behaviors of agents. In the DRE, the agents decide their actions based not only on the strategic judgment obtained by reinforcement learning but also on their intrinsic fear emotion. In the simulation experiments, we confirmed that the agents with the DRE took actions for realizing the social behaviors and adapted to the environmental change. In a future work, we will investigate the effects of the parameters ε_s and ε_e in the AD module on the emergence of social behaviors.

Abstract— **It has been reported in many papers that the number of eye movements increases and the mean fixation durations on individual objects decreases when the road situation becomes more complex. In this paper eye-movement analysis has been used for understanding the mechanism of visual search of drivers. For the aim, two experiments in which the subjects drove the driving simulators have been conducted. We analyzed the relationship between the eye movement of drivers and the characteristics of their front scenes while driving in driving conditions. In the first experiment it was confirmed that the frequency of saccade became higher and fixation time became shorter in case of the turn event condition among three driving events, where the pixel difference extracted as the visual information from the driver's front scene became larger. In the second experiment the same relationship between the characteristics of eye movements and the driver's front scenes were confirmed by considering the three driving events, running straight, turning corners at a crossing and prediction task of hazard in the urban course. The pixel difference of the driver's front scene influenced the eye movements while driving. These results of experiments about driver's cognitive processing while driving suggested that eye movements depends on the amount of information contained in the front scene defined by the pixel difference.**

I. INTRODUCTION

Driving is such a complex task that the drivers must control steering, accurate level, display of going direction by signals every moment based on the configuration around own car, simultaneously. The driving environment has become more complex as the cars increases on the road and also amount of structures as the traffic signs, the eye-catching shop front and advertising billboards are constructed along the road. Then, the drivers visual environment has become more complex [1][2]. In such the complex and restless driving environment, lack of visual attention to the situation of their own car and the other cars causes traffic accidents or crashes. Therefore, the driver must concentrate on the driving task. Keeping the visual attention for the driving environments high level required the resource of the cognitive perception and recognition for the visual information processing. For example, the driving performance suffered during cell phone and remote passenger conversations as compared with in-car passenger conversations [3]. Since the conversation by the cell phone makes the driver's driving performance decrease and thereby causes the traffic accident, the use of cell phone while driving is prohibited by the law in Japan. A high complex environment on the road is congested with the cars or pedestrians, demands the more cognitive resources for the visual processing in order to keep the car safe.

The eye movements are generated so as to gather the visual information about the driving environment. Informative regions of a scene are fixated for significantly longer than less informative regions [4]. In general, the frequency of saccade and mean fixation durations provide a good measure of the visual attention. Increasing the complexity of the visual scene (by adding vehicles, road furniture, or irrelevant signing), increases the frequency of eye movements and decreases the mean fixation durations on individual objects while driving[5][6][7][8][9]. However, when the driving situations become more dangerous, the presence of a hazard in the scene causes a focusing of attention such that the fixation duration increase, saccade lengths decrease, the spread of search reduces[10]. The policy of visual information processing while driving is different according to the driving situation in order to avoid the traffic accident or risk[11].

A driver must process much visual information while driving a car. For the driving task they gather the meaning visual information of environment by the eye movement. Since the fixation duration and the frequency of saccade which characterize the eye movement depend on the visual scene of driving situation, the eye movement is function of visual scene. Although a lot of factors to effect the eye movement as experience of driving[12], driving situation, the visual scene cause the eye movement in this paper, therefore, it is assumed that the drivers eye movements was a function of visual stimuli of the driver.

In this paper we investigate the characteristics of the eye movements of driver while driving with regard to the driving events and analyze the relationship between the characteristics of eye movements and the peripheral vision. For the aim of present research the eye movements of drivers are measured

using the driving simulator and the driver's front view on their peripheral vision are recorded. The mean fixation duration and the frequency of saccade of eye movements were summarized as the characteristics in the period of driving events and the difference of the driver's front view were calculated as the index of complexity of the driving task. We attempt to identify the underlying reasons for change of the policy of eye movements according to the driving configuration, such as going straight, turning corner etc., while driving.

This paper is organized as follows: Section 2 describes the experimental methods and equipments, and the configuration of the two experiments. Section 3 describes the results of two experiments about the eye movements and the front view of drivers, and shows the relationship between the eye movement and the front view of drivers. Lastly the final conclusions are presented in Section 4.

II. Experimental Method

A. *Expeimental Equipments*

(1)Driving simulator

The automobile driving simulator (DA-D1102: HONDA Motor Co. Ltd.) was used to simulate a driving work. Fig. 1 shows the driving simulator used in this study. This simulator is usually used for driver trainees or novices to learn safe driving techniques. The simulator is implemented on an advanced 6-axis motion base (sway-motion device) that can simulate closely automobile dynamics in real traffic situations, and visual scenes of driving a road from a viewpoint of the driver is presented on a front screen and three mirror-CRTs. The driver's front view is illustrated in Fig.1 (b). A distance from the front screen to the driver's seat is 1511mm. The front screen is wide and curved so as to surround the driver, and then the driver's visual field is covered by the front screen as shown in Fig.1 (b). The configurations of the driver in the simulator are illustrated in Fig. 2. Using the driving simulator, the driver can drive several kind of driving courses with varying in some kinds of automobile conditions, such as weather and car and human actions (e.g., dashing out in front of a driver's automobile). In this driving simulator two driving modes are selected, the automatic transmission changing mode and the manual transmission changing mode. The automatic mode was used since the driver must concentrate the visual stimuli while driving in the experiments.

(2) Eye movement tracker

During simulated driving, eye movements of the driver and driving road scene were recorded by a head-mounted eye tracking system (EyeLink II: SR Research Ltd., see also Fig. 3). Two eye cameras track right and left eyes respectively. A scene camera on a head band records visual scene that the participant views. In a scene camera either a color or high resolution black and white scene camera is used to generate 30

frames (60 fields) of a scene image per second. The scene image is also streamed to the overlay box, by which participants' gaze position (indicated by a fulfilled circle) is superimposed with the visual scene. The host PC converts gaze position data, obtained by the eye cameras, into position data on the visual scene image captured by the head mounted scene camera. The host PC also analyzes eye movement events in real-time.

B. Participants

Participants were five males, who were 22 aged students of the university. All the participants have regular class automobile licenses in Japan with normal or corrected-to-normal vision. All the participants were given enough explanation for the present experiments and gave informed consents to the experiments before participation. The participants were instructed through a practical lesson and verbal instruction as the driving lessons in the driving simulator.

C. Driving Scene in two experiments

In this paper two experiments with different driving configurations using the driving simulator were conducted in order to investigate the visual information strategy of drivers while driving. The driving configurations of two experiments are changed in the view point of the simplicity of driving scenery and driving velocity so as that the visual task required while driving would be the different level in two experiments.

In the first experiment the driving configuration is set to the situation of driving in a suburb of the city, where there is only road in a wide field without any buildings and traffic facilities, such as shops, traffic equipments and so on. The condition of weather is set to a clear and fine day. The abstract of driving course is shown in Fig. 4(1), in which there are the straight road, curve, and the crossing. The front views in these driving conditions are simple or monotonous sceneries as shown in Fig. 5. In the rural roads situation there are few stationary objects and no moving objects. e.g., no cars and no pedestrians appear on the driving course. In this configuration the drivers see the only road and a distant view as the front scene while driving. Therefore, it is seemed that the cognitive work load of a driver was set relatively lower level in the first experiment since all the driver has to do are only to concentrate the road situation for driving safety.

In the second experiment the driving configuration was set to the situation of driving in the city (urban) on a sunshine day. The visual scenes of drivers on urban roads were more complex or complicated than on the rural ones. The abstract of driving course of the second experiment is shown in Fig.

(2) residual of pixel of front scenes

Figure 7. Residual picture of driver's front scene while driving

4(2) and the front views in these driving conditions are shown in Fig. 6. In this configuration, the pedestrians, the buildings and shop front located along the road and the traffic equipments such as the traffic signs and signal. The moves of other cars and the pedestrians keep step based on the driving scenario in the driving scenes. This driving simulator contains a risk awareness program that is designed to take participants through a route containing several hazards such as children crossing the road and unexpected door open of a parking car. The driving course used in the second experiment contains two hazards, unexpected door open of a parking trailer and sudden crossing of a car as shown in Fig. 4(2). The front view scenes of the second experiment are shown in Fig. 7. The driving environments of the second experiment fall into three categories, normal (driving on a straight road), turn event (turning at crossing and joining to the main road), and hazard event (door open and car sudden-out).

Mentioned above, it was seemed that the cognitive visual resources were required more in the second experiment than in the first experiment since the driver's visual tasks while driving were loaded more in the second experiment. For keeping safety drivers not only have to pay attention the other cars and pedestrians movement consciously, but also have to predict the likely driving events as the pedestrians rush out into the road and the front car suddenly stop every time. In the second experiment the objects and the driving events to be particularly concerned are set as a driving scenario.

D. Procedure

Participants drove the predetermined courses on the DA-D1102 driving simulator wearing the eye tracking camera (see Fig. 3). After calibration of the eye tracking system they were seated at the simulator and asked to adjust the seat. The participants were instructed to drive the predetermined course as they would do normally and follow the traffic regulations.

In the first experiment the participants drove the course in a suburb of the city at the predetermined speeds, 30 km/h or 60 km/h. Since it was difficult to turn the corner in the crossing at the predetermined speed, they were instructed to reduce the car speed so as to turn the corner well in the crossing. Although the driving speed was not kept at predetermined speed, the driver had to be encouraged to speed up the car to the predetermined speed 30 km/h or 60 km/h in the driving course. Therefore, it was seemed that the driver's cognitive mental workload while driving at 60 km/h is larger than at 30 km/h.

The iteration number of trials was three in each speed condition for each participant. In a trial at the predetermined speed a driver drove the course three times. After calibration of the eye tracker the participants drove the predetermined course three times at 30km/h speed condition, and then did it three times at 60km/h speed condition. The next trial was performed after the intervals of several minutes as a rest and last trial was done with same procedure. While the driving experiments using the driving simulator eye movements of the participants were measured and the front view of them were recorded in digital video. The characteristics of eye movement such as the saccade and fixation were extracted from the recorded eye movement data after the all trials were completed.

In the second experiment the participants were asked to drive the simulator on the predetermined course with the current of the other car. The iteration number of trials was three. In a trial they drove once around the course as shown in Fig. 4(b). The task to keep the predetermined speed was not imposed to them since it is difficult to keep the fixed velocity due to a lot of

events. In the second experiment the driving. The participants were same with ones of the first experiment, but the second experiments were carried out on the different day with the first experiment because of the fatigue of participants.

E. Extract of charactoristics of eye movement and front view while driving

In these experiments eye movements of drivers were measured while driving in two road conditions. For considering the relationship between the eye movements and the peripheral vision, the characteristics of eye movements and peripheral vision should be extracted from the eye movement data and driver's frontal scene during the experiments. Generally speaking, the frequency of saccade and mean fixation durations provide a good measure of the visual attention. The frequency of saccade and mean fixation duration were extracted as an eye movement property in each period according to the driving events.

The difference of gray levels between two pictures represents the edge of objects. In Fig.7 shows the two consecutive frame images and the picture representing the gray level difference of them. The increase of the gray level difference means that the number of objects in the visual scene increases and the complexity of the visual scene for the driver becomes higher level. This index for the complexity of the front scene of a driver was defined using the difference of the front picture, and the relationship between this index and driver's eye movements are discussed through the results of experiments. The visual information of the front scene was quantified based on the pixel change of them. The i -th quantity of the pixel change of the picture is defined by the difference of pixel-value between i -th frame image and (i+1)-the frame image included in the front view. In the total quantity of the difference of each frame included in a period of driving event is calculated by summation of the difference value in each frame. This total gray level difference of frame image was defined as the characteristics of the front scene in the period according to the driving task.

In the first experiment three categories of driving events, running straightly on the course, running curve along course and turning the corner at the crossing, were considered as the task seemed to be required the different cognitive level. The characteristics of the eye movements and the front scene of drivers were calculated in case of the periods according to the three categories about driving tasks in two speed condition, 30 km/h and 60 km/h. In the second experiment, the periods of three driving categories, operation of running straightly, operation of turning the corner in the crossing and hazard prediction event, were determined in the driving course. The driving task periods of the turning operation and hazard prediction were set to 6 sec, 3sec before the event and 3sec after the event. The start time and end time of period was determined so as to center the driving event on the middle of the period.

III. EXPERIMENTAL RESULS

A. Time period of driving evets

The frequency of saccades and mean fixation duration were recorded as the characteristics of eye movements of drivers while driving. For the aim to investigate the eye movement while driving in relation to the front scene, the driving scenes were categorized into three driving events. Thus, the segments of the driving were determined so that these measures were summarized in three kinds of driving events according to the three road situations. The examples of time sequent of the events and the period time are shown in TABLE I. The time sequence of driving events was different between the subjects because of the difference of the car speed of each subject, and also the driving event periods were different with ones of other subjects.

In the first experiment the whole course was divided into three categories and the start and end times of the period corresponding to the three driving events were identified in each trial by analyzing the recorded front scene video. An example of the event period was one in the first trial driving of subject A which was shown in TABLE I (a). The total time for driving the course in 30km/h and 60km/h was 273.77sec and 157.39sec, respectively. 7 straight road events, 10 curvature events and 3 turning events were contained in the one driving trial. The driving trials were repeated three times. The average

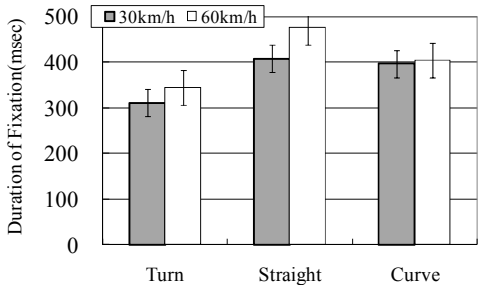

Figure 8. Mean fixation duration in first experiment.

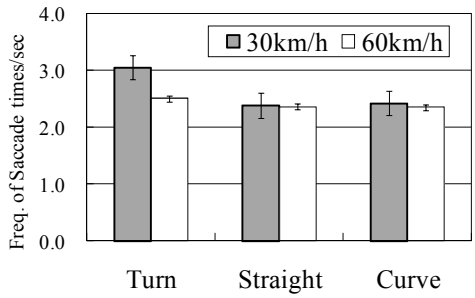

Figure 9. Frequency of saccade in first experiment.

of the frequency of saccades and mean fixation duration during the same events were summarized in each subject.

In the second experiment the driving event periods were also identified by analyzing the scene video, running straight, turning at a crossing, and prediction of hazard. The period time of the turning operation and prediction of hazard was fixed as 6sec. The example of the driving task period in the second experiment is shown in TABLE I (b).

B. Results of first experiment

(1) Eye movement while driving events

The eye movements of five subjects were recorded while driving in the suburb course in the first experiment. The characteristics of eye movements in three driving events, straight event, curve event and turn event, were summarized as the results of eye movements. The mean fixation duration and the frequency of the saccade in each driving event are illustrated in Fig.8 and Fig.9, respectively. The mean fixation duration in left or right turning at a crossing was shortest among the three events, and the one in driving on the straight road was longest in both 30km/h and 60 km/h conditions. While, the frequency of saccade in left or right turning at a crossing is highest and one while driving at a straight road is lowest. The same tendency of eye movements while the driving events was similar to the result of the subjects.

The results of one way ANOVA with respect to the traffic event conditions are shown in TABLE II (1) and (2). For the mean fixation duration, the significant main effects of the driving events were detected in four subjects expect "subject E" in 60km/h speed condition. For the frequency of saccade, the significant main effects of the traffic events were detected in four subjects expect "subject E" in both speed conditions.

note : * means that the significant effect is detected

(2) Pixel difference of front scene as index of complexity

In this paper the complexity of the visual scene were defined by the ever-changing front view of driver as shown in Fig. 7. The increase of the gray level difference means that the number of objects in the visual scene increases and the complexity of the visual scene for the driver became higher level. The gray level difference of the front scene of subjects during the experiment were calculated and summarized in each traffic event as shown in Fig. 10. The average of the gray level difference of the front scene during the period of each traffic event is illustrated. The gray level difference in turning at the crossing is larger than one in the other events, driving on the straight road or curvature. The same tendency of front scene while the driving events as each other is confirmed in each result of the subjects.

(3) Comparison between characteristics of eye movement and the complexity of front view

For considering the relationship between eye movement and the front scene, the correlation coefficients between the

	3	-0.303	0.141	-0.130	0.041

difference of pictures and gazing time, times of saccade were calculated as shown in TABLE III. Even though there exits the variance the positive correlation between the frequency of saccade and the difference of front scene and the negative correlation between the mean fixation duration and the difference were detected for all subjects. These results suggest that the change of peripheral vision influences the visual information processing while driving and consequently causes the quick and instantaneous eye movements, and also, this busy eye movements were required to compensate the lack of visual information to keep the vehicle safe.

C. Results of second experiment

(1) Eye movement while driving events

In the second experiment the eye movements of five subjects were recorded while driving in the city course, in which several events were prepared containing the two hazard events provided by the risk awareness program of the driving simulator. The analyzing periods were defined with three categories, normal (driving on a straight road), turn event (turning at a crossing and merging to the main road), and prediction event of hazard (door open and car sudden-out). The characteristics of eye movements in three driving events were summarized as the results of eye movements. The mean fixation duration and the frequency of the saccade while each driving event are illustrated in Fig.11 and Fig.12, respectively. The ANOVA of frequency of saccadic eye movement and fixation time while the driving with respect to the driving events were conducted ant significant effect were confirmed as shown in TABLE VI.

(2) Pixel difference of front scene as index of complexity

The gray level difference of the front view of subjects during the experiment were calculated and summarized in each traffic event as shown in Fig. 13. The average of the gray level difference of the front view during the period of each traffic event is illustrated. The mean fixation duration became longer in order to “Straight”, “Turn”, and “Hazard”. The frequency of

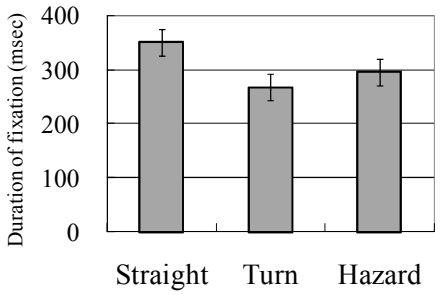

Figure 11. Mean fixation duration in second experiment.

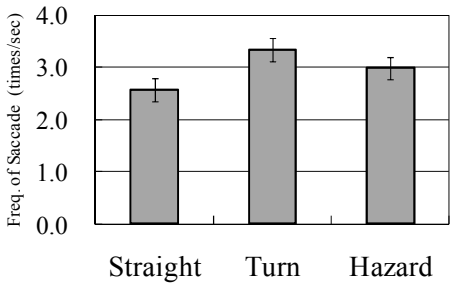

Figure 12. Frequency of saccade in second experiment.

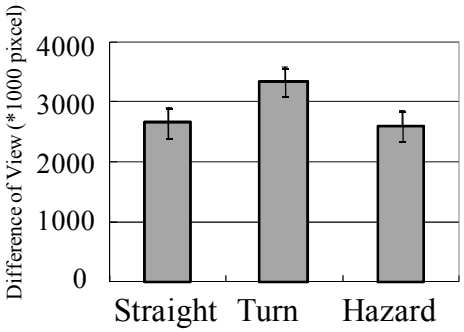

Figure 13. Difference of front view of drivers in second experiment.

saccade and the difference of the view became larger in the reverse order. The gray level difference in the turn event is larger than one in the other events.

(3) Comparison between characteristics of eye movement and the complexity of front view

It was confirmed that the relationship between the eye movements and background view also existed in case of the drive of the city course except the hazard situation. In the hazard situation the relationship between them were different with one in the normal driving situation since the eye movement was caused by the different mechanism. The correlation coefficient between the two kinds of characteristics of eye movements and the front scenes were shown in TABLE V. I a lot of driving trials the correlation between them were confirmed

D. Discussion

In general, the frequency of saccade becomes higher and the duration of fixation became longer in the more complicated

situation so as to get more information from environment. However, the saccadic movements are required frequently so as to get the information around own car for avoiding the accidents, therefore, the fixation duration of drivers became shorter [5][6][8]. Considering these results about characteristics of eye movements while driving in the first experiment, the results of the first experiments suggested that the complexity of the front views in the three traffic events were different, and the traffic events effected the eye movement of drivers. In other words, the results of the first experimented that the driving operation on the straight or curve road was an easier task for the driver than the one on the turning operation at the crossing since the frequency of saccade became smaller and the duration of fixation became longer.

In the second experiment, the differences of the properties of eye movements among the driving events were not detected significantly by the ANOVA as shown in TABLE IV. The correlation between the characteristics of eye movements and the front scene was confirmed as shown in TABLE V. It was reported as "focusing of attention" that the mean fixation duration became longer than the normal situation in the hazard situation [3]. Thus, since the hazard situation required the more visual resources to keep safe or occupied the visual attention, the relationship between eye movements and the front scene was not detected in the hazard situation.

IV. CONCLUSION AND FUTUREWORK

In this paper, the two driving experiments were conducted on the course in rural area and urban area, in which the driving events, such as running straightly or turning at the crossing, were contained. The different amount of cognitive resources of drivers was required according to the driving events to keep the car safe in these experiments. After driving experiments, the characteristics of eye movements and the driver's front scene corresponding to the driving events were extracted from the eye movement data and the recorded video. The present study illustrated the relationship between the characteristics of eye movements and the front scene. The larger became the frequency of eye movements, the larger became the extracted characteristics of the scene video in two experiments. These results suggested that when the index defined by the difference of pixel in the front scene became larger, the eye movement might be generated more frequently.

In this paper the characteristics of the front scene were simply defined by the difference of pixel contained in it. It is the future work to consider the index of their attention in relation to the eye movements.

***Abstract*— Walking is a fundamental human ability necessary for everyday life. We have developed an omnidirectional walker (ODW) for walking support to those who have walking disabilities. It is necessary for the ODW to know which direction the user is intending to go during walking support. A novel interface is proposed for the ODW to recognize directional intention according to the user's forearm pressures which are measured by force sensors embedded in the armrest. The relationship between forearm pressures and directional intention was extracted as fuzzy rules and an algorithm is proposed for directional intention identification based on distance type fuzzy reasoning method. In this paper, we conduct walking support experiments with the proposed method. The results show that the algorithm is applicable to directional control in walking support.**

Keywords- walking support; omnidirectional walker; directional intention identification; distance type fuzzy reasoning method

I. INTRODUCTION

There are many people with walking disabilities due to either age or accidents. Therefore, the development of walking machines that can efficiently conduct walking rehabilitation and walking support is highly desirable. In previous studies, the authors along with colleagues have developed an omnidirectional walker (ODW) [1][2]. This walker allows omnidirectional movement. In walking rehabilitation, training programs are stored in the walker so that rehabilitation can be carried out without the presence of physical therapists. Its effectiveness in walking rehabilitation was verified by clinical tests [3][4].

In walking support, it is necessary for the ODW to know the direction the user intends to go based on user manipulation. Actual directional intent must, however, be identified from physical manipulation because a user's directional intent and physical manipulation are not always mutually consistent. In this paper, a novel interface is proposed to recognize a user's directional intention according to the forearm pressures exerted to the ODW by the user with wrists and elbows. The forearm pressures are measured by 4 sensors embedded in the ODW's armrest [5][6]. The relationship between forearm pressure and directional intention was extracted as fuzzy rules and an algorithm was proposed for directional intention identification based on distance type fuzzy reasoning method (DTFRM) [7][8]. The effectiveness of the algorithm was verified by experiment results. However, in the previous experiments the ODW was fixed on the ground. The intentioned directions were identified only when the ODW was stationary. If the ODW moves while the subject pushes it, forearm pressures should differ due to body sway and change of the supporting foot. This is not convenient in real walking support. Therefore, in this paper, we examine the effectiveness of the proposed method in walking support experiments when the ODW moves. The results show that users can control the ODW with the proposed method by adjusting direction as they walk.

II. STRUCTURE AND MODEL OF THE OMNIDIRECTIONAL WALKER

The structure of the ODW is shown in Fig. 1. The most important feature of the walker is the use of omniwheels. An arrangement of four omniwheels at the bottom of the walker body enables the walker to move in any direction while maintaining its orientation.

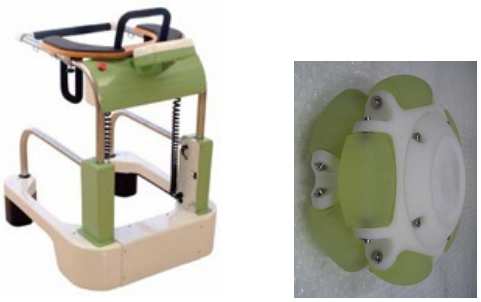

Figure 1. ODW and one of its omni wheels.

TABLE I. PHYSICAL PARAMETERS OF THE WALKER

Parameter	Value	Unit
Height	900–1200	mm
Arm	600	mm
Mass	58	kg
Maximum load	77	kg
Maximum speed	0.25	m/s

The physical parameters of the ODW are listed in Table 1. Two telescopic poles are designed to support both the upper part of the walker and the load from the user. The walker height is adjustable from 900 to 1200 mm to accommodate the different heights of the users. The mass of the walker is 77 kg and the maximum speed is set to 0.25 m/s to ensure user safety. The coordinate settings and structural model are shown in Fig. 2.

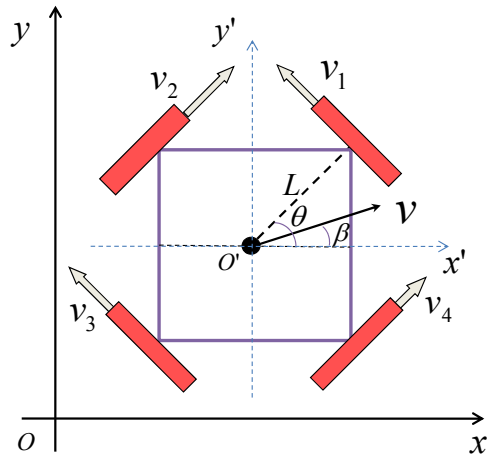

Figure 2. Structural model of the omnidirectional walker.

$\sum(x, y, O)$: Absolute coordinate system.

$\sum(x', y', O')$: Translation coordinate system of $\sum(x, y, O)$.

v: Speed of the ODW.

v_i: Speed of an omniwheels (i=1,2,3,4).

L: Distance from the center of the walker to each omniwheel.

β: Angle between the x'-axis and the direction of v.

θ: Angle between the x'-axis and the position of the first omniwheel.

Using the coordinate system shown in Fig. 2, the kinematic equations of the ODW are

$$\begin{cases} v_1 = -v_x \sin\theta + v_y \sin(\frac{\pi}{2} - \theta) + L\dot{\theta} \\ v_2 = v_x \cos\theta + v_y \cos(\frac{\pi}{2} - \theta) - L\dot{\theta} \\ v_3 = -v_x \sin\theta + v_y \sin(\frac{\pi}{2} - \theta) - L\dot{\theta} \\ v_4 = v_x \cos\theta + v_y \cos(\frac{\pi}{2} - \theta) + L\dot{\theta} \end{cases} \quad (1)$$

where $v_x = v\cos\beta$ and $v_y = v\sin\beta$ are the x and y components of the walker's velocity, respectively.

III. DIRECTIONAL CONTROL BY FOREARM PRESSURES USING DISTANCE TYPE FUZZY REASONING METHOD[7][8]

Force sensors to measure the user's forearm pressure are embedded in the ODW armrest as shown in Fig.3, to identify directional intention based on the pressure information from the sensors. This novel interface can also be applied to other apparatuses such as wheelchairs. It has the following three advantages: 1) Safety during walking is ensured because the users need not intentionally manipulate devices to input directional instructions. 2) Cost is lower without using any biological measurement system compared with other direct interfaces that determine the human intentions through EEG or EMG [9].

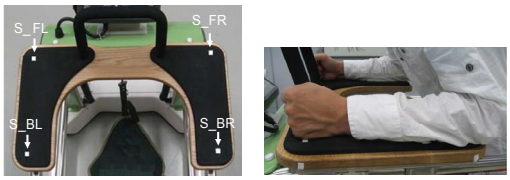

Figure 3. Equipment of load sensors.

The relationship between directional intention and forearm pressures was investigated in a measurement experiment. Eight healthy male volunteers aged 20-25 yr participated in the experiment. Subjects were instructed to push the ODW with their forearms as if they wanted to go in the following 8 directions: 1) 0° - Right (R), 2) 45° - Forward right (FR), 3) 90° - Forward (F), 4) 135° - Forward left (FL), 5) 180° - Left (L), 6) 225° - Backward left(BL), 7) 270° - Backward (B), and (8) 315° - Backward right (BR). There is great relevance between forearm pressures and directional intention, which can be referenced to identify directional intention from forearm pressure. Means and standard deviations (SD) of sensor output for the 8 subjects on each intended direction are listed in Table 1 (The unit is 0.025kgf, abridged for convenience below).

TABLE II. SENSORS' OUTPUT STATISTICS

	w_fr		w_fl		w_br		w_bl	
	mean	***SD***	***mean***	***SD***	***mean***	***SD***	***Mean***	***SD***

BL	3.4	3.2	74.1	30.7	82.6	32.9	607.9	174.8
B	3.0	2.7	16.9	9.7	454.9	117.7	440.5	83.8
BR	66.9	30.8	3.2	2.7	575.4	179.4	109.8	36.9

w_fr, w_fl, w_br, and w_bl are outputs of sensors S_FR, S_FL, S_BR and S_BL.

Directional intention can be reasoned from forearm pressures using the fuzzy rules about relevance between forearm pressures and directional intentions extracted in Section 3. Based on these results, the following fuzzy rules were extracted as fuzzy rules, used as knowledge in fuzzy reasoning.

$$Rule^i : if \quad w_fr = A^i_{fr} \quad w_fl = A^i_{fl}, \quad w_br = A^i_{br}, \quad w_bl = A^i_{bl} \quad \Rightarrow \quad y = \beta^i \quad i = 1,2,\cdots,8$$

where i is numbers 1) - 8) in Table 1 and β^i ith directional intention. A is a triangle-type fuzzy set defined by the data in Table 1, with its vertices being (mean – SD, 0), (mean, 1) and (mean + SD, 0). The fuzzy sets in the fact to be input are fuzzy singletons whose membership functions are 1 at the points of average outputs of the four sensors. Reasoning result, the intended direction, is also a fuzzy singleton.

$$Fact: \; w_fr = a_fr, w_fl = a_fl, w_br = a_br, w_bl = a_bl$$

$$Result: \; y = \beta$$

The DTFRM is used to reason directional intention from forearm pressure. An angle can be specified by innumerable degrees. However, the conclusion of DTFRM is affected by the specific degrees due to its asymptotic characteristic. If, for example, the distances between input fact and $Rule^1$, $Rule^8$ are much smaller than those between facts and the other rules, the reasoning conclusion, or intended direction, should be between R and BR due to the asymptotic characteristic. When calculating the conclusion, if R is specified as 0° and BR is specified -45°, then conclusion $\beta \in (0,-45)$, between R and BR. However, if R is specified as 0° and BR is specified 315°, then conclusion $\beta \in (0,315)$, not between R and BR, because direction R and BR are adjacent to each other while 0° and 315° are far distant. Therefore, when calculating the reasoning result, the degrees for specifying directions are determined as follows. The consequent degree of the fuzzy rule whose antecedent has the smallest distance among all the rules is determined as $\alpha \in [0,360)$. The degrees for specifying the other directions are determined as $\gamma \in (\alpha - 180, \alpha + 180]$. If, for example, when $Rule^7$ has the smallest distance, $\beta^1 \sim \beta^8$ are determined as 360°, 45°, 90°, 135°, 180°, 225°, 270°, 315°. When $Rule^1$ has the smallest distance, $\beta^1 \sim \beta^8$ are determined as, 0°, 45°, 90°, 135°, 180°, -135°, -90°, -45°.

IV. Direction Control Experiment

A path tracking experiment was carried out to verify the directional intention identification method. In the experiment, a healthy male volunteers aged 31 yr was instructed to push the ODW using his forearms to follow a 1.5m×1.5m square on the ground. Since the subject placed his arm against the armrest to partially support body weight throughout the experiments, even when not intending to go any direction. Therefore, the pressures for direction identification should be stable and significantly larger than the baseline due to body support. In the experiment, the directional intention was calculated when one second of data meet the two following conditions: 1) During this second, outputs of at least one sensor were all larger than 100. 2) During this second, SDs of outputs of all the sensors were less than 20. The first condition ensures that increases in pressures are significant. The second condition ensures that the pressures are stable.

The experiment results were shown in Fig.4, Fig.5 and Fig.6. Fig.4 shows the path tracking results of 6 attempts. Fig.5 shows the sensor's outputs during the 6th attempt. Fig 6 shows the reasoning results of the 6th attempt. In the experiment, the subject adjusted the direction of the walker as he walked. He revised the direction from time to time on the way until reaching the goal. It is indicated by the results that the proposed algorithm is applicable in walking support.

There might be three main reasons for the errors in the path tracking experiment: 1) Human beings cannot control their forearm pressure accurately. 2) The fuzzy rules are based on statistical experiment results. Individual differences are not considered. 3) During path tracking, error happens due to the center of gravity shift and the load changes caused by the user [10-12].

V. Conclusions

This study examined the effectiveness of the proposed directional intention identification method. The path tracking experiment indicated the applicability of the method in walking support.

In addition to the straight movements in the experiment, rotation movements, clockwise and anticlockwise rotation, are also very important during walking. Rotation movements are not considered in the current study because rotational intentions cannot be denoted by angles, which are different from the straight directional intentions. Rotational intentions can also be expressed by the forearm pressures. For example, we can define that pushing S_FR and S_BL means to rotate clockwise and S_FL and S_BR means to rotate anticlockwise. Future work will deal with this problem by adding knowledge of rotational intentions to the knowledge base.

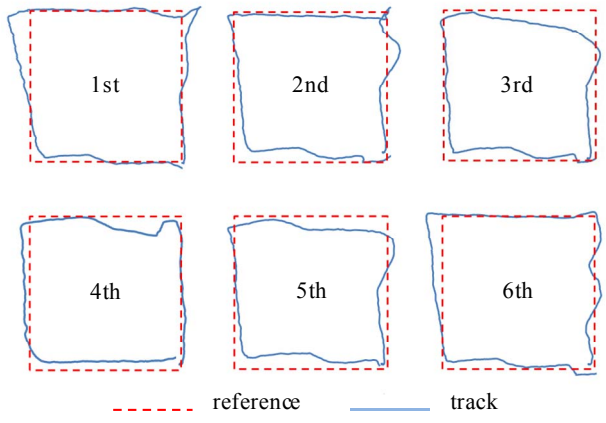

Figure 4. Path tracking results

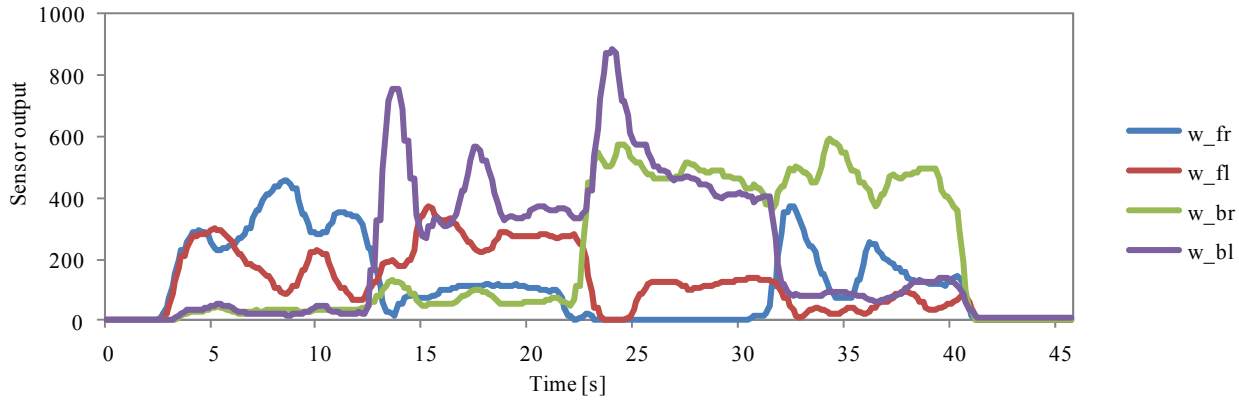

Figure 5. Sensors' outputs of the 6th attempt

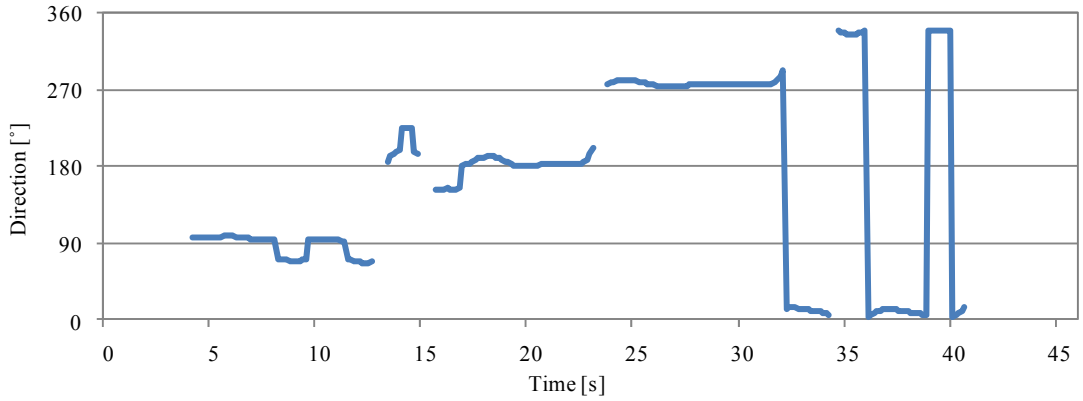

Figure 6. Reasoning results of the 6th attempt. The blank period is caused by the data that do not meet the 2 conditions. Although the reasoning results vibrate shaply from 34s to 42s, their directions are similiar.

***Abstract*—We decide and execute our action from many types of environmental information in our daily lives even if we are not conscious of being guided. The human action induced from the oncoming person's movement is the collision avoidance of passing each other. In collision avoidance, we chiefly judge the avoidance direction from visual information. Especially, it is important to get the information from oncoming person's body part and avoidance timing in each other. Then, we make an experiment to judge the avoidance direction by watching the masking movie of oncoming person's body part. By evaluating this judgment time, it was clarified oncoming person's body part is leg in collision avoidance. Next, it especially paid attention to oncoming person's leg, and the relation between the walking cycle and leg position in avoidance judgment is evaluated. From this result, the avoidance judgment is possible because the traveling direction can be controlled by the leg when the leg is lifting and landing. It was clarified that oncoming person's walking cycle is important in the action decision during collision avoidance. So we propose the action decision model based at the walking cycle.**

***Index Terms*—action decision model, collision avoidance, visual motion, walking cycle**

I. Introduction

As for us, a safe walking is possible in the crowded situation. We plan not to collide with the other person, and the purpose of this is to execute it the decision of the action. However, it is difficult in the situation very crowded at the event site and the disaster, etc. to walk safely [1]. Attention is distributed in the inducement by the emergency light and the arrow when trying to head for a target place in such a place and the situation, and consideration is not turned by the inducement presentation thing. Then, it is important to make a unconscious inducement system thought that the congestion situation doesn't influence us easily, and our safety is kept direction where it should walk by controlling person's flow.

We examine the use of the galvanic vestibular stimulation (GVS) as a device of such an unconscious inducement. GVS behave on the vestibular apparatus, and change the perception of the direction of gravitational force. The movement related in the direction of center of gravity undertakes the influence of unconsciousness by this action. For example, it is reported that the direction of walking changes right and left into giving the illusion that posture has collapsed to the pedestrian by giving GVS , and the unconscious correction of the posture [2-3]. Up to now, the possibility that the effect of the inducement is achieved in a consecutive periodic motion has been pointed out from the walking [4] and minion [5-6] inducement by GVS.

On the other hand, we are generating the walking rhythm by using CPG(Central Pattern Generator) [7-8] that exists in the spinal cord while walking. Therefore, a smooth, steady walking is achieved in the place where it walks the plain, the stairs, the crowd, and for the first time. It is thought that the rhythm of CPG is related to the timing generation in various processes included in walking of perception and the action decisions and the motion executions etc. It is necessary to stimulate drawing out the effect of the inducement on the pedestrian by GVS to its maximum in the appropriate timing based on the walking cycle. Then, we construct a model of pedestrian's action decision process based on a walking cycle to optimize the intervention effect to walking with the device such as GVS. Concretely, the scene of passing each other of the one to one is taken up as a daily walking. We presume the influence specifying oncoming person's body necessary for the action decision at the time of passing each other. And, the influence of the self-movement when passing each other on generation is discussed.

II. Action Decision Process of Passing Each Other

In this study, we targets an action of passing each other to which the others observation, the self-decision making and motion generation for the action decision by walking. In addition, to make the model simple, the pedestrian goes straight, and the situation in which the direction is that oncoming person may evade the collision with the pedestrian. In this case, the pedestrian observes others, judges the direction of evasion from information in other's body site, decides own evasive action based on it, and is executing his movement (Fig. 1).

As for the judgment of others' evasion directions, the body site that seems to be important. So we evaluated to the judgment by using movie of passing each other by masiking others' body sites. From the result of the using others' body sites, we consider the influence of own evasive action. Finally, we measure the body site thought to receive the influence by using the motion capture system and evaluate whether the motion generation based on the self action decision gives the

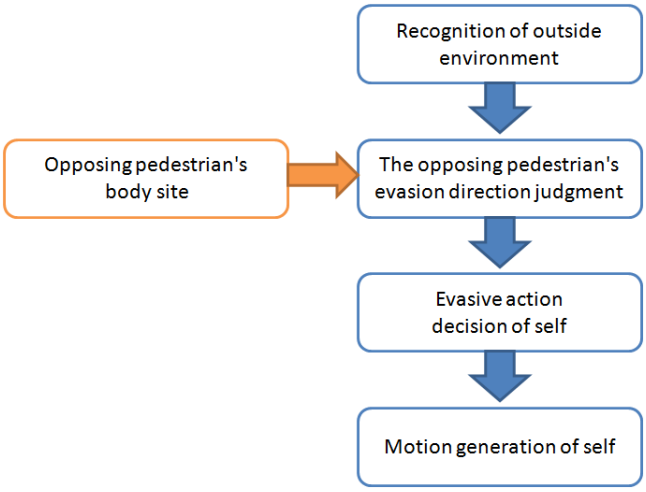

Fig. 1. Pedestrian's Action Decision Process

Fig. 2. Masking Movie of Passing Each Other Used by Experiment

effect to own body site.

A. Gazing Body Part in Passing Each Other

When passing each other with the person, we judge own direction of evasion from body features of those who oppose it by obtaining from the sight. Then, we measure the time that hangs to the judgment when the movie that does oncoming person's body site in masking is presented, and presume the body site necessary for the judgment.

1) Method: Subjects see the movie that those who oppose it projected onto the projector pass each other leaving the screen by about three meters in standing position, and judges oncoming person's direction of evasion. And subjects were stepping to image walking, and push the button in oncoming person's direction of evasion momentarily at the time of understood oncoming person's direction of evasion. However, the correction in the direction of evasion is no object.

The movie used by the experiment masked the specific body site all of about 300 frames, and integrated it again (Fig. 2). Oncoming person's body was classified into three (head, body, and foot), and the either was masked because the pedestrian had gazed at oncoming person's foot and breast by using eye track camera. Information obtained from the body site is limited by using the masked movie, and an important body site is specified from delay of the judgment by the limitation for the estimation of the direction of evasion.

2) Results: Figure 3 is a result of having totaled the number of judgments of body sites where the evasion judgment is delayed (N=3). The result that the judgment time became long when it had the foot in masking was shown. Then, it is thought that we do the evasion judgment by using information on our feet when passing each other. However, the delay has been generated by not only one's feet but also the masking of the head and the upper-body. It is thought that the head and the upper-body are seen and judged when the judgment is difficult only by oncoming person's feet. Thus, we examined the possibility that the body site where the evasion judgment was done according to the walking phase (position of the foot when walking) is different (Fig. 4).

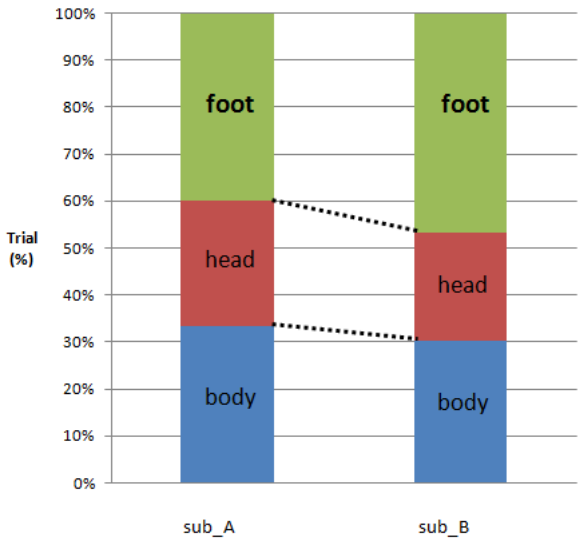

Fig. 3. Body Site Where the Delay of Judgment by Masking

B. Walking Phase in Evasion Judgment

We make a hypothesis with different body site at which it gazed when the evasion judgment is done according to oncoming person's walking phase at the time of passing each other. Next, how the walking phases of the body site and those who opposed it by the gaze influenced was examined.

1) Method: The subjects stand leaving the screen by 3 meters, step to image walking. They push the button in the direction momentarily at the time of understood oncoming person's direction of evasion. However, the correction in the direction of evasion is no object.

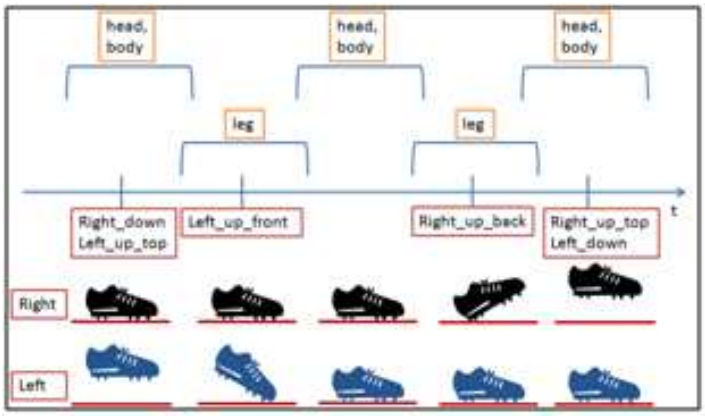

Fig. 4. Conceptual Chart of Walking Cycle and Evasion Judgment Body Part

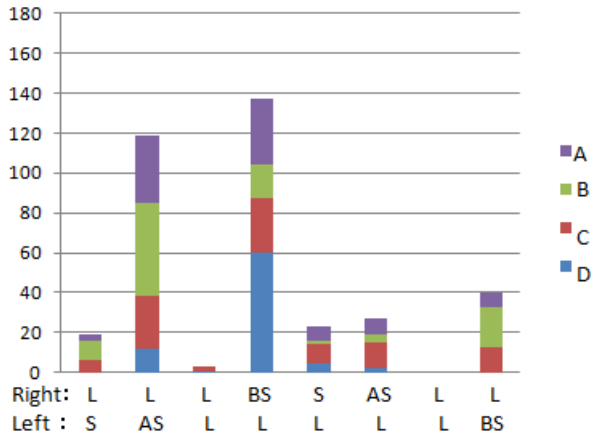

Fig. 5. Evasion judgment distribution when left leg is stepped forward. L: Landing, BS: Before Swing, S: Swing, AS: After swing.

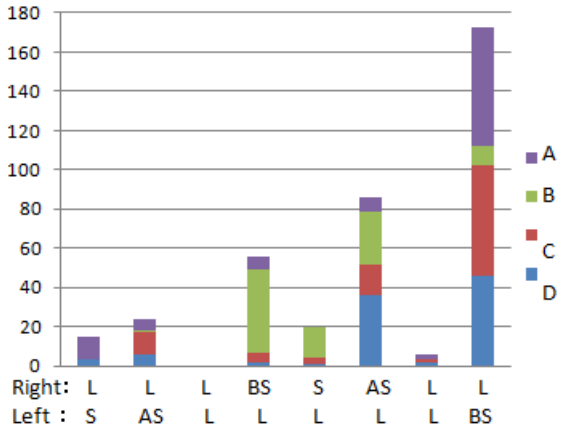

Fig. 6. Evasion judgment distribution when right leg is stepped forward. L: Landing, BS: Before Swing, S: Swing, AS: After swing.

The movie used took the situation of passing each other of the one to one from the other subject side. Four of those who opposed it directed the right and left foot stepped forward, and walked ten times of left evasion ten times of right evasion. In addition, to evaluate the walking phase, the movie of the side foot position was recorded synchronizing with movie of passing each other.

2) Results: Four subjects saw 378 animations a day in the experiment, the evasion judgment was done, and it experimented on it for five days. Average judgment timing of each movie was calculated from the experiment, and the walking phase when judged that was analyzed. The walking phase classified a foot right and left respectively in four states "Landed phase", "Before swing phase", "Swing phase", and "After swing phase".

Figures 5 and 6 are graphs where the number of judgments of walking phases of a momentary each foot that the evasion judgment was done was shown dividing into four oncoming pedestrians. In the graph, the phase is shown, "L: Landing, BS: Before Swing, S: Swing, AS: After swing". Figure 5 is distribution of the phase in the judgment trice when stepping forward from the left leg. The judgment result has concentrated for the period of AS for the period of BS in the right leg in the left leg. Figure 5 is distribution of the phase in the judgment trice when stepping forward from the right leg. The judgment result is Figure 5, the oncoming phase, and has a lot of judgments in the period of BS in the left leg in AS in the right leg. As a result, it is suggested that a lot of evasion judgments be done in "Before swing phase" and "After swing phase" in the walking phase in operation of passing each other.

C. Walking Phase in Generating Evasion Motion

As for pedestrian's action decision process, it has been understood that there is a judgment process of depending on oncoming person's walking phase in addition to the process of others observation and decision of self-action and execution of self-movements. Not only these factors however but also in own motion generation, it is possible to a distance of self and oncoming pedestrian and the influence of own walking phase. Then, the moved distance of subject's body (especially, feet) at the time of passing each other is measured by using the motion capture system, the physical exertion for passing each other is begun, and timing is examined.

1) Method: The distance between oncoming pedestrian and subject is about 5.2 meters, and they start at time when the oncoming pedestrian put down his hand both simultaneous. At this time, both oncoming pedestrian and subject go straight. The subject evades to the right and left directed beforehand, and the oncoming pedestrian goes straight and passes each other. The evasion distance was directed to avoid it when seeming to collide with subject with oncoming pedestrian.

The subject threaded 13 point in total marker of head 3 points, shoulder 2 points, waist 2 points, knee 2 points, and ankle 4 points, and oncoming pedestrian threaded 8 points of waist 2 points, knee 2 points, and ankle 4 points in total. The subjects walked ten times respectively in right evasion and left evasion. The motion capture device used the one of made of Motion Analysis, 12 cameras, and the sampling rate 250Hz.

2) Results: A right and left rate vector greatly changes into straight advancement so that the subject may evade right and left so as not to collide with the oncoming pedestrian. We analyzed the moment when a right and left speed of the ankle had greatly changed into the right and left as 0.16m/second or more as for the threshold as motion generation timing. Figures 7 and 8 show the frequency of the walking phase when the motion of each subject being tested is generated. In the graph, the phase is shown, "L: Landing, BS: Before Swing, S: Swing, AS: After swing". Figure 7 is a momentary walking phase with which subjects generated the evasion motion left, and the motion generation is often done in the section where the left leg has landed. Figure 8 shows a momentary walking phase in which the evasion motion to the right side is generated, and subjects generate the motion with both of right legs when landing and the left leg have landed. As a result, the timing at the motion generation is suggested that the foot in the direction of evasion landed. However, when the left leg had landed, the motion was generated about right evasion. Here, the motion generation tends to do generally by own working foot. The tendency to generate the motion when the foot in the direction of evasion had landed was suggested from experimental result at left evasion. On the other hand, the motion that moved at half cycle is generated in the direction of evasion by the left leg at right evasion. As a result, we assume whether subject's working foot influences.

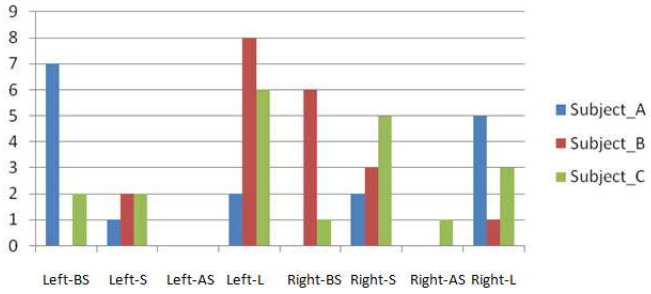

Fig. 7. Walking Phase at Motion Generation When the Left Side is Evaded

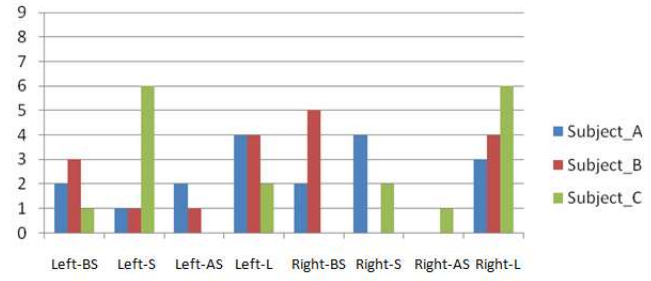

Fig. 8. Walking Phase at Motion Generation When the Right Side is Evaded

III. Discussion

A. The pedestrian's action decision based on walking cycle

From these experiments, it was shown that we have been influenced when passing each other at the action decision and the motion generation according to an oncoming pedestrian and own walking cycle.

Oncoming person's body site is observed and the direction of evasion is judged the start when the pedestrian passes each other (Fig. 9-1). Concretely, the direction of evasion is judged from information on oncoming person's feet in "Before swing phase" and "After swing phase" by which those who oppose it can control the direction of the foot. In L and S that the control of the foot is difficult, it is thought that the direction of the upper-body and the face is seen, and the direction for which the oncoming person's heads is judged.

The pedestrian action decision after the direction of evasion is judged undertakes the influence of oncoming person's walking phase (Fig. 9-2). Because the pedestrian has decided it the action according to the body site (especially, walking cycle) at which it gazed by the evasion judgment, the influence is undertaken from oncoming person's walking phase though it only has to do the evasion judgment according to arbitrary timing.

This timing at the motion generation depends on own walking phase though the exercise is generated after the decision of the self action. That is, the motion is generated when the foot in the direction of evasion can be controlled, and a lot of the timing occurs to after swing phase (Fig. 9-3).

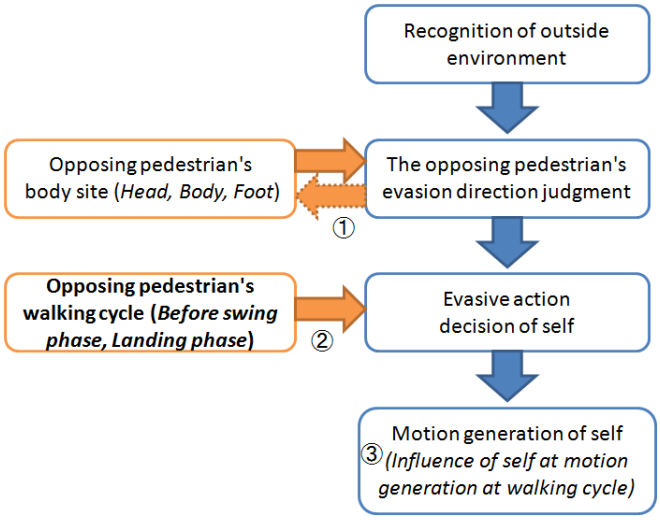

Fig. 9. Pedestrian's Action Decision Process Model in Passing Each Other

B. Possibility of Inducement of Pedestrian Based on Action Decision Model

In this study, we have experimented the understanding of the action decision process at the time of person's passing each other based on the hypothesis that an effective inducement by aiming at human action inducement under unconsciousness,

and putting out the inductive stimulus according to the walking cycle according to appropriate timing.

It is thought that we observe others' body sites and presume others' directions of evasion. However, there is a possibility of correcting the evasion judgment that the self decided when inducing it here with the sight device etc. so that the self may do the evasion judgment. Therefore, it is improper as the timing of the inducement presentation.

On the other hand, self decides the action according to others' walking cycle (3.2). Because the action decision timing has synchronized with the others' behavior, there is a possibility that it is caused to the inducement by inducing the pedestrian before the action decision. It is expected that the action decision of unconsciousness is performed by the inducement as for this method because there is no correction feedback by own intention. In addition, the action decision causes a high effect of the inducement because it influences the motion generation that the self controls. It is thought that it is the most effective before own evasive action is decided to induce it under such consideration.

IV. Conclusion

In this study, it experimented passing each other of the one to one for the clarification of the decision process of the walking action that aimed at the action inducement of unconscious. As a result, it was suggested that an oncoming pedestrian and own walking cycle influence at an action decision of the self and own motion generation. However, it is necessary to increase the number of subjects so that the possibility that the motion generation is influenced by the working foot may remain.

In addition, it wants to examine the inducement device including GVS, and to examine the inducement experiment.

***Abstract*— In order to realize intelligent agents such as autonomous mobile robots, Reinforcement Learning is one of the necessary techniques in control systems. It is desirable in terms of knowledge or skill acquisition of agents that reinforcement learning is based only upon rewards instead of teaching signals. However, there exist many problems to apply reinforcement learning to real-world tasks. The most severe problem is a huge number of iterations in the learning phase. In order to deal with the problem, the instruction approach for reinforcement learning agents based on sub-rewards and forgetting mechanisms were proposed and shown to be effective. However, the relationship between the instruction and the learning performance of reinforcement learning has not been adequately clarified. In this study, in order to clarify the instruction performance in the reinforcement learning, we propose an instruction knowledge acquisition method for the reinforcement learning scheme by the particle swarm optimization (PSO) algorithm. Through numerical experiments of the mountain car task and the Acrobat task, we show the validness of the proposed approach in terms of learning speed and accuracy.**

Keywords: Reinforcement Learning, Q-Learning, Fuzzy Q-Learning, Instruction, PSO, Machine Learning

I. INTRODUCTION

The Reinforcement Learning[1-4] will be one of the necessary techniques to realize intelligent agents such as autonomous mobile robots. The reinforcement learning is a desirable idea that can acquire the skill and knowledge without using the teaching signal based upon only the rewards from environments. However, the huge iterations of the trial for accomplishment of the reinforcement learning become a problem in actual applications in which the appropriate learning of the compound task or complicated task is needed. This huge trial frequency is one of the issues of the reinforcement learning. In order to deal with the complicated task problem, several effective approaches are studied. For relaxation of task complexity, several types of hierarchical reinforcement learning have been proposed to apply to actual applications[5,6]. The hierarchical reinforcement learning has been widely recognized as an effective scheme for complicated tasks. However, the approach is based on the assumption that the compound task is decomposed hierarchically into subtasks as internal models of the agent in advance. The assumption is sometimes not suitable for learning of agents in an unknown environment, i.e. basic concepts of the reinforcement learning. When we consider realizing the automatic task decomposition function by means of the reinforcement learning, improvement of learning performance such as iterations and precision of acquisition is indispensable for the reinforcement learning technique as well as a concrete segmentation technique of the learning results. The authors proposed an instruction based reinforcement learning applying sub-rewards and forgetting mechanisms[7,8] in order to improve the learning performance of reinforcement learning agents. In the study, we aimed at constructing a new learning scheme that can utilize the instruction, i.e. not strictly teaching, in the reward based reinforcement learning scheme and showed effectiveness in terms of the necessary learning speed in the reinforcement learning process through numerical experiments of not so complicated tasks. However, the relationship between the instruction and the learning performance of the reinforcement learning has not been adequately clarified. In this study, in order to clarify the instruction performance further in the reinforcement learning, we propose an instruction knowledge acquisition method for reinforcement learning scheme by the particle swarm optimization (PSO) algorithm[9]. The efficacy is shown by the numerical experiment of the mountain car task and the Acrobot task.

The paper is organized as follows. In section 2, we discuss the issue of instructions for task acquisition. In section 3, we introduce a learning method based on the instruction. An instruction knowledge acquisition algorithm is proposed in section.4. Then the results of numerical experiments are shown in section 5. Finally, conclusions are drawn in section 6.

II. INSTRUCTIONS FOR TASK ACQUISITION

The skillful task performed by human experts is indispensable even in the modern society. Even in a highly automated factory, skillful experts usually take part in important tasks. Moreover, tasks in traditional artistic crafts such as ceramic art or woodwork are also highly skillful. On the other hand, techniques in sports can also be said to be skillful for not only the athlete but also general people in our daily life. Since it is obvious that the sports are good for health, learning the techniques(task acquisition) in the sports is necessary process to all the people. Even injured people under treatment, struggle to restore their movement functions through rehabilitation physical trainings which are difficult tasks for themselves as though skillful techniques of the sports.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

There exist many skillful tasks to acquire in many areas.

Though the skillful task is highly complicated at a glance through an observation, many tasks consist of the combination of simple sub-tasks. As seen from the potential ability of human recognition, the simple task is clearly performed from the selected inputs among huge information, such as vision, sound, and measured data. The comprised simple task is not difficult itself to be developed into an automated machine owing to the modern technology progress. However the task decomposition without knowledge is not easy to develop. In the soft computing area, the automatic task decomposition by the computer system has been studied. Modular neural network[10,11] is proposed to realize the modularization of learning results. This is equivalent to the task decomposition represented as "gating network." Modular fuzzy model[12] is also proposed to deal with the problem. The task decomposition without knowledge is more difficult without explicit teaching.

This problem corresponds substantially to the reinforcement learning concept. The model for the reinforcement learning is usually constructed as a memory type, neural network, fuzzy model, locally weighted regression, CMAC and so on. However, non structured model acquired is essentially a mimic system that is not robust for changes of environment, condition, and so on. Moreover, the segmentation of native acquired model is an important problem to realize the task decomposition. Recently, study of the task decomposition is advanced by learning by the intrinsic motivation[13,14]. The methods are based on internal rewards to formulate behavioral rules abstracted from the results of the reinforcement learning expressed as action rules. In the abstraction process, the segmentation of learning is an indispensable and essential technique. Although they are promising techniques in terms of task decomposition or task acquisition of complicated tasks of the agent, the substantial difficulty of the intrinsic reward concept is still remained in actual applications.

On the other hand, in terms of realization of applicable task decomposition or task acquisition, the authors proposed an "Instruction based reinforcement learning"[7,8] applying environmental sub-rewards and forgetting mechanism in the agent and showed promising results through not so complicated tasks. We consider that there exist some situations that the environmental sub-reward is more suitable than the intrinsic concept in the task acquisition. "Instruction" plays an important role in acquiring the task of human works. For example, when we teach someone the skill we already have, we often give only an instruction as a knack or a point that is necessary to perform the skill, instead of teaching every detail including trivial matters in the task procedure. Our motivation of "Instruction based reinforcement learning" is to realize such instructions in the reinforcement learning scheme. The basic concept is to give "instruction" that is not strict and fragmental compared with the teaching data used in the teaching based learning such as the multi-layered perceptron,

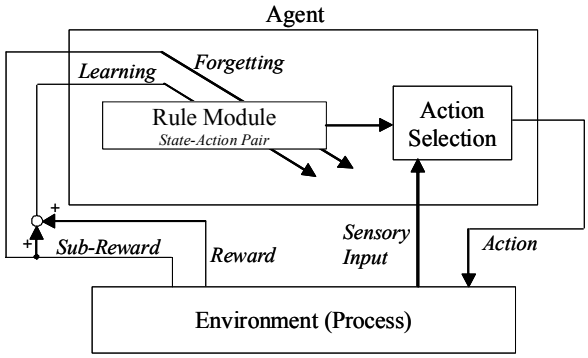

Figure 1. Conceptual Diagram of Instruction Based RL Architecture

to the reinforcement learning agent. The instruction concept can be realized as sub-rewards in addition to the main reward as well as forgetting mechanism to improve the learning performance in the reinforcement learning process.

However, there exist a lot of tasks difficult to give the instructions even by the skillful human experts. Moreover, the instruction concept is essentially subjective and is not clear its optimality or validness in terms of the reinforcement learning. Our primary motivation in this study is to investigate the relationship between instructions and learning performance of the reinforcement learning. Since the instruction can be considered as additive information to accelerate the learning process of the task, valid instruction is necessary to the task acquisition. Furthermore the instruction acquisition might lead to significant tools to analyze the skillful task and to hand down the skillful task to the next generation by interacting human and agent(robot) models. In this study, in order to clarify the instruction performance further in the reinforcement learning, we propose an instruction knowledge acquisition method for the reinforcement learning scheme

III. LEARNING METHOD BASED ON INSTRUCTION

In order to commission sub-rewards mechanism appropriately, the issue of consistence maintenance between sub-rewards and the main reward should be dealt with. Then we proposed a learning algorithm based on sub-rewards with forgetting mechanism and eligibility trace[7, 8]. The sub-rewards are defined corresponding to necessary state-action pairs. Moreover, when the agent obtains the sub-reward, forgetting mechanism is applied at the same time. Fig.1 shows the conceptual diagram of proposed learning architecture.

A. Q-learning algorithm

In Q-learning reinforcement learning algorithm, an optimal policy is formulated by maximizing rewards received over time. Q-function is defined as values for each pair of state and action:

$$Q(x_t, a_t) = Q(x_t, a_t) + \alpha\left(r_{t+1} + \gamma \max_{\eta} Q(x_{t+1}, \eta) - Q(x_t, a_t) \right) \quad (1)$$

where x_t is the state vector of t-th input, a_t is the t-th action,

r_{t+1} is a reward, γ is a discount rate, and α is a learning rate. The reward based on the sub-reward is defined as:

$$r_{t+1} = hr_{t+1} + R_{t+1} \tag{2}$$

where hr_{t+1} denotes a sub-reward, and R_{t+1} is a main reward. At learning, neither a sub-reward nor a main reward distinguishes the kind. Therefore, the possibility of inconsistency of the expectation reward in the reinforcement learning is not negligible. Then, forgetting is executed also at giving the instruction to maintain consistency of the expectation reward. Forgetting mechanism is defined as:

$$Q(x,b) = \Gamma \cdot Q(x,b), \qquad b \neq a_t, 0 \leq \Gamma \leq 1 \tag{3}$$

where Γ is a forgetting parameter and a_t is the current action.

B. Fuzzy Q-learning algorithm

In Fuzzy Q-Learning[15], Q-function is approximated by the fuzzy model. The fuzzy model is defined by FCS (Fuzzy Classifier System) form[16] as:

$$if\ x_t\ is\ A_j\ then\ a_t\ is\ c_j^k\ with\ q_j^k \tag{4}$$

where c^k_j is a k-th concrete action, A_j denotes the fuzzy set defined in the input states, and q^k_j is the Q-value of the j-th rule. The output Q-value is calculated as:

$$Q(x_t, c^k) = \frac{\sum_{s=1}^{m} h_s \cdot q_s^k}{\sum_{s=1}^{m} h_s} \tag{5}$$

where h_s denotes the membership degree of the rule and m is the number of the fuzzy rules. From (1), the TD error that should be corrected is defined as:

$$\Delta Q(x_t, a_t) = \left(r_{t+1} + \gamma \max_{\eta} Q(x_{t+1}, \eta) - Q(x_t, a_t) \right) \tag{6}$$

The correction of the q-value in the rule is defined as follows by the request of the gradient of (5) and (6).

$$\Delta q_j^k = \Delta Q(x_t, a_t) \cdot \frac{\partial Q(x_t, a_t)}{\partial q_j^k} = \Delta Q(x_t, a_t) \cdot \frac{h_j}{\sum_{s=1}^{m} h_s} \tag{7}$$

where a_t is the action c^k in this equation. The maximum Q value at the right of (6) is obtained from (5).

Moreover, when the sub-reward and forgetting are applied to the fuzzy Q-learning, (2) and (4) are applied based on the next equation that modifies the Q value.

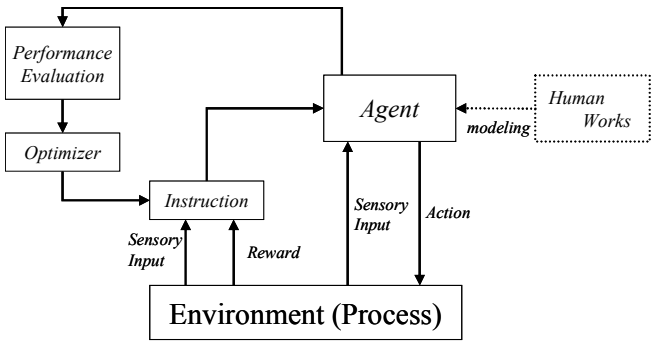

Figure 2. Conceptual Diagram of Instruction Knowledge Acquisition

$$\begin{aligned} q_j^b &= \Gamma \cdot q_j^b \\ \Gamma &= 1 - (1-\beta)\left(1 - \mu(d,b)\right) \cdot h_j, \ \ 0 \leq \beta \leq 1 \end{aligned} \tag{8}$$

where μ is a membership function that shows the degree of agreement of selected action d and the other actions b, and β is a forgetting parameter. The degree of forgetting becomes high when we set a small value as the parameter.

The eligibility trace can also be successfully applied at the same time of the instruction[8].

IV. Instruction Knowledge Acquisition by PSO Algotrithm

Our objective in this study is to acquire effective instructions through reinforcement learning simulations. Fig.2 shows the conceptual diagram of instruction knowledge acquisition. Let us assume that the human works such as actions or movement are modeled as the agent or the robot. By evaluating the learning performance using episode lengths, appropriate instructions are decided through optimization procedures. Empirically, there could exist many alternatives of good instructions. In order to deal with such nature, we adopt PSO algorithm to acquire the instructions.

A. Particle swarm optimization algorithm

Particle swarm optimization[9] is a population-based iterative search procedure, which simulates the social behavior such as flocks of birds or schools of fish. N individuals, referred to as particles, constitute a swarm. Each particle is a candidate solution to the D dimensional problem. The position of the *i-th* particle at *t-th* iteration is represented by:

$$X_i^{(t)} = \left(x_{i1}, x_{i2}, \cdots, x_{iD} \right) \tag{9}$$

During the search process, the particle successively adjusts its position toward the global optimum according to two factors. The best position encountered by itself (pbest) is denoted as:

$$P_i = \left(p_{i1}, p_{i2}, \cdots, p_{iD} \right) \tag{10}$$

The best position encountered by the whole swarm (gbest) is denoted as:

$$P_g = \left(p_{g1}, p_{g2}, \cdots, p_{gD}\right) \tag{11}$$

Its velocity at t iteration is represented by:

$$V_i^{(t)} = \left(v_{i1}, v_{i2}, \cdots, v_{iD}\right) \tag{12}$$

The position at the next iteration is calculated according to the following equations:

$$V_i^{(t)} = \lambda\left(\begin{array}{l} w * V_i^{(t-1)} + c_1 * rand(\,) * \left(P_i - X_i^{(t-1)}\right) \\ \qquad + c_2 * rand(\,) * \left(P_g - X_i^{(t-1)}\right) \end{array}\right) \tag{13}$$

$$X_i^{(t)} = X_i^{(t-1)} + V_i^{(t)} \tag{14}$$

where c_1 and c_2 are two positive constants, called cognitive learning rate and social learning rate respectively; *rand*() is a random function in the range [0;1] ; w is inertia factor; and , λ is a constriction factor. In addition, the velocities of the particles are confined within $[V\text{min}, V\text{max}]^D$. If an element of velocities exceeds the threshold Vmin or Vmax; it is set equal to the corresponding threshold. From equation (13) and (14), it can be seen that the velocity determines search direction and step-size simultaneously for the particle according to the social learning and the cognitive learning.

The point of the instruction for the reinforcement learning is defined as a particle (position X) for PSO algorithm in this study. The particles(instruction points) search towards the point in which the trial episode lengths of learning are minimized.

V. NUMERICAL EXPERIMENTS

In order to evaluate the performance of the proposed approach, the numerical experiments are conducted for the mountain car task and the Acrobot task. The search of the instruction points is performed by using PSO algorithm.

Each parameter of PSO is as follows. c_1 and c_2 are 2.0, respectively. The number of particles in the swarm is 10. Constriction factor λ is set as 0.1. Inertia factor w is set as 1.0. Let us assume that the positions of particles are also confined within the rage $[X\text{min}, X\text{max}]^D$. In this study, Xmax is set as 100, and Xmin is set as -100. The state variables including the action for the instruction are normalized to $[X\text{min}, X\text{max}]^D$ according to the task. In the mountain car task, the dimension of the state is three(position, speed, and acceleration operation of the car agent). In acrobat task, the dimension of the state is five (angle and angular velocity of the first link, angle and angular velocity of the second link, and torque operation of the Acrobot).

Initial positions of particles are decided at random within the range of Xmin and Xmax. The number of generations of PSO is set as 100 in this study.

A. Mountain Car Task(Crisp)

Fig.3 shows the settings of the mountain car task. The purpose of this task is to climb a right-hand mountain. The power of the car agent is restrained as lower value than the gravity. Therefore, the acquisition of the action knowledge that shuttles several times, enlivens, and reaches a goal becomes indispensable. The state of the agent (car) is two continuous values of speed v_t and position p_t. The action can be selected from {-1, 0, 1}. The action is each full throttle retreat (-1), zero throttle (0), and full throttle advancement (+1). When the car finishes climbing the mountain, the reward is given. Agent's initial state was assumed to be p_0=-0.5 and v_0=0. The state is quantized by the crisp partition. The number of partitions is 15, the learning rate α is 0.10, and the discount rate γ is 0.95. The simulations are conducted 100 times. The averaging value is used to evaluate. The agent tries the mountaineering 5 times by one simulation. When the following condition is satisfied, the instruction is given to the agent. When the state and the action of the agent falls into the range of the instruction point(particle) as shown in Fig.4, the instruction is applied to the agent. In the figure, position p and

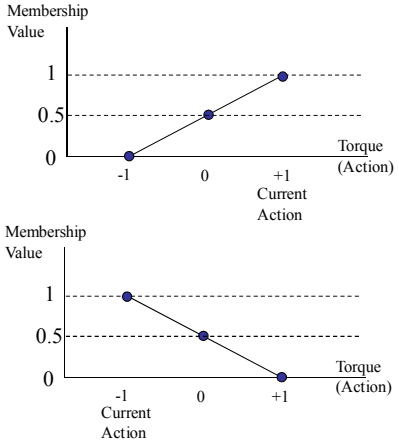

Figure 9. Membership Function for Forgetting

speed v of the instruction are normalized from position x_p and x_v of the particle in PSO. Moreover, the action a is defined as +1(full throttle advancement) when x_a is positive, and action a is defined as -1(full throttle retreat) when x_a is negative. α_v and α_p are predefined parameters to decide the range of the instruction, and $0<\{\alpha_v, \alpha_p\}<= 1.0$. The range of the instruction becomes wider if they are set near 1.0. α_v and α_p are set as 0.1, in this study.

The membership function for the state quantization for the agent is shown in Fig.5. The averaged episode lengths of the initial states of the particles and the averaged episode lengths after the 100 generations in PSO are shown in Fig.6. About 700 or more of the averaged episode length is decreased by the proposed method. As for the #9, we can see the averaged episode length becomes 5551 from initial value of 6831, i.e. decrease over 1200 episodes. Fig.7 shows the initial 100 trial process of the #10, i.e. the best instruction, after the optimization as well as the results without the instructions. Fig.8 also shows the initial 25 trial process. It is confirmed that the episode lengths are decreased by the proposed algorithm.

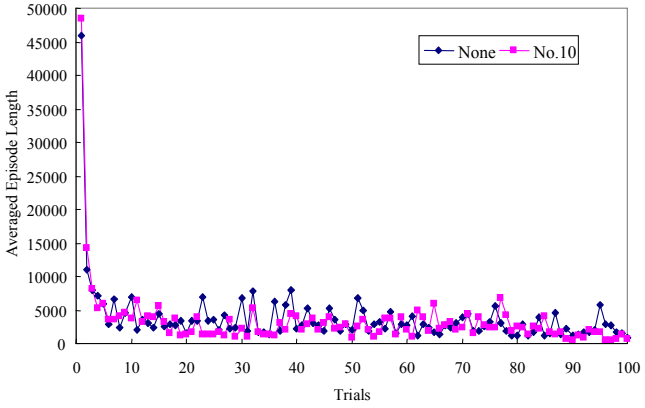

Figure 11. Results of Fuzzy Mountain Car Task*(No.10)*

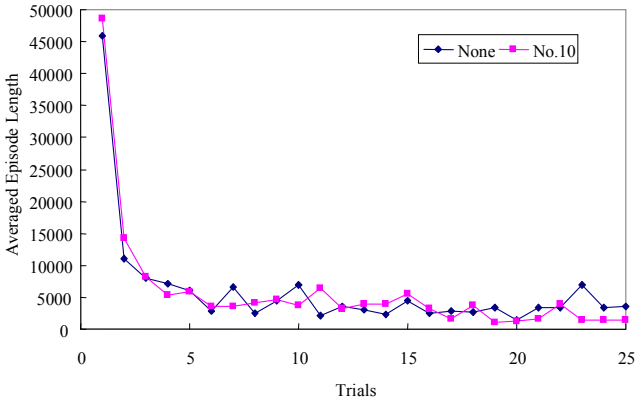

Figure 12. Result of Fuzzy Mountain Car Task*(No.10)*

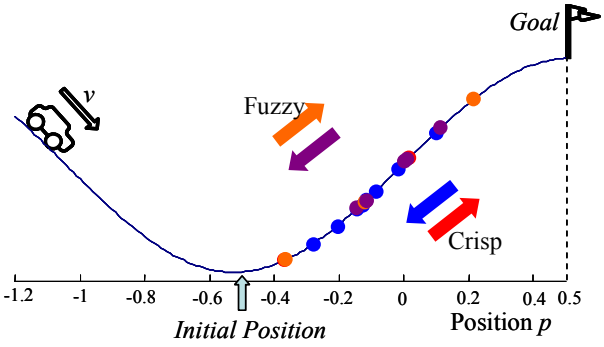

Figure 13. Crisp and Fuzzy Instruction Points

B. *Mountain Car Task(Fuzzy)*

Fuzzy Q-Learning agent is evaluated applying the instruction acquisition. The state is partitioned according to the membership functions of 25 fuzzy sets as shown in Fig.5. The degree of agreement in (8) that employs forgetting is assumed to be formulated as the membership functions shown in Fig.9. The averaged episode lengths of the initial states of the particles and the averaged episode lengths after the 100 generations in PSO are shown in Fig.10. About 3000 or more of the averaged episode length is decreased by the proposed method. As for the #10, we can see the averaged episode length becomes 11931 from initial value of 17036, i.e. decrease over 5000 episodes. Fig.11 shows the initial 100 trial process of the #10 after the optimization along with the results without the instructions. Fig.12 also shows the initial 25 trial process. It is confirmed that the total episode lengths are decreased by the proposed algorithm (from 367906 to 324872).

Examples of typical instruction points are shown in Fig.13. The action of a full throttle advances is decided around the initial position and the goal as the instruction. The full throttle retreat is decided in the other parts. These results are similar to the results by the Crisp partitioned agents.

C. *Acrobot task (Crisp)*

Acrobot is a mimic system of the "horizontal bar" of human gymnastics. The objective of the task is to swing the tip of the robot up to the predefined height as shown in Fig.14. A unique characteristic of the task is that the robot adjusts only the second joint torque being affected by its dynamics to achieve the goal. The dynamical equations of the Acrobot are as follows:

$$
\begin{aligned}
&d_{11}\ddot{\theta}_1 + d_{12}\ddot{\theta}_2 + h_1 + \phi_1 = 0 \\
&d_{21}\ddot{\theta}_1 + d_{22}\ddot{\theta}_2 + h_2 + \phi_2 = T \\
&d_{11} = m_1 r_1^2 + m_2 l_1^2 + m_2 r_2^2 + 2m_2 l_1 r_2 \cos\theta_2 + I_1 + I_2 \\
&d_{12} = m_2 r_2^2 + m_2 l_1 r_2 \cos\theta_2 + I_2 \\
&d_{21} = m_2 r_2^2 + m_2 l_1 r_2 \cos\theta_2 + I_2 \\
&d_{22} = m_2 r_2^2 + I_2 \\
&h_1 = -m_2 l_1 r_2 \left(2\dot{\theta}_1 + \dot{\theta}_2\right)\dot{\theta}_2 \sin\theta_2 \\
&h_2 = m_2 l_1 r_2 \dot{\theta}_1^2 \sin\theta_2 \\
&\phi_1 = \left(m_1 r_1 + m_2 l_1\right) g \sin\theta_1 + m_2 r_2 g \sin\left(\theta_1 + \theta_2\right) \\
&\phi_2 = m_2 r_2 g \sin\left(\theta_1 + \theta_2\right)
\end{aligned}
$$

where θ_1, θ_2 are the angles of joint1 and joint2, $\dot{\theta}_1$, $\dot{\theta}_2$ are the angular velocities of joint1 and joint2, and $\ddot{\theta}_1$, $\ddot{\theta}_2$ are the angular accelerations of joint1 and join2, respectively. T is the torque applied to the joint2. m_i is mass, l_i is length, r_i is length to center of mass, and I_i is moment of inertia of link$i$, respectively. Actual setting of constant parameters is as m_i =1, l_i =1, r_i =1, I_i=1 (i=1,2), and g=9.8 in this study. The angular velocities are bounded by $\dot{\theta}_1 \in [-4\pi, 4\pi]$ and $\dot{\theta}_2 \in [-9\pi, 9\pi]$. The target height H is set as 0.5. The equations of motion are numerically solved by means of Runge-Kutta method in 0.05sec interval. The sampling period is 0.2 sec. The agent chooses the torque T from {-1,0,1} as action at every sampling

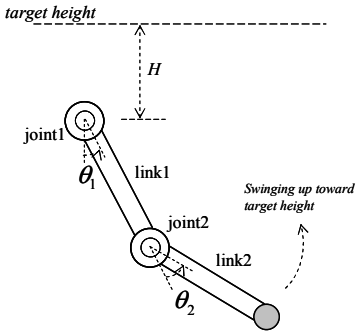

Figure 14. Acrobot Task

TABLE I. ACROBOT INSTRUCTION POINTS

Particle number	Acrobot Instruction Points				
	θ_1	$\dot{\theta}_1$	θ_2	$\dot{\theta}_2$	*act*
1	0.49	3.44	-0.53	1.79	1
2	0.83	3.85	-0.60	2.83	1
3	0.64	6.81	0.27	-3.25	1
4	1.04	0.64	-1.11	4.83	-1
5	0.57	3.55	-0.42	2.73	1
6	0.70	3.77	-0.31	2.81	1
7	1.44	7.04	-1.41	0.93	1
8	-0.21	2.34	-0.29	0.89	-1
9	-0.70	-6.56	2.52	-18.1	1
10	0.19	2.59	-1.37	-2.98	1

time(step). The number of partitions is 19 as shown in Fig.15, the learning rate α is 0.20, and the discount rate γ is 0.95. The agent tries the mountaineering 5 times in one simulation and the simulation is conducted 100 times. The averaged episode length is used to evaluate the learning performance.

When the following condition is satisfied, the instruction is given to the agent. The condition of the angle is defined in the same way of the mountain car task experiments as follows:

$$\frac{|\theta\max|\cdot x_\theta}{|X\max|}-\frac{|\theta\max|}{Partition\ size}\le\theta\le\frac{|\theta\max|\cdot x_\theta}{|X\max|}+\frac{|\theta\max|}{Partition\ size} \quad (15)$$

where θ denotes the state value of the angle, x_θ is the normalized particle state corresponding to the angle value, and $|X\ \max|$ is the maximum range value of the particle state. $|\theta\ \max|$ is the maximum range value of the angle. *Partition size* is a parameter of granularity of PSO search. The other conditions of states such as angular velocities are defined in the same manner.

The averaged episode lengths of the initial states of the particles and the averaged episode length after the 100 generations in PSO are shown in Fig.16. About 2000 or more of the averaged episode length is decreased by the proposed method. As for the #7, we can see the averaged episode length becomes 11951 from initial value of 22724, i.e. decrease over 10000 episodes. Fig.17 shows the initial 50 trial process of the #10 after the optimization along with the results without the instructions. It is confirmed that the total episode lengths are decreased drastically by the proposed algorithm (from 9169856 to 4721048 episodes). The acquired instructions by PSO algorithm are shown in TABLE.I. Fig.18 schematically depicts the examples of the acquired instruction points of Acrobot by the proposed algorithm. Although the Acrobot task is high dimensional and complicated task that the appropriate instruction is not clear intuitively, the proposed algorithm performs successfully the acquisition of the instruction in the reinforcement learning. Moreover, the episode length, i.e. the learning performance, can be drastically decreased by giving

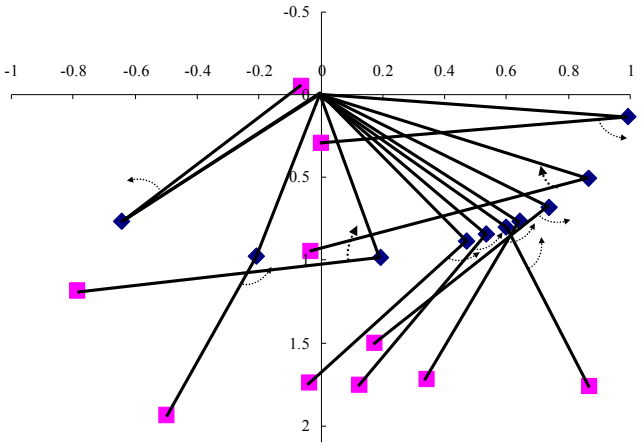

Figure 18. Acquired Instructions of Crisp Acrobot Task

even only one instruction point acquired by the proposed algorithm. It can be considered that this is because the necessary knack existing in the task is successfully acquired by the proposed algorithm.

VI. CONCLUSION

In this study, in order to clarify the instruction performance in the reinforcement learning, we proposed an instruction knowledge acquisition method for the reinforcement learning scheme by the particle swarm optimization (PSO) algorithm. Through numerical experiments of the mountain car task and the acrobat task, we showed the validness of the proposed approach in terms of learning speed and accuracy. Moreover, the effective instruction point for the reinforcement learning process was successfully acquired even in the Acrobot task that was the complicated task. In this study, the number of the instruction was assumed as 1 for simplicity. Our future plan includes acquisition of appropriate combination of some instructions for high dimensional and complicated tasks.

***Abstract*— This paper presents the application of a methodology for daily reservoir inflow forecasting in Brazilian hydroelectric plants. The methodology is based on Fuzzy Inference Systems (FIS) and the technique used for adjusting of the model parameters is an offline version of the Expectation Maximization (EM) algorithm. In order to automate the application of the methodology and facilitate the analysis of the results, a tool that allows managing streamflow forecasting studies and visualizing their information in graphical form was developed. A case study was applied to the data from three Brazilian hydroelectric plants whose operation is under the coordination of the Electric System National Operator. They are located in the Grande basin, a part of the Parana basin with two main rivers: the Grande and the Pardo. The benefits of the model are analyzed using statistics calculations, such as: root mean square error, mean absolute percentage error, mean absolute error and mass curve coefficient. Besides that, graphics that compare the registered and predicted streamflow are presented. The results show an adequate performance of the model, leading to a promising alternative for daily streamflow forecasting.**

Keywords: Inflow forecasting; Fuzzy systems; Hydroelectric plants; Reservoir management; Computacional tool.

I. INTRODUCTION

One of the great economic and environmental challenges facing humanity nowadays is the production of electricity. In Brazil, the power generation is assigned to the task of planning and scheduling of hydroelectric plants. The objective of this task is to ensure an economic and reliable operation policy for the system.

Forecasting of streamflows is an important step for planning and scheduling of hydroelectric power system. However, this step is still one of the most difficult issues in hydrological science because it is characterized as a problem dynamic, uncertain and nonlinear. The purpose of forecasting is to support decision-making, help operate reservoirs, assess resource capabilities and determine pricing for the out-of-province sale of energy.

Several researches have been devoted to the formulation and development of models that aims to improve the quality of hydrological prediction. In general, the models are assigned to one of three broad categories: *deterministic*, *conceptual* or *parametric*.

Deterministic models describe the rainfall-runoff process using physical laws of mass and energy transfer. Conceptual models provide simplified representations of key hydrological process using a perceived system. Parametric models use mathematical transfer functions to relate meteorological variables to runoff [1].

Deterministic and conceptual models require a large amount of high-quality data associated with hydrological, meteorological and natural geographical characteristics as well as human activities. Parametric models do not presuppose a detailed understanding of the basin's physical characteristics, nor does it require extensive data preprocessing [2]. Therefore, neural network and fuzzy systems are particularly powerful in situation where it is difficult to determine the physical process or when it is not possible to obtain a physical interpretation of the mathematical model representation [3]. Their potential for inflow forecasting is demonstrated in [4], [5] and [6].

In [7], an offline Fuzzy Inference System (FIS) was used for predicting annual inflows that are disaggregated in the respective monthly samples used for long-term hydropower scheduling. The use of these tools for the daily or hourly forecasting may be an interesting alternative that complements time series analysis for inflow modeling, usually performed in hydroinformatics via physical and conceptual models [8].

Given the importance of streamflow forecasting for power generation systems, this paper presents a Takagi-Sugeno (TS) FIS for daily inflow forecasting. The learning algorithm is based on the offline version of the Expectation Maximization (EM) algorithm. The objective is to improve the quality of this information, contributing to the choice of an operational policy that meets the consumer market in an economic and safe way.

The context of this paper is organized as follow. Initially, Section II presents the model general structure and the optimization algorithm. Then, in Section III a case study is shown. This section is divided in four items. The first describes the study area and the data collection; in the second item the methodology and the modeling are explained; the third shows the tool used in this work and the fourth item presents the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

results and discussions. After that, in Section IV the conclusions are presented.

II. MODEL DESCRIPTION

Model detailed is already used in different applications involving time series forecasting. It was originally proposed as a model initialization of the adaptive fuzzy system model proposed in [8]. In order to increase the clarity of this paper a general description of the model structure is presented next.

A. General Structure

The model structure adopted, as its name indicates, is mainly based on the first order TS-FIS [9].

Let denote the input vector at instant time k as $x^k = [x_1^k \quad x_2^k \quad ... \quad x_p^k]$. The output model for the correspondent input x^k is denoted by y^k. The input space represented $x^k \in R^p$ is partitioned into M sub-regions, each represented by a fuzzy rule (Fig. 1).

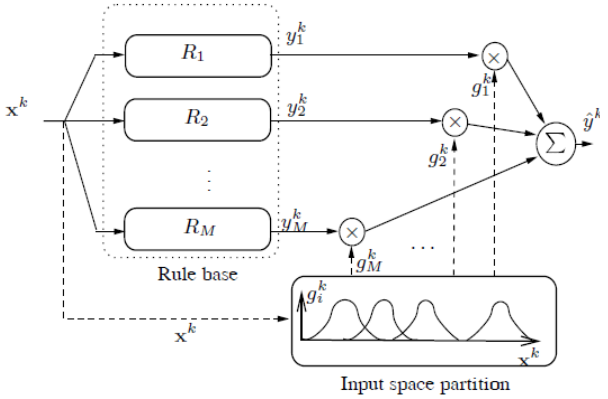

Figure 1. General model structure.

The antecedents of each If-Then fuzzy rule (R_i) are represented by their respective centers $c_i \in R^p$ and covariance matrices $V_i|_{p\times p}$. The consequents are represented by local linear models, with outputs y_i^k, $i = 1,..,M$ defined by:

$$y_i^k = \phi^k \times \theta_i^T \tag{1}$$

where $\phi^k = [1 \quad x_1^k \quad x_2^k \quad ... \quad x_p^k]$ is the extended input vector where the first component is increased for considering a constant term in the local linear model; $\theta_i = [\theta_{i0} \quad \theta_{i1} \quad ... \quad \theta_{ip}]$ is the coefficient vector of the local linear model related to the i^{th} rule.

Each input pattern has a membership degree associated with each region of the input space partition. This is calculated through membership functions $g_i(x^k) \in [0,1]$ that vary according to centers and covariance matrices related to the fuzzy partition, and are computed by:

$$g_i(x^k) = g_i^k = \frac{\alpha_i P[i \mid x^k]}{\sum_{q=1}^{M} \alpha_q P[q \mid x^k]} \tag{2}$$

where α_i are positive coefficients satisfying $\sum_{i=1}^{M} \alpha_i = 1$ and $P[i \mid x^k]$ is defined according to:

$$P[i \mid x^k] = \frac{1}{(2\pi)^{p/2} \det(V_i)^{1/2}} \exp(-(x^k - c_i) V_i^{-1} (x^k - c_i)^t) \tag{3}$$

where $\det(\cdot)$ is the determinant function. The final model output $\hat{y}^k$ is calculated by a non-linear weighted average of the local outputs and its respective membership degrees. Thus, the predicted value of the output variable for future time instant k is given by:

$$\hat{y}^k = \sum_{i=1}^{M} g_i^k y_i^k \tag{4}$$

B. Optimization Algorithm

The EM algorithm has been used for the optimization of several computational intelligence based methods, such as the works presented in [8], [10] and [11]. Therefore, this work suggests the use of the offline EM algorithm for the optimization of the FIS parameters.

First, the FIS structure is initialized. In order to define the number of rules M to codify in the model structure, the unsupervised Subtractive Algorithm (SC) is used over the input-output training data set [12]. Initial values for spreads codified in the covariance matrix are the same used by the SC algorithm. Therefore, the FIS structure is initialized as follows:

- $c_i^0 = \psi_i^0|_{1...p}$ where $\psi_i^0|_{1...p}$ is composed of the first p components of the i^{th} center found by the SC algorithm;
- $\sigma_i^0 = 1.0$;
- $\theta_i^0 = \left|\psi_i^0\right|_{p+1} 0...0\Big|_{1\times p+1}$, where $\psi_i^0|_{p+1}$ is the $(p+1)^{th}$ component of the i^{th} center found by the SC algorithm;
- $V_i^0 = r_a^2 I$, where I is a $p \times p$ identity matrix and r_a is the spread parameter used by the SC algorithm;
- $\alpha_i^0 = 1/M$.

After this initialization, model parameters are readjusted on the basis of the offline EM algorithm, (see [13] for the complete formulation), with the objective of maximizing the log-likelihood $\Im$ of the observed values of y^k at each M step of the learning process. This objective function is defined by:

$$\Im(D,\Omega)=\sum_{k=1}^{N}\ln\left(\sum_{i=1}^{M}g_i\left(x^k,C\right)\times P\left(y^k\middle|x^k,\theta_i\right)\right) \quad (5)$$

where N is the number of input-output patterns used for model optimization, $D=\{x^k,y^k\mid k=1,\ ..,\ N\}$, Ω contains all model parameters and C contains just the antecedents parameters (centers and covariance matrices). As noticed, for maximizing $\Im$, it is necessary to know the data distribution. Due to the lack of knowledge of the real distribution of precipitation and inflow data, the model is adjusted assuming a normal distribution of the observed records.

III. CASE STUDY

A. Study Area and Data Collection

The case study considers a part of the Paraná basin, located in the south of Brazil. It considers three power plants located in the Grande basin, a part of the Parana basin with two main rivers, the Grande and Pardo rivers. Caconde (CAC) reservoir plant and Euclides da Cunha (EDC) run off hydro plant are part of a cascade at the Pardo river, whereas the Água Vermelha (AVE) reservoir hydro plant is located in the Grande river cascade. All these power plants are under the management of AES-Brasil company.

Data available correspond to a continuous period of three years from 1st January 2005 to 31st December 2007. Accumulated daily rainfall data for the catchment area associated with each plant were supplied by SOMAR company while average daily inflow data were supplied by AES. Table I summarizes some statistics observed during the indicated period for the overall time series where *Max* = Maximum, *Min* = Minimum and *S Dev* = Standard Deviation.

From this table, we can notice that Agua Vermelha inflows present the highest mean and variability, whereas Canconde has the lowest ones. On the other hand, Agua Vermelha presents an average rainfall lower than the ones registered in the other two hydro plants, but both – Caconde and Euclides da Cunha – present similar rainfall statistics in terms of mean and standard deviation, specially in terms or magnitude level if compared to Agua Vermelha.

TABLE I SOME STATISTICS FOR ALL THE TIME SERIES USED IN THE CASE STUDY.

Alias	Inflows				Runoff			
	Max	*Min*	*Mean*	*S. Dev*	*Max*	*Min*	*Mean*	*S. Dev*
CAC	339	14	59	53	711	0	4.07	9.23
EDC	714	21	95	90	686	0	4.13	9.45
AVE	8641	537	2316	2066	2573	0	3.65	8.38

B. Methodology and Modeling

Input patterns consider both, past and future precipitation information and past inflow data. Therefore, a general input pattern is defined as:

$$x^k=[x_1^{\,k}\quad x_2^{\,k}\quad ...\quad x_p^{\,k}]=[r_1^{\,k}\quad ...\quad r_a^{\,k}\quad s_1^{\,k}\quad ...\quad s_b^{\,k}] \quad (6)$$

where $a\in Z^+$ indicates the number of components of the input vector containing past and future rainfall information represented by r and $b\in Z^+$ represents the number of input vector terms containing past inflow records (s), with $p=a+b$. It means that if we are forecasting the streamflow for time instant k, rainfall terms composing the input patterns will consider the last a-1 accumulated D days rainfall lags, the expected accumulated D days rainfall for instant k, as well as the last b inflows recorded up to k-1 as input variables. For the next h steps ahead, forecasted inflows and rainfall will be necessary.

With the purpose of improving the explanatory power of rainfall time series for each hydro plant, the FIS model uses as rainfall variable the accumulated precipitation of the last D days, where D is selected by maximizing the correlation coefficients between observed runoff and accumulated precipitation during those D days. Optimal D values for all the three inflow time series as well as correlation coefficient achieved are presented in Table II.

TABLE II OPTIMAL D VALUES, CORRELATION COEFFICIENTS AND LAGS CONSIDERED FOR BUILDING INPUT PATTERNS CONSIDERING RAINFALL AND RUNOFF INFORMATION.

Alias	D	Correlation	a	b
CAC	5	0.73	5	3
EDC	5	0.71	5	3
AVE	11	0.75	4	3

Table II also shows the number of lags a and b considered as input variables for modeling each model. These numbers of lags to were selected by maximizing the model performance for a multi-step ahead daily inflow forecasting task, with time horizon varying from one to twelve days ahead. As observed, in the case of runoff (b), the first three lags of each streamflow time series were considered as input variables. In the case of accumulated precipitation, lags considered varied from 5 to 11 days.

After input-output patterns are built, data set is normalized to the unit interval and then split up in two subsets, a training data set and a testing data set. The training data set was composed by the first two years of historical data whereas the testing data set was composed by the last one. Initial spreads for the SC algorithm ($r_a^{\,2}$) was equal to 1.25.

Performance assessment and model validation was performed considering the root mean square error (RMSE (m^3/s)), mean absolute percentage error (MAPE (%)), mean absolute error (MAE (m^3/s)) and mass curve coefficient (E), which is frequently used in hydrology for the validation of hydrological models [14] and is defined by the following equation:

$$E = \frac{\sum_{k=1}^{N}(y^k - \bar{y})^2 - \sum_{k=1}^{N}(y^k - \hat{y}^k)^2}{\sum_{k=1}^{N}(y^k - \bar{y})^2} \quad (7)$$

where $\bar{y}$ is the observed mean inflow. The first sum in the numerator denotes the total square error (SE) achieved assuming as forecast inflow the historical mean for all *k*. The second sum denotes the SE achieved by the evaluated model (FIS). Therefore, the closer E is to the unity, the better the model is, since the respective SE will be lower than the SE given by the mean. In this case the use of a more complex model would be justified by the improvement of the accuracy in the forecasting process.

C. *Tool Developed*

A tool to automate the application of the proposed methodology was developed. The software project and the computational implementation of this tool use the object-oriented paradigm and the C++ programming language. For searching information in the database the Structured Query Language (SQL) is used.

Fig. 2 presents the main interface of the system. It allows managing streamflow forecasting studies. Besides that, it facilitates the analysis of the results because these can be visualized in graphical form.

The interface presented in Fig. 2 is divided in frames. In the first frame on the left, the studies of streamflow forecasting are shown using a hierarchical structure for visualization. In the next frame, on the middle, the hydroelectric plants and the measurements stations are listed. Different icons distinguish them. The last frame on the right presents five sheets of which three have highlighted. The first one make possible to choose the period for which the study will be realized. So, this tool is able to predict the future streamflows or trying to reproduce the past streamflows. The second sheet shows one chart of recorded and predicted inflows and one chart of the precipitations for the period. The third sheet presents the results in spreadsheets.

This tool allows eight actions with the studies: create, duplicate, rename, delete, save, import data, edit data and run the study. Besides, it is possible export the results of a study for electronic spreadsheets, like Excel.

D. *Results and Discussions*

Performance metrics are summarized in Table III, for a given forecasting horizon *h* varying from *1,..12*. Since the FIS provides a different forecasted trajectory for each time instant, columns 2 to 13 present average errors of the last 353 trajectories predicted from one to twelve steps ahead.

As expected, observing any of the metrics, because of the prediction error of previous steps are fed into the input pattern for the next step ahead, the model performance becomes degraded as the forecast horizon aparts from the actual time instant. However, given that the minimum value of the mass curve coefficient goes from almost 77% to 99%, we can consider that the model presents an adequate performance due to its capability of explaining the hydrological process in at least 77%.

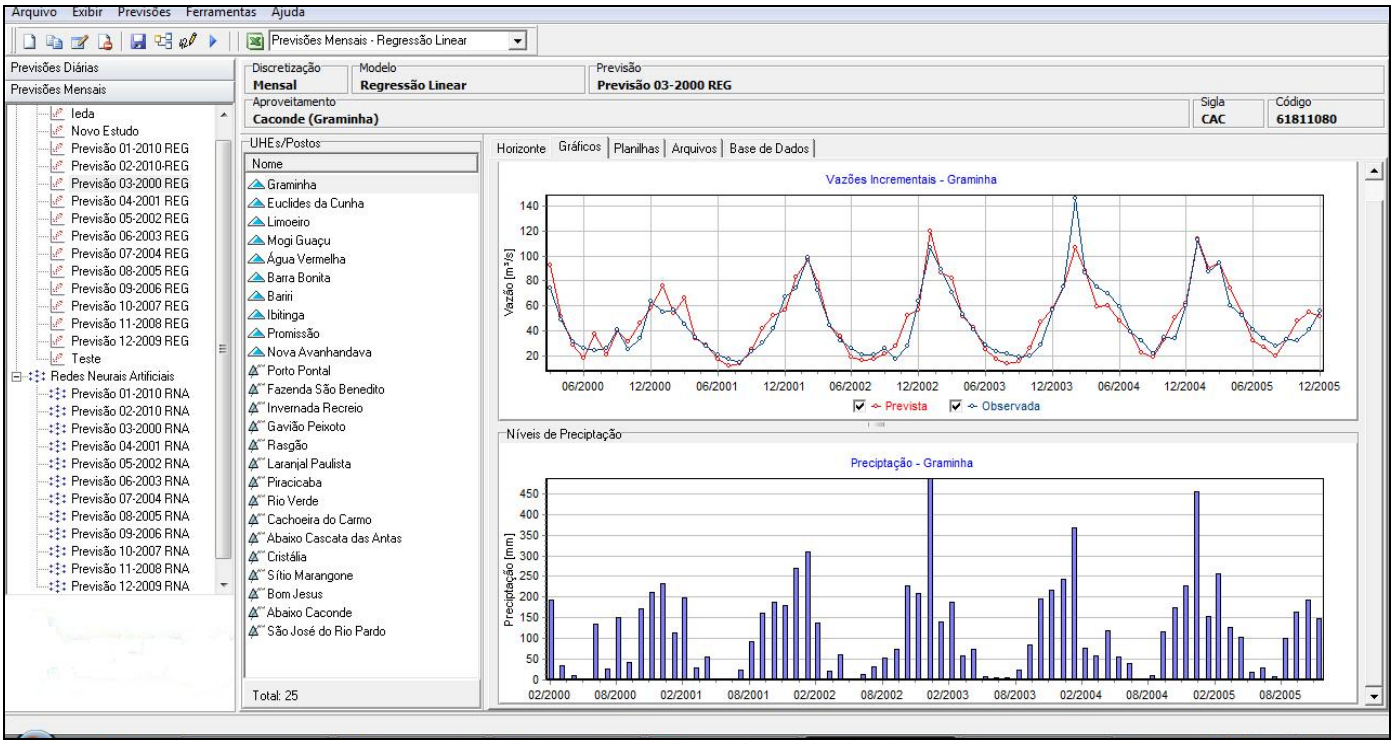

Figure 2. Main interface of the tool developed for forecasting streamflows.

EDC	0.94	0.91	0.88	0.87	0.85	0.84	0.82	0.81	0.80	0.79	0.78	0.77
AVE	0.99	0.99	0.99	0.99	0.98	0.98	0.97	0.97	0.96	0.96	0.95	0.94

Fig. 3 depicts the evolution of MAPE and E from one up to twelve days ahead of forecasted inflow records. Since Caconde and Euclides da Cunha inflows belong to a different magnitude level if compared to Agua Vermelha, their results will be compared and analyzed simultaneously.

The worse performance in terms of MAPE was achieved for Caconde hydroplant. Nevertheless, given that this metric is a relative index, it is necessary to consider at least one other absolute performance metric. So, analyzing RMSE and MAE values, results achieved for Caconde outperformed the ones obtained for Euclides da Cunha. Though, considering the mass curve coefficient, the fuzzy system achieved a similar performance for both inflow time series, as also depicted in Fig. 3.

Forecasted trajectories for one step ahead and for one up to twelve steps ahead are depicted in Fig. 4 and 5, for Caconde and Euclides da Cunha, respectively. We can observe that, the difficulty for predicting inflows increase during humid periods, since the different trajectories obtained at the beginning of the year tend to apart from the observed one with the increase of the lead time and specially before the peak flows. In general, performance metrics point to an adequate and similar model performance in both cases, which is expected due to the nature of Euclides da Cunha hydroelectric (a run off plant).

On the other hand, considering results obtained for Agua Vermelha, the FIS presented the lowest MAPE but the highest MAE, which is expected due to the inflows levels. In terms of explanatory power, the FIS presented a mass curve coefficient varying from 94% to 99%. Forecasted results are illustrated in Fig. 6. Again, we can notice the effect of the lead time and uncertainties over the forecasted inflow trajectories.

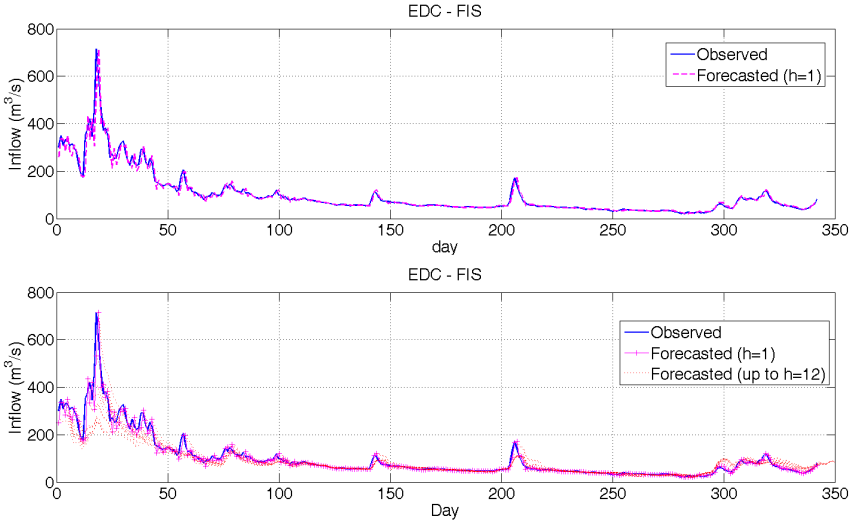

Figure 5. One step ahead and one up to twelve steps ahead daily inflow forecasting for Euclides da Cunha hydroplant.

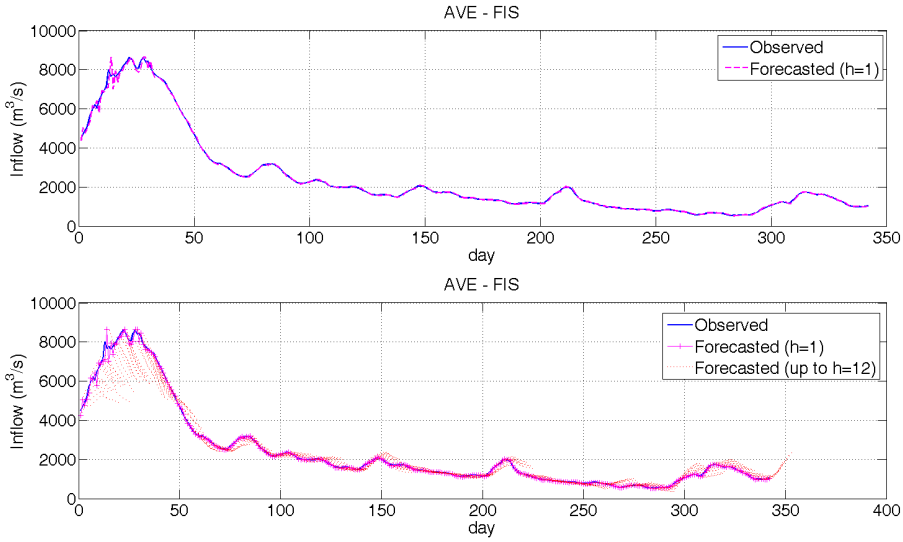

Figure 6. One step ahead and one up to twelve steps ahead daily inflow forecasting for Agua Vermelha hydroplant.

IV. CONCLUSIONS

This work presented an application of Fuzzy Inference Systems (FIS) for multi-step ahead daily inflow time series forecasting. The technique used for adjusting of the model parameters is an offline version of the Expectation Maximization (EM) algorithm.

The case study considered three Brazilian hydroelectric plants: Caconde (CAC), Euclides da Cunha (EDC) and Água Vermelha (AVE) that are located in the Parana basin. Theirs operation is under the coordination of Electric System National Operator and under management of AES-Brasil company.

A tool was developed in order to automate the application of the methodology and facilitate the analysis of the results. This tool allows managing streamflow forecasting studies and visualizing their information in graphical form.

Although the results shows very promising, it is evident the need research about alternative for improving multi-step ahead forecasting results. Future works involve the use of a different learning algorithm for the fuzzy inference system in order to avoid the normality hypothesis over the time series distribution, as well as the use of adaptive reorganizable fuzzy model in order to deal with the higher variability presented during humid periods. Comparison with other proposals is also considered.

***Abstract*—For our present life anytime, anywhere access to the network can communicate with the ubiquitous computing. it is essential to human life. We should be able to agree that communication will be enabled. For our present life, anytime, anywhere access to the network can communicate with the ubiquitous computing. Such as the ubiquitous era approached, interaction between the user and the computer has become an important issue. In this paper we use EEG signals to extract the user's intention recognition data, which the Mirror Neuron System Based on HMMs and GMMs to model the convergence of the hybrid model is proposed. This is based on a kind of biological signals using EEG signals to the user's intention recognition techniques have been studied. In addition, EEG signals is generated based on the model, using the user intention recognition method have been studied. The proposed model will be applied in the field of neuro robotics.**

I. INTRODUCTION

The last century, AI(Artificial Intelligent) field (problem solving, pattern recognition, decision-making) was a tremendous progress. The idea for the robot AI robot 'thinks' you want to empower people to start in the desires. AI robot, such as differences of level perceptual, emotional, and cognitive, was insufficient points. Therefore, we implemented a much more seamless system for human robot interaction is required. Meanwhile, today's information and communication technology breakthrough by the user computing system through anywhere, anytime access to information needed to build an infrastructure that can have been going. Accordingly, the ubiquitous and user-centered environment built on active service, the core technologies necessary to provide the domestic and foreign research institutes and universities have been actively focusing on. In ubiquitous computing environment, the circumstances of the computer and the user intent is consistent with the self-awareness must be able to provide the best service. To implement this, a critical underlying technology is the user's intention recognition technology. Recognition technology is intended to process the information collected from various centers, fusion is applied to the reasoning and learning. Thus, to infer the intent of people, recognized as the technology to existing information and emotional situation for the individual to perform the recognition, there are many case studies[1][2].

According to the latest neuroscience research into the human brain called mirror neurons, the nerve was the existence of the doctrine[3][4]. Mirror neurons are brain cells in the premotor cortex. First identified in macaque monkeys in the early 1990s, the neurons also known as "monkey-see, monkey-do cells" fire both when a monkey performs an action itself and when it observes another living creature perform that same action[5]. Though it has been impossible to directly study the analogue of these neurons in people (since human subjects cannot be implanted with electrodes), several indirect brain-imaging measures, including EEG, have confirmed the presence of a mirror neuron system in humans[6]. The human mirror neuron system is now thought to be involved not only in the execution and observation of movement, but also in higher cognitive process, language, for instance, or being able to imitate and learn from other's actions, or decode their intentions and empathize with their pain[7][8].

There have been many studies Mirror neurons in the department of brain neuroscience, and psychology. But so far the engineering models of mirror neurons are the basic steps.

In this paper, the user intent recognition, a method for effectively is proposed for engineering modeling of mirror neurons. Original intent of the user to recognize the techniques used in the HMMs and GMMs are created by combining a hybrid model. This is based on a kind of biological signals using EEG signals to the user's intention recognition techniques have been studied. In addition, EEG signals is generated based

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

on the model, using the user intention recognition method have been studied. The proposed model will be applied in the field of neuro robotics. This paper is organized as follows.

In chapter 2, mirror neurons, and background information on user intent recognition is described, Section 3 describes the proposed hybrid model, and Section 4 describes the conclusions and future research.

II. THEORY FOR SYSTEM

A. *Mirror neuron system in humans*

Action observation studies in the mid 1990s using both TMS(Transcranial Magnetic Stimulation) and PET(Positron Emission Tomography) provided some evidence for the existence of the human MNS(Mirror Neuron System)[6][9]. Especially imitation was closely associated with MNS when researchers began to report the relation between mirror neurons and imitation in humans using MRI(Magnetic Resonance Imaging) and fMRI(Functional Magnetic Resonance Imaging). These reports provided the foundation for examining whether human areas relating to imitation of hand actions had mirror properties. Based on the research that mirror neurons discharge more during the execution than the observation of an action, and that an individual simultaneously observes and performs an action during imitation, it was predicted that human mirror neuron areas would show higher activity during execution than during observation of an action, and highest activity during imitation. This in sum reflects the activity attributable to action observation and execution[10][11].

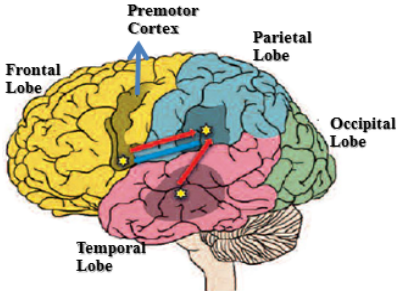

Figure 1. The distribution of mirror neurons

The human MNS is especially important for imitative behavior early in life. And imitation is a pervasive type of learning in humans, and the understanding of its primary neural mechanisms is noticeably important. It is associated with the user's intention recognition. Because, according to other people's words and actions that recognize the person's intent is for the most basic instincts. Therefore, when describing the behavior of actors, by analyzing the signals, as opposed to the user's intent is to identify.

B. *Intention recognition using EEG data extraction*

In the previous study, when each of the letters imagine the ideation center and Broca's area was measured from the EEG signals. This is based on the person you imagine what a particular word on when the change in EEG was found[12]. Using this data, data to recognize the user's intention were analyzed by ERSP(Event-Related Spectral Perturbation) and ITC(Inter-Trial Coherence) methods. We were building a database to recognize user's intention based on these data.

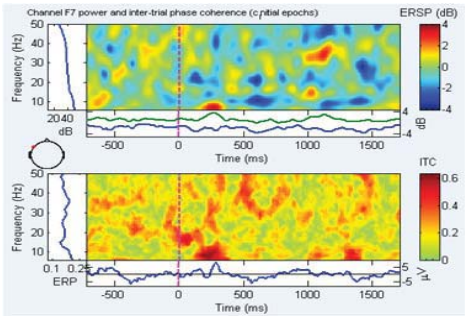

Figure 2. When we imagine letter C, spectrum of ERSP and ITC

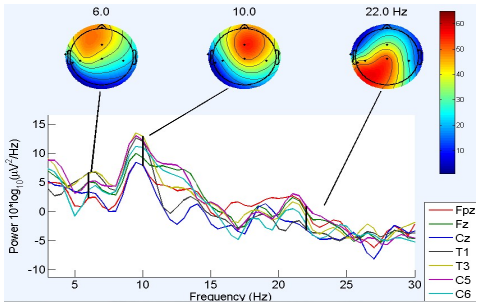

Figure 3. Analysis with EEGLAB, when we listen to dance music and the frequency by the average power spectrum EEG data

C. *Hidden Markov Models*

HMMs (Hidden Markov Models) has been widely used in pattern classification, speech recognition and gesture recognition. In addition, the user with the user's intent is to produce a secreted sequence data to determine whether the top because you can see a problem in the field of intention recognition can be effectively applied[13][14].

HMMs Hidden States that we do not know the status of the probabilistic transition process Observable symbol that raises the probability of realistically modeling the transition process is a double stochastic process.

HMMs as the symbols $\lambda = (\pi, A, B)$ is expressed as the number of hidden state variables, N, Observable symbol that when the number of M, has the following components[15].

1) $Q = \{q_1, q_2, \cdots\cdots, q_n\}$: set of hidden states
2) $V = \{v_1, v_2, \cdots\cdots, v_m\}$: set of observable symbol
3) $O = \{o_1, o_2, \cdots\cdots o_{t-1}, o_t\}$: sequence consists of observable symbol
4) π_i : initial probability vector of hidden state
5) A_{ij} : state transition matrix
6) B_{ij} : confusion matrix

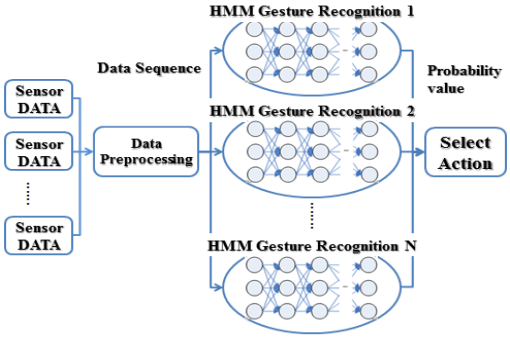

Figure 4. HMM models for recognizing the different behaviors

HMMs Hidden States that we do not know the status of the probabilistic transition process Observable symbol that raises the probability of realistically modeling the transition process is a double stochastic process.

HMMs as the symbols $\lambda = (\pi, A, B)$ is expressed as the number of hidden state variables, N, Observable symbol that when the number of M, has the following components[15].

7) $Q = \{q_1, q_2, \cdots\cdots\cdots, q_n\}$: set of hidden states
8) $V = \{v_1, v_2, \cdots\cdots\cdots, v_m\}$: set of observable symbol
9) $O = \{o_1, o_2, \cdots\cdots o_{t-1}, o_t\}$: sequence consists of observable symbol
10) π_i : initial probability vector of hidden state
11) A_{ij} : state transition matrix
12) B_{ij} : confusion matrix

After the fact, the model defined by HMMs in order to use the following three problems (Evaluation, Decoding, Learning) must solve. Therefore, the three kinds of solutions to the problem, several algorithms have been widely used. When estimating the probability of the problem, Forward / Backward algorithm can be solved using, and determine the issue of optimal order is one of the Viterbi algorithm of dynamic programming techniques are used. Finally, estimate the parameters of the EM algorithm called the Baum-Welch algorithm is employed and can be solved[15]. For more information on HMM and then you can see in the paper[16].

D. Gaussian Mixture Models

Gaussian probability distribution, albeit the most widely used distribution data, based on the average of the group together as a form of a unimodal only one possible representation is limited. Therefore, the general form of probability model capable of expressing need, this time to consider it the most easily combined with the multiple Gaussian model is being created. This is called GMMs (Gaussian Mixture Models). M simple probability density function (or component [component]) is defined as a linear combination of the entire probability density function is expressed as the following equation.

$$p(x \mid \Phi) = \sum_{j=1}^{M} p(x \mid w_j, \Phi) P(w_j) \tag{1}$$

Where w_i is a component, $P(w_i)$ is the prior probability or mixed parameters. And $p(X \mid w_i, \Phi)$ is the vector of the parameters Φ, when told, is the probability density of the ingredients. $X = \{x_k\}$ log-likelihood of the sample were as follows.

$$\begin{aligned} L(\Phi \mid x) &= \sum_k \log p(x_k \mid \Phi) \\ &= \sum_k \log \sum_j p(x_k \mid w_j, \Phi) P(w_j) \end{aligned} \tag{2}$$

Equation (2) does not have an immediate solution. Therefore, these problems can be solved using EM(Expectation Maximization)algorithm[17]. EM algorithm is performed in two stages, as follows: posterior probabilities was calculated using Bayes' theorem.

$$p(w_j \mid x_k, \Phi) = \frac{p(x_k \mid w_j, \Phi) P(w_j)}{\sum_l p(x_k \mid w_l, \Phi) P(w_l)} \equiv h_{kj} \tag{3}$$

Where the d-dimensional gaussian density components if you choose to be, $p(x \mid w_j, \Phi) \sim N_d(\mu_j, \sum j)$ is as follows.

$$p(x \mid w_j, \Phi) = \frac{1}{(2\pi)^{d/2} \left| \sum j^{1/2} \right|} \exp[-\frac{1}{2}(x - \mu_j)^T \sum j^{-1} (x - \mu_j)] \tag{4}$$

So , the equation (3) can be expressed equation(4). As a result, equation (5) is represented by Gaussian probability.

$$h_{kj} = \frac{g_j \left| \sum j \right|^{-1/2} \exp[-\frac{1}{2}(x_k - \mu_j)^T \sum j^{-1} (x_k - \mu_j)]}{\sum_l g_l \left| \sum^{l} \right|^{-1/2} \exp[-\frac{1}{2}(x_k - \mu_l)^T \sum j^{-1} (x_k - \mu_l)]} \tag{5}$$

However, $g_l \equiv P(w_j)$

III. Hybrid Model of HMMs and GMMs

Hybrid model based on the class variable mixture GMMs and HMMs based on the components are configured. Hybrid models take advantage of the positive aspects of each model used in the combination. Each of the types of models included in the training data, it is possible to collect specific information. For example, GMMs are more likely to capture the structural information. While HMMs in the sequence, the transition is to extract information. The choice of a single model, it can interfere with the performance of the classification. Before making a decision of the classification, the hybrid model has output to improve the stability of method and performance. We think this situation, combined results from two models that use a hybrid model of the sum rule is proposed. Sum rule for the probabilities of each model in estimating the error is known to be robust. Given a set of weights $\{w_i; i = 1 \cdots L\}$ for L number of classifiers, and k classes, a given brain activity data, x is assigned to a model of M_n.

$$\sum_{i=1}^{L} w_i P(M_n \mid x_i) > \sum_{i=1}^{L} w_i P(M_l \mid x_i) \qquad l = 1, \cdots, k \; ; l \neq n \quad (6)$$

A small training set to minimize the error rate classifier decides the value weighted. Figure 5. Illustrates the proposed model.

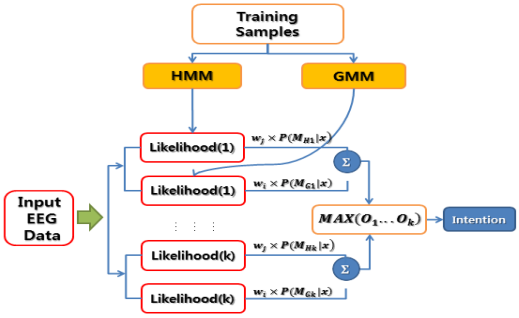

Figure 5. Hybrid model of HMMs and GMMs

HMMs and GMMs in Figure 5, M is the result of the hybrid model we ultimately need to find the error rate of recognition model, removing the maximum value of the optimized sequence.

IV. Conclusions

In this paper, HMMs and GMMs as shown in Figure 5, the convergence of the proposed hybrid model. Hybrid models take advantage of the positive aspects of each model used in the combination. Each of the types of models included in the training data, it is possible to collect specific information. The choice of a single model, it can interfere with the performance of the classification. Before, both models making a decision on the classification of a performance and how to improve the stability of the output. Conventional HMMs to recognize only the user's intentions in the posterior probability classifier to minimize the error rate of Gaussian Neural Network based on GMMs were added. Error rate as shall be determined appropriately weighted values and operations are expected to increase the speed and accuracy. Next simulation compares the performance of the proposed algorithm will be tested.

Abstract— **Input variables selection plays a critical role in data-driven modelling, especially for complex systems with high dimensionality between the input/output space. In this paper, a new artificial neural network based forward input selection scheme is proposed. The objective of the proposed scheme is to select the smallest number of important variables as model inputs, which will then be used for neural-fuzzy data modelling. The proposed input selection scheme is applied to a case study of Charpy impact energy prediction, with data extracted from an industrial database. Model performance has been compared with previous results where a much larger input set was used. Simulation results show that the number of inputs for the Charpy data model can be significantly reduced with little performance degradation. Also, the performance of the proposed scheme outperforms both the standard correlation analysis and fuzzy clustering based input selection schemes**

Keywords: Model input selection; fuzzy clustering; neural network; neural fuzzy system; Charpy impact energy.

I. INTRODUCTION

Data-driven modelling is becoming more popular due to the rapid growth in computing power, the wide availability of data/information, and the readily available software packages where different data modelling strategies can be readily implemented and tested. Modelling tools and algorithms have also evolved into more complex structures capable of dealing with highly non-linear and multi-dimensional input/output data. However, in many real-world modelling scenarios, the available data often contain hundreds or even thousands variables, and the influences of many variables on associated outputs are not well understood. For such complex modelling tasks, a heavy-handed input selection method is essential, so that the dimension of the final model input space can be reduced to a manageable size. Due to the increasing demand for modelling large scale data, as is almost always the case in data mining [1], research in model input selection methodologies is becoming a hot topic area. Artificial neural network (NN) is a very popular model framework, due to the existence of well-established error back-propagation training algorithms and its capability of being a universal approximator for complex nonlinear mapping [2]. As the computational intensity and the number of training samples required increase exponentially with the input space dimension, applications of NN model in very high dimensional problems quickly become prohibitive. Several methods have already been investigated for input selection in the past, aimed at assisting NN modelling for a large number of potential inputs. A concise review can be found in [3], with the focus being on input selection methods using mutual information criterion and genetic algorithms. Fuzzy logic systems are another popular modelling paradigm, and a variety of related input selection schemes have been developed [4-5]. It is even more important to use a small input set in fuzzy modelling than NN, as one of the key advantage of transparency related to a fuzzy logic system will be lost even when the number of inputs is moderate. Feature transformation [1, 6], including principal component analysis and independent component analysis, is often very effective in order to reduce the nominal number of inputs, but one needs to be reminded of the fact that the individual features thus formatted involve a combination of the original variables, and the physical interpretation of such features may not be easy. Input selection via feature transformation is not considered further in this paper.

In this paper, an NN-based forward input selection scheme is proposed. The input selection scheme belongs to the category of model based direct search [5], and it starts by selecting only one input from all the potential inputs such that the corresponding model trained on the selected input produces the best model performance when compared to all other NN models with a different single input. The first input identified is thus ranked as the most important input variable, and will always be included in the subsequent enlarged input set. As an exhaustive search of input combinations leads to an exponential growth with the number of potential inputs in computation, hence it is infeasible for a search particularly involved with a large number of variables. The forward input selection scheme provides a pragmatic yet an effective solution to find the smallest number of important variables, and upon which a compact data model can be developed. The remainder of the paper is organized as follows. Section 2 introduces the aim, objective and motivation for input selection in neural-fuzzy data modelling, and describes two commonly used input selection methods based on correlation analysis and fuzzy importance ranking. In Section 3, an NN-based forward input

selection scheme is developed, together with the key techniques for the implementation of the forward input selection scheme. Section 4 is devoted to the application of the proposed input selection scheme to a case study problem of Charpy impact energy data modelling, with the data extracted from an industrial database. The preliminary results of the developed model are compared to models derived from other input configuration schemes, including correlation coefficient analysis, fuzzy importance ranking, and to some previously developed models using the full input data. Finally, Section 5 concludes the paper with suggestions for future research.

II. Some Common Input Selection Methods

Input variable selection is a vital step in complex system modelling where the input–output relationship is often not well understood. An unnecessarily large number of inputs can be detrimental for effective data modelling, not only that the high dimensional space will cause difficulties due to 'the curse of dimensionality', but also the irrelevant inputs tend to confuse the true input-output relationships. Moreover, it is well-known that the number of data examples needed to tune a model grows exponentially with the dimension of the input space, and the resource required for collecting an increasing large data set with good quality is very expensive. As pointed out in [7], the objective of input variable selection is three-fold: improving the model prediction performance, providing faster and more cost-effective predictors, and providing a better understanding of the underlying process that generated the data in the first place.

Most of human experience is limited to low-dimensional spaces, partly due to the fact that we live in a low 3D space. A large degree of unease will be felt if humans are confronted with a high dimensional space, even if it is slightly larger than 3D. Our visualization ability and degree of imagination will easily run out of limit when facing a higher dimensional space, and many properties of these high dimensional spaces often appear to be counter-intuitive. Smits et al [8], for example, summarised some of these counter-intuitive properties: (i) samples sizes with the same data density increase exponentially with dimensionality; (ii) an increasingly large radius is needed to enclose a given fraction of data points even when the data are uniformly distributed; (iii) most data points are closer to an edge than to another internal data point, which indicates extrapolation is the norm rather than the exception in higher dimensional space; and (iv) almost every point is an outlier in its own projection on the line defined by the prediction point and the origin. In the following, two common input selection methods based on correlation analysis and fuzzy clustering ranking are briefly introduced, and later they will be compared with the NN-based forward input selection scheme to be developed in Section III.

A. Input Selection Based on Correlation Analysis

The correlation coefficient analysis can prove sufficient enough to help identify the input/output dependency if the process under investigation is linear [3]. Even if the system relating the original data is nonlinear, correlation analysis is often worthwhile as it can help to reach a better understanding of the data to be modelled. The Pearson's correlation coefficient can be calculated via the following equation:

$$\rho_{ij} = \frac{\sum_{k=1}^{N}(x_i(k)-\bar{x}_i)(x_j(k)-\bar{x}_j)}{\sqrt{\sum_{k=1}^{N}(x_i(k)-\bar{x}_i)^2 \sum_{k=1}^{N}(x_j(k)-\bar{x}_j)^2}} \quad (1)$$

where $\rho_{ij} \in [-1, 1]$ is the correlation coefficient between variable x_i and x_j, $x_i(k)$ is the value of the kth sample, N is the total number of samples, and $\bar{x}_i$ is the corresponding sample mean. When one of the variables is an output, ρ_{ij} represents the linear dependency between the output and the given input, otherwise it indicates the co-linearity between the two involved inputs.

A compact form to summarize all the correlation coefficients is a correlation matrix, which is particularly useful when a large amount of variables are involved. A correlation matrix $\boldsymbol{R}$ is defined as follows:

$$\boldsymbol{R} = [\rho_{ij}]_{n\times n} = \begin{pmatrix} \rho_{11} & \cdots & \rho_{1n} \\ \vdots & \ddots & \vdots \\ \rho_{n1} & \cdots & \rho_{nn} \end{pmatrix} \quad (2)$$

Where ρ_{ij} is the correlation coefficient defined in (1), n is the total number of data variables. $\boldsymbol{R}$ is a symmetric matrix with $\rho_{ij} = \rho_{ji}$, and all the diagonal elements $\rho_{ii} = 1$.

The full correlation matrix provides one with the mutual linear dependency among each pair of variables. A large $|\rho_{ij}|$ value represents a strong linear correlation, hence a large dependency between the two variable i and j. As such, the application of correlation analysis for model input selection can be of double fold. First, the dominant correlation coefficients among the potential input variables are identified and they can then be used to detect the redundant input variables, which can and need to be eliminated to reduce the potential input space dimension. Second, the large correlation coefficients among the input variables and the outputs can be used to identify those variables to be selected as the important model inputs, while these variables corresponding to insignificant correlation coefficients are removed from the model input consideration. It should be noted here that the correlation coefficients defined in (1-2) only indicate the linear dependency between the involved variables, while no causal relationship can be inferred. Table I lists the input-output correlation coefficients obtained from the Charpy impact energy data, ordered in columns by the magnitude. The full correlation matrix also reveals that there is no severe redundancy among the 16 original input variables, with the most dominant correlation coefficients being $\rho_{12,13} = 0.59$, $\rho_{8,9} = 0.53$, $\rho_{7,8} = 0.48$, and $\rho_{14,16} = 0.46$. The association of the variable x_i, $i = 1, 2, \ldots, 16$ and its physical name is given in Table IV.

TABLE I. The Input-Output Correlation Coefficients

x_i	ρ	x_i	ρ	x_i	ρ	x_i	ρ
x_{15}	0.38	x_{10}	-0.19	x_{12}	0.12	x_{11}	*0.02*
x_4	-0.28	x_6	0.18	x_1	-0.12	x_5	*0.02*
x_{14}	0.24	x_2	-0.15	x_3	0.08	x_7	*0.01*
x_{13}	0.20	x_{16}	0.13	x_9	0.08	x_8	*0.00*

B. Input Selection via Fuzzy Clustering

There exist many different methods of using fuzzy logic for input selection [4], including fuzzy c-means clustering, optimal Mahalanobis distances, 'fuzzy curves' method, etc. In this paper, the input selection method presented in [9] has been adapted for identifying the important input variables. An initial fuzzy model was first generated through the competitive clustering method using all possible m variables as the initial inputs. The initial fuzzy model has p fuzzy rules, which best divide the full model data into p clusters centred at $c_i \in R^m$ (i = 1, 2, …, p). The fuzzy model structure used for input selection is shown in Fig. 1, where ϕ_i is the membership function set (consists of p members) related to the ith input variable, and Rz_i is the range of z_i which represents the output change attributed to the ith input x_i taking values from across the corresponding centre locations in $\{ c_{ki} , k = 1, 2, \ldots, p\}$.

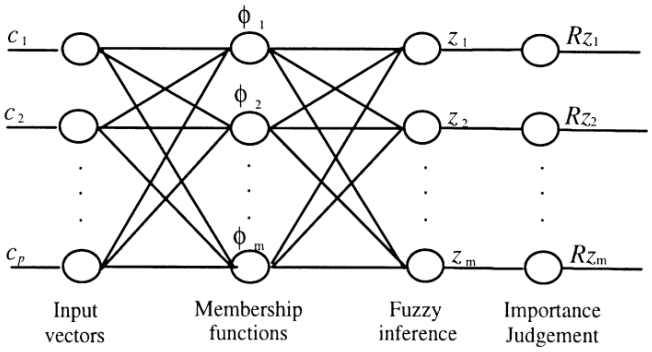

Figure 1. Fuzzy model structure for input variable selection [9]

The basic idea of ranking the importance of each input variable from the above initial model is based on calculating the contribution of individual input variations to the model output. The larger the output change caused by a specific input variable variations quantifying by its central locations of in the p clusters, the more important this input variable is. The fuzzy model shown in Fig. 1 provides an effective mechanism to test the importance of individual input variables. If all antecedent clauses except the one associated with a particular input x_i under scrutinizing are kept constant, the resulting fuzzy model output variations can be captured in the specific output route Rz_i while all the other output routes Rz_j, $j \neq i$, will be constant. Hence, with the inputs including the full variations specified by the cluster centers $\{c_k , k = 1, 2, \ldots, p\}$, output variations for each input variable can be extracted from the corresponding output nodes Rz_1, Rz_2,… Rz_m in Fig. 1. An importance factor designed to provide criteria for input variable selection is based on the magnitude of output variations attributed to individual inputs, defined as follows:

$$F_i = Rz_i / \max(Rz_1, Rz_2, \ldots, Rz_m) \quad (3)$$

Where $F_i \in (0, 1]$ is the importance factor for the ith variable x_i, and Rz_j, j = 1, 2, …, m are the output variation range associated with the corresponding input x_j variations. The x_i associated with F_i = 1 is the most important input variable.

Two important design parameters, the cluster radius r_c and the membership width σ_c, are responsible for controlling the initial fuzzy partition of the full input data space, and hence determine the initial fuzzy rule structure. These parameters need to be tuned carefully, as they directly influence the quality of input variable ranking. For the Charpy impact energy data after being normalized into a high dimensional hyper-cube, these two design parameters are selected as r_c = 0.7 and σ_c = 0.2. The initial fuzzy model obtained contains 36 fuzzy rules, and the importance factor for all the original input variables are listed in Table II, ordered in columns according the value of the associated importance factor F_i.

TABLE II. THE INPUT IMPORTANCE FACTOR

x_i	F_i	x_i	F_i	x_i	F_i	x_i	F_i
x_9	1.00	x_8	0.59	x_2	0.40	x_{10}	*0.26*
x_5	0.85	x_{15}	0.58	x_{16}	0.31	x_{14}	*0.13*
x_4	0.84	x_{12}	0.56	x_{11}	0.30	x_3	*0.13*
x_{13}	0.60	x_1	0.53	x_7	0.26	x_6	*0.10*

III. NN-BASED FORWARD INPUT SELETCION

A. NN-Based Forward Input Seletcion

An artificial neural network model based forward selection procedure is proposed here to assist identifying the most important input variables for data-driven modelling. A 3-layer feed-forward neural network is adopted as the base model, and its output can be expressed as follows [10]:

$$\hat{y}(k) = \sum_{j=1}^{M} w_j \varphi_j (\sum_{i=1}^{n} w_{ij} x_i(k) + w_{j0}) + w_0 \quad (3)$$

where $\hat{y}(k)$ is the NN output prediction for the kth sample, w_j and w_{ji} are the relevant NN weighting coefficients at the output layer and hidden layer, respectively, w_0 and w_{j0} are the bias of the output layer and hidden layer, respectively, ϕ_j is the nonlinear activate function of the jth hidden neuron, n is the dimension of the NN input space, and M is the total number of hidden neurons.

A forward input selection procedure is proposed with the above NN model as a performance evaluator. The input selection is implemented through an iterative process, starting from selecting a single input for the NN modelling. All the potential inputs are sampled as the single input candidate, and the neural network model with the minimum root mean squared error (RMSE) is identified as NN*. The inputs corresponding to the ones used in NN* are ranked as the most important inputs identified so far. In the next iteration of input selection, the inputs of the NN is increased by one from the identified input set, with the newly increased input selected from all remaining potential input candidates. The above forward input selection procedure is repeated until either a sufficient number of inputs identified or no performance improvement achieved by adding more inputs. The NN training procedure used here is adapted from the one used in [11], with critical training parameters fixed via trial-and-error tuning. The number of hidden neurons is determined by the dimension of the input using heuristic rules, as optimisation here will be too computationally cost. The iterative forward input selection algorithm is summarized as follows:

Step i: Initialisation. Set $\boldsymbol{x}^* = \{\}$ and n_{max} - the maximum number of inputs allowed. Put all the variables into the potential input candidate set $\boldsymbol{X} = [x_1, x_2, \ldots, x_N]$, where N is the maximum number of potential input variables.

Step ii: Start a new iteration of input selection. For each of the potential input candidate $x_j \in \boldsymbol{X}$ perform neural network modelling with extended input $\boldsymbol{x}^j = [\boldsymbol{x}^*, x_j]$ and $H = \min(5, 2*\dim(\boldsymbol{x}^j))$. Compute the corresponding NN model performance $J(\boldsymbol{x}^j)$, j = {1, 2, …, $dim(\boldsymbol{X})$}. In this step, all the NN models has the same number of inputs $n = \dim(\boldsymbol{x}^*) + 1$, and there is a total number of $N - \dim(\boldsymbol{x}^*)$ neural network models trained.

Step iii: Identify the optimal inputs obtained so far. Determine the optimal inputs in the current iteration $\boldsymbol{x}^* = \boldsymbol{x}^{j*}$, where j^* is determined by using the criterion $j^* = \text{argmin}_j J(x^j)$. Update the potential input set $\boldsymbol{X}$ by eliminating the associated x_{j*} ($\boldsymbol{X} = \boldsymbol{X} \setminus x_{j*}$). Notice here that the dimension of the potential input candidate set is reduced by one in each iteration.

Step iv: Termination check. If the best NN performance in the current round $J(x^*)$ does not improve over the previous one, or if $dim(\boldsymbol{x}^*) >= n_{max}$, or if $\boldsymbol{X}$ is empty, then go to Step v, otherwise return to Step ii for the next iteration of optimal input selection.

Step v: Final input ranking. The elements in $\boldsymbol{x}^*$ are the most important input variables identified by the NN forward selection procedure. The importance ranking is the order of inclusion of the elements in $\boldsymbol{x}^*$.

Table III summarises the input variable ranking results for the Charpy impact energy data using the NN-based forward input selection procedure. Due to its powerful input-output mapping capability, a NN-based framework can deal with nonlinear behaviour in the data set effectively. However, the computations involved in this NN-based forward input ranking are rather heavy, especially when a large high dimensional data set is involved. For the Charpy data input ranking task with a moderate 16 potential inputs, a total number of 120 neural networks need to be trained via some kind of error back-propagation algorithm. The procedure may meet some difficulties for ranking very high dimensional input space, as not only the number of neural networks need to be trained will be much larger, but also the training for each individual NN with a large number of inputs will be computing and resource intensive.

TABLE III. INPUT RANKING USING THE NN FORWARD SELECTION

Rank	$\boldsymbol{x_i}$	***Rank***	$\boldsymbol{x_i}$	***Rank***	$\boldsymbol{x_i}$	***Rank***	$\boldsymbol{x_i}$
1	x_{15}	5	x_6	9	x_8	13	x_5
2	x_2	6	x_7	10	x_{11}	14	x_{12}
3	x_4	7	x_1	11	x_{10}	15	x_{14}
4	x_{16}	8	x_3	12	x_{13}	16	x_9

B. Neural Fuzzy Modelling with Reduced Input Variables

Neural networks and adaptive fuzzy systems are two widely used data modelling paradigms, due to the existing of well-established training algorithms and their ability as universal approximator [11, 12]. Both models can approximate any continuous non-linear function with arbitrary accuracy, provided that enough hidden neurons or fuzzy rules have been used. After the optimal model inputs with significantly reduced dimension has been identified, a final data model can be developed using an appropriate neural fuzzy modelling framework. In this paper, a feed-forward neural network is chosen for the final stage of data modelling. The number of hidden neurons H, which is the most critical NN structure parameter, is optimised through an interactive search method. Fig. 2 shows the iterative NN training strategy incorporating structure optimisation, implemented using the built-in training utilities provided by the MATLAB Neural Network toolbox [13]. The search range for the hidden neurons [H_{min} ~H_{max}] for the NN structure optimisation should be tuned according to the complexity of the data, as well as the dimension of the input space. The Levenberg-Marquardt training algorithm [14-15] is adopted to carry out the error back-propagation, and an earlier training stopping option is also added within the NN training routine in order to prevent the NN model from being over-fitting.

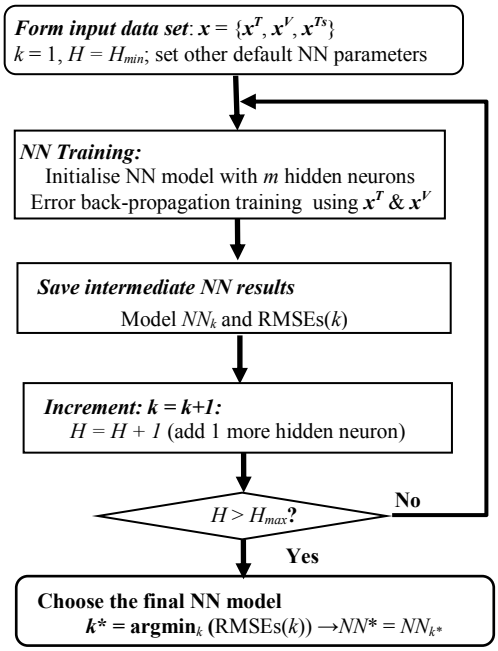

Figure 2. An iterative NN training scheme with structure optimisation

IV. CASE STUDY - CHARPY IMPACT DATA MODELLING

A. Overview of the Charpy Imapct Energy Data

The Charpy impact energy data, together with its relevant input variables, were extracted from an industrial database pertaining to TATA Steel Europe. The data set consists of 1661 records, each with measurements of the steel chemical compositions, heat treatment specifications, and Charpy impact

test conditions. Some important statistics of the Charpy data are summarised in Table IV.

TABLE IV. CHARPY IMPACT DATA STATISTICS

x_i	*variable name*	*min - max*	*mean*	*σ (std.)*
x_1	Test Depth (mm)	5.5 - 146.0	20.8	14.5
x_2	Specimen Size (mm)	11 - 381	172.5	80.8
x_3	Test Site (coded)	2 - 6	3.80	1.12
x_4	C (% wt)	0.13 - 0.52	0.394	0.058
x_5	Si (% wt)	0.11 - 0.38	0.255	0.032
x_6	Mn (% wt)	0.41 - 1.75	0.841	0.217

x_{16}	Testing Temp. (C).	-59 - 23	-8.0	26.0
y (output)	Impact Energy (J)	6.1 - 241.3	89.70	6.13

It is known that the above Charpy impact energy data are difficult to model, due to the existence of a large scatter in the measurements, the poor repeatability of the Charpy impact test and the highly sparse sample distribution. Several previous studies have been conducted on the modelling of this data set, where the focus is on model performance improvement by using advanced modelling strategies [16-19]. The work presented in this paper represents a first attempt aimed at further model input optimisation.

B. NN Modelling Results for Reduced Inputs

The reduced input sets containing 9 variables are selected from the original 16 input variables according to the different input selection methods discussed` earlier, and are used as the final inputs for the Charpy impact energy data modelling. The reduced input Charpy data are then divided into three data subsets, for training ($\boldsymbol{x}^T$), validation ($\boldsymbol{x}^V$) and testing ($\boldsymbol{x}^{Ts}$). The data ratio of $\boldsymbol{x}^T$:$\boldsymbol{x}^V$:$\boldsymbol{x}^{Ts}$ is set to 60:25:15, identical to most of the previous modelling work so that the performances are directly comparable. The maximum number of iterations (epochs) for the inner NN training is set to 200, and the training algorithm is fixed to the Levenberg-Marquardt algorithm. The search range for the hidden neurons is set to H_{min} = 5 and H_{max} = 20. Some typical results obtained via the iterative NN modelling scheme as shown in Fig. 2 are presented below.

According to the NN-based forward input selection scheme (see Table III), the reduced model input set $\boldsymbol{x}_N$* is as follows:

$$\boldsymbol{x}_N^* = [x_{15}, x_2, x_4, x_{16}, x_6, x_7, x_1, x_3, x_8]^T \quad (4)$$

The optimal NN model trained from $\boldsymbol{x}_N$* has m* = 12 hidden neurons, and the model performance achieved is RMSE(T, V, Ts) = (15.52, 18.36, 19.83). Fig. 3 shows the NN model predictions of the Charpy impact energy against the measurements for the validation and testing data set. Prediction accuracy is better for the training data set, which is not shown due to the constraints in space.

Similar modelling practices have also been carried out for the reduced model inputs selected using the correlation coefficient criterion and the fuzzy input importance ranking criterion. The corresponding constituents for the reduced model input sets, according to Tables I-II, are given as follows:

$$\boldsymbol{x}_F^* = [x_9, x_5, x_4, x_{13}, x_8, x_{15}, x_{12}, x_1, x_2]^T$$
$$\boldsymbol{x}_C^* = [x_{15}, x_4, x_{14}, x_{13}, x_{10}, x_6, x_2, x_{16}, x_{12}]^T \quad (5)$$

Where $\boldsymbol{x}_F^*$ is the reduced input set selected using the fuzzy input importance ranking, and $\boldsymbol{x}_C^*$ is the reduced inputs obtained by the input-output correlation. The optimised NN model trained using $\boldsymbol{x}_F^*$ produces a RMSE(T, V, Ts) = (18.84, 23.47, 27.49), with H* = 15 hidden neurons. Similarly, the NN model generated based on $\boldsymbol{x}_C^*$ has a RMSE(T, V Ts) = (15.57, 20.99, 20.53), with H* = 16. The NN predictions for the testing data set from these two models are shown in Fig. 4, and Table V summarises the RMSE performance comparisons, including performances from some previously developed models [17-19].

Modelling Methods	**Number of Inputs**	**Train Error**	**Validation Error**	**Test Error**
Neural-Fuzzy [17]	16	16.7	-	20.40
GrC – NF [18]	16	14.66	21.24	20.42
GA – NN [19]	16	14.32	17.94	18.96
NN – Corr. Inputs	9	15.57	20.99	20.53
NN – Fuzzy Inputs	9	18.84	23.47	27.49
NN – NN Inputs	9	15.52	18.36	19.83

C. Brief Discussions

The NN based forward input selection scheme performs best among the three input selection methods considered in this paper. Considering the large uncertainty involved in the Charpy impact energy measurements, the RMSE error performance of below 20 achieved by the proposed modelling scheme is good. The reduced input set identified by the correlation analysis leads to a better NN model than that of using fuzzy ranking input selection. This may indicate that a more careful tuning is needed when complicated methodology such as the fuzzy input ranking is to be used.

The model performance using a reduced 9-input obtained via NN-based forward input selection scheme is in par with the previous developed models where the full 16 input variables were used. The NN-based forward input selection scheme outperforms the Neural-Fuzzy model being reported in [7]. It also produces better RMSE performances for the validation and testing data sets, as compared to the Granular Computing Neural Fuzzy (GrC-NF) model [18], but a slightly worse RMSE value for the training data set. The performances for the validation and testing data are deemed to be more important than that of the training data, due to the possible model over-fitting phenomenon. The GA-NN model, with the structure and the parameters optimised using a GA-based algorithm, did produce an overall better RMSE performance than the current reduced input model, but the difference is not significant. It may be argued that the significant reduction of input dimension (from 16 to 9), may be worth the slight increase in RMSE.

V. CONCLUSIONS

In this paper, an NN-based forward input selection scheme is proposed to deal with the optimal input selection problem. The principle for selecting the most importance input variables relies on a direct search among the potential candidates for model performance optimisation. Input selection plays an important role in data-driven modelling in general, especially for complex systems with a large number of potential inputs. After the reduced input set is identified, it can be used in an appropriate modelling scheme for the final data model development. In this paper, a feed-forward NN model framework is employed to deliver the final data model. The integrated model-input selection and model optimisation are implemented using the MATLAB Neural Network toolbox, with the training guided by an error back-propagation algorithm. The number of hidden neurons, a critical parameter determining the NN structure, is also optimised in the final NN modelling stage. The model prediction performance, in terms of RMSE, is then compared to two other input selection methods, one based on correlation analysis, and the other based on fuzzy input ranking. Preliminary results obtained in the case study for Chary impact energy prediction show that the NN-based forward input selection method produces the best overall model performance among the three input selection methods compared.

The model performance obtained from the NN-based forward input selection is also compared with the performances of some previous developed Charpy impact energy prediction models, including the neural-fuzzy model, the granular computing neural fuzzy model, and the NN model with structure optimised via a genetic algorithm. Even though all the previous models used the full 16 model inputs, the NN model developed in this paper with a reduced 9 inputs managed to outperform two out of three previous models, while a slight RMSE performance deterioration is recorded in the third case of full input NN model with genetic algorithm based structure

optimisation. However, the benefit of a much compact model, resulting from a smaller input space, should generally outweigh the small RMSE-based performance loss. In training data requirement, for example, 512 training samples will be needed to train for the reduced input model proposed in this paper assuming a training data density of 2 samples per input, while a huge number of 655336 training data samples will be required to provide the same training data density across the high input space of 16 dimensions. This is an overwhelming 128 fold increase in training data requirement from a 9-input model to a 16 input model. This shows one of the 'counter intuitive' properties of a high dimensional space: the effect of reducing the number of inputs is also exponential, albeit in the reverse direction.

One disadvantage of using the proposed NN-based forward input selection is that the computational resources required are still high, and may be prohibitive for very large scale data with a high dimension. Hence, designing novel fast input raking algorithms based on the forward input selection principle will be beneficial. Also, due to the intensive calculations involved in error back-propagation algorithm, developing a fast NN training algorithm will be worth the effort. We will investigate new methodologies relating to these fields in future research.

ACKNOWLEDGMENT

Financial support from the UK-EPSRC is acknowledged under Grant EP/F023464/1. The authors wish to thank Tata Steel Europe for providing the Charpy impact energy data used in this research as well as expert knowledge for the data pre-processing and modelling.

***Abstract*—This work proposes a new Stereo Vision-Based Self-Localization System (SVBSLS) for the RoboCup soccer humanoid league rules for the 2010 competition. The humanoid robot integrates the information from the pan/tilt motors and stereo vision to accomplish the self-localization and measure the distance of the robot and the soccer ball. The proposed approach uses the trigonometric function to find the coarse distances from the robot to the landmark and the robot to the soccer ball, and then it further adopts the artificial neural network technique to increase the precision of the distance. The statistics approach is also used to calculate the relationship between the humanoid robot and the position of the landmark for self-localization. The experimental results indicate that the localization system of SVBSLS in this research work has 100% average accuracy ratio for localization. The average error of distance from the humanoid soccer robot to the soccer ball is only 0.64 cm.**

Keywords- Back propagation neural network; humanoid robot; Robo Cup 2010; self-localization, stereo vision

I. INTRODUCTION

The research of robots is one of the most important issues in recent years. In the numerous robot researches, the development of autonomous robots is attracted mostly. Accompanying the advancement of robotics and artificial intelligence, the autonomous robots cannot only handle simple and monotonous problems, but also have independent thoughts to deal with the complex states in the unpredictable and dynamic environments. All these functions rely on a powerful vision system, and therefore the vision system is one of the most critical techniques for the autonomous robot system. In the RoboCup soccer humanoid league competition, the vision system is used to collect various environment information as the terminal data to finish the functions of object recognition, coordinate building, robot localization, robot tactic, barrier avoiding, etc. A good self-localization system for a humanoid soccer robot cannot only make the robot acquire the information quickly and accurately in the whole field, but also make an appropriate decision correspondingly. For easy manipulation we can preset all the locations in the field as a Cartesian coordinate system, and the robot will self-localize itself by the coordinate system. In recent years, the competition fields of RoboCup [1] and FIRA Cup [2] become more and more conformed to human environments. Fig. 1 shows the RoboCup soccer fields for humanoid kid-size of 2009 and 2010, respectively. The sizes of the landmark pole and landmark goal in the field become smaller [3-4]. In other words, the reference checkmarks for self-localization become less and less, and how to use less landmarks and increase the degree of accuracy become important issues [5-6].

Zhong et al. [7] proposed three types of techniques for robot localization. The first approach is based on the stereo vision. This approach can obtain a lot of information such that the distance measurement between the camera and the target is accurate enough [8] to increase the accuracy of localization. The second one is based on the omni-directional vision. Although this method obtains better features, the omni-directional device causes geometry distortions to the perceived scene [9]. The third one uses the monocular vision technique. However, it must have robust features within a specific region [10]. SLAM [11] is an algorithm for localization and mapping simulation and is appreciated by many researchers. Although this algorithm has better efficiency, it needs complex image processing procedures and is difficult to be applied to the embedded system for real time humanoid soccer robot applications. For the implementation of the humanoid soccer robot, real time is the main issue, and we need a less complicated but high efficient localization method. Therefore for the humanoid soccer robot competition purpose, we propose a visual self-localization approach, stereo vision-based self-localization system (SVBSLS), which uses two CCD cameras and a set of pan/tilt motors on the robot head to find the various features and analyze the environmental information of the RoboCup 2010 soccer field [4].

The rest of this paper is organized as follows. Section II presents the related background such as the general color based object recognition methods, intrinsic parameters of the CCD, and distance measurement. Section III describes the proposed approach, SVBSLS. The experimental results of SVBSLS applied to the humanoid soccer robot are described in Section IV. Section V compares and analyzes the self-localization for humanoid robot by SVBSLS and other approaches. Finally, Section VI gives a brief conclusion.

II. BACKGROUND

A. Intrinsic Parameters of the CCD Camera

The vision-based distance measurement needs the intrinsic parameters, such as focal distance and horizontal viewpoints, of the CCD camera. Generally the camera makers rarely provide such parameters. Even if they provide such parameters, the mechanical mechanism, processing circuits, and lens distortion may cause deviations of the parameters. Actually we can find the intrinsic parameters of the CCD cameras regardless of the CCD branes.

The relationship of the distance between the CCD camera and the object and some parameters are shown in Fig. 2. In Fig. 2, OP is the optical origin; $2\theta_H$ is the horizontal viewpoints, and D_{OP} is the distance between OP and the edge of the CCD lens.

In order to find the distance between the CCD center and the object, θ_H and D_{OP} must be found first. We can capture the width of an object, $D_{H1}(max)$, with a pre-defined position, D_A, and the width of the same object, $D_{H2}(max)$, with a pre-defined position, D_B. The two captured frames can be combined to form Fig. 3. By the trigonometric functions we can derive θ_H in (1):

$$\theta_H = \cot^{-1}\left(2\times\frac{D_{K2}-D_{K1}}{D_{H2}(max)-D_{H1}(max)}\right) \tag{1}$$

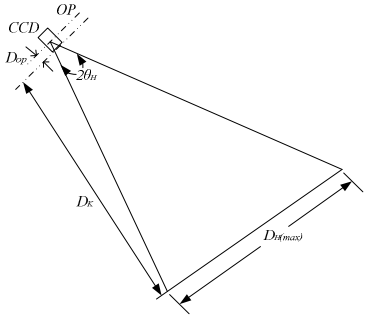

Figure 2. The internal parameters diagram of a CCD camera.

By the theorem of similar triangles, D_{OP} can be found as shown in (2) and (3).

$$\frac{D_{OP}+D_{K1}}{D_{OP}+D_{K2}}=\frac{D_{H1}(max)}{D_{H2}(max)} \tag{2}$$

$$D_{op}=\frac{D_{K2}D_{H1}(max)-D_{K1}D_{H2}(max)}{D_{H2}(max)-D_{H1}(max)} \tag{3}$$

The above approach can be applied to find the intrinsic parameters for any kind of CCD cameras. Once D_{OP} is found, the distance between the camera and the object can be measured by IBDMS (image-based distance measuring system) [12-13].

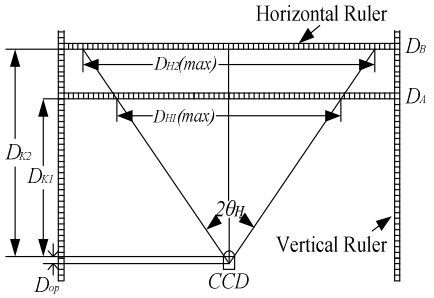

Figure 3. The intrinsic parameters measuring system[12-13].

B. Image-Based Distance Measuring System (IBDMS) [12-13]

The IBDMS (image-based distance measuring system) uses two fixed lasers to project the laser beams to the object to measure the distance between the CCD camera and the object. Fig. 4 is the diagram of the location relationship of the CCD camera and the object. The unit of D_{SH} is cm that is the actual length of the distance between the two lasers. F_H is the pixel numbers that the laser beams project to the object in a picture frame. If the maximum horizontal pixels that a CCD camera can catch in a picture frame is $F_H(max)$, the maximum width (in cm as unit) that a CCD camera can reach can be calculated as (4):

$$D_H(max)=\frac{F_H(max)}{F_H}\times D_{SH} \tag{4}$$

According to Fig. 4, the distance D_K (with unit of cm) between the CCD camera and object can be calculated with the intrinsic CCD parameters as mentioned in the previous subsection as (5):

$$D_K=\frac{1}{2}\times D_H(\max)\times D_{SH}\times\cot(\frac{\theta_H}{2})-D_{op} \tag{5}$$

In the RoboCup 2010 rule, the landmark pole is a cylinder with diameter equal to 10cm. when the IBDMS is applied to measure the distance between the CCD camera and the landmark pole, the two lasers of the original IBDMS can be removed, and we call this approach without lasers as modified IBDMS.

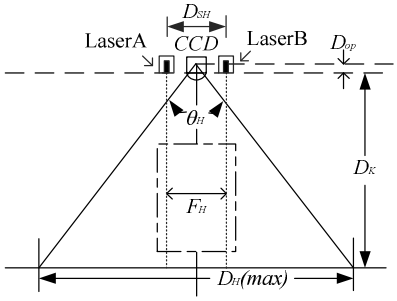

Figure 4. The location relationship of the CCD camera and the object.

III. THE PROPOSED METHOD

This research work uses the parallax of a stereo (binocular) vision system to establish the stereo vision-based self-localization system (SVBSLS) for a humanoid soccer robot used in the Robo-Cup 2010 kid-size humanoid robot soccer competition. Basically there are two main issues in this research: *1)* how to utilize the landmarks, such as the landmark poles and landmark goals, of the competition field to find the coordinate of the humanoid robot in a 2-D coordinate system, *2)* how to measure the accurate distance of the humanoid robot and the soccer ball. Here we have to overcome the difficulties caused by the CCD camera intrinsic parameters such as focal distance and visual angle. The humanoid soccer robot can be adjusted by the tactics dynamically, such as localizing before competition, measuring the distance of the robot and the soccer ball during competition, or localizing during competition.

For the localization algorithm, it needs several procedures: establishment of the coordinate system, object searching, object identification, the distance measurement between the robot and object, refinement of the measured distance, and the adjustment of the location of the robot and the landmarks. In the distance measurement, we use the modified IBDMS approach and the parallax of the stereo vision system. For precision and convenience considerations, the soccer field is treated in a 2-D coordinate system. In the object detection, the two cameras of the stereo vision system catch images in RGB 24-bit colorful formats, respectively. The RGB images are then converted to the HSV colorful formats, and here we only utilize *H* and *S* data and further convert them to the binarization format with proper threshold values. The binarization data are processed to reduce noises to increase the correctness and integrity for object recognition. According to the processed binarization data we can distinguish the object as landmark pole, landmark goal, or soccer ball. If the object is a landmark pole or landmark goal, it will try to localize the robot itself and output the coordinate values to the system. If the object is a soccer ball (we call this as a distance mode), it will try to measure the distance between the robot and soccer ball and output the distance value to the system.

A. Establishment of the Coordinate System

If the coordinate of a geometric map is available, it will be convenient to retain a lot of information in the whole field. For easy manipulation of the self-localization of a robot, the coordinate system of the field must be established in advance. In this research work, before processing the localization we must establish two appropriate coordinate systems. One is called "absolute coordinate system" on the field, and the other is called "relative coordinate system" in the picture frame. It needs four steps to establish the absolute coordinate system: *1)* to estimate the sizes of the soccer field and the robot; *2)* to find the interested position in the soccer field; *3)* to divide the field into several blocks with the same size and assign the interested position block; *4)* according to the proportion of the robot in the field to adjust the value in each block. Through these coordinate systems, the location of the robot, landmark pole, and landmark goal can be located explicitly.

B. Object Searching

Since the objects (landmark poles and landmark goals) are the fixed features in the 2010 RoboCup soccer field, we treat the objects as the reference for localization. In the initialization of the orientation, the robot keeps searching one of the objects until finding it. After finding the object, the two cameras of the system will take the interested feature by converting the image from RGB to HSV space, respectively, as shown in Fig. 5. In order to remove the influence of brightness of light, it takes the *H*- and *S*- spaces only. Finally, each camera will mark five feature points, upper left (X_1,Y_1), upper right (X_2,Y_2), lower left (X_3,Y_3), lower right (X_4,Y_4), and center (X_C,Y_C), for the object in the picture frame, as shown in Fig. 6. According to the five feature points in each picture frame, we can calculate the horizontal lengths (in pixels) FH_{Lx}, FH_{Rx} and vertical lengths FH_{UPx}, FH_{DOWNx} (where x is either 1 or 2; 1 represents the left camera, and 2 represents the right camera) for each of the two cameras. The parallax (in pixels) of the two cameras can be calculated as follows:

$$\Delta N = |FH_{L1} - FH_{L2}| = |FH_{R1} - FH_{R2}| \quad (6)$$

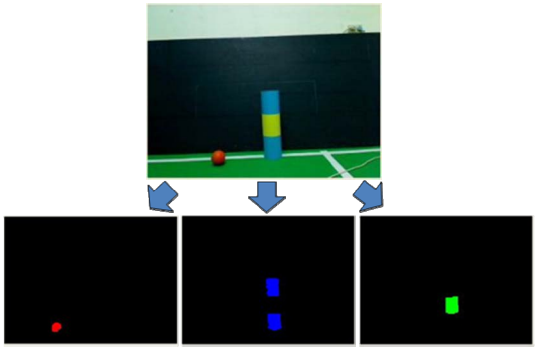

Figure 5. Color model transformation.

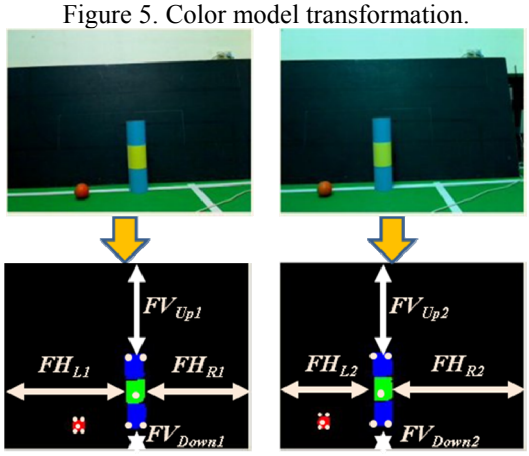

Figure 6. The upper left, upper right, lower left, lower right, and center of the object in the two cameras.

C. Object Recognition Method

According to the color segmentation method, it can fast and easily extract the orange soccer ball in the field, but it is not enough to recognize the landmark goals and landmark poles. The colors of the landmark goals and landmark poles are yellow and blue, and by color segmentation the extraction of the landmark goals and landmark poles may not be correct as shown in Fig. 7. Therefore we have to use more features and

information to extract them. Since the competition field is not complicated, a simple recognition method can be used to reduce the computation complexity. The landmark pole is a cylinder with three colors. Let us look at one of the landmark pole with the upper and bottom layers in blue, and the center layer in yellow; this one is defined as the BYB-landmark pole, and the diagram is shown in Fig.8. The color combinations of the other one are in contrast of the previous one, and the landmark pole is defined as the YBY-landmark pole. The labels of the BYB-landmark pole can be calculated by (7). The YBY landmark pole is in the same manner as the BYB-landmark pole.

$$O_{BYB}(x,y) = L_B^u(x,y) + L_B^v(x,y) + L_Y^w(x,y) \quad (7)$$
$$if \ \left|L_B^u(x_c) - L_B^v(x_c)\right| < \beta_B \cap L_B^u(y_{\max}) < L_Y^v(y_c) < L_B^w(y_{\min})$$

where L_B^u is the pixel of the u-th blue component in a picture frame, y_{min} and y_{max} the minimum value and the maximum value for the object u at y direction in the picture frame respectively, x_c and y_c the center point of the object at the horizontal and vertical direction respectively. The vertical bias value β is set as 45 empirically. The landmark pole is composed of two same color objects in the vertical line, and the center is in different color. If it can find an object with this feature, the system treats this object as the landmark pole and outputs the frame coordinate data. Equation (8) is used to define the label of the soccer ball.

$$O(x,y) = L_O^u(x,y), if \ \alpha_1 \le \frac{L_O^u(x_{\max}) - L_O^u(x_{\min})}{L_O^u(y_{\max}) - L_O^u(y_{\min})} \le \alpha_2 \cap A_u \text{ is the maximum} \quad (8)$$

where L_O^u is the pixel of the u-th orange component in a picture frame. Since the soccer ball is very small in the picture frame, in order to avoid the noise the soccer ball is treated as the maximum orange object and with a shape ratio of height to width approximately equal to 1. Empirically α_1 and α_2 are set to 0.8 and 1.2, respectively. The landmark goal recognition is defined in (9).

$$G_B(x,y) = L_B^u(x,y),$$
$$if \ L_B^u(x,y) \notin O_{BYB}(x,y) \cap L_B^u(x,y) \notin O_{YBY}(x,y) \cap A_B^u > \gamma_B \quad (9)$$

where L_B^u is the pixel of the u-th blue component in a picture frame. Since the blue landmark goal is composed of the blue object and it is not a part of the YBY-landmark pole or BYB-landmark pole. The size of the landmark goal in the field is larger than other objects, and empirically the parameter γ is set as 50. The yellow landmark goal is in the same manner as the blue landmark goal.

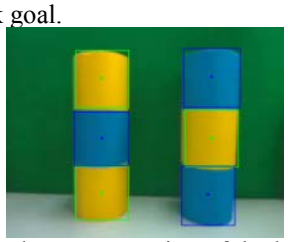

Figure 7. False segmentation of the landmark pole.

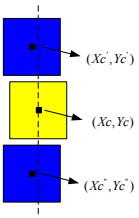

Figure 8. The diagram of the landmark pole.

To get robust FH_L, FH_R, FH_{UP}, and FH_{DOWN}, the object shape must be completely displayed in the picture frame, as shown in Fig. 9(b). Figs. 9(a) and 9(c) show the incomplete objects with partial object displayed in the picture frame. If it finds an incomplete object in the picture frame or the object could be occluded by other robots, the system will command the robot to activate some proper movements to find a complete object. In order to insure the completeness of the object, the pixel values between the edge of the object and the edge of the frame should be greater than some appropriate values.

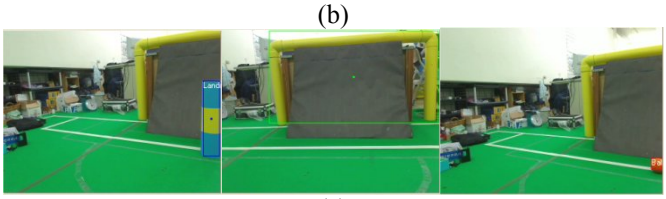
(b)



(c)

Figure 9. Object searching: (a) incomplete object, (b) complete object, (c) incomplete object.

D. Distance Measurement between the Robot and Object

The distance measurement between the robot and the object is based on the parallax of the stereo vision. The modified IBDMS as mentioned in the previous section is applied to measure the distance between the CCD camera and object (the landmark pole, landmark goal, or soccer ball) for the RoboCup 2010 rule. Fig. 10 shows the relationship of the camera and the object. In Fig. 10, Δh is the length of the distance between the two cameras and D_H is the parallax in unit of cm. D_H can be converted by the parallax ΔN (in pixels) and Δh as follows:

$$D_H = \frac{\Delta h \times F_H(max)}{\Delta N} \quad (10)$$

where $F_H(max)$ is the maximum horizontal pixels that a camera can reach in a picture frame. FH_{L1}, FH_{R1}, and FH_{L2}, FH_{R2} are the lengths in pixels for horizontal lengths of the landmark pole in the image frame. By the modified IBDMS

approach, the distance D_K (photo-distance) between the CCD camera and the landmark can be found as follows:

$$D_K = \frac{1}{2} \times D_H \times \cot\theta_H - D_{OP} \quad (11)$$

Due to the non-ideality of the CCD lens and the light illumination the measurement of D_K may not be accurate enough. It can be fine-tuned by the artificial neural network technique. The neural network technique is described in the following subsection.

E. Stereo Vision-based Self-localization System (SVBSLS)

Based on the above concepts, the self-localization system, stereo vision-based self-localization system (SVBSLS), is proposed for the humanoid soccer robot for RoboCup 2010 competition. The proposed SVBSLS consists of six steps, and the operation flow of this self-localization mechanism is shown in Fig. 11. The six steps are:

Step 1: Establish the coordinate system.
Step 2: Search objects.
Step 3: Recognize objects.
Step 4: Measure the distance between the robot and objects.
Step 5: Fine-tune the measured distance.
Step 6: Find the coordinate of the robot in the competition field.

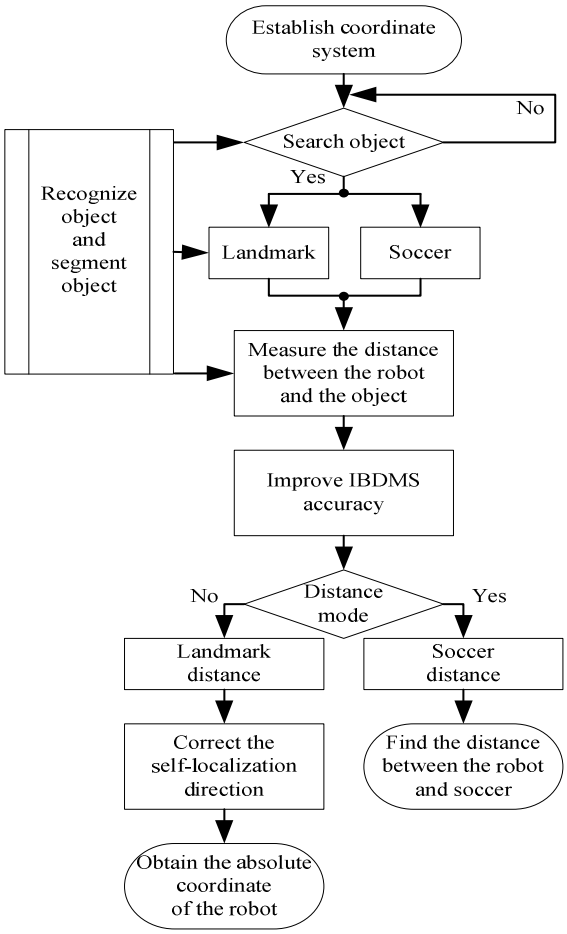


Figure 11. The SVBSLS flowchart for the humanoid robot.

IV. THE EXPERIMENT RESULTS

A. The Experimental Environment and the Robot Vision Module

The experiments are based on the feature of the competition field for 2010 RoboCup soccer humanoid league. The field contains two landmark goals and two landmark poles, and it has unique color combinations for the interesting features as shown in Fig. 12. Because the width of the robot shoulder is 26cm, we set the unit length of the coordinate to be 30cm in length and the competition field can be divided into 29×17 blocks as shown in Fig. 13.

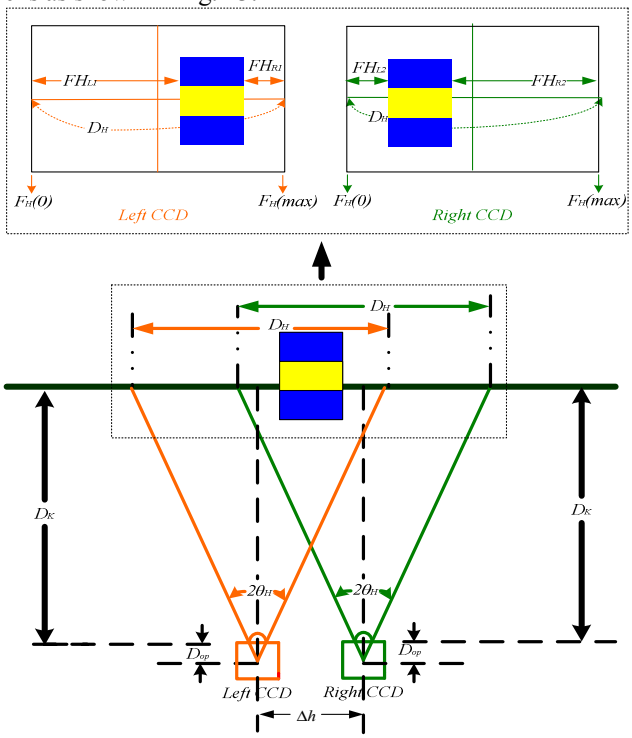

Figure 10. Three-dimension distance measurement.

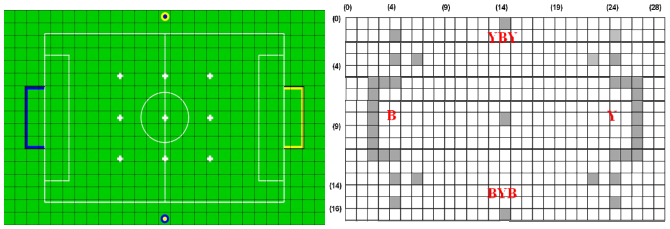
Figure 12. Configuration of the RoboCup soccer field for humanoid kid-size in 2010.

The experimental robot vision module is consisted of two CCD cameras with distance of 10cm and a set of pan/tilt motors. The CCD camera is the Logitech QuickCam® Professor [14] for Notebooks, and the motor is ROBOTIS Dynamixel AX-12 [15]. The input of the robot vision module is RGB 24-bit and the resolution is 960×720 pixels, and the frame rate is 4 fps (frame per second). For simulation, the computer CPU is Intel Core 2 Duo CPU 2.1GHz, and the development tool is Borland C++ Builder 6.0. The output is the

absolute coordinate of the humanoid robot in the competition field.



(a) (b)

Figure 13. The RoboCup soccer field: (a) the original field with 29×17 blocks, (b) the coordinate of the soccer field (2010).

B. The Parallax ΔN of Stereo Vision Analyses

We measured the parallax ΔN in a given distance with different pan/tilt motor angles, and the results are shown in Table 1. According to Table 1, as the same distance the parallax ΔN is the same with different pan/tilt motor angles. Therefore, our SVBSLS does not need to calibrate the non-linear distortion caused by the visual angle of the lens, and it can measure the distance of the object as soon as the camera sees the complete object in the picture frame.

Table 1. The parallax ΔN of the landmark pole in a given distance with different pan/tilt motor angles. (a) The parallax ΔN of the landmark pole in a given distance with different pan motor angles. (b) The parallax ΔN of the landmark pole in a given distance with different tilt motor angles.

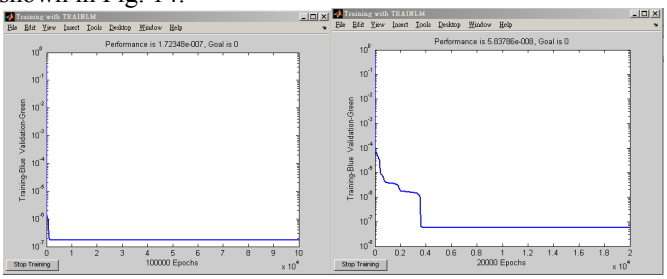
C. Precision Simulation of the Distance Measurement

For the BPN network approach, we need data for the two neurons in the input layer (ΔN and the rough distance D_K) to measure the distance to the landmark and the input layer (ΔN and rough distance D_K) to measure the distance to the soccer ball. The total training samples are 247. The hidden layer is one. Because the absolute coordinate system of the soccer field is fixed, we can train the on-line data beforehand. The simulation result indicates that the most suitable number of neurons is six. The learning rate is 0.1, and the output layer is one. After finishing the on-line training, the relationships between the information of the frame and the distance can be found, and then it can operate the off-line process for the invariable parameters (relationships) to improve the precision of the distance. The precision can reach 0.028cm for the landmark distance measurement and 0.005cm for the soccer ball distance measurement, and the simulation results are shown in Fig. 14.



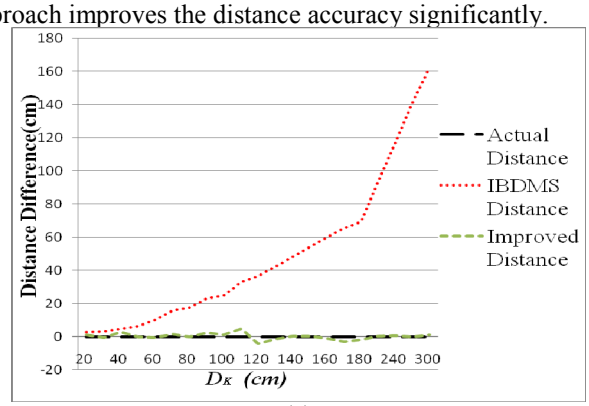
(a) (b)

Figure 14. The errors between the simulated and real distances are: (a) 0.028cm in the landmark distance measurement and (b) 0.005cm in the soccer ball distance measurement.

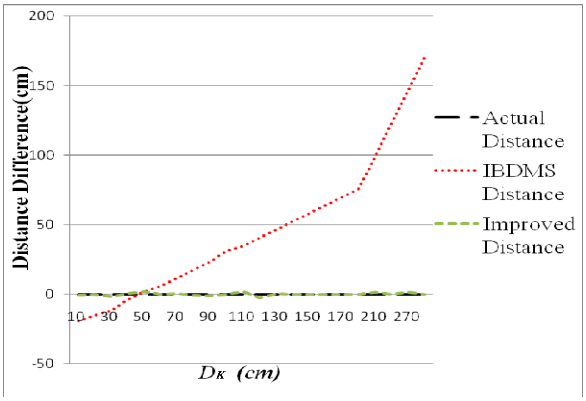
I. COMPARISONS AND ANALYSES

A. The Analyses for the Actual Measuring Distance

This work uses modified IBDMS and NNIBDMS techniques to measure the distance between the robot and landmark and the distance between the robot and soccer ball from 10cm to 300cm. Fig. 15 shows the errors between the measuring distance and actual distance, and the results are listed in Table 2. In the distances from 10cm to 300cm, the average and maximum errors for the modified IBDMS are 48.96cm, 51.03cm, and 162.16cm, 170.52cm, respectively. On the other hand, those of the NNIBDMS are 1.38cm, 0.64cm, and 2.49cm, 4.55cm, respectively. The proposed NNIBDMS approach improves the distance accuracy significantly.



(a)



(b)

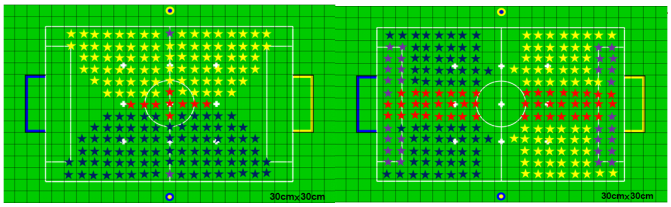
Figure 15. The distance differences of the actual distance and the modified IBDMS and NNIBDMS approaches, (a) Landmark distance, (b) Soccer ball distance.

Table 2. Comparisons of the maximum and average errors for different methods.

Landmark distance		
Methods	**Average error**	**Maximum error**
Modified IBDMS	48.96 cm	162.16 cm
NNIBDMS	1.38 cm	4.55 cm
Soccer ball distance		
Methods	**Average error**	**Maximum error**
Modified IBDMS	51.03 cm	170.52 cm
NNIBDMS	0.64 cm	2.49 cm

B. The Results of the Self-localization in the Competition Field

The distances measured between the robot and landmarks as mentioned in the previous subsection are applied to the SVBSLS to localize the robot itself. The localization results of using the distances measured by the modified IBDMS and NNIBDMS are compared. The experiments include the localization by using the distance from the robot to the landmark pole and the distance from the robot to the landmark goal. There are 247 coordinate positions in Fig. 16. The yellow and blue star signs stand for the correct localization by using the NNIBDMS approach for distance measurement. The purple star signs stand for the correct localization by using the modified IBDMS or NNIBDMS approaches for distance measurement. The red star signs stand for the correct localization with both landmark pole and landmark goal by using the NNIBDMS approach for distance measurement. Table 3 shows the comparisons for the robot localization by using SVBSLS with modified IBDMS and NNIBDMS approaches for distance measurement. The correct rate for the SVBSLS approach with the NNIBDMS approach is 100%; on the other hand that of the localization by the modified IBDMS is only 13.77%. The main reason of the lower correct rate is due to the worse accurate measuring distance results.



(a) (b)

Figure 16. The correct localization by using SVBSLS with modified IBDMS and NNIBDMS approaches, (a) Landmark pole, (b) Landmark goal.

Table 3. Comparisons of the correct rates for SVBSLS with different distance measurement methods.

Total experimental points = 247(blocks)			
Situation	**Correct**	**Incorrect**	**Accuracy rate**
IBDMS	34	213	13.77%
SVBSLS	247	0	100%

C. The Comparisons of Monocular Vision and Binocular Vision

In this subsection we compare the localization results of SVBSLS approach with those of the monocular vision approach, AVBSLS [16], under the same experimental environment. The errors of the distance measurement by the NNIBDMS approach with monocular vision (AVBSLS) and binocular vision (SVBSLS) are shown in Fig. 17. The results are summarized in Table 4. The average and maximum errors of the distance measurement by AVBSLS are 2.68cm and 12.86cm, respectively. On the other hand, those by SVBSLS are 1.38cm and 4.55cm, respectively. The proposed SVBSLS approach increases the distance measurement accuracy significantly.

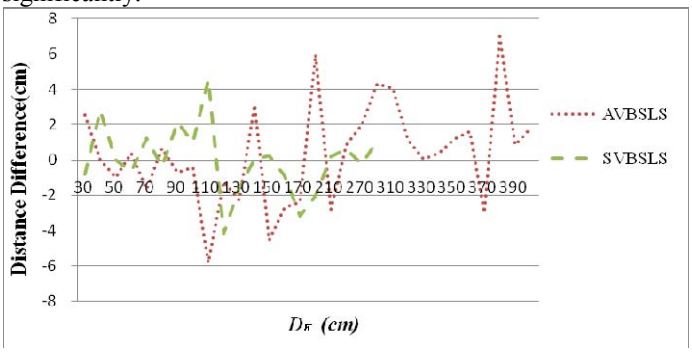


Figure 17. The distance errors by using AVBSLS and SVBSLS.

The correctness of the localization by using AVBSLS and SVBSLS is shown in Fig. 18 with 247 coordinate positions. The red star signs stand for the correct localization results. Table 5 shows the correct rates of the localization by using AVBSLS and SVBSLS approaches. The correct localization rate of the AVBSLS is 93.5%, but it must have robust features within a specific region. On the other hand, the SVBSLS approach can have a 100% correct rate without any restriction.

Figure 18. The localization results of AVBSLS and SVBSLS, (a) AVBSLS, (b) SVBSLS.

Table 4. The average and maximum errors of the distance measurement by AVBSLS and SVBSLS.

Landmark		
Methods	**Average error**	**Maximum error**
AVBSLS	2.68 cm	12.86 cm
SVBSLS	1.38 cm	4.55 cm

Table 5. The comparisons of the correct localization rate with AVBSLS and SVBSLS.

Total experimental points = 247(blocks)			
Situation	**Correct**	**Incorrect**	**Accuracy rate**
AVBSLS	231	16	95.5%
SVBSLS	247	0	100%

CONCLUSIONS

Self-localization is one of the most important issues for the humanoid soccer robot. This research work proposes a very efficient vision approach, stereo vision-based self-localization system (SVBSLS), to localize the soccer robot itself during the soccer competition for the 2010 RoboCup rule. In order to emulate the human being, the mechanism of the SVBSLS consists of only two CCD cameras and a set of pan/tilt motors on the head of the humanoid soccer robot. We use the landmarks of the soccer field as the reference points to correctly self-localize the humanoid robot. In the SVBSLS approach, we have to measure the distance between the robot and the landmark. The modified IBDMS approach is used to measure the intrinsic parameters of the CCD camera and further to calculate the distance between the robot itself and the landmark or soccer ball. The BPN technique is used to refine the calculated distance to a more accurate one (NNIBDMS). By the SVBSLS approach with the NNIBDMS technique, the accuracy rate of the self-localization of the humanoid soccer robot can reach 100%, the average error of distance from the humanoid soccer robot to the soccer ball is only to 0.64cm. Since the resolution of the CCD camera is 960×720 pixels, the frame rate is only 4 fps. Although it is enough for the robot soccer competition, the computation efficiency can be improved by using the technique of hardware acceleration. The bottleneck (such as the color transform) can be overcome by hardware approach, and the image processing can be improved such that the robot can operate more smoothly.

***Abstract*— In this paper, we propose a novel second order paradigm called *optimal input normalization* (OIN) to solve the problems of slow convergence and high complexity of MLP. By optimizing the non-orthogonal transformation matrix of input units in an equivalent network, OIN absorbs separate optimal learning factor for each synaptic weight as well as the threshold of hidden unit, leading to an improvement in the performance for MLP training. Moreover, by using a whitening transformation of negative Jacobian matrix of hidden weights, a modified version of OIN called *optimal input normalization with hidden weights optimization* (OIN-HWO) is also proposed. The Hessian matrices in both OIN and OIN-HWO are computed by using *Gauss- Newton* method. All the linear equations are solved via *orthogonal least square* (OLS). Regression simulations are performed on several real-life datasets and the results show that the proposed OIN has not only much better convergence rate and generalization ability than *output weights optimization-back propagation* (OWO-BP), *optimal input gains* (OIG) and even *Levenberg-Marquardt* (LM) method, but also takes less computational time than OWO-BP. Although OIN-HWO takes a little expensive computational burden than OIN, its convergence rate is faster than OIN and often close to or rivals LM. It is therefore suggested that OIN-based algorithms are potentially very good choices for practical applications.**

Keywords- multilayer perceptron (MLP), orthogonal least square (OLS), Gauss-Newton, output weights optimization back propagation (OWO-BP), optimal learning factor (OLF), hidden weights optimization (HWO), Schmidt procedure

I. INTRODUCTION

The *multilayer perceptron* (MLP) has several favorable properties, such as universal approximation[1] and the ability to mimic Bayes discriminant [2] which make it a popular tool for many regression and classification applications including finance and weather predication [3,4], automatic controller [5], image and documents retrieval [6,7] and data mining [8].

A. Notation and Primary of MLP

Given a dataset with N_v training patterns $\{(\mathbf{x}_p, \mathbf{t}_p)\}$, where p=1 to N_v denotes the index of pattern, the typical topology of a fully-connected feed-forward MLP which consists of three layers, namely, input layer, hidden layer and output layer is shown in Figure 1. The numbers of units in input layer, hidden layer and output layer are denoted as N, N_h and M, respectively. All these three layers are connected to each other by synaptic weights.

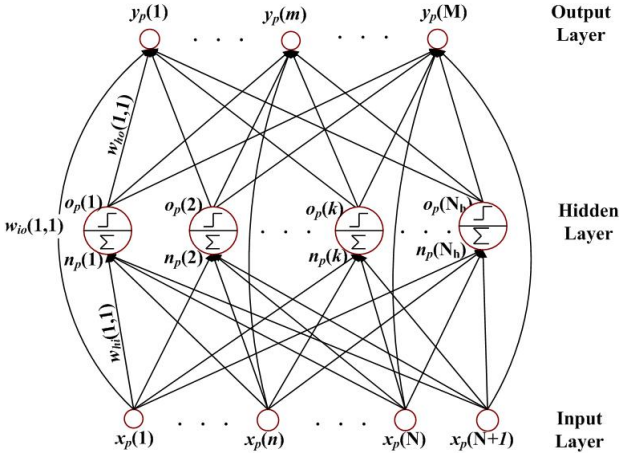

Figure 1. The architecture of a fully connected feedforward MLP

In Figure 1, $\mathbf{x}_p=[x_p(1), x_p(2),\ldots x_p(N+1)]^T$ denotes the input unit vector of p^{th} pattern which consists of N+1 input units, where $x_p(N+1)$ is an augmented input unit for conveniently handling the threshold of each hidden unit by setting $x_p(N+1)=1$ and $\mathbf{t}_p=[t_p(1), t_p(2),\ldots t_p(M)]^T$ denotes the corresponding desired output vector of p^{th} pattern which consists of M desired output units.

If i=1 to (N+1), m=1 to M and k =1 to N_h., then $\mathbf{W}_{ih}=\{w_{ih}(i,k)\}$ denotes all the hidden weights linking from input units to hidden units with N by N_h dimension. $\mathbf{W}_{ho}=\{w_{ho}(k,m)\}$ represents all the output weights linking from hidden units to output units with N_h by M dimension. For full-connected feed-forward MLP, there are another kind of weights directly link from input units to output units which called bypass weights $\mathbf{W}_{io}$. All the bypass weights.$\{w_{io}(i,m)\}$,are denoted as $\mathbf{W}_{io}$ with N by M dimension.Then, the net function of hidden units is denoted as $\mathbf{n}_p=[n_p(1),n_p(2),\cdots,n_p(N_h)]^T$. For k^{th} hidden unit, $n_p(k)$,is denoted as

This paper is sponsored by National Natural Science Foundation of China (No. 60970047) and Innovation foundation of Shandong University (No. 2010TS001).

$$n_p(k) = \sum_{i=1}^{N+1} w_{ih}(i,k)x_p(i) = (\boldsymbol{W}_{ih})^T \boldsymbol{x}_p \quad (1)$$

Thus, if the corresponding output vector of hidden units which called activation function is denoted as $\mathbf{O}_p=[O_p(1),O_p(2),\cdots,O_p(N_h)]^T$, then the output value of k^{th} hidden unit, $O_p(k)$ is given by

$$O_p(k) = f\left(n_p(k)\right) \quad (2)$$

where, $f(\cdot)$ denotes the nonlinear hidden layer activation function, which generally is taken as sigmoid function

$$f\left(n_p(k)\right) = \frac{1}{1+e^{-n_p(k)}} \quad (3)$$

Finally, the output vector of MLP $\mathbf{y}_p=[y_p(1), y_p(2),\cdots \boldsymbol{y}_p(M)]^T$ is summarized as,

$$\mathbf{y}_p = (\mathbf{W}_{io})^T \mathbf{x}_p + (\mathbf{W}_{ho})^T \mathbf{O}_p \quad (4)$$

For batch mode training of MLP, the typical error function $\mathbf{E}$ is *mean squared error* (MSE) which is defined as

$$\mathbf{E} = \frac{1}{N_v}\sum_{p=1}^{N_v}\sum_{m=1}^{M}\left[t_p(m) - y_p(m)\right]^2 \quad (5)$$

where $t_p(m)$ denotes the desired value and actual value of m^{th} output unit, respectively. If $\mathbf{W}$ denotes all the synaptic weight matrix, then the output vector, $\mathbf{y}_p$ is the function of $\mathbf{W}$ then the general main purpose of training MLP is to optimize the weight matrix, $\mathbf{W}$, by minimizing the MSE function , $\mathbf{E}$, based on some optimal training rules. In such case, $\mathbf{E}$ can also be represented as $\mathbf{E}(\mathbf{W})$.

B. Gradient Descent Algorithm

One of the earliest training algorithms for optimizing weights is gradient descent back propagation algorithm [10]. In such case, the hidden weight matrix, $\mathbf{W}_{ih}$, is updated as

$$\mathbf{W}_{ih} \leftarrow \mathbf{W}_{ih} + z \cdot \mathbf{G}_{ih} \quad (6)$$

where $\mathbf{G}_{ih}=\{g_{ih}(n, k)\}$ is a (N+1) by N_h negative Jacobian matrix of hidden weights which is given by

$$\mathbf{G}_{ih} = \frac{1}{N_v}\sum_{p=1}^{N_v}\mathbf{x}_p\left(\boldsymbol{\delta}_p\right)^T \quad (7)$$

where $\boldsymbol{\delta}_p = [\delta_p(1), \delta_p(2) \ldots, \delta_p(N_h)]^{\mathrm{T}}$. $\delta_p(k)$ is the delta function corresponding to for k^{th} hidden unit and is formulated as

$$\delta_p(k) = f'\left(n_p(k)\right) \cdot \sum_{m=1}^{M}\delta_o(m) \cdot w_{ho}(k,m) \quad (8)$$

where $[\delta_o(1), \delta_o(2), \cdots, \delta_o(M)]^T$ is denoted as $\boldsymbol{\delta}_o$ which represent the delta function for output units and is normally given by

$$\boldsymbol{\delta}_o = 2(\mathbf{t}_p - \mathbf{y}_p) \quad (9)$$

Let $\mathbf{W}_o=[\mathbf{W}_{io}: \mathbf{W}_{ho}]$ denote the combined output weight matrix with (N+1+N_h) by M dimension, then the equation for updating $\mathbf{W}_o$ is given by

$$\mathbf{W}_o \leftarrow \mathbf{W}_o + z_1\mathbf{G}_o \quad (10)$$

where z_1 is the learning factor and $\mathbf{G}_o$ is the gradient matrix of error function with respect to $\mathbf{W}_{\mathrm{o}}$.

If $\mathbf{X}_p = [\mathbf{x}_p: \mathbf{O}_p]$ with (N+N_h+1) by 1 dimension, then $\mathbf{G}_o$ is formulated as

$$\mathbf{G}_o = \frac{1}{N_v}\sum_{p=1}^{N_v}\mathbf{X}_p(\boldsymbol{\delta}_o)^T \quad (11)$$

From (6) and (10), we can easily find that the learning factors, z and z_1 have the directly effects on the convergence rate of MLP.

To choose appropriate z and z_1, many researchers have suggested that learning factor should be optimized separately for different synaptic weights [11]~[14]. However, for many MLP training algorithms, the definitions of learning factor z and z_1 were either assigned to be the fixed values or tuned empirically. Although these methods can show fast convergence rates for some specific applications, they are suffered from lots of efforts to find out the proper learning factors. Also, these methods have some error oscillations during training.

C. Output Weights Optimization Back Propagation (OWO-BP)

The OWO-BP algorithm is a fully optimal learning method which convergences fast without any error oscillation [15]. The OWO-BP algorithm includes two stages: the *output weights optimization* (OWO) and *back propagation* (BP).

In OWO stage, since the output units have linear activation functions, the OWO procedure is equal to solve a set of linear equations. In this case, the output weight vector $\mathbf{W}_{\mathrm{o}}$ is given as follows

$$\mathbf{W}_o = \mathbf{R}_o\mathbf{C}_o^T \quad (12)$$

Here, $\mathbf{R}_o$ is the autocorrelation matrix of $\mathbf{X}_p$ with (N+N_h+1) by (N+N_h+1) dimension and $\mathbf{C}_o$ is the correlation matrix of between output vector $\mathbf{y}_{\mathrm{p}}$ and $\mathbf{X}_p$ with dimension of M by (N+N_h+1). The calculations of $\mathbf{R}_o$ and $\mathbf{C}_o$ are given respectively as

$$\begin{cases} \mathbf{C}_o = \frac{1}{N_v}\sum_{p=1}^{N_v}\mathbf{y}_p\mathbf{X}_p^T \\ \mathbf{R}_o = \frac{1}{N_v}\sum_{p=1}^{N_v}\mathbf{X}_p\mathbf{X}_p^T \end{cases} \tag{13}$$

In this case, (12) can be directly solved by using orthogonal least square (OLS) which is achieved by Schmidt procedure[15].

In BP phase, the learning factor z is optimized which introduces the concept of *optimal learning factor* (OLF) z and the optimization of z for all the hidden weight is given by Newton's method as

$$z = -\frac{\frac{\partial \mathbf{E}}{\partial z}}{\frac{\partial^2 \mathbf{E}}{\partial z^2}} \tag{14}$$

where $\frac{\partial \mathbf{E}}{\partial z}$ and $\frac{\partial^2 \mathbf{E}}{\partial z^2}$ are the first order and the second order derivative of error function, with respect to the learning factor, z, which are computed , respectively as,

$$\begin{cases} \frac{\partial \mathbf{E}}{\partial z} = \frac{-2}{N_v}\sum_{p=1}^{N_v}\sum_{i=1}^{M}\left(t_p(i) - y_p(i)\right)\cdot\frac{dy(i)}{dz} \\ \frac{\partial^2 \mathbf{E}}{\partial z^2} = \frac{2}{N_v}\sum_{p=1}^{N_v}\sum_{i=1}^{M}\left[\frac{dy(i)}{dz}\right]^2 \end{cases} \tag{15}$$

where $\frac{dy(i)}{dz}$ is derived by following equation

$$\frac{dy(i)}{dz} = \sum_{k=1}^{N_h} w_{oh}(i,k) f'\left(n(k)\right)\sum_{n=1}^{N+1} g(k,n)\, x_p(n) \tag{16}$$

As the training of output weights is equivalent to solving linear equations and the learning factor z is optimized by using second order Newton's method, OWO-BP performs much better than gradient descent based BP with much less computations than LM. However, as OWO-BP only computes single OLF for all hidden weights, it cannot guarantee it is the global optimal factor for the entire error surface. Hence, OWO-BP doesn't exhibit faster convergence rate than LM.

D. The Plain Levenberg-Marquardt Algorithm

The plain *Levenberg-Marquardt* (LM) algorithm [17]~[20] is a sub-optimal learning factor method which updates all synaptic weights by following formulation

$$\mathbf{W} \leftarrow \mathbf{W} - (\mathbf{H} + \lambda \cdot \mathbf{I})^{-1}\nabla \boldsymbol{f}(\mathbf{W}) \tag{17}$$

where $\mathbf{H}$ is Hessian matrix of error function with respect to $\mathbf{W}$ with (N+N_h+1) by (N+N_h+1) dimension, λ is a controlling factor for tuning the direction of method towards first order or second order method, $\nabla \boldsymbol{f}(\mathbf{W})$is gradient matrix of a quadratic function of $\mathbf{W}$ and $\mathbf{I}$ is identity matrix. As LM algorithm optimizes all the synaptic weights by using the second order Newton's method, this algorithm converges significantly better than many other MLP training algorithms. However, due to the huge computations for calculate Hessian matrix H and its inversion matrix, which costs O(N^3), as well as lots of efforts to choose proper value of λ, LM suffers from huge computations leading to impractical application.

E. Optimal Input Gains algorithm

Compared with LM and OWO-BP, *optimal input gains* (OIG) algorithm is a fully optimal learning algorithm which embeds optimal learning factors into so-called optimal input gains [21]. OIG introduces a novel way to update hidden weights by optimizing an input unit transformation matrix in an equivalent MLP network. This transformation matrix is shown as

$$\mathbf{A} = \begin{bmatrix} a(1) & 0 & \cdots & 0 & 0 \\ 0 & a(2) & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & a(N) & 0 \\ 0 & 0 & \cdots & 0 & a(N+1) \end{bmatrix} \tag{18}$$

where [a(1), a(2),⋯, a(N+1)] is called input gain vector and is denoted as **a**. Hence, the input transformation equation is given by

$$\bar{\boldsymbol{x}}_{\boldsymbol{p}} = \mathbf{A}\mathbf{x}_{\mathbf{p}} \tag{19}$$

By optimizing input gain vector **a**, the hidden weight can be updated as,

$$\mathbf{W}_{ih} \leftarrow \mathbf{W}_{ih} + \mathbf{a} \cdot \mathbf{G}_{ih} \tag{20}$$

Compared (20) with (6), it can be easily seen that the input gain vector , **a,** in fact takes the role of learning factor for training hidden weight matrix $\mathbf{W}_{ih}$.

Due to absorbing optimal learning factors into optimal input gains instead of obtaining optimal learning factor z directly, OIG converges much faster than OWO-BP with much less computation burden than LM.

In this paper, we proposed a more generalized optimal transformation matrix of input units. By optimizing this transformation matrix, a new algorithm which called *optimal input normalization* (OIN) improves the convergent rate and generalization than OIG.

The rest of paper is organized as follows: in the section II, we present the motivation for OIN and its mathematic derivation as well as the improved version of OIN which called OIN-HWO. In section III, the algorithm procedure of OIN as well as OIN-HWO is represented. In section IV, the simulation results on several benchmarks are analyzed. In section V, the conclusions and some suggestions on future enhancements are present. Acknowledgements and references are given in section VI and section VII, respectively.

II. OPTIMAL INPUT NORMALIZATION (OIN)

A. Motivation for OIN

The motivation for OIN comes from the well-known fact that if the input units are normalized to zero-mean, then the training error will be improved by non-orthogonal transformation of input units [22]. Thus, the non-orthogonal transformation matrix **A** is expressed as

$$\mathbf{A}=\begin{bmatrix}1 & 0 & \cdots & 0 & -m(1)\\ 0 & 1 & \cdots & 0 & -m(2)\\ \vdots & \vdots & \ddots & \vdots & \vdots\\ 0 & 0 & \cdots & 1 & -m(N)\\ 0 & 0 & \cdots & 0 & 1\end{bmatrix} \tag{21}$$

where $[m(1),(2)\cdots m(N)]$ is the mean vector of the input units. Hence, the n^{th} transformed input unit $\bar{x}_p(n)$ is given by

$$\bar{x}_p(n)=x_p(n)+m(n) \tag{22}$$

where n=1 $\cdots N$. This leads to the following lemma for the transformation of input unit to an equivalent network which is defined as [20].

Lemma: *Consider a nonlinear network with input unit vector* $\mathbf{x}_p\in R^{N+1}$*, with the restriction* $\mathbf{x}_p(N+1)=1$ *and output vector* $y\in R^M$ *and a second network in which the input unit vector* $\bar{\mathbf{x}}_p=\mathbf{A}\cdot\mathbf{x}_p$ *has corresponding output vector* $\bar{\mathbf{y}}_p\in R^M$ *then two networks are strongly equivalent if* $\forall\,\mathbf{x}_p\in R^{N+1}$, $\bar{\mathbf{y}}_p=\mathbf{y}_p$.

Based on the above theory, the negative Jacobian matrix of equivalent transformed network, $\bar{\mathbf{G}}_{ih}$ is given by derived from the original network, $\mathbf{G}_{ih}$, where

$$\bar{\mathbf{G}}_{ih}=\frac{1}{N_v}\sum_{p=1}^{N_v}\bar{\mathbf{x}}_p\left(\boldsymbol{\delta}_p\right)^T=\frac{1}{N_v}\sum_{p=1}^{N_v}(\mathbf{A}\mathbf{x}_p)\left(\boldsymbol{\delta}_p\right)^T=\mathbf{A}\mathbf{G}_{ih} \tag{23}$$

If we map the transformed input units back to the original network, then the relation between the negative Jacobian matrix of mapped MLP network, which is denoted as $\bar{\bar{\mathbf{G}}}_{ih}$, and $\mathbf{G}_{ih}$ is described as

$$\bar{\bar{\mathbf{G}}}_{ih}=(\mathbf{A}^T\mathbf{A})\mathbf{G}_{ih}=\bar{\mathbf{A}}\mathbf{G}_{ih} \tag{24}$$

where $\bar{\mathbf{A}}=\mathbf{A}^{\mathbf{T}}\mathbf{A}$ is a new transformed matrix with (N+1) by (N+1) dimension.

From (24), we can infer that only if **A** is non-orthogonal matrix, then $\bar{\mathbf{A}}$ could be useful for transformation from $\mathbf{G}_{ih}$ to $\bar{\bar{\mathbf{G}}}_{ih}$. In this case, the mapped back MLP will not be equal to the original MLP. Hence, by optimizing the non-orthogonal A, the training error of the mapped back MLP could be decreased more rapidly than that of the original one. This motivates us to propose the current OIN model.

Compared to OIG, the transformation matrix **A** of our proposed paradigm OIN has a more generalized form as

$$\mathbf{A}=\begin{bmatrix}a(1) & 0 & \ldots & 0 & b(1)\\ 0 & a(2) & \ldots & 0 & b(2)\\ \vdots & \vdots & \ddots & \vdots & \vdots\\ 0 & 0 & \cdots & a(N) & b(N)\\ 0 & 0 & \cdots & 0 & a(N+1)\end{bmatrix} \tag{25}$$

Here, [a(1), a(2), ..., a(N+1)] and [b(1), b(2), ..., b(N)] are called input gain vector which denoted as **a** and input bias vector which denoted as **b**, respectively. In these case, the $\bar{\mathbf{A}}$ is derived into the following symmetrical formation

$$\begin{aligned}\bar{\mathbf{A}}&=\mathbf{A}^{\mathbf{T}}\mathbf{A}\\ &=\begin{bmatrix}a(1)a(1) & 0 & \ldots & 0 & a(1)b(1)\\ 0 & a(2)a(2) & \ldots & 0 & a(2)b(2)\\ \vdots & \vdots & \ddots & \vdots & \vdots\\ 0 & 0 & \cdots & a(N)a(N) & a(N)b(N)\\ b(1)a(1) & b(2)a(2) & \cdots & b(N)a(N) & \sum_{n=1}^{N}a(n)b(n)\end{bmatrix}\\ &=\begin{bmatrix}\bar{a}(1) & 0 & \ldots & 0 & \bar{b}(1)\\ 0 & \bar{a}(2) & \ldots & 0 & \bar{b}(2)\\ \vdots & \vdots & \ddots & \vdots & \vdots\\ 0 & 0 & \cdots & \bar{a}(N) & \bar{b}(N)\\ \bar{b}(1) & \bar{b}(2) & \cdots & \bar{b}(N) & \bar{a}(N+1)\end{bmatrix}\end{aligned} \tag{26}$$

By substituting $\mathbf{G}_{ih}$ with $\bar{\bar{\mathbf{G}}}_{ih}$ in (6), the hidden weights of the mapped back MLP , $\bar{\bar{w}}_{ih}(n,k)$ and $\bar{\bar{w}}_{ih}(N+1,k)$,where n=1 to N ,k=1 to N_h, are updated ,respectively, as

$$\begin{cases}\bar{\bar{w}}_{ih}(n,k)\leftarrow\bar{\bar{w}}_{ih}(n,k)+z\cdot[\bar{a}(n)g_{ih}(n,k)\\ \qquad+\bar{b}(n).g_{ih}(N+1,k)]\\ \bar{\bar{w}}_{ih}(N+1,k)\leftarrow\bar{\bar{w}}_{ih}(N+1,k)+\\ z\cdot[\bar{a}(N+1)g_{ih}(N+1,k)+\sum_{j=1}^{N}\bar{b}(j).g_{hi}(j,k)]\end{cases} \tag{27}$$

If $z\cdot\bar{a}(n)$ and $z\cdot\bar{b}(n)$ are denoted as $\bar{\bar{a}}(n)$ and $\bar{\bar{b}}(n)$ respectively, then by comparing (27) with (6), it can be easily inferred that $\bar{\bar{a}}(n)$ and $\bar{\bar{b}}(n)$ absorb the learning factor z for each hidden weight of hidden unit as well as the threshold of hidden units. This results into the *optimal input normalization* (OIN) algorithm which gives more concern for thresholds of hidden units more than OIG.

B. Derivation of OIN

If $[\bar{\bar{a}}(1),\bar{\bar{a}}(2),\cdots\bar{\bar{a}}(N+1)\ ]^{\mathrm{T}}$ is denoted as **a** and $[\bar{\bar{b}}(1),\bar{\bar{b}}(2),\cdots\bar{\bar{b}}(N+1)]^{\mathrm{T}}$ is denoted as **b** , then [**a:b**] is denoted as **ab** which is a vector with (2N+1) by 1 dimension. Here, we use Gauss-Newton's method to optimize **ab**, which is formulated as

$$\mathbf{ab}=\mathbf{H}_{ab}^{-1}\mathbf{G}_{ab} \tag{28}$$

where $\mathbf{H}_{ab}=\begin{bmatrix}\mathbf{h}_{aa} & \mathbf{h}_{ab}\\ \mathbf{h}_{ba} & \mathbf{h}_{bb}\end{bmatrix}$ denotes the Hessian matrix with dimension of (2*N*+1) by (2*N*+1) and $\mathbf{G}_{ab}=[\mathbf{G}_a:\ \mathbf{G}_b]$ denotes the negative Jacobian matrix with dimension of (2*N*+1) by 1, where $\mathbf{G}_a$ and $\mathbf{G}_b$ are expressed , respectively, as

$$\begin{cases}\mathbf{G}_a=\dfrac{\partial \mathbf{E}}{\partial \mathbf{a}}=\dfrac{-2}{N_v}\cdot[\dfrac{\partial \mathbf{y}_p}{\partial \mathbf{a}}]^T\left[\mathbf{t}_p-\mathbf{y}_p\right]\\ \mathbf{G}_b=\dfrac{\partial \mathbf{E}}{\partial \mathbf{b}}=\dfrac{-2}{N_v}\cdot[\dfrac{\partial \mathbf{y}_p}{\partial \mathbf{b}}]^T\left[\mathbf{t}_p-\mathbf{y}_p\right]\end{cases} \tag{29}$$

From *m*=1to $(N+1)$, *u*=1 to *N* , then the each element of $\mathbf{h}_{ab}$, $\mathbf{h}_{ba}$ $\mathbf{h}_{aa}$ and $\mathbf{h}_{bb}$ are denoted as $h_{\mathrm{ab}}(m,u)$, $h_{\mathrm{ba}}(u,m)$, $h_{\mathrm{aa}}(m,m)$ and $h_{bb}(u,u)$, respectively and are calculated as,

$$\begin{cases}h_{ab}(m,u)=h_{ba}(u,m)=\dfrac{\partial^2\mathbf{E}}{\partial\bar{\bar{a}}(m)\partial\bar{\bar{b}}(u)}\approx 2\cdot\dfrac{1}{N_v}\sum\limits_{p=1}^{N_v}\sum\limits_{i=1}^{M}\dfrac{\partial y_p(i)}{\partial\bar{\bar{a}}(m)}\cdot\dfrac{\partial y_p(i)}{\partial\bar{\bar{b}}(u)}\\ h_{aa}(m,m)=\dfrac{\partial^2\mathbf{E}}{\partial\bar{\bar{a}}(m)^2}\approx 2\cdot\dfrac{1}{N_v}\sum\limits_{p=1}^{N_v}\sum\limits_{i=1}^{M}\dfrac{\partial y_p(i)}{\partial\bar{\bar{a}}(m)}\cdot\dfrac{\partial y_p(i)}{\partial\bar{\bar{a}}(m)}\\ h_{bb}(u,u)=\dfrac{\partial^2\mathbf{E}}{\partial\bar{\bar{b}}(u)^2}\approx 2\cdot\dfrac{1}{N_v}\sum\limits_{p=1}^{N_v}\sum\limits_{i=1}^{M}\dfrac{\partial y_p(i)}{\partial\bar{\bar{b}}(u)}\cdot\dfrac{\partial y_p(i)}{\partial\bar{\bar{b}}(u)}\end{cases} \tag{30}$$

.The net function , $n_p(k)$ in (1) is rewritten as

$$n_p(k)=\sum_{n=1}^{N}\bar{\bar{w}}_{hi}(n,k)\cdot x_p(n)+\bar{\bar{w}}_{hi}(N+1,k) \tag{31}$$

By substituting (31) and (27) into (4) and differentiating the first order of $\mathbf{y}_{\mathrm{p}}$ with respect of **a** and **b**, we obtain $\dfrac{\partial y_p(i)}{\partial\bar{\bar{a}}(m)}$ and $\dfrac{\partial y_p(i)}{\partial\bar{\bar{b}}(u)}$ by following equations

$$\begin{cases}\dfrac{\partial y_p(i)}{\partial\bar{\bar{a}}(m)}=\sum\limits_{k=1}^{N_h}w_{ho}(k,i)\cdot O_p'(k)\cdot\left[g_{ih}(m,k)\cdot x_p(m)\right]\\ \dfrac{\partial y_p(i)}{\partial\bar{\bar{b}}(u)}=\sum\limits_{k=1}^{N_h}w_{ho}(k,i)\cdot O_p'(k)\cdot\begin{bmatrix}g_{ih}(N+1,k)\cdot x_p(u)\\ +g_{ih}(u,k)\end{bmatrix}\end{cases} \tag{32}$$

where $O_p'(k)=f'\left(n(k)\right)$.

As $\mathbf{W_{ho}}$ can be obtained by using OWO from (12) shows, $\mathbf{H}_{ab}$ and $\mathbf{G}_{ab}$ in (28) can be calculated by (29)(30)and (32).

Finally, to obtain optimal **ab** in (28), here we use the *orthogonal least square* (OLS) method which is performed by using Schmidt procedure [15].

C. OIN-HWO

The concept behind HWO method [16] is that it uses separate error function for training each hidden weight. In such case, the error function of j^{th} hidden unit, $E_\delta(j)$,where *j* is from 1 to N_h, .in HWO is expressed as

$$E_\delta(j)=\sum_{p=1}^{N_v}\left[\delta_p(j)-\sum_{n=1}^{N+1}g_{hwo}(j,n)x_p(n)\right]^2 \tag{33}$$

$\mathbf{G}_{hwo}$ is derived from Newton's method as

$$\mathbf{G}_{hwo}\mathbf{R}=\mathbf{G}_{ih} \tag{34}$$

where **R** is the input auto-correlation matrix of input unit vector $\mathbf{x}_{\mathbf{p}}$. By this whitening transformation of $\mathbf{G}_{\mathrm{ih}}$, the input dependence can be eliminated, which makes the $\mathbf{H}_{\mathrm{ab}}$ is non-singular and the optimization **ab** is available. The set of linear equations in (34) is solved by using OLS. Thus, by substituting $\mathbf{G}_{ih}$ into $\mathbf{G}_{hwo}$, we can get a modified version of OIN called OIN-HWO**.**

III. PROCEDURE

The procedure of OIN in batch mode training is shown as follows:

Step1: Initialize input weight matrix $\mathbf{W}_{\mathrm{ih}}$ by using normal distribution function and net control.

Step2: Use OWO by (12) to get the optimal output weight matrix, $\mathbf{W}_o$, initially at first iteration.

Step 3: If the iteration does not end, then use (7) and (8) to get the negative Jacobian matrix $\mathbf{G}_{ih}$ for OIN or use (7), (8) and (34) to get $\mathbf{G}_{hwo}$ for OIN-HWO; else go to Step 10.

Step 4: Solve (28) ~ (32) to obtain optimal input normalization vector, **ab**, by using Schmidt procedure.

Step 5: Update the hidden weights of mapped back MLP by (27), $\bar{\bar{\mathbf{W}}}_{ih}$, for OIN based on $\mathbf{G}_{ih}$ or $\mathbf{G}_{hwo}$.

Step 7: Use these new hidden weights to get new output values of hidden units, $\mathbf{O}_p$, by (2).

Step 8: Calculate new optimal output weight matrix $\mathbf{W}_o$ in (12).

Step 9: Combine new $\bar{\bar{\mathbf{W}}}_{ih}$ and $\mathbf{W}_o$ to get actual output vector $\mathbf{y}_p$ in (4) and use (5) to get new training MSE, **E**.

Step 10: Return to Step 3 and repeat the above steps until get to the end of iterations.

IV. EXPERIMENTAL RESULTS

We perform our simulations for two versions of OIN on several datasets and show the performance by comparing the results with OWO-BP and LM. All the simulations run on Intel Core2 Duo P8700. The number of training iterations for each simulation is fixed to 100, namely, N_{it}=100. For better comparison, all the synaptic weights are initialized using the same method which is given by section III Step (1)~(2). Thus, the training iteration will start after OWO and the first training error will start at the same point.

A. Description of Datasets

The datasets which we use are called "Twod", "Single2", "Mattrn" and "Concrete", respectively. All these datasets used for simulation are publicly available and the input units

of all these datasets have been normalized to be zero-mean and unit variance..

The first three are from the Image Processing and Neural Networks Lab repository [23] and the last one is from UCI Machine Learning Repository [24,25]. Among these datasets, "Twod" is used to invert the surface scattering parameters from an inhomogeneous layer above a homogeneous half space, where both interfaces are randomly rough. "Mattrn" is used for inversion of random two-by-two matrices; "Single2" is used for inversion of surface permittivity, the normalized surface rms roughness, and the surface correlation length found in back scattering models from randomly rough dielectric surfaces. "Concrete" dataset is used to approximate the nonlinear function of age and ingredients of concrete compressive strength.

All of the numbers of patterns, input units, output units and hidden units of these datasets are denoted as N_v, N, M, and N_h , respectively, as listed in TABLE I. In order to learn how each algorithm deals with the co-linearity of each dataset, all the co-linearity of datasets are also listed in Table I.

TABLE I. THE STRUCTURE OF MLP AND CO-LINEARITY FOR EACH DATASET

Datasets	N_v	N	M	N_h	Co linearity
Twod	1768	8	7	10	high
Single2	10000	16	3	8	high
Mattrn	2000	4	4	12	high
Concrete	1030	8	1	15	low

Under the above training conditions, the training MSEs of OIN, OIN-HWO, OIG, OWO-BP and LM are plotted version the time spent after 100 iterations are shown in Figure 2, respectively.

B. Training Error Versus Computational Time

From Figure 2(a)~(d), we can see that OIN shows faster converging rates than OWO-BP and OIG , even rivals LM in (c) as well as OIG does. The total training time spent by OIN is a little longer than OIG but shorter than OWO-BP.

Also, it can be easily seen that OIN-HWO always shows better converge rate than OIN even close to or rivals LM as (a)~(c) shown. OIN-HWO takes a little longer training time then OIN, OIG and OWO-BP. However, compared with LM, the training time spent by OIN-HWO is much less.

C. K-fold Cross Validation

Furthermore, we use k-fold cross validation procedure to evaluate the generalization abilities of OIN and OIN-HWO with comparison with OIG, OWO-BP and, LM. Here, k=10. The procedure of k-fold cross validation is described as follows.

We split each dataset randomly into 10 non-overlapping parts of equal size and combine 9 parts of 10 for training leaving the remaining one part for testing. This procedure is repeated until we have exhausted all 10 combinations. Then, by training all these combinational datasets and then testing on the remaining dataset, we obtain the training MSE and validation MSE of each algorithm on each dataset. The results are listed in Table II.

From Table II, we can see that both training error and validation error of OIN are smaller than OIG and OWO-BP, even smaller than LM on "Single 2" dataset. OIN-HWO shows much better training and validation errors than OIN, even rivals LM on these four datasets. That means our proposed paradigm OIN and OIN-HWO can be seemed as a potential robust approach for practical applications.

V. CONCLUSION

In this paper, we present a novel MLP training algorithm called optimal input normalization (OIN) and its improved version OIN-HWO. Several simulations on real-life datasets and the k-fold cross validation show that the proposed OIN and OIN-HWO greatly improve the converging rates and generalization abilities of OIG, OWO-BP and even LM, respectively. Moreover, as they spend much less computational time than LM, OIN and OIN-HWO are potentially good choice for real life applications.

Future work will give more detailed analysis the effects of co-linearity of different dataset on OIN performance and develop the novel OIN algorithm combined with other network such as RBF, SVM etc..

VI. ACKNOWLEDGMENTS

Abstract– **In this paper an original approach is proposed which makes possible autonomous scenes recognition performed on-line by an evolving self-learning classifier. Existing approaches for scene recognition are off-line and used in intelligent albums for picture categorization/selection. The emergence of powerful mobile platforms with camera on board and sensor-based autonomous (robotic) systems is pushing forward the requirement for efficient self-learning and adaptive/evolving algorithms. Fast real-time and online algorithms for categorisation of the real world environment based on live video stream are essential for understanding and situation awareness as well as for localization and context awareness. In scene analysis the critical problem is feature extraction mechanism for a quick description of the scene. In this paper we apply a well known technique called spatial envelop or GIST. Visual scenes can be quite different but very often they can be grouped in similar types/categories. For example, pictures from different cities across the Globe, e.g. Tokyo, Vancouver, New York, Moscow, Dusseldorf, etc. bear the similar pattern of an urban scene – high rise buildings, despite the differences in the architectural style. Same applies for the beaches of Miami, Maldives, Varna, Costa del Sol, etc. One assumption based on which such automatic video classifiers can be build is to pre-train them using a large number of such images from different groups. Variety of possible scenes suggests the limitations of such an approach. Therefore, we use in this paper the recently propose evolving fuzzy rule-based classifier, simpl_eClass, which is self-learning and thus updates its rules and categories descriptions with each new image. In addition, it is fully recursive, computationally efficient and yet linguistically transparent.**

Key words - **scene recognition, evolving fuzzy rule based classifier, GIST, image processing**

I. INTRODUCTION

The rapid evolution of MEMS (Micro-Electro-Mechanical Systems) has brought to our lives hundreds of sensors which can fit in the palm of our hand and also be embedded in personal devices such as PCs, PDAs, tablets and mobile devices. One of the sources of information (a kind of a sensor) which is integrated within such devices is the video camera. Thanks to these built-in cameras it is possible to obtain video input from nearly all portable devices nowadays.

There is a body of research which is focused on the event detection such as landmarks [1]-[2] and on scene recognition such as [3]-[4]. In the field of scene recognition, there are works that developed intelligent photo albums such as [5] or photo retrieval and classification systems as [6]. However, only in [1] the algorithm that has been used is recursive, on-line, adaptive and can be embedded on a chip. Most of the other published approaches are off-line, computationally expensive and not suitable for embedded applications.

A very important by-product of having computationally lean algorithms is the energy efficiency. In terms of energy consumption one can differentiate between two types of digital capturing images; i) one is CCD (charge coupled devices), and the other one is ii) CMOS (complementary metal oxide semiconductor). Both of them convert images into electric charges. In terms of functioning, the former determines a charge for every pixel which is transferred into another chip as an analogue signal; the latter defines a voltage charge for each pixel conversion and performs digitalization by itself. Although, both offer an excellent imaging performance, CMOS is widely used because it is more energy efficient compare to CCD [7]. It also offers more functionality such as discretization and signal digitalization integrated on the chip than CCD. However, the picture quality of CMOS is not as good as the ones that can be obtained from a CCD camera.

Consequently, in order to maximize the performance and energy consumption of these devices, quick and cheap algorithms in terms of resources will have an important role.

For this purpose, we have developed and studied new algorithms based on recursive and computationally efficient evolving classifiers [8]-[9]. We used GIST descriptor [10]-[11] to compute the features from images. The idea of this descriptor is quite simple; it aims to develop a low dimensional representation of the scene but without partitioning. Basically, GIST feature instances are defined by perceptual dimension such as roughness, openness, naturalness, expansion. All these characteristics represent the spatial structure of a scene. They are easily computed using spectral and superficial localized information. In addition, the use of GIST in scene recognition has been widely experimented [12]-[13].

The evolving fuzzy rule-based classifiers that we will apply in this study [8]-[9] represent a new paradigm of online self-learning which combines the classifier design and classification (prediction) and can also be used as unsupervised tool for clustering (the labeling of clusters can be left for the user). Similar techniques of evolving classifiers have been recently reported in human activity recognition [14] and intelligent robotics applications [15].

The remainder of the paper is organized as follows; in section II related works are presented; in section III feature

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

extraction method is given; in section IV image processing methods are described, in section V the evolving classifier is portrayed, a summary of the entire approach is given in section VI; section VII analyses experimental results and finally section VIII concludes the paper.

II. Related Work

Nowadays, the topic of natural scene classification has been widely studied. Fundamentally, most of the publications focus on modeling the scene using statistical information which is fed later to classification. They differ in the selected method to compute the features. For example [16] which is one of the first works in the field, proposed a feature framework which differentiate between indoor and outdoor scenes. It uses low level features such as; texture, color, and frequency information. Some standards, such as MPEG-7 offer a detailed description of these features. Other, more complex studies, try to relate graphical model with object recognition [17]. Further approaches also try to split the scene semantics concepts [18]. For this purpose, grids of sub-regions of the image are created and later semantics concepts (depicted in semantic nets) are related to these regions. One outstanding contribution to this field was the work [10] which used GIST [11] to build efficient classifiers. However, their work is in off-line mode.

Many other studies used GIST-based scene descriptors. For example [19] used GIST combined with clustering methods to recognize landmarks in the scene. In [20] the recognition of facial expression is enhanced by using context information of the scene using GIST descriptors. In [21] a context-based recognition approach was presented for mobile robots capturing the GIST-based description of the scene.

Evolving classifiers has also been used for recognizing landmarks [22] and for autonomous self-location of mobile robots [9]. In this paper we propose an innovative approach to automatic scene analysis using on-line and evolving self-learning fuzzy rule-based (FRB) classifier that is *potential free*. This results in an algorithm which is computationally and energy efficient and very precise.

III. Gist Descritpion of a Scene

Usually, it is said that humans are able to recognize a scene from a single glance. This is because our brain captures a spatial representation of the scene, recognizing some meaningful objects or salient information of the scene. However, our rational capacities cannot process all information of a complex scene in just a single glance. What our brain does is to just construct a representative picture of perceptual and conceptual low-level (color, contours); intermediate (shapes, texture regions) and high-level information (semantic knowledge). Based on behavioral studies, Friedman [12] observed that regardless of the visual complexity of the scene, humans are able to recognize either categories or special layout of the scene.

More recently, based on Friedman's fundamental studies, a team at MIT studied the application of the GIST to images [10],[22]-[23] to analyze characteristics and properties of images, in order to create a structured summary of a real-world scene. It is stated that descriptive factors exist that can be instrumental for the diagnostic structure of the scene. Torralba et al. came up with the example that urban zones are structured vertically while the forests are textured [11].

Unlike the other approaches, which partition the scene in bins, the standard GIST-based approach considers the scene as a whole, but analyses it spectrally. Consequently, there is no need to detect individual landmarks and objects in the scene. Instead, a scene can be represented by a vector of spectral values. These values are spatial envelope properties such as expansion, openness, roughness.

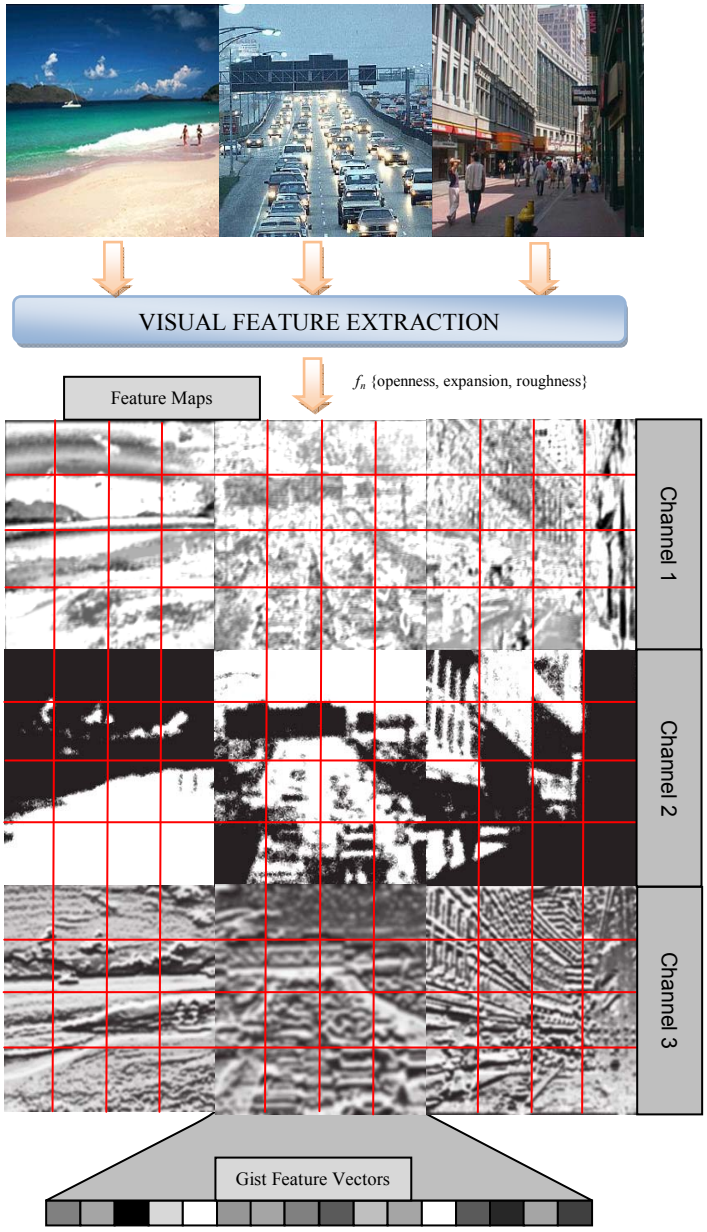

Fig 1. Feature vector of spatial envelop properties

Each property is equivalent to a dimension of the spatial envelope space. These features are meaningful enough to describe the spatial structures of the scene. To estimate these properties spectral and coarsely localized information is used.

To have a rough idea of how GIST-based analysis works let's consider the fundament of the approach.

Most widely used image-based representation for the analysis of the spectral dynamic properties is provided by the discrete Fourier Transform (FT). FT filters represent the spatial domain of the input figure in a frequency domain of sine and cosine components. The discrete form of the FT is a sampled version of it. In other words, it is a set of most representative samples of frequencies. FT-based image representations have shown to have a very good performance in scene recognition problems.

In the fundament of GIST approach are Gabor filters which bear some similarity to Fourier filters. However, the former ones are defined by harmonic functions modulated by Gaussian distributions. As a result of adjustment into Gaussians, these types of filters are limited by frequency bands. With a judicious selection of frequencies (e.g. by successive factors of 2, by octaves), a succession of Gabor filters can be assimilated to a wavelet transform. It results in a very good method of image compression and discretization.

In Figure 1 several Gabor filters with selected channels are computed on a grid of the image (4x4) and indexed into an array. This array is called GIST of the scene. This array represents the spatial layout of the scenes, i.e two images with similar array values (layout) are often similar scenes and vice versa.

IV. Online Preprocessing of Features.

For online recognition of scenes, a fast computation of features is necessary. This can be achieved by means of a fast/recursive computation of parameters. On this sense, in the literature we may find several research works which already have considered this issue. For example, [25] proposes an efficient and recursive computation of Gabor filters to cope with the multi-resolution/orientation of images (which can be a computational intense process). Other works like [26] defined a fast computation of Gabor functions using a bi-orthogonal condition to compute the dual frames. A very precise solution to increase speed on computation of Gabor features is to compute the Gaussian envelope recursively. This way, [27] proposes a recursive way to compute the Gaussian kernel of the Gabor filter general formula [28].

In most of the cases, number of Gist features from the resultant Gabor filters applied, is usually big. In our case, the resultant 4x4 grid partition leads to a feature map of 544 gist features (from 34 Gabor features per region). Consequently, a dimensionality reduction algorithm should be also considered. Although, the recursive computation of these methods is not as extended as the ones of Gabor filters, there has been some progress in this line.

Most widely, used approaches to attain this dimensional reduction are by means of methods such as Principal Component Analysis (PCA) or Fast Independent Component Analysis (FastICA). The latter is already formulated as a computationally efficient method; the former by definition is not. However, there are some works that have recently achieved to formulate the computation of PCA values online [29].

Based on the trend of some works in biology and biotechnology, PCA/ICA projections are reinforced with a Linear Discriminant Analysis (LDA) to increase the description power of features regarding to the class.

1) Recursive Principal Component Analysis (PCA)

It is one of the most commonly used approaches for feature extraction/reduction. Principal Component Analysis (PCA) addresses the issue of correlation of raw input data by orthogonalisation. PCA mainly aims to transform the raw data that are, usually, correlated into a smaller set of uncorrelated variables. Summarizing, we may say that the transformation of new variables are performed by linear combinations of the original (measured) variables. In this connection, the overall number of variables that are required to be measured is not being reduced; what is reduced is the number of inputs to the classifier (manipulated variables by the classifier) by preserving the majority of the information in terms of data variance which is useful for correct classification.

It is mainly based on producing new variables maximising the variance of the data. PCA is very helpful in revealing the hidden dynamics that is often 'hidden' in a raw signal. This method is completely unsupervised (that makes easy to compute it online) and does not take into account any category or label. Its main target is to find efficient orthogonal projections explaining the variance of the data most. In the standard (offline) version of PCA, projections are evaluated by the value of their associated eigen-values. The number of desired orthogonal directions must be defined previously. This is because each projection has to be orthogonal to its previous, independently of the first computed one that will be update according to the coming data.

As it has been discussed before, in this work we aim to perform in an online/real time basis. In order to get a recursive/fast implementation of PCA we can follow the steps suggested by [29].

PCA projections are represented by the eigen-values, *v*. They can be calculated as follows:

$$v_k = \frac{1}{k}\sum_{i=1}^{k} u_i \cdot u_i^T \cdot \frac{v_{i-1}}{\|v_{i-1}\|} \tag{1}$$

Note u denotes an orthogonal projection and k is the current time instant/sample.

This expression is based on the definition of *v* as $\gamma \cdot x = C \cdot x$ and $v = \gamma \cdot x$ where γ is the magnitude of the eigen-value, $\|v\|$, and C the covariance matrix.

Expression (1) can be expressed recursively by weighting its current and last estimates by $\frac{k-1}{k}$ and $\frac{1}{k}$ respectively; then we get:

$$v_k = \frac{k-1}{k} \cdot v_{k-1} + \frac{1}{k} \cdot u_k \cdot u_k^T \cdot \frac{v_{k-1}}{v_{k-1}} \tag{2}$$

As a result, it is possible to estimate recursively orthonormalized values to guarantee maximum independence of directions. Thus, parting from the first order eigenvector a new one is estimated by subtracting its orthogonal projection. The formula which describes this projection u_j is as follows:

$$u_k = u_{k-1} - u_{k-1}^T \cdot \frac{v_{k-1}}{\|v_{k-1}\|} \cdot \frac{v_k}{\|v_k\|} \quad (3)$$

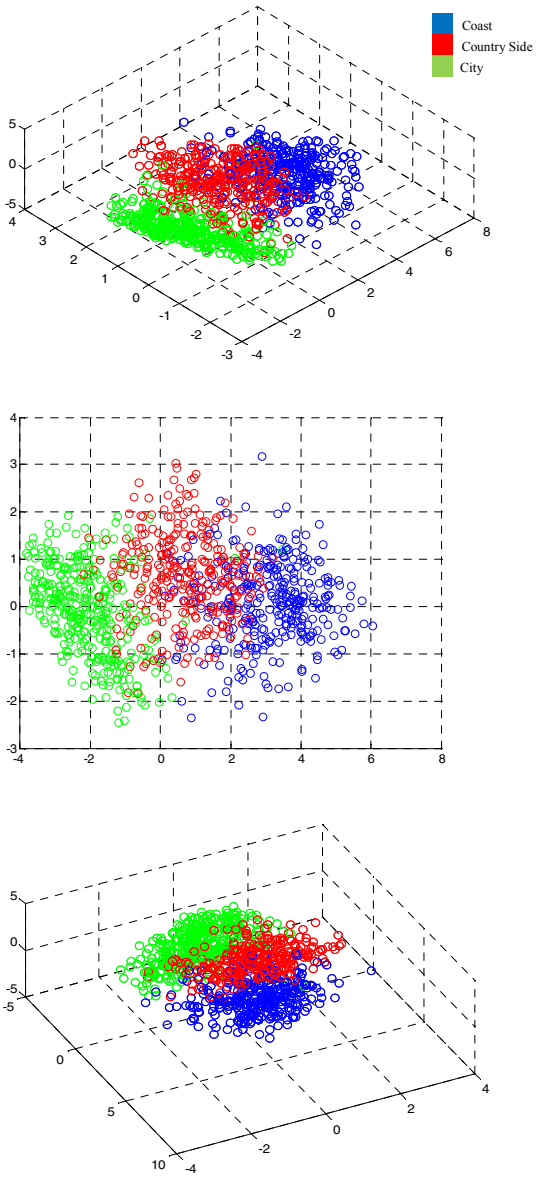

Fig 2. rPCA-LDA applied to data with three categories.

2) Recursive Linear Discriminant Analysis (LDA)

Methods explained above are very useful for reducing correlation and number of inputs to the classifier. However, they do not take into account what category of scene data belongs to. They just get the best representation of data based on its initial values (inputs) without considering the output. We want to classify and recognize categories. Hence, bearing in mind that scenes are categorized, LDA can be applied, it is considered to use LDA to improve the description power of features, this time regarding to the class label (outputs in terms of the classifier).

While PCA/ICA finds the best projections of data in a way that maximises their separability, LDA helps finding these directions which will be best to distinguish between different classes (scenes categories). A combination of both, PCA and LDA has proven to be an effective pre-processing technique in spectroscopy. LDA method is based on the sample variance (σ^2) and sample variance per class (σ_c^2). They are used to form scatter matrices (S_b and S_w). S_w denotes the within-class scatter matrix. Likewise, S_b represents a singular matrix denoted as between-classes scatter matrix. The separation between those matrices is defined as a measure of the signal-to-noise ratio for class labelling. Eigenvectors of $S_{w^{-1}}$ and S_b are consider the best coordinates to discriminate classes better. Thus, new projections of data enhance a separation between categories. In [29] a recursive method is presented to compute both LDA and PCA (fig. 2).

V. Evolving Fuzzy Rule-based Classifiers

In this paper we use evolving fuzzy-rule based (FRB) classifiers of the eClass family [8], namely *eClass1* [8] and a simplified version called *simpl_eClass1* [30]. The evolving classifiers are characterized by self-learning of both structure and parameters and use evolving Takagi-Sugeno FRB models [31]. The structure of both the classifiers is based on first-order multi-input multi-output (MIMO) type FRB model of the following form.

$$Rule^i : IF\left(x_1 \; is \sim x_1^{i*}\right) AND ... \left(x_n \; is \sim x_n^{i*}\right) THEN\left(\mathbf{y}^i = \mathbf{x}_e \boldsymbol{\theta}^i\right) \quad (4)$$

where $\mathbf{y}^i = [y_1^i \;\; y_2^i \;\; \ldots \;\; y_m^i]$ is the m-dimensional output of i^{th} rule, $\mathbf{x}_e = [1 \;\; x_1 \;\; \ldots \;\; x_n]$ is the extended input vector, $\boldsymbol{\theta}^i$ is the matrix of local sub-system parameters given as:

$$\theta^i = \begin{bmatrix} a_{01}^i & a_{02}^i & \cdots & a_{0m}^i \\ a_{11}^i & a_{12}^i & \cdots & a_{1m}^i \\ \vdots & \vdots & \cdots & \vdots \\ a_{n1}^i & a_{n1}^i & \cdots & a_{nm}^i \end{bmatrix}$$

The rules of the classifiers are formed around focal points (cluster centres), where a focal point is a representative of all the data samples within a cluster. The consequent parameters of the rules are estimated using weighted recursive least squares (wRLS) approach [31]. *Simpl_eClass1* differs from *eClass1* mainly due to the learning mechanism which is potential/density free [30]. In order to determine whether an incoming sample is a new focal point, *eClass1* requires calculation of a *potential/density* value [8],[31] for the incoming sample and update of potentials/densities of all the existing focal points. Thus, the computational complexity of *eClass1* (similarly to *eTS*) is *O(N),* where *N* is the number of

existing focal points (respectively fuzzy rules). On the other hand, the determination of focal points in *simpl_eClass1* requires only mean value calculation, and it can be calculated recursively as each sample arrives (same as in *simpl_eTS+* [32]). Thus, in *simpl_eClass1* the computational complexity is reduced from *O(N)* to *O(1)* – by a factor of *N*. A detailed description of *simpl_eClass1* is presented in [30].

In both the classifiers, before the rule learning phase, the actual label of a given sample is converted into numeric form in order to enable the consequent part of a rule to be represented in the form of (4). For example, for a two class problem, *class 1* can be represented as *y = [1 0]*, and *class 2* as *y = [0 1]*. Similarly, for a three class problem, *class 1* is *y = [1 0 0], class 2* is *y = [0 1 0]*, and *class 3* is *y = [0 0 1]*. As can be observed from the representation, the dimension (*m*) of *y* is same as the number of classes. For the classification task, the classifiers estimate the overall output (***est_Y***) by weighted sum of outputs of all the rules using (5)-(6). The index corresponding to the highest value element of ***est_Y*** is assigned as the class label for the sample as given in (7) – so called winner takes all principle which is usually used in classification. For example, suppose for a given sample the value of ***est_Y*** is determined to be *est_Y= [0.45 0.23 0.78]* in a three class problem, then the sample is assigned class label *3*.

$$\mathbf{est_Y} = \sum_{i=1}^{N} \lambda^i \mathbf{y}^i; \ \lambda^i = \frac{\tau^i}{\sum_{j=1}^{N} \tau^j} \tag{5}$$

$$\tau^i = \prod_{j=1}^{n} \mu_j^i(x_j), \quad i = [1, N], \quad \mu_j^i = e^{-\frac{\left\|\mathbf{x} - \mathbf{x}^{i*}\right\|^2}{2(r_j^i)^2}} \tag{6}$$

where **estY** is the overall estimated output, τ^i is the firing strength of the i^{th} rule, $(r_j^i), i = [1, N], \ j = [1, n]$ is the spread of the membership function.

$$Class = Class^{i*}, \quad i* = \arg\max_{i=1}^{m}(\mathbf{est_Y}) \tag{7}$$

VI. Proposed Evolving Online Method.

The procedures explained above might be concatenated in a single process instance by instance. It does mean that just from a standalone data source for example a frame from a camera. The proposed method must be able to recognize pre-defined categories and also any other that has not appeared before, as a result of the evolving nature of the algorithm.

In figure 3, the entire process is represented. A single data sample or frame for a video camera is obtained and formatted to a representative numeric model. The transformation model used in this work is based on a RGB color map, however other geometrical representations such as HSL or HSV could be considered. This image representation is handed to another module where the resultant color map is partitioned and over those partitions GIST is applied. Applying *32* different feature maps and partitioning the data on *4x4* regions per map, a total of *512* features are obtained per image. For a learning model this number of features implies a very high number of dimensions in most cases. A data compression technique is highly recommended, hence GIST features are handed to another module where PCA (for compression) in addition to LDA (enhance feature categorization) is used. A reduced data set of *22* features is obtained after this process, and then an evolving fuzzy rule base model is build up from the scratch. In first iteration, first sample will be considered as a rule and next samples update the FRB model adding, removing or updating new rules. New rules may be associated to one of existing categories and improve interpretation of that category. On other hand, by means of a small supervision or a simple rules monitoring, a new rule can be considered as a start point of a new category.

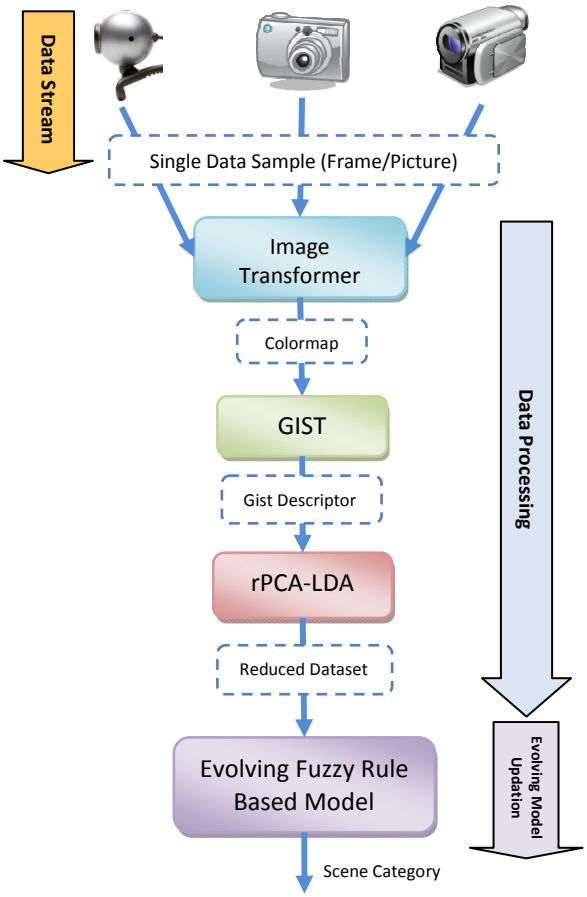

Fig. 3. Processing order of different modules (approaches) to work in a fully online (sample by sample) basis.

VII. Experimental Results and Evaluation

In this section the proposed classification scheme for scene recognition (*eClass_Scenes*) which includes recursive PCA-LDA as well as two versions of evolving classifier: a FRB (eClass) and a potential free version (simpl_eClass). These approaches are compared with several well known classifiers. These classifiers are organized in two groups: i) static, off-line classifiers, and ii) on-line and evolving classifiers. The first ones, generally, provide higher classification rate, but impose heavy requirements on the memory and computational resources. Some of them can process the data incrementally but they keep most of the data in the memory and process all

of them at once. On the other hand, the latter, process the data sample by sample (on-line) always and may be able to adapt their structure (evolve) as a reaction to the variance in the data pattern. A less complex model is obtained from their adaptation and evolution. It is principally due to the on-line processing mode they operate. Significantly less computational resources are required. For this reason, they use to have a better performance in terms of memory consumption and CPU usage which compensate a slight lower accuracy.

The selected data set [33] to test the previous mentioned methods contains *8* outdoor scene categories: street, open country, inside city, forest, coast, mountain, tall buildings and highways. In total, they are *2600* colour images of *256x256* pixels. A confusion matrix of experiments is presented in Figure 4. In this experiment features were reduced to *22* out of *512* initial inputs using rPCA-LDA. Classifications rates vary between *79%* and *81%*. Although, in some cases categories were independently recognized with more than *90%* of accuracy, for instance Inside City, Open Country, Mountain and Forest. By contrast, one category was recognized with less than a *90%*. This is the case of highways. This category could wrongly be identified as coast. It is understandable that mirages of sunny highways could resemble sea water channels.

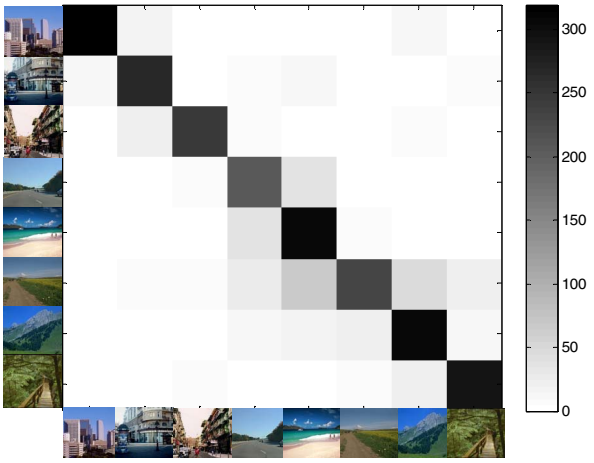

Figure 4. Confusion matrix for classification of scenes.

TABLE II. EVALUATION TIMES FOR THE WHOLE APPROACH

Method	Mean Time (seconds)
RGB Format + GIST	310.73 ms
rPCA-LDA	0.104 ms
Evolving Fuzzy Classifier	0.6/0.2 ms

TABLE I. EVALUATION PARAMETERS USING RPCA-LDA

Method	Evaluation Parameters		
	Accuracy Rate	*Time, ms*	*Number of Rules-SV-K*
Evolving			
eClass1	79.1578%	0.648	31
Simple_eClass1	80.580357%	0.240	29
Non-Evolving			
NaiveBayes	79.6646%	10	-
Nearest Neighbour	74.3187 %	0.31	8
SVM Classifier	80.2935%	2	140

VIII. CONCLUSION

The foundation of a new approach for a fast automatic categorization of visual scenes is presented in the paper. It combines GIST feature selection and PCA-LDA methods with a self-learning evolving fuzzy rule-based classifier with very light computational load (*simpl_eClass*). *Simpl_eClass* can work in real-time, on-line and is linguistically transparent. The proposed approach is compared thoroughly with possible alternative methods including off-line and incremental approaches and the results demonstrate that it outperforms them computationally, in terms of complexity and transparency (Table I). The approach has a latency of approximately *0.3* seconds in total (including spatial descriptors, pre-processing, model updating and estimation) which makes it perfectly usable in real-time application. Moreover, this is calculated based on a Matlab application, an application using C or on-chip VHDL will further reduce this latency. It is important to stress that the computational time of model update is significantly smaller than that of the other approaches. Figure 5 clearly demonstrates that eClass1 and simpl_eClass outperform other methods in terms of accuracy.
To conclude we may say that scene classification can be important for scene analysis and a better understanding of the differences in scenes etc. The results are promising as Evolving Fuzzy Classifiers can compete with renowned SVM approach despite incrementally trained where SVM sees all

the samples at once in a batch setting; furthermore, the number of structural components (rules) is significantly lower than in case of SVM (support vectors).

***Abstract*—A new approach to real-time human activity recognition (HAR) using evolving self-learning fuzzy rule-based classifier (eClass) will be described in this paper. A recursive version of the principle component analysis (PCA) and linear discriminant analysis (LDA) pre-processing methods is coupled with the eClass leading to a new approach for HAR which does not require computation and time consuming pre-training and data from many subjects. The proposed new method for evolving HAR (eHAR) takes into account the specifics of each user and possible evolution in time of her/his habits. Data streams from several wearable devices which make possible to develop a pervasive intelligence enabling them to personalize/tune to the specific user were used for the experimental part of the paper.**

Keywords- human activity recognition, fuzzy rule-based classifiers, evolving systems, wearable sensors, accelerometers.

I. INTRODUCTION

Nowadays due to the increase of the average age of the population in the world as well as due to the dramatic increase of the capacities and availability (including lower costs, power consumption, size) of versatile computing and communication platforms there is a rising interest in areas of research such as Ambient Intelligence (AmI), Ubiquitous and Pervasive Computing, autonomous machine learning etc. Traditional machine learning and intelligent systems can only partially address all of the challenges because of the requirements such as personalization, adaptation, human-intelligible (often linguistic) interface and transparency (reluctance to use 'black-box' solutions even if they perform well. Inside this AmI there is an important interest in the Human Activity Analysis. It may serve as a basis for a better understanding of human habits and relations.

Trying to address all of these challenges, an emerging trend in computational intelligence which borrows heavily from adaptive systems, systems identification, fuzzy rule-based models, machine learning and pattern recognition have recently been prominent – the development of evolving systems [1]. They are characterized by the ability to self-learn and self-adapt their structure as well as to tune their parameters. They are also, usually, human-intelligible (transparent). Evolving systems, and classifiers, in particular [2] can evolve their structure to reflect the habits and behavior of a specific human user. In this way, they can be personalized. This is very useful because, for example, same type of activities (such as *walking*) is usually performed by younger individuals in a quite different manner as compared to more mature individuals. Users with different complexions perform activities with a different intension or energy.

Evolving systems is a new paradigm which requires a different type of real-time, on-line learning which combines structure learning with the parameter learning. In this study we will take the evolving fuzzy rule-based (FRB) type classifier (eClass) as a starting point and will develop a more advanced pre-processing mechanism specifically suitable for the activity –recognition task that we have.

HAR is also an area of intensive research recently [3] [4]. Very often it relies on cameras and video signals [4], however these methods often have problems related to person occlusion in the camera range, selecting a good viewpoint to track the person, privacy connotations, etc. More recently, wearable sensors have offered a very promising and attractive opportunity to collect information directly from the human body. This approach has the advantage of monitoring the human/subject continuously and without invading his privacy.

HAR problem was already addressed in several works in real-time mode using wearable sensors. For example, in [5] an activity recognition system which retrieves information from several wearable sensors is used. In [6] an *iPhone* is used to recognize simple activities such as *running, walking, bicycling*. In these works the training is carried out collecting expert knowledge from many subjects and creating a general model or creating a personal model from training provided from a particular user. However, a cross-personal model which is just trained from one subject and evolves itself with the next one, without expert knowledge or large training sets of different users would be more attractive.

A previous work [8] has involved evolving classifier in the HAR field for the first time, but it was limited to using binary data from light power switches. However, evolving system has not been involved yet in a HAR context using a complex signal domain such as acceleration from wearable sensors.

This paper is organized as follows; section II provides a description of various sensors used; in section III the pre-processing and feature selection approach, that is particularly suitable for this problem, is presented; in section IV the eHAR system is described along with the mechanism of its self-learning and adaptation, and in section V the proposed approach is being evaluated and compared with the possible alternatives. Finally, section VI concludes and outlines the future perspectives.

II. WEARABLE SENSORS

The miniaturization of electronic circuits has made possible increasing the number of devices that one can pervasively wear or even carry in a pocket or as a part of another device. One of the most prominent pervasive micro sensors which can be applied close to the body or as a wearable item is the accelerometer. A large number of manufactured products bring on board accelerometers such as smart phones, high-tech shirts, sports watches, hearings and so on. Hence, in this research we will consider accelerometers as preferred devices of study across in the wearable context.

There are analogue and digital accelerometers; the former produce a voltage that is proportional to the acceleration while the latter outputs pulse with modulated (PWM) signal. Accelerometers can be classified based on the number of axes they consider. For easy recognition tasks, two axes are often enough. However, the higher the number of axes the more sources of information we get for the motion of the object. Although, accelerometer data seems to be highly correlated, the influence of centripetal and gravitational forces leads to randomisation of the correlation either negatively or positively according to the movement. A well planned pre-processing procedure (see next section) can further significantly minimise the correlation effect. Another characteristic to bear in mind is the maximum swing of the accelerometer. It can be computed using the tilt which is the inverse of the tangent of the quotient of two vectors. In order to measure the tilt, only a swing of $\pm 1.5g$ can be enough; in order to conduct very basic recognition of activities such as walking, running or stopping a swing of $\pm 2g$ may be required; however, in order to measure more complex activities such as sudden switches between different types of motion (sudden stop - abrupt movement, etc.) the accelerometer have to handle a swing of $\pm 5g$ or more. Sensitivity is also very important, but it directly depends on the quality of the device itself or the inter-mediation of other devices; for example, when an accelerometer is embedded in a smart phone, its accuracy could be reduced by conflicts with other in-built devices or can be influenced by the position of the sensor inside the phone. Finally, the bandwidth is, perhaps, the most critical aspect of the experiment, because it can restrict or facilitate the level of cognition of a movement. In order to take into account the vibration as well as the acceleration changes or tilt during the movement the bandwidth should be set up accordingly (for example, at least *150 Hz*).

Accelerometers use a *3D* Cartesian coordinate system to represent the direction of the vector of acceleration. When a device is moving along an axis, the acceleration is positive is moving towards positive coordinates, on the contrary, the acceleration is negative.

A. Placement of the Sensors on the Body

Devices that a user can carry such as phones, MP3 players, etc. can have different placement on the body. The location on the human body of the sensors which are part of these devices is very important in respect to facilitating the recognition of specific activities. For example, in case we aim to recognise if someone is *standing up*, it is best to attach the sensor to the leg of the subject; however, in case we aim to recognise if an individual is "*writing on the white board*", a combination of sensors placed on body's arms and legs would be required. Hence, the position of the sensor on the body is of a crucial importance in order to collect informative signal for activity recognition using wearable sensors. The need to add multiple sensing points increases with the complexity of the activity.

A lot of research has been carried out recently aiming to clarify the number of sensors and locations where sensors can be applied aiming to maximise the recognition rate. For example, statistical analysis has been used in [7] to discover the most significant placements of sensors as well as a heuristic method have been defined to cope with this problem. However, in real life applications activity recognition should be made as pervasively as possible avoiding affecting individual's behaviours and habits. For example, it is expected not to force an individual to wear a sensitive object every time in the same place and same position in order to keep certain level of freedom of movement for the user. Moreover, this individual cannot have the same motion habits/patterns as the other. Consequently, the data that are collected from the sensor will not be the same for each individual. Therefore, personalisation is an important issue in human activity recognition and self-adaptive/evolving models [8] can address this problem by self-learning classifiers aiming to recognise human activity of a specific individual adapting to the personal specifics and self-developing their mechanism of classification. In evolving classifiers learning can take place on-line and the classifier structure evolves adapting to an individual's specifics

B. Hardware Instrumentation

In order to get data samples and test the algorithms, we have used several portable devices which can be considered as wearable. Some of these sensors have processing capacities on-board and others are data transducers. In particular, we considered:

1) SunSPOT: It is a hardware/software platform developed by Oracle/Sun Microsystems in 2007 [9]. It has characteristics of a wireless sensor, i.e data can be relayed to a base station via sockets and also forwarded to all sensors. The radio range is 10 meters (USA version allows up to 100m). SunSPOT sensors have embedded a *3*-axial accelerometer that can be set to measure accelerations over a scale of $\pm 6g$. The device is programmable in Java ME through an embedded virtual machine (Squawk VM), Figure 1.

Fig 1. SunSPOT (on a palm and attached to the arm; size 63x38x25mm)

2) Nokia N97: It is a Smart Phone which can be used as a data collection platform. The reason we consider *Nokia N97* is to study a commonly used device as a sensor platform. Usually mobile/cell phones are carried in different locations: a pocket, a bag, on a mobile belt bag, etc. They are completely personal which allows training procedures to be adapted to the specific phone owner (personalised). Consequently, the data collected from these devices is highly representative. *Nokia N97* has a fully programmable Symbian Environment on board and a *3*-axial accelerometer with a scale of ±*8g*, Figure 2.

Fig 2. Nokia 97 Smartphone. Size 117 x 55 x 16 mm.

3) Porcupine: This device is a small wearable sensing module which was developed initially at Lancaster University, UK. A further, improved version of *Porcupine* was developed at the Embedded Sensing Systems group, Techincal University, Darmstadt, Germany. *Porcupine* is based on a *Zigbee* board [10]. The latest version of the *Porcupine* has up to 4GB of memory, 6 tilt switches, 2 light sensors, a temperature sensor, real time clock and a low power 3-axis 3-D accelerometer. The sampling frequency of the accelerometer can be tuned in the range between *0.5Hz* to *1.6kHz* for *X* and *Y* axes, and a range of *0.5Hz* to *550Hz* for the *Z* axis, Figure 3.

Fig 3. Porcupine Sensor v2.5 with modular sensor and plastic cases (Image Source: Embedded Sensing System Group, TU Darmstadt, Germany).

III. PRE-PROCESSING AND FEATURE SELECTION

A. *Pre-processing*

As a result of the chaotic nature of acceleration data, it is extremely complex to recognise human activities based on the raw data. The main characteristic of a human activity is often hidden in the raw data. In addition, due to the non-stationary nature of the motion and other characteristics of human activity an adaptive approach (including in respect to feature selection) requires online update of classifier structure as well as of its parameters. This means the classifier structure (including its inputs – features) to be updated in parallel with the recognition task which means to evolve.

Pre-processing is an important stage of any machine learning and pattern recognition algorithm which provides a valuable level of interpretability from raw data in respect to the input data. This stage is usually done off line on the basis of a large number of training data from a number of subjects. This approach has obvious disadvantages in respect of the representativeness of the training data, the large amount of time and memory needed to process the data. It includes several tasks, such as; i) outliers and missing data detection, ii) data cleaning and filtering, iii) data normalisation or standardisation, iv) feature extraction and feature selection. Pre-processing is often done off-line. It is important to mention that pre-processing can increase the recognition rate by up to 40%. In this study we propose and test several pre-processing methods which are particularly suitable for adaptive and evolving classifiers.

B. *Feature Selection*

Feature selection aims to reduce the computation level and enhance recognition characteristics based on the analysis of the importance of each feature (usually in terms of statistical characteristics) [7]. Although real-time algorithms work in a sample-per-sample basis, for recognizing human activity from motion sensor it is recommendable to use short time windows as instances [11]. For example, if the sampling frequency is *50Hz* a data instance represents *20ms* which is a very short period to get a representative motion pattern.

The features for the classifier that is supposed to recognise the human activity are usually different statistical characteristics of the signal. For example, [5] suggest using the following features:

- *Mean value of the signal;* this represents the local posture of the body;
- *Standard deviation:* It corresponds to the amount of motion presented in the signal. This is very valuable information to differentiate activities with a very different pattern such as *walking* and *running*, for example;
- *Energy of the signal:* It represents the stress. The energy of the signal indicates the dynamics of the motion.
- *Correlation:* It helps differentiate simple from complex movements. For example, both *walking* and *running* have similar acceleration pattern in all dimensions whereas *climbing stairs* have a very different pattern in two dimensions.

All these features are computed for a window with size of 268 samples with an overlap of 128 samples, Figure 4.

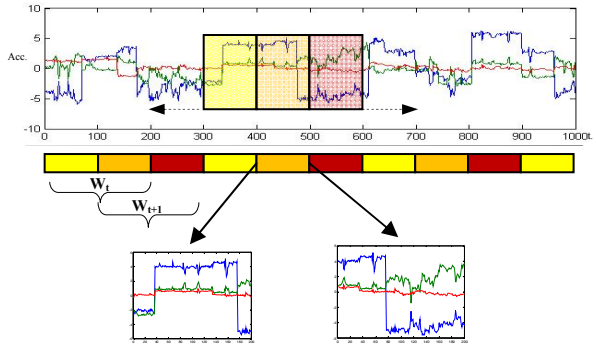

Fig.4 Sampling Windows

C. Feature Extraction.

Due to the same physical principles, different accelerometer axes exhibit some correlation regardless of which human activity is being monitored. For example, significant values of the correlation has been found between axes *(R^2=0.4)* in human motion.

1) Principal Component Analysis (PCA): One of the most widely used approaches for feature extraction which successfully addresses the issue of correlation of raw input data by orthogonalisation is the Principal Component Analysis (PCA). PCA aims to transform the raw data that are, usually, correlated into a smaller set of uncorrelated variables. In this transformation the new variables are linear combinations of the original (measured) variables and in this sense, the overall number of variables that are required to be measured is not being reduced; what is reduced is the number of inputs to the classifier (manipulated variables by the classifier) by preserving the majority of the information in terms of data variance which is useful for correct classification.

PCA has been applied widely in various areas, including spectroscopy, computing vision, intelligent sensors. It is based on producing new variables maximising the variance of the data. PCA is very helpful in revealing the hidden dynamics that is often '*hidden*' in a raw signal. It relies on so called singular value decomposition (SVD) by which the most efficient direction in terms of classifying the data is being determined. This efficient representation is achieved by projection in a least-squares (LS) sense. To get these projections a covariance matrix, C is computed and thereafter a new matrix, V of eigen-values and eigen-vectors, which diagonalise the previously computed matrix, are worked out. Once the matrix V has been computed, eigenvectors, denoted as matrix w are sorted in decreasing order regarding their respective eigen-values. Data is standardized and projected onto the matrix, w.

2) Linear Discriminant Analysis (LDA): PCA is very useful in reducing the correlation and reducing the number of inputs to the classifier (thus the computational complexity). However, PCA does not take into account what activity corresponds to certain motion pattern, i.e. it takes only input data into account and not the class labels (outputs in terms of the classifier).

If data is arranged based on the classes (activity types), that we expect to have, so called Linear Discriminant Analysis (LDA) approach can be applied. While PCA get projections of input data in a way that maximises their separability, LDA helps finding these directions which will be best to distinguish between different classes (activities). A combination of both, PCA and LDA has proven to be an effective pre-processing technique in spectroscopy. Sample variance (σ^2) and sample variance per class (σ_c^2) are used to form scatter matrices (S_b and S_w). S_w denotes the **within**-class scatter matrix.

Likewise, S_b represents a singular matrix denoted as **between**-classes scatter matrix. The separation between those matrices is defined as a measure of the signal-to-noise ratio for class labelling.

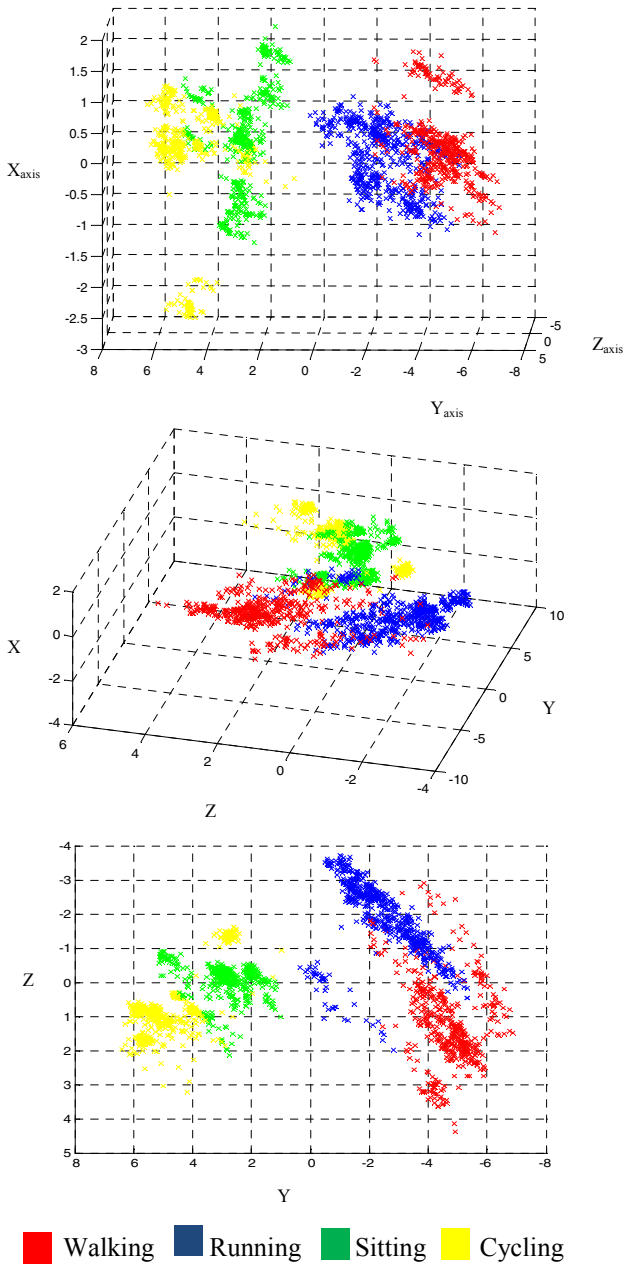

Fig. 5 Features grouped by labels after rLDA-PCA applied

Hence, a criterion function J is computed on the basis of these two matrices, in the following form:

$$J(w) = \frac{w^T S_b w}{w^T S_w w} \quad (1)$$

Values of w which maximizes J are taken as desirable projections of data regarding not just their features (inputs to the classifier) but the class label (output) such as activity type.

3) On-line, recursive PCA, rPCA: All the procedures described above regarding pre-processing techniques such as PCA and LDA are calculated off-line and require, therefore, all the training data to be available beforehand, high memory/storage and high computational power capacities. They have been applied in face recognition problems [12], but are not suitable for real-time, on-line applications in their original form. In this study we need a recursive implementation of the combination of PCA-LDA [12]. This approach is applicable on-line and in real-time. PCA and LDA are compatible techniques because whereas PCA tries to find better projections of data according features, LDA finds what projections discriminate classes better.

PCA projections represented by the eigen-values, v can be calculated expressed as suggested by [11] as follows:

$$v_k = \frac{1}{k}\sum_{i=1}^{k} u_i \cdot u_i^T \cdot \frac{v_{i-1}}{\|v_{i-1}\|} \tag{2}$$

where u denotes an orthogonal projection and k is the current time instant/sample.

This expression is based on the definition of v as $\lambda \cdot x = C \cdot x$ and $v = \lambda \cdot x$ where λ is the magnitude of the eigen-value, $\|v\|$ and C the covariance matrix.

This expression, (2) can be expressed recursively by weighting its current and last estimates by $\frac{k-1}{k}$ and $\frac{1}{k}$ respectively; then we get:

$$v_k = \frac{k-1}{k} \cdot v_{k-1} + \frac{1}{k} \cdot u_k \cdot u_k^T \cdot \frac{v_{k-1}}{v_{k-1}} \tag{3}$$

The algorithm estimates ortho-normalized vectors to ensure maximum independence of the directions. Thus, from the first order eigenvector a new one is computed by subtracting its orthogonal projection. The formula which describes this projection u_j is as follows:

$$u_k = u_{k-1} - u_{k-1}^T \cdot \frac{v_{k-1}}{\|v_{k-1}\|} \cdot \frac{v_k}{\|v_k\|} \tag{4}$$

4) On-line recursive LDA, rLDA: In order to get the desired projections in terms of LDA we have to calculate the between-, and within- classes scatter, S_b and S_w recursively:

$$S'_{wk} = S'_{wk-1} + \left(Y_k - \left(\sigma_c^2 - \sigma^2\right)\right) \cdot \left(Y_k - \left(\sigma_c^2 - \sigma^2\right)\right)^T \tag{5}$$

$$S_{wk}^{-1} = \frac{S'^{-1}_{w(k-1)} + \left(Y_k - \left(\sigma_c^2 - \sigma^2\right)\right) \cdot \left(Y_k - \left(\sigma_c^2 - \sigma^2\right)\right)^T S'^{-1}_{w(k-1)}}{1 + \left(Y_k - \left(\sigma_c^2 - \sigma^2\right)\right)^T \cdot S'^{-1}_{w(k-1)} \left(Y_k - \left(\sigma_c^2 - \sigma^2\right)\right)} \tag{6}$$

$$S_{wk} = A_{k-1} \cdot S'_{wk} \cdot A_{k-1}^T \tag{7}$$

$$S_{wk}^{-1} = A_{k-1} \cdot S'^{-1}_{wk} \cdot A_{k-1}^T \tag{8}$$

$$S_b = A_{k-1} \cdot \left(\sum_{i=1}^{c} n_i \cdot \left(\sigma_c^2 - \sigma^2\right) \cdot \left(\sigma_c^2 - \sigma^2\right)^T \right) \cdot A_{k-1}^T \tag{9}$$

where $Y_k = x_k - \mu$ is the variance; A_k is the matrix of desired orthogonal projections (eigenvectors) S_w^{-1} and S_b.

An explanatory diagram of the combination of both methods in a same time step, *k* is shown in Fig. 6. At the end of the algorithm desired eigenvectors which guarantee best projections and features that enhance the separation between classes of activities are provided. Consequently, the raw data, *x* are being mapped onto the feature space, *f* (see Fig. 5).

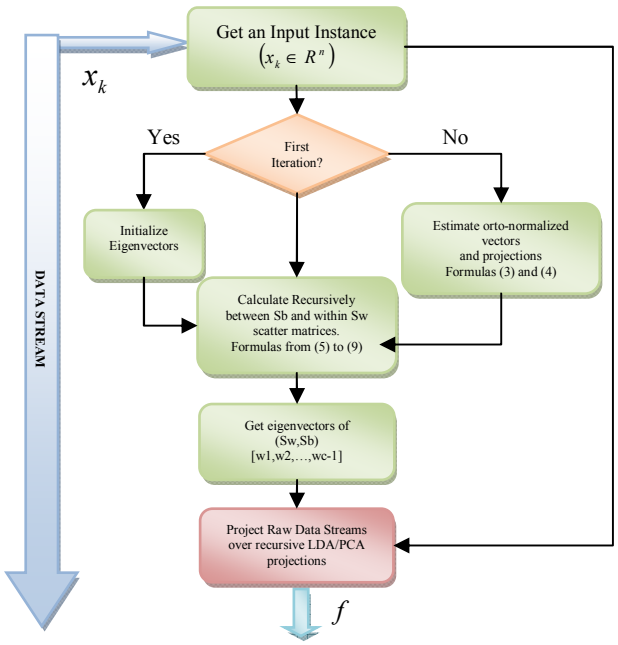

Fig. 6 rLDA-PCA scheme

IV. Evolving Classifier

A classifier is a mapping from the feature space to the class label space. In this study we will develop and apply a self-learning evolving fuzzy rule-based (FRB) classifier, eClass [2]. The structure of the FRB classifiers consists of a set of fuzzy logic (IF-THEN) rules, the fuzzy sets that define the linguistic terms such as '*Low*', '*Medium*', '*High*' etc., aggregation operators such as '*AND*', '*OR*', '*NOT*' and number of inputs/features, *n*. In our study we consider an evolving FRB classifier, *eClass* which is characterised by having an evolving (not fixed) structure of the following form [1]:

$$R^i: \; IF\left(f_1 \; is \; \sim f_1^{i*}\right) \; AND \; ...\left(f_n \; is \; \sim f_n^{i*}\right) \; THEN \; \left(L^i\right) \tag{10}$$

where $f = [f_1, f_2, ..., f_n]^T$ is the vector of features – for our study we consider *n=16*; R^i denotes the i^{th} fuzzy rule; *i=[1, N];N* is the number of fuzzy rules; $\left(f_j \; is \; \sim f_j^{i*}\right)$ denotes the j^{th} fuzzy set of the i^{th} fuzzy rule; *j=[1,n]* ; f^{i*} is the focal point of the i^{th} rule antecedent (note that this is a prototype - a real, existing data sample not the mean). L^i is the label of the class of the i^{th} prototype (focal point).

This set of fuzzy rules (note, that due to its evolving nature their number, N is not fixed) defines with its antecedent/premise (IF) part a *16-D* feature space, $f \in R^{16}$ and with its consequent part it determines in a fuzzy way (with a degree of fulfilment) the class label (activity), L_i, $i=[1, K]$.

The inference in *eClass* is produced by 'winner takes all' rule [1]:

$$L = L^{i^*}; i^* = \arg\max_{i=1}^{N}\left(\tau^i\right) \tag{11}$$

where τ^i denotes the firing level of (degree of confidence in) the i^{th} fuzzy rule, which is determined as a product of the membership values, u_j^i of the j^{th} feature, $j=[1,n]$ to the fuzzy set $(f_j \, is \sim f_j^{i^*})$:

$$\tau^i = \prod_{j=1}^{n} \mu_j^i(f_j); \; i = [1, N] \tag{12}$$

The membership functions that describe the degree of association with a specific prototype are usually of Gaussian form (characterized by good generalization capabilities and coverage of the whole feature space):

$$\mu_j^i = e^{-\frac{1}{2}\left(\frac{d_j^i}{r_j^i}\right)^2}; \quad i = [1, N]; \quad j = [1, n] \tag{13}$$

Where d_j^i is the distance between a sample and the prototype (focal point) of the i^{th} fuzzy rule; r_j^i is the spread of the membership function, which also represents the radius of the zone of influence of the fuzzy rule.

A. Learning eClass

Normally, classifiers use evolutionary algorithms or gradient-based based schemes to be trained-offline. Some examples of this are NN combined with back propagation. Evolving intelligent systems such as eClass are designed to be fully on-line in estimating and training. This is achieved by means of an evolving (self-developing) FRB structure. This FRB structure is created from data-stream inputs $z = \left[f^T, L\right]^T$. Focal points are generated to describe the nature and dynamics of the signal.

This process of self-calibration resembles adaptive control and estimation. Two phases are formed during the process:

i) class estimation (classification);
ii) Update or evolution of the model.

In the first phase the class label is unknown, consequently it is estimated. During the second phase this same class label is used as a supervisory information to update the model structure (so named process of ***structure evolution***), as well as its internal parameters.

There are a couple of differences between *eClass* and conventional classifiers:

i) Starting from scratch, the fuzzy rule-base structure self-develops itself. On the other hand, the structure of a conventional classifier is determined off-line (and then fixed).
ii) Also the on-line learning process considers this flexible rule-base structure.

The overall fuzzy rule base structure has a K number of sub-rule based with the same number of consequents. However, the number of rules must be not less than the number of classes ($N \geq K$). That's to say, every data from a non-previously seen label, automatically becomes a prototype. Model updating procedures (replacement and removal of rules) makes this situation temporal. Later, this prototype is usually replaced by more descriptive prototypes. In this sense, *eClass* learns from the scratch and a fixed class number does not need to be set.

The partitioning model is generated by a density model which defines the potential or density of each point in the feature space. For this reason, a Cauchy function of the sum of distance between a particular data sample and all other data samples of its same class label *(L)*, in the feature space [2];

$$D_k^i(z_k) = \frac{1}{2 - \left[1/\sqrt{\sum_{j-1}^{n+1}(z_k^i)^2}\right]\sum_{j-1}^{n+1} z_k^i b_{k-1}^i} \tag{14}$$

$$k = 2,3,... \qquad D_1(z_1) = 1$$

where $b_k^i = b_{k-1}^i + \sqrt{\frac{\left(z_k^i\right)}{\sum_{j=1}^{n+1}(z_k^j)^2}}, b_1^i = \sqrt{\frac{(z_1^i)^2}{\sum_{j=1}^{n+1}(z_1^j)^2}}$

$i = [1, n+1]$ and $z = [f^T, L]^T$ is the input/output vector.

The use of a density model comes from the following principle: "every point with the highest density is chosen to be the focal point (prototype) for the antecedent of a fuzzy rule'. By means of this procedure, it is possible to define rules with high descriptive power.

The data density model needs to be updated each time a new data sample is added; logically, density values of the existing prototypes have to be updated. This procedure is also done in a recursive way:

$$D_K^L(z_l^{i^*}) = \frac{(N_k^l - 1)D_{k-1}^l(z_l^{i^*})}{N_k^l - 1 + \left[(N_k^l - 2)\left(\frac{1}{D_{k-1}^l(z_l^{i^*})} - 1\right) + d(z_l^{i^*}, z_k)\right]} \tag{15}$$

The updating of the model procedure is a follows: The density of the new data sample is calculated recursively using formula (14) and after this calculation, updating of the density/potential of each existing prototype is computed recursively using (15). After both densities have been computed/updated, conditions are inspected. If the density of the new data sample is higher than any other previously existing prototypes of the same class *L;* then it is a good candidate to become a prototype of a new rule. It means that this point has enough descriptive power.

$$D_k^L(z_k) > D_k^L\left(z_L^{i^*}\right), \; \forall i^* \in N^L \tag{16}$$

In the previous case, a new fuzzy rule around the new added

prototype is formed. This condition leads to a gradual increase of the sub-rule-base. This is one of the fundaments why this computational process is named "evolving".

$$z^{(N^L+1)*} \leftarrow z_k \quad (17)$$

One the new generated prototype has been created; its new density is set to 1. Its density value is updated, according to the influence of this prototype on each new collected data sample (15):

$$D_k^L\left(z^{(N^L+1)*}\right) \leftarrow 1 \quad (18)$$

It is possible that after adding a rule from a new prototype to the model, this rule would be ambiguous or existing prototypes already describe this behaviour/characteristic. Hence, each time a fuzzy rule is added it is also verified whether any of the existing prototypes of the current sub-rule base are already described by this rule to a degree higher than e^{-1}:

$$\exists i, i = [1, N^L]; \quad \mu_i^j(z^{N^L+1}) > e^{-1} \quad \forall j, j = [1, n] \quad (19)$$

If any of the existing prototypes satisfy condition (19), all rules that correspond to them are removed from the sub-rule-base (indeed, they are replaced for the new formed rule).

The spread of membership functions of the sub-rule-base of the respective class are also recursively updated on the basis of the data distribution:

$$r_k^i = \rho r_{k-1}^i + (1-\rho)\sigma_{k-1}^i; \; i = [1, N^L] \quad (20)$$

Note ρ as learning parameter; it sets how fast the spread of the membership functions will concur to the local scatter of that prototype; the normal used value is 0.5.

V. Experimental Results and Evaluation

In this section the proposed classification scheme for human activity recognition (*eClass_HAR*) which includes recursive PCA and LDA as well as the evolving FRB Classifier, *eClass* is compared with several well known classifiers. These classifiers are grouped in two groups: i) static, off-line classifiers, and ii) on-line and evolving classifiers. The former, generally, provide higher classification rate, but impose heavy requirements on the memory and computational resources. They keep most of the data in the memory and process all of them at once. On the other hand, the latter, process the data sample by sample (on-line) and may be able to adapt their structure (evolve) as a reaction to the variance in the data pattern. As a result of this adaptation and evolution they result in less complex models and due to the on-line processing manner they require significantly less computational resources. For this reason, they use to have a better performance in terms of CPU and memory usage which compensate the somewhat lower accuracy.

All the results of the comparison are tabulated in Table I. As it can be seen, the proposed *eClass_HAR* classifier is very competitive. It has very low memory requirements and CPU usage. Classification rate is also higher than that of any other on-line classifier and very competitive with the off-line classifiers.

TABLE I Comparison Table

Off-line Classifiers	Memory, KB	Max. CPU, %	Class. rate
Hoeffding Adaptive Tree	2.3	10%	81%
Incremental Naïve Bayes	4.868	14%	76.53%
Nearest Neigbour (Euclidean Distance)	3.64	47%	72%
Kstar (Entropic Distance Measure)	4.624	50%	83.55%
Locally-Weighted Learning + Naïve Bayes	1.853	48%	75.16%
On-line Classifiers			
OzaBagASHT (Adaptative Tree)	0.105	18%	70.53%
OzaBagADWIN (Adaptative Windowing + Adaptative Tree)	0.992	13%	70.61%
SingleClassifierDrift (Drift Detection+ Adaptative Tree)	0.012	8%	49.99%
SingleClassifierDrift (Drift Detection + Incremental Naïve Bayes)	0.01	6%	63.41%
AdaHoeffdingOptionTree (Adaptative Tree + Incremental Naïve Bayes)	0.01	8%	70.45%
eClass_HAR (proposed)	**0.02**	**5%**	**71.4%**

Figure 7 shows an evolution graph of the classification rate produced by eClass_HAR. The top plot shows that recognition rate may drop during the first subject of test (the classifier can start with a pre-training on a different set of subjects or 'from scratch'). Following the first subject, the classifier self-tunes its parameters as well as its self-learns its structure (evolves) and, as a result, raises its classification rate. After an increase to values around 70-80% there is some saturation (and even reverse). This is due to the known phenomena in signal and data processing that 'more data not always brings more useful information'.

The bottom plot illustrates the effect of self-learning by temporal re-training. Because of the low computational requirements of the algorithm, it is also possible to update the classifier online by providing in real-time ground truth (activity labels). Several such update periods (with duration of 1 to 2 min) were used in real-time. It is obvious that they helped eClass_HAR to increase the classification rate to 83-84% which surpasses all off-line classifiers. It is due to the fact that the classifier adapts its structure (fuzzy rules) to match better the nature and dynamic of the data stream.

In Table II, a confusion matrix is presented which includes all activities that has been considered. It can be seen that the general activities such as *walking, running*, *lying down* or even sporty ones (such as *bicycling*) are classified with higher rates. On the other hand, there are also two intermediate activities that are composed of several sub-activities. These are *vacuuming* and *stretching*. The classification rates for these activities are fluctuating because they involve several general activities. In order to overtake this issue, larger windows or

feedback from objects via integrated sensors would help to increase the classification rates. This will be studied and reported in a further publication.

TABLE II. CONFUSION MATRIX

	Walking	Running	Bicycling	Standing	Lay down	Vacuuming	Stretching	Sitting
Walking	**89.42**	0	9.12	1.46	0	0	0	0
Running	18.11	**76.38**	3.15	2.36	0	0	0	0
Bicycling	4.67	0	**89.25**	5.61	0	0	0.47	0
Standing	0	0	0	**99.14**	0.43	0	0.43	0
Lay down	0	0	0	9.02	**90.98**	0	0	0
Vacuuming	7.25	0	19.85	10.31	2.29	**58.78**	1.53	0
Stretching	4.17	0	23.33	27.50	0.00	37.50	**7.50**	0
Sitting	0	0	0	1.33	23.11	0	4.44	**71.11**

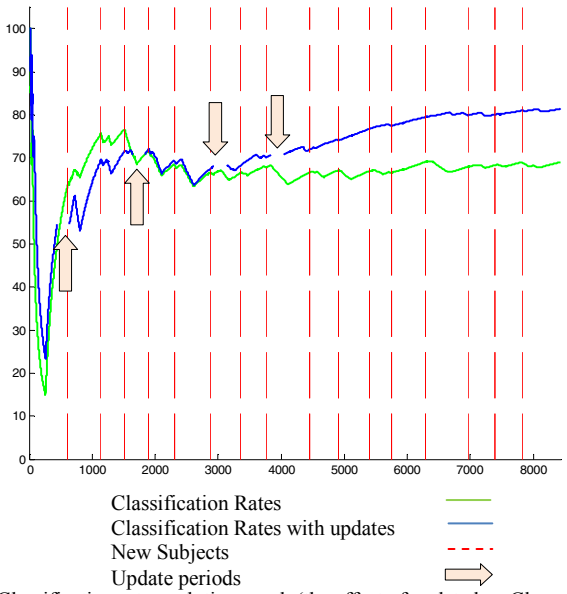

Fig 7. Classification rate evolution graph (the effect of update by eClass_HAR is clearly seen to improve the classification rate despite switching to new subjects).

VI. CONCLUSION

This work presents the ground of a new paradigm of processing HAR data - eHAR. Evaluation and experimentation has shown that results are very promising. This new evolving paradigm applied to the HAR systems provides self-adaptation and self-learning capabilities. In this sense, the classifier is able to evolve its FRB structure to reflect the evolution of the habits and behaviour of a specific human user or a change to a new user (see Figure 7). In this way, eHAR enabled intelligent devices can be personalized. For example, same type of activities (such as *walking*) is usually performed in a different manners by different people depending on age, habits etc. Users with different complexions perform activities with a different intension or energy. The performance of eHAR is very competitive in comparison with existing off-line and incremental approaches (see Table I). Off-line approaches, however, require a huge amount of training data, time and computational resources and less relevant for new users (see also Figure 7). Incremental approaches are outperformed by eHAR, but more importantly, they do not keep an evolving structure as the proposed approach does. The proposed approach is also linguistic (IF-THEN rules can be easily extracted that are human-intelligible.

***Abstract*—Modeling large volumes of flowing data from complex systems motivates rethinking several aspects of the machine learning theory. Data stream mining is concerned with extracting structured knowledge from spatio-temporally correlated data. A profusion of systems and algorithms devoted to this end has been constructed under the conceptual framework of granular computing. This paper outlines a fuzzy set based granular evolving modeling - FBeM - approach for learning from imprecise data. Granulation arises because modeling uncertain data dispenses attention to details. The evolving aspect is fundamental to account endless flows of nonstationary data and structural adaptation of models. Experiments with classic Box-Jenkins and Mackey-Glass benchmarks as well as with actual Global40 bond data suggest that the FBeM approach outperforms alternative approaches.**

***Index Terms*—Data Stream, Evolving System, Granular Computing, Online Learning, Time Series.**

I. Introduction

Continuous data stream processing has become a task of primary importance mainly due to the emergence of industrial sensor networks and small scale computing devices that produce massive amounts of data from their environments. In online settings, large unbounded datasets stream in high frequency and bring uncertainty in their instances. Data streams demand fast single-scan-through-the-data algorithms to identifying and storing essential information. Rethinking many existing data mining and machine learning techniques is necessary to consider structural adaptation of information systems based on sequences of never-seen-before instances.

Recent research on evolving granular systems [1]-[7] lays emphasis on granulated views of detailed data and computing with granules coarser than the data in order to simplify complex real-world problems and provide low cost solutions. As stated by Zadeh [8] and Yao [9], granular computing exploits the tolerance for imprecision, uncertainty and partial truth to achieve tractability, robustness and better rapport with reality. The flexibility of handling dynamics within granular framework enables us to describe granules in different application domains without deep knowledge about the underlying problem. Narrow time and space constraints of online environment as well as understandability requirements inspire granulated views of the data and computing at coarser granularities.

Fuzzy set based evolving modeling FBeM approach belongs to the framework of granular computing because it uses fuzzy-type information granules to construct granular maps that associate input granular datum to output granular datum. Fuzzy granules warrant the generality of the structure of the data and give algorithms with simple math and rules describing their meaning. Building fuzzy sets from uncertain data is the FBeM strategy for lodging noise and disturbances. Basically, FBeM systems look to streaming data under different resolutions and decide when to shift back or forth between simpler or more detailed granularities. Structured representation of data streams by means of a set of fuzzy rules that carry the very essence of the information mirrored in the data is a wealthy contribution.

FBeM benefits from fuzzy granular objects to summarize information-in-motion and assist decision making. Models in FBeM are created on the fly and evolved as requested by the data stream. Supported data sources include sensors, web traffic, audio and video, financial data, climate data, etc. The FBeM learning algorithm creates and fosters granules recursively, steered by the information flow. Eventually, the quotient granular structure may be optimized, refined or coarsed, agreeing with inter-granule relationships.

Structurally, FBeM models combine functional and linguistic fuzzy systems to provide singular and granular approximations of nonstationary functions. Functional fuzzy systems are generally more precise whereas linguistic fuzzy systems are more interpretable. Accuracy and interpretability require tradeoffs and one usually prevails over the other. By combining functional and linguistic systems into a single modeling framework, $\cup$-closure for short, FBeM takes advantage of both systems simultaneously. At the practical level, experts usually prefer that online systems give approximated results as well as tolerance bounds on the approximations.

This paper addresses time series prediction. Examples on predicting the Box-Jenkins, Mackey-Glass and Global40 time series emphasize the complementarity of the functional and linguistic parts of FBeM and illustrate the usefulness of the approach. The FBeM predictor makes no specific assumption about the properties of the data sources in experiments, but rather lets the data stream guide learning freely.

The remainder of this paper is organized as follows. Section II addresses the granular fuzzy modeling approach, the FBeM structure and its characteristics. The associated data-stream-driven recursive learning algorithm is detailed in Section III. Section IV presents results of time series predictions with

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

FBeM playing the role of an evolving predictor. Section V concludes the paper and suggests issues for further investigation.

II. Fuzzy Set Based Evolving Modeling

FBeM is an evolving modeling approach that produces higher level information granules based on more detailed streaming data and recursive learning algorithm. A $\cup$-closure granular structure ensues from more specific local models. Incremental learning procedures cast the FBeM structure to track new concepts, cope with uncertainty, and provide singular and granular approximations of nonlinear functions. FBeM addresses the problem of unbounded databases and the scalability issue. It deals with computationally hard problems outer approximating the solution.

An FBeM model conveys a set of If-Then fuzzy rules extracted from the data. The set of rules means a granular representation of a complex system. Learning in FBeM starts from scratch, i.e., no granules and rules need to be preconceived nor the amount of evolved granules ceiled. Granules and rules are created and adapted on the fly, dynamically, steered by the behavior of the process function over time. Whenever data instances arrive, a decision mechanism is trigged and either granules and rules are inserted into the FBeM structure or parameters of existing granules are adapted.

FBeM rules manage information granules. For each granule there exists a corresponding rule. They are gradually evolved over time. Experts may wish to provide a verbal description about the process using their intuition and experience. Evolving fuzzy modeling, Fig. 1, supports both, learning from data streams and learning from experience.

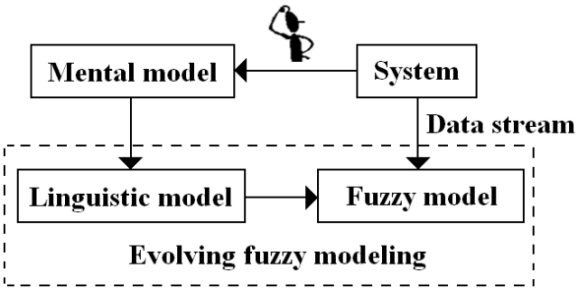

Fig. 1. Evolving fuzzy modeling

In FBeM models, rules R^i governing information granules γ^i are of the type

$$\begin{aligned}\text{IF } &(x_1 \text{ is } A_1^i) \text{ AND...AND } (x_j \text{ is } A_j^i) \text{ AND...AND } (x_n \text{ is } A_n^i)\\ \text{THEN } &(y_1 \text{ is } B_1^i) \quad \text{AND} \quad \bar{y}_1 = p_1^i(x_j \forall j) \quad \text{AND}\\ &\ldots\\ &(y_k \text{ is } B_k^i) \quad \text{AND} \quad \bar{y}_k = p_k^i(x_j \forall j) \quad \text{AND}\\ &\ldots\\ &\underbrace{(y_m \text{ is } B_m^i)}_{\text{linguistic}} \quad \text{AND} \quad \underbrace{\bar{y}_m = p_m^i(x_j \forall j)}_{\text{functional}} \quad ,\end{aligned}$$

where x_j and y_k are variables of the data stream $(x, y)^{[h]}$, $h = 1, ...$; A_j^i and B_k^i are membership functions built in light of the data being available; p_k^i are approximation polynomials. The collection of rules R^i, $i = 1, ..., c$, forms the rule base. Rules born and grow on-demand whenever the structure of the data calls for improvements in the current model. It is worth noting that an FBeM rule combines both, linguistic and functional consequents. The linguistic part of the consequent outer approximates functions and provides interpretability of the results. The functional part of the consequent offers singular approximation of functions and precision. Using this structure, FBeM takes advantage of both, linguistic and functional systems, within a single modeling framework.

A. Rule Antecedent

Granulation of data into fuzzy objects A_j, $j = 1, ..., n$, can be based on grid, tree or scatter partitioning. Grid partition divides attributes in finer parts $\{A_j^1, ..., A_j^c\} \prec A_j$ of equivalent size (top-down approach). Low-level granules represent more specific concepts; $\prec$ is a fine relation. A fixed fuzzy grid is easily interpretable but suffers with concept change, learning in unknown domain, and coexistence of different granularities in the data stream. Tree partition results from cuts of larger granules. Trees are more flexible than grids since sub-trees A_j^i, refinements of A_j, can be sliced independently. Trees may experience the problem of excessive partitioning due to large amount of features and concept drift. Scatter fuzzy partitioning uses subsets A_j^i which can be extended to fuzzy hyperboxes in a product space by means of alpha level sets. The scattering process clusters the data into information granules when appropriate. Granules are positioned at arbitrary locations into the product space. An aspect to be taken into account with scattering-type granulation refers to searching for a suitable amount of partitions, their positions and sizes. Figure 2 illustrates the different types of data granulation.

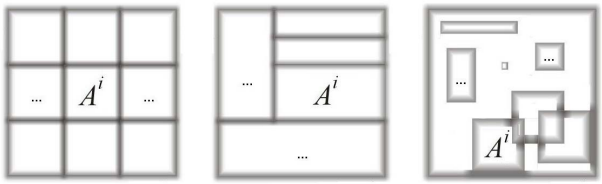

Fig. 2. Grid, tree and scattering granulation

In this work, the FBeM system is equipped with scattering-type granulation mechanism. Accommodating data into conveniently placed and sized granules leaves substantial flexibility for incremental recursive adaptation and freedom in choosing the internal representation of the granules. Online environment claims for opportune creation and rearrangement of fuzzy structural objects from time to time. Essentially, FBeM seizes Gaussian membership functions as formal granular objects to wrap uncertainty in the data of streams. Gaussians are quite easily converted to hyperboxes by means of alpha level sets.

A Gaussian fuzzy subset $A_j^i = \mathcal{G}(\mu_j^i, \sigma_j^i)$ is characterized by a modal value μ_j^i and spread σ_j^i. Features that make the Gaussian representation suitable include: (*i*) easiness of acquiring the necessary parameters. The modal and spread values are captured straightforwardly from a data stream; (*ii*) infinite support does not ignore data. Because data ranges are

unknown before learning, the support of Gaussians extends across the whole domain; (*iii*) smoothness and continuously differentiable surface. On representing uncertainty, Kreinovich [10] under certain assumptions has shown that Gaussian functions are the most adequate choice for representing imprecise measurements.

B. Rule Consequent

Consequent of FBeM rules joins functional and linguistic fuzzy information to approximate actual system outputs and provide tolerance bounds on the approximation. The functional part of the consequent p_k^i comprises singular local functions whereas the linguistic part depicts corresponding information granules B_k^i occurring along the domain of output variables k.

Here we assume affine local functions of the type

$$p_k^i = a_{0k}^i + \sum_{j=1}^{n} a_{jk}^i x_j \tag{1}$$

for all instances measured from the process function f and that activate the fuzzy hyperbox delineated by the granule γ^i. In general, each p_k^i can be of different type and is not required to be linear. For instance, higher order polynomials could be used to approximate f. However, the number of coefficients to be identified increases substantially, especially when the number or variables n is large. FBeM approximands p_k^i estimate f within the domain of granule γ^i. The recursive least mean square (RLMS) algorithm is used to determine the corresponding coefficients a_{jk}^i.

Gaussian representation allows all granules to overlap. Therefore, each rule in FBeM contributes to the system output. FBeM singular output is determined as a weighted mean value over all rules,

$$p_k = \frac{\sum_{i=1}^{c} min(A_1^i, ..., A_n^i) p_k^i}{\sum_{i=1}^{c} min(A_1^i, ..., A_n^i)}. \tag{2}$$

This assure smooth transition between overlapped functions.

Similarly to the approach for embodying antecedent of rules A_j^i, consequents of rules B_k^i benefit from scattering-based granulation and fuzzy hyperboxes to cluster output data streams skillfully. We assume Gaussian fuzzy subsets $B_k^i = \mathcal{G}(\mu_k^i, \sigma_k^i)$ to assemble granular objects in the output space by the same motivations previously described for A_j^i.

Granular output such as B_k^i may enrich decision making and sometimes provides more useful information than the specific numerical output p_k. Whilst being very specific using p_k we risky being incorrect, being unspecific from B_k^i we turn ourselves assure with a certain confidence of being correct. Sacrificing accuracy pays the price of the guarantee of correctness. Information granules tend to reflect the essence of the structure of the underlying data stream and emphasize the interpretability of the result.

III. Recursive Online Learning

FBeM learns online from a stream of instances $(x, y)^{[h]}$, $h = 1, ...$, where $y^{[h]}$ is known given $x^{[h]}$ or will be known at some latter step. Each pair (x, y) is an observation of the target function f. When f changes with the time we say that the function is nonstationary. Modeling nonstationary functions requires tracking time-varying functions $f^{[h]}$. Data streams require choosing a modeling framework and designing recursive algorithm to decide when and how to proceed structural and parametric adaptation of models.

The learning procedure to evolve fuzzy granular systems FBeM can be summarized as follows:

Begin
 Do
  1: Input a new instance $(x, y)^{[h]}$, $h = 1, ...$
  2: Accommodate possible new information
   2.1: Create a new information granule and a rule
   2.2: Adapt existing granules and rules
  3: Discard instance $(x, y)^{[h]}$
  4: Optimize the quotient granular structure
End

Steps 1 and 3 of the learning procedure emphasize the essence of data stream driven algorithms, i.e., instances are read and discarded one at a time. Historical data are dispensable and evolution stands continuously. Granular systems evolve whenever new information appears in the data, step 2. When a new instance does not fit current knowledge, the procedure is to create a new information granule and a rule governing the granule, step 2.1. Conversely, if a new instance fits current knowledge, the procedure adapts existing granules and rules, step 2.2. Eventually, the quotient structure may be optimized, coarsed or refined, according with inter-granules relationships, step 4. Next sections detail the procedure.

A. Creating Rules

In FBeM no rule does necessarily exist before learning starts. Rules are born and evolve when data are input. A new granule γ^{c+1} is created adding a rule R^{c+1} to the current collection of rules $R = \{R^1, ..., R^i, ..., R^c\}$. Whenever the current collection of rules is not sufficiently activated by an instance $x^{[h]}$ so to support a confident output, a new granule is created. FBeM assumes that the instance $x^{[h]}$ brings new information about the process.

Formally, let $\rho \in [0, 1]$ be a threshold value that determines whether to create or adapt rules. If

$$min(A_1^i, ..., A_n^i) \leq \rho \quad \forall i, \tag{3}$$

then the FBeM structure is extended. Note that if ρ is set to 0, then the FBeM system is structurally stable and unable to capture eventual concept shift. Conversely, if ρ equals 1, the FBeM system creates a rule for each new instance, which is not practical. Life-long adaptability is reached through maintaining a condition between the extremes, see Fig. 3.

The role of ρ is crucial in determining the granularity of FBeM models. Choices of ρ impact model accuracy and model transparency, e.g, shifting back and forth between values of ρ

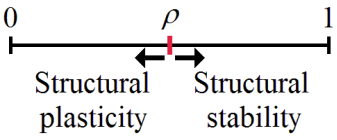

Fig. 3. Plasticity-stability tradeoff and the role ρ in FBeM systems

results in different granulated views of the same process in different levels of detail.

A new granule γ^{c+1} is initially represented by membership functions, A_j^{c+1} and B_k^{c+1}, with parameters

$$\begin{aligned} \mu_j^{c+1} &= x_j^{[h]}, \\ \mu_k^{c+1} &= y_k^{[h]} \text{ and} \\ \sigma_j^{c+1} = \sigma_k^{c+1} &= 1/2\pi, \end{aligned} \tag{4}$$

i.e., the Stigler approach for standard Gaussian functions [11]. The coefficients of local-valued polynomials p_k^{c+1} are set to

$$\begin{aligned} a_{0k}^{c+1} &= y_k^{[h]} \\ a_{jk}^{c+1} &= 0, \ j \neq 0. \end{aligned} \tag{5}$$

With that initial parameterization, preference is given to the design of granules balanced along all dimensions rather than granules with unbalanced geometry. Therefore, FBeM follows the principle of the balanced information granularity [12] and tends to give more specific rules in the sense of Yager [13].

B. Adapting Rules

Rule adaptation consists in (*i*) expand or contract objects A_j^i and B_k^i to accommodate new data; (*ii*) move granules γ^i toward denser regions of data over the input and output domains; and simultaneously (*iii*) adjust coefficients of local approximation functions p_k^i.

A rule R^i is adapted always it is sufficiently activated by a data instance $x^{[h]}$ according to

$$min(A_1^i, ..., A_n^i) > \rho. \tag{6}$$

Geometrically, the instance rests into a region highly influenced by the granule γ^i. To include $x^{[h]}$, FBeM updates the modal value and the spread of membership functions A_j^i recursively as follows:

$$\mu_j^i(\text{new}) = \frac{(\varpi - 1)\mu_j^i(\text{old}) + x_j}{\varpi^i} \tag{7}$$

$$\sigma_j^i(\text{new}) = \frac{(\varpi^i - 1)}{\varpi^i}\sigma_j^i(\text{old}) + \frac{1}{(\varpi^i - 1)}(x_j - \mu_j^i(\text{new}))^2 \tag{8}$$

where ϖ^i stands for the number of times that the granule γ^i has been activated by the data stream. Notice that values are recursively computed and they do not need data accumulation. Also, only the most active rule for $x^{[h]}$ is chosen for adaptation.

Adaptation of fuzzy sets of rules consequents B_k^i uses output data $y_k^{[h]}$. Polynomial coefficients a_{jk}^i are updated based on the standard RLMS algorithm and takes advantage of the new instance that has activated γ^i. Storage of a number of recent instances may be useful to guide alternative coefficient identification algorithms, e.g., data chunks oriented algorithms. However, it comes with some additional cost concerning memory and processing time.

C. Setting the Granularity

The granularity threshold ρ takes values in the unit interval according to prediction errors. Levels of activation of rules for a given input $x^{[h]}$ are compared to the value of $\rho^{[h]}$ to define either structural or parametric changes of FBeM systems. Values of ρ influence the granularity and understandability of local models. In the most general case, FBeM starts learning with an empty rule base and ignorance about the task and the properties of the data. Therefore, it is fair to initialize ρ in an intermediate condition to permit structural stability and plasticity equally. We use $\rho^{[0]} = 0.5$ as default initial value.

Let E be the maximum square error between predictions $p_k(x^{[h]})$ and actual values $y_k^{[h]}$, then

$$e_k = (y_k^{[h]} - p_k(x^{[h]}))^2, \ k = 1, ..., m, \tag{9}$$

and

$$E = max(e_1, ..., e_k, ..., e_m). \tag{10}$$

Assume E_D is the desired prediction error, and let ρ learn values for itself from

$$\rho(\text{new}) = \rho(\text{old}) + \alpha(E_D - E), \tag{11}$$

where α is a learning rate. Decision makers have authority over the value of E_D and may wish it to be zero. Clearly, very small values of E_D conduct ρ to 0 and lead data overfitting. Practice suggests trade-offs to attain acceptable approximation error and useful granular abstractions and compactness of the original dataset into interpretable rules. Recursive adaptation of the granularity of FBeM systems alleviates guesses on how fast and how often the structure of the data changes.

D. Coarsening the Quotient Structure

As the data arrive and granules are identified, relationships between pairs of granules may be strong enough to justify forming a larger and more abstract granule that inherits the essence and nature of the lower level smaller granules. Quantitative analysis of inter-granule relations requires a suitable metric to measure the distance between uncertain objects.

With Gaussian membership functions as internal representatives of granules, the expected distance between uncertain instances belonging to two different granules, say γ^{i_1} and γ^{i_2}, may be given by:

$$\begin{aligned} D(\gamma^{i_1}, \gamma^{i_2}) = \frac{1}{n}\sum_{j=1}^{n} ||\mu_j^{i_1} - \mu_j^{i_2}||^2 + \sigma_j^{i_1} + \\ + \sigma_j^{i_2} - 2\sqrt{\sigma_j^{i_1}\sigma_j^{i_2}}. \end{aligned} \tag{12}$$

This distance has demonstrated to be of fast calculation and more accurate than e.g. distance between means in L^p spaces [14]. The relation considers uncertain data and the specificity of the information, which is in turn inversely proportional to the spread. FBeM combines granules using the lowest entry of $D(.)$ for any pair of granules of the current collection and a decision criterion, which may be either based on a threshold value Δ, or expert judgment in respect of the convenience of the combination.

A new granule γ^i, coarsening of γ^{i_1} and γ^{i_2}, is constituted by Gaussian membership functions with modal value

$$\mu_j^i = \frac{\frac{\sigma_j^{i_1}}{\sigma_j^{i_2}}\mu_j^{i_1} + \frac{\sigma_j^{i_2}}{\sigma_j^{i_1}}\mu_j^{i_2}}{\frac{\sigma_j^{i_1}}{\sigma_j^{i_2}} + \frac{\sigma_j^{i_2}}{\sigma_j^{i_1}}},\ j = 1, ..., n, \tag{13}$$

and spread

$$\sigma_j^i = \sigma_j^{i_1} + \sigma_j^{i_2},\ j = 1, ..., n. \tag{14}$$

These are heuristic relations that basically take into account the proportion of uncertainty of each granule being combined to determinate the location and size of the new granule. The same coarsening relations hold for output variables k. The coefficients of the new local polynomial are

$$a_{jk}^i = \frac{1}{2}(a_{jk}^{i_1} + a_{jk}^{i_2}),\ j = 0, ..., n. \tag{15}$$

Naturally, combining granules reduces the number of rules in FBeM systems and redundancy.

E. Removing Granules

A granule should be removed from the FBeM structure if it seems to be inconsistent with the current concept. Common removing strategies either (*i*) retire stale granules by age, (*ii*) exclude the weakest granules based on error values or (*iii*) delete the most inactive granules. In FBeM, we opt by the strategy of deleting inactive granules. Stale granules may still be useful in the current environment while weak granules are attempted to be invigorated through adapting parameters of singular and granular functions.

FBeM granules are deleted when they become inactive during a number of processing steps, h_r. If the application requires memorization of rare events, or if cyclical drifts are expected, then it may be the case to let all granules live forever. Removing inactive granules periodically helps to keep the rule base updated.

IV. Time Series Prediction

Observing past outcomes of a system to estimate its future behavior: time series prediction is based on the idea that the series carry the potential information needed to predict their future values. Analyzing data produced by actual phenomena can give good insights into the phenomena itself and knowledge about the rules underlying the data.

Chaotic time series are commonly found in natural phenomena [15]-[16]. Models of chaotic time series are useful both to test some hypothesis or theory about the generating phenomena to predict future values of the series, and to decide on mechanisms to control future values. In this avenue, researchers have relied on methods based mainly on looking at trends, moving averages, and graphical patterns to perform predictions. Most of these are linear approaches, e.g. the Box-Jenkins method, linear regression, Kalman filtering, and suffer of some shortcomings [17]. More recently, predicting approaches into the realm of soft computing, e.g. wavelet networks, fuzzy and neuro-fuzzy predictors, have emerged. These approaches have advantages over the traditional statistical ones [18] because generally they are nonlinear in nature thus approximating complex dynamics more easily.

Although classical neural networks and fuzzy systems can approximate any nonlinear continuous function, they usually demand high quality training data and time-consuming off-line learning. Learning system models from data streams in online mode is a challenging task for most of the classical statistical and emergent computing techniques. Therefore, there exists substantial room for further developments of predictors able to perform online learning using data streams.

A. Problem Statement

Forward prediction of a time series can be stated as follows. Given a finite sequence of observations of a discrete time series, namely, $x^{[h]}$, $x^{[h-1]}$, ..., $x^{[h-M]}$, find the continuation $x^{[h+1]}$, $x^{[h+2]}$, ... This involves setting a scalar M and encountering a function f such that a future value, e.g. $x^{[h+1]}$, can be predicted by

$$\hat{x}^{[h+1]} = f(x^{[h]}, x^{[h-1]}, ..., x^{[h-M]}). \tag{16}$$

This is equivalent to modeling the time series as

$$x^{[h+1]} = f(x^{[h]}, x^{[h-1]}, ..., x^{[h-M]}) + \zeta^{[h+1]} \tag{17}$$

with $\zeta^{[h+1]}$ being a white noise process. If the statistics of the time series are non-Gaussian or the time series is the result of some nonlinear operation, the function f is nonlinear. When the characteristics of the time series change with time we say f is nonstationary. Nonlinear nonstationary functions require that online adaptive models identify time varying relations $f^{[h]}$ to perform prediction.

B. Box-Jenkins Gas Furnace

The Box and Jenkins gas furnace benchmark data [19] consist of 9-second-sampling measurements recorded from a combustion process of an oxygen-methane gas mixture. The proportion of gases was randomly changed during the process. The original dataset consists of 296 time indexed instances of the gas flow rate into the furnace $x^{[h]}$ and the concentration of carbon dioxide $y^{[h]}$ emitted.

The task of the FBeM system is to identify the level of carbon dioxide at instant h, $y^{[h]}$, using the preview observation

$y^{[h-1]}$ and the gas rate four steps before $x^{[h-4]}$. This premise prevails in literature works due to positive correlation between these state variables. FBeM scans the data only once to build the system structure and adjust parameters. This is to emulate a data stream. The rule base is initially empty.

Starting parameters to be set include $\alpha = .05$, $E_D = .04$, $\Delta = .08$ and $h_r = 300$. These are values that have particularly worked well for a range of problems. In this experiment we prioritized the compactness and performance of the model.

Training and testing are performed concomitantly from $h = 5$ to 296. First, the estimation $y^{[h]}$ for a given instance $(x^{[h-4]}, y^{[h-1]})$ is provided by the system (testing). Then, parametric and structural adaptation is carried out when necessary (training). Training is necessary whenever an instance carries new information significantly mismatching the current knowledge. Sample-per-sample testing-before-training approach portrays the true online data stream context.

Performance evaluation is made based on the root mean square error:

$$RMSE = \sqrt{\frac{1}{H}\sum_{h=1}^{H}(y^{[h]} - p^{[h]})^2} \tag{18}$$

and the non-dimensional error index:

$$NDEI = \frac{RMSE}{std(y^{[h]} \forall h)}, \tag{19}$$

which ponders the $RMSE$ by the inverse of the standard deviation of the underlying data.

Table I summarizes the results. It emphasizes the FBeM performance against alternative models in identifying levels of carbon dioxide smoked out of the furnace. The results of Table I show that FBeM is the most accurate model according to the $RMSE$ and $NDEI$ indices. FBeM reaches the best performance using an average of 2.61 ± 0.55 rules during learning with a maximum of 3 rules, as shown in Fig. 4. The algorithm does not take advantage from large amount of local processing units as evidenced in the figure, but from a combination of ingredients concerning with structural assumptions, peculiarities of the learning algorithm, and fuzzy granular framework to achieve the performance.

Figure 4 illustrates FBeM one-step singular and granular predictions for the gas furnace problem. The granular prediction $\mu \pm \sigma$ associated to the more meaningful singular prediction p is an important information which may help decision making giving an idea about a range of values around the prediction.

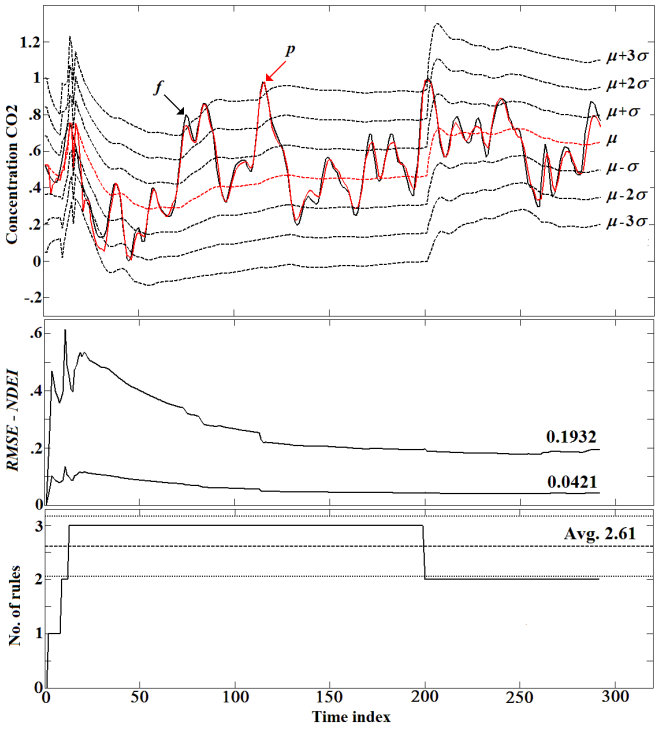

Fig. 4. FBeM singular and granular one-step prediction, and evolution of the error indices and number of rules for the Box and Jenkins gas furnace data

Rules of particular interest can be displayed at any time. For example, a rule at $h = 296$ is:

R^i: IF $x^{[h-4]}$ is $\mathcal{G}(.4192, .1269)$ AND $y^{[h-1]}$ is $\mathcal{G}(.6523, .1516)$ THEN $y^{[h]}$ is $\mathcal{G}(.6503, .1497)$ AND $p^i = .2514 - .0656x^{[h-4]} + .8128y^{[h-1]}$.

C. Mackey-Glass

The Mackey-Glass equation described by:

$$\frac{dx}{dt} = \frac{Ax^{[t-\tau]}}{1 + (x^{[t-\tau]})^C} - Bx^{[t]}, \; A, B, C > 0, \tag{20}$$

is a time delay differential equation that behaves chaotically or periodically depending on the values of its parameters and on the time delay τ. The equation may represent a model of feedback control systems.

The task of FBeM is constructing a function:

$$x^{[t+\xi]} = p(x^{[t]}, x^{[t-\Delta]}, ..., x^{[t-D\Delta]}). \tag{21}$$

Similar to many studies on this series we admit $\xi = 85$, $\Delta = 6$, $D = 3$; and $A = 0.2$, $B = 0.1$, $C = 10$, $\tau = 17$ for the parameters of the Mackey-Glass equation to generate a state

vector. Data are presented sequentially to the FBeM system one at a time. The system starts learning from scratch, with no rules nor pre-training.

To evaluate the effect of different parameterizations, we conduct two experiments. Firstly, FBeM^1 prioritizes a compact structure and adopts $\alpha = .05$, $E_D = .06$, $\Delta = .2$ and $h_r = 2000$. Second, FBeM^2 focuses high accuracy at the price of a larger structure and employs $\alpha = .1$, $E_D = .01$, $\Delta = .1$ and $h_r = 8000$. We resort to the sample-per-sample testing-before-training approach from $h = 105$ to $h = 11898$. Table II shows the performance of the FBeM models and that of other online models for the Mackey-Glass prediction problem.

Table II shows that FBeM^1 is supported by a relatively compact structure, 3.23 ± 0.56 rules with a maximum of 5 rules, similar to eTS, IBeM and xTS, to give competitive results in terms of the $RMSE$ and $NDEI$ indices. Figure 5 details the results of this experiment. The figure illustrates the singular prediction p of the Mackey-Glass series provided by FBeM^1, and the evolution of the number of rules and error indices during the learning steps. Granular prediction is omitted for clarity. Lastly, FBeM^2 makes use of 27.87 ± 4.11 rules with a maximum of 33 rules to sponsor the smallest prediction error and overcome the performance of the remaining approaches.

In case equation f represents the production of white blood cells to defend the human body against pathogen, as in Glass and Mackey [29], FBeM granular prediction may represent, for example, the range of normal activity of hematopoietic stem cells. The effectiveness of the approach in predicting chaotic time series without prior knowledge about the data is clearly verified in this experiment.

D. Brazilian Global40

Currently, the most negotiated Brazilian sovereign bonds are the Global 2040, which were issued in 2000, with 40 years maturity. Price movements define the bond rentability: higher prices imply lower rentability. Thus, if investors believe that the bond price will increase and the rentability decrease, they should buy the bond before this expected movement. On the other hand, if the investors believe the bond price will decrease and the rentability increase, they should behave contrariwise. Predicting bond price movements is a crux issue from the point of view of the investors on their portfolio decisions.

Variable selection may enhance the prediction ability of FBeM as well as provide useful insights about the data source. Time series carry a limited number of indispensable variables, while the remainders tend to confuse the underlying predictor. The input variables of FBeM may be M consecutive measurements of the time series or we may perform selection of $n < M$ variables, which are not necessarily sequential. In this experiment, variables were chosen based on a partial autocorrelation function of the Global40 bond price, similar to [30]. Coincidently, autocorrelation analysis has suggested $x^{[h-1]}$ and $x^{[h]}$ for one step ahead, $x^{[h+1]}$, prediction.

To evaluate the relative performance of the FBeM predictor, we consider daily bond prices from August 11, 2000 to January 16, 2007, testing-before-training in a sample-per-sample basis, and the following parameters: $\alpha = .03$, $E_D = .01$, $\Delta = .1$ and $h_r = 500$. Table III shows the results on one-step-ahead prediction of the bond price. The result using FBeM makes use of 2.25 ± 1.05 rules, with a high of 4 rules during steps $h = 863$ to $h = 1149$ as portrayed in Fig. 6. The FBeM approach achieved error indices equivalent to the ePL approach employing a structure almost as compact as ePL. However, FBeM offers additional information concerning with

V. Conclusion

This work has suggested fuzzy set based evolving modeling as a framework to learn from online data streams. The FBeM algorithm recursively granulates data instances to output singular and linguistic granular approximations of nonstationary functions. The system combines good accuracy of functional fuzzy models with the advantage of better semantic interpretation of linguistic models. The usefulness of the FBeM approach in prediction was verified using the classic benchmarks Box-Jenkins and Mackey-Glass and actual data of the Global40 time series. Comparisons with alternative approaches have shown the effectiveness of the FBeM modeling approach. Further work shall discuss different forms of manifestation of information granules in data streams and the role FBeM to capture the essence of the information in the data.

***Abstract*—In this paper a new evolving parameter estimation algorithm for a local model network under special consideration of combustion engine modelling is presented. For practical applications computational speed, incorporation of prior knowledge and the interpretability of the local models is of great interest. Accordingly, a robust and efficient online training algorithm with a particular focus on computational requirements involved in dynamic system identification of complex nonlinear processes is presented. The incremental construction of the model tree allows to gradually increase the model complexity while a proper initialisation of new model parameters is easily possible. The proposed evolving local model network is validated using real measurement data from a state-of-the-art 4-cylinder EURO5 diesel engine.**

***Index Terms*—System identification, local model network, online learning, engine modelling**

I. Introduction

Evolving model structures are becoming a more and more essential factor in the automotive industry. Recent publications have addressed automatic adaptation techniques and evolving schemes for data-based modelling, e. g. [1], [2], [3], [4]. Such models are trained *online* and it is necessary to adjust, refine, extend, and evolve the already trained model when new data are available, [1]. The model is evolved sample by sample and its complexity is gradually increased due to the fact that it is not practicable to completely rebuild the model using all measurement data. Accordingly, new rules are created and an update of the model parameters during the operation of the system is required.

In the context of data-driven modelling, fuzzy systems are an established approach for nonlinear system identification. These so-called *grey-box* models allow to reduce the model complexity, if physical (or other) insight into the nature of the object is available, [5]. In automotive industry, *local model networks* (LMN) are a widely used concept, e. g. [6], [7]. Local model networks offer a versatile structure for the identification of nonlinear static and dynamic systems and provide not only accurate but also *interpretable* models and therefore allow a better understanding of the true system than pure black-box models, e. g. [8], [9], [10].

Especially in engine modelling, evolving model structures are of great interest in order to provide an online model of the engine during testbed runs, see e. g. [11]. Internal combustion (IC) engines are typically calibrated on testbeds which involves the determination of a number of functional relationships between measured input and output data. In this context, the *design of experiments* (DoE) for testbed runs is closely related to the model adaptation. Generally, *optimal* experiment design is targeted to retrieve the information which is required to properly parameterise a model with as little effort as possible, [12]. Typically, the experiment design is performed offline and prior to the testbed run based on prior knowledge about the process under consideration. The availability of an evolving model allows to optimise the experiment design online (model based) during the testbed run. Accordingly, *model based DoE* employs an intermediate model in combination with a statistical criterion to design optimal experiments, e. g. [13]. Model based DoE can also be used to take into account local process limits in terms of engine protection and combustion stability (i. e. the driveable area of the engine) which are not known in advance. In such cases a model which has been trained online allows to predict and avoid the violation of certain operational limits.

The main contribution of the present paper is a new evolving optimisation algorithm for a local model network that can build the model incrementally whenever new data are available. Important requirements for the practical applicability in engine modelling are low computational effort, proper initialisation, and robustness of the optimisation algorithm. The proposed online training algorithm is based on the local model network presented in [14]. Here, the global process description is obtained by recursively bisecting the input space. The bisection is carried out in such a way that the nonlinear process can reasonably accurately be described by the local models in the resulting subdomains. The use of an incremental tree has proven to be an effective model building strategy in both offline and online modelling, e. g. [15], [16], [17]. An important advantage of these hierarchically constructed models is their robustness and training speed.

The proposed algorithm is not restricted to axis orthogonal splits and offers a higher flexibility compared to e. g. [15], [6]. Especially in online system identification, where the operating range of a process (e. g. driveable area of the engine) is generally not known a priori, arbitrary (axis oblique) splits are required for an optimal partitioning of the input space. Thereby, the incremental construction of the model tree allows

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

to gradually increase the model complexity while a proper initialisation of new model parameters is easily possible. A difficult part in online learning of incremental trees is the decision when to grow the tree, see [16]. In this paper a splitting rule based on statistical measures is proposed.

The remainder of this paper is structured as follows: In section II the architecture of the local model network is shortly reviewed. In section III the online training algorithm is presented. In section IV a practical application of *dynamic* online system identification using real measurement data from a state-of-the-art diesel engine is presented.

II. Local Model Network Architecture

Local model networks interpolate between different local models, each valid in a certain region of a input space. Each local model - indicated by subscript i - consists of two parts: The *validity function* $\Phi_i(\tilde{\boldsymbol{x}}(k))$ and its *model parameter vector* $\boldsymbol{\theta}_i$. Thereby, Φ_i defines the region of validity of the i-th local model.

The *local* estimate for the output is obtained by

$$\hat{y}_i(k) = \boldsymbol{x}^T(k)\boldsymbol{\theta}_i, \tag{1}$$

where $\boldsymbol{x}^T(k)$ denotes the regressor vector. In dynamic system identification, the regressor vector $\boldsymbol{x}(k)$ comprises past system inputs and outputs. For static models, the regressor vector contains arbitrary functions (e. g. polynomials) of the input signals.

All local estimations $\hat{y}_i(k)$ are used to form the global model output $\hat{y}(k)$ by weighted aggregation

$$\hat{y}(k) = \sum_{i=1}^{M} \Phi_i(k)\hat{y}_i(k), \tag{2}$$

where

$$\Phi_i(k) = \Phi_i(\tilde{\boldsymbol{x}}(k)) \tag{3}$$

and M denotes the number of local linear models. Thereby, the elements in $\tilde{\boldsymbol{x}}(k)$ span the so-called partition space and are chosen on the basis of prior knowledge about the process and the expected structure of its nonlinearities. Especially in dynamic identification, the dimension of the partition space and furthermore the complexity of the optimisation problem can thus be reduced dramatically when prior knowledge about the nonlinear behaviour of the process is available, see also [6].

The computation of the validity functions Φ_i is based on a logistic discriminant tree. Exemplarily, a hierarchical model tree with three local models is depicted in Fig. 1. Each node corresponds to a split of the partition space into two parts and the free ends of the branches represent the actual local models with their parameter vector $\boldsymbol{\theta}_i$ and their validity functions Φ_i. The overall nonlinear model thus comprises M local models and $M-1$ nodes which determine their regions of validity.

Generally, for the representation of the discriminant function in the d-th node a logistic sigmoid activation function is chosen, c. f. [18]:

$$\varphi_d(\tilde{\boldsymbol{x}}(k)) = \frac{1}{1+\exp(-a_d(\tilde{\boldsymbol{x}}(k)))} \tag{4}$$

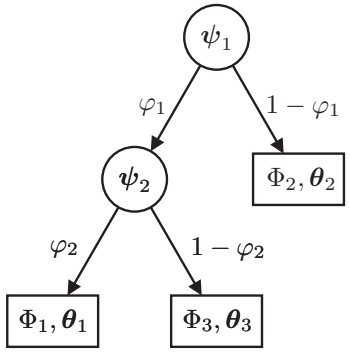

Fig. 1. Logistic discriminant tree

with

$$a_d(\tilde{\boldsymbol{x}}(k)) = \begin{bmatrix}1 & \tilde{\boldsymbol{x}}^T(k)\end{bmatrix}\begin{bmatrix}\psi_{d0}\\ \tilde{\boldsymbol{\psi}}_d\end{bmatrix}. \tag{5}$$

Here, $\tilde{\boldsymbol{\psi}}_d^T = \begin{bmatrix}\psi_{d1} \dots & \psi_{dp}\end{bmatrix}$ denotes the weight vector and ψ_{d0} is called bias term. The discriminant functions φ_d are used to calculate the validity functions Φ_i, c. f. [19].

The validity functions for the layout in Fig. 1 are obtained by

$$\Phi_1 = \varphi_1\varphi_2, \tag{6}$$

$$\Phi_2 = 1-\varphi_1, \tag{7}$$

$$\Phi_3 = \varphi_1(1-\varphi_2). \tag{8}$$

A main advantage of this hierarchical discriminant tree is that a partition of unity throughout the partition space is guaranteed and no normalisation side effects like reactivations can occur.

III. Evolving Local Model Network

An incremental model construction allows to gradually increase the complexity of the local model network: When the number of local models M is increased by one, the *worst* local model (indexed by l) of the logistic discriminant tree in Fig. 1 is replaced by a new node and two adjoining local models are appended, see Fig. 2. On the one hand this strategy allows a proper initialisation of the new model parameters while on the other hand the computational demand is low.

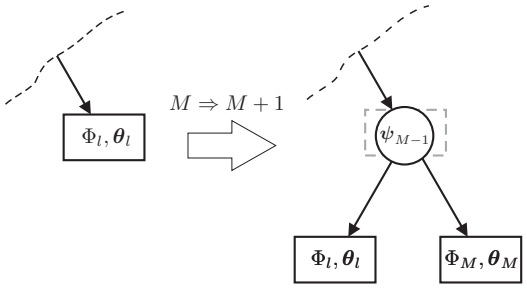

Fig. 2. Incremental tree construction

In order to reduce the computational demand, only the weight vector of the new node $\boldsymbol{\psi}_{M-1}$ is optimised while

all other weight vectors are retained. A disadvantage of this strategy is that the computation of the weight vector $\boldsymbol{\psi}_{M-1}$ and the consequent parameters substantially depends on previous splits. Due to the fact that each split is optimised subject to previous splits, a *global* optimum can generally not be guaranteed. However, a global (simultaneous) optimisation of *all* weight vectors and local model parameters of the LMN results in a much higher computational effort which is not desired and inapplicable for online engine modelling.

A flowchart of the *online* training algorithm is depicted in Fig. 3. The online identification task comprises four subtasks:

- *Build initial model:* The construction of the initial model is based on an *initial data block* using the batch training algorithm, c. f. [14].
- *Split optimisation and parameter update (see section III-A):* Optimisation *and* update of the actual node (discriminant function). Update of the consequent parameters of each local model (LM) using the new data sample.
- *Model extension (see section III-B):* Statistical assessment of the actual LMN in order to decide whether to extend the model tree.
- *Initialisation of new LMs (see section III-C):* Determine a proper initialisation of new parameters.

A. Split Optimisation and Parameter Update

In the online training, the *actual* number of data - indicated by N - is increased by one in each loop. The online adaptation of the local model network can be divided into two subtasks:

1) *Partitioning process:* Find an optimal weight vector $\boldsymbol{\psi}_{M-1}^T = \begin{bmatrix} \psi_{M-1,0} & \tilde{\boldsymbol{\psi}}_{M-1}^T \end{bmatrix}$ for the new node.
2) *Local model parameter estimation:* Update of the consequent parameters of *all* local models.

In this section, the optimisation of the actual (most recent) split and the parameter update of all local model parameters is presented.

1) Partitioning Process: Due to the incremental model construction, only the weight vector of the actual node $\boldsymbol{\psi}_{M-1}$ is optimised while all other weight vectors are retained. The optimisation of the weight vector is based on the cost function

$$\begin{aligned} J &= \frac{1}{2}\sum_{k=1}^{N} \Phi_l(k)\left[y(k)-\hat{y}_l(k)\right]^2 + \\ &\quad +\Phi_M(k)\left[y(k)-\hat{y}_M(k)\right]^2 \\ &= \frac{1}{2}\sum_{k=1}^{N} e_l^2(k) + e_M^2(k), \end{aligned} \tag{9}$$

where

$$e_l(k) = \sqrt{\Phi_l(k)}\left[y(k)-\hat{y}_l(k)\right] \tag{10}$$

and

$$e_M(k) = \sqrt{\Phi_M(k)}\left[y(k)-\hat{y}_M(k)\right] \tag{11}$$

are the *weighted* local prediction errors of the adjoining models l and M, respectively.

Obviously, the weight vector $\boldsymbol{\psi}_{M-1}$ and the two adjoining models with their local model parameters $\boldsymbol{\theta}_l$, $\boldsymbol{\theta}_M$ have to be optimised simultaneously, see also Fig. 1.

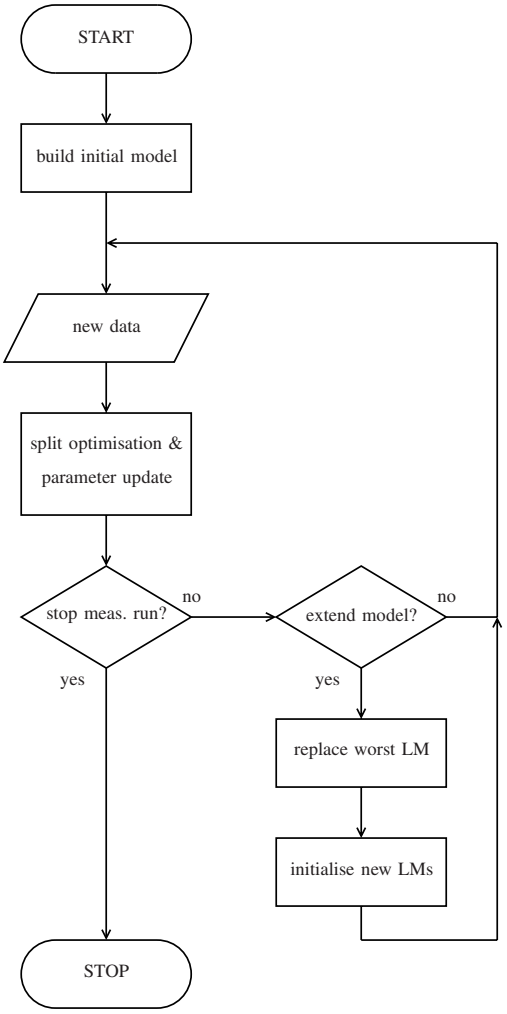

Fig. 3. Flowchart diagram for the online training

With $\Phi_l = \Phi_l(\boldsymbol{\psi}_{M-1})$ and $\Phi_M = \Phi_M(\boldsymbol{\psi}_{M-1})$ a direct solution for the optimisation problem with respect to $\boldsymbol{\theta}_l$, $\boldsymbol{\theta}_M$ and $\boldsymbol{\psi}_{M-1}$ is not possible because the computation of the consequent parameters $\boldsymbol{\theta}_l$ and $\boldsymbol{\theta}_M$ depends on the weight vector $\boldsymbol{\psi}_{M-1}$ and vice versa. Consequently, a *nonlinear least squares* method is applied for the minimisation of (9). A recursive formulation of the nonlinear least squares algorithm, in order to reduce the computational demand, can be found in e. g. [20].

Another important issue in fuzzy modelling is the interpretability of the local models, [21], [10]. Only consequent parameters obtained by local estimation (weighted least squares) allow the interpretation of the consequent parameters as a local linearisation of the nonlinear system, [9]. The particular choice of (9) aims at a *locally* weighted least squares optimisation of the consequent parameters so that local interpretability is conserved.

2) Parameter Update: While the update of the consequent parameters $\boldsymbol{\theta}_l$ and $\boldsymbol{\theta}_M$ is based on a nonlinear least squares algorithm, the online training of the local model network also

requires the update of all other local model parameters when a new observation is available. Due to the fact that the validity functions, i. e. the weight vectors $\boldsymbol{\psi}_j, j = 1, \ldots, M-2$, of these models are not modified during the split optimisation, these parameters can be updated using the conventional weighted least squares method. A recursive formulation of the weighted least squares algorithm is easily possible which helps to reduce the computational demand, see e. g. [22].

B. Model Extension

In online learning the number of local models strictly depends on the currently available data. Too many local models can result in overfitting or even loss of identifiability while a simplistic model yields an inaccurate description of the process. In this section a statistically motivated splitting rule is proposed in order to automatically detect when an extension of the model structure is reasonable.

The splitting rule is based on the assumption that the residual distribution of each local linear model follows a χ^2 distribution for Gaussian white noise and a proper choice of the model structure, i. e. the number of local models.

Using the χ^2 distribution the confidence interval for the variance of the model error of the i-th local model $\sigma_{e_i}^2$ is obtained as

$$\frac{DOF_i}{\chi^2_{1-\alpha/2,DOF_i}} s_i^2 \leq \sigma_{e_i}^2 \leq \frac{DOF_i}{\chi^2_{\alpha/2,DOF_i}} s_i^2, \qquad (12)$$

with the error probability α and the remaining statistical degrees of freedom DOF_i. In (12) s_i^2 is the estimated variance of the model error based on the currently available data and $\sigma_{e_i}^2$ the *unknown* true variance.

In the online training the estimated variance and the degrees of freedom change over time as the number of data increases, i. e. in each iteration step new data (a new observation) are available. The χ^2 distribution is used to determine if a local model of the updated LMN performs significantly worse using the additional data sample. The hypothesis that the current local model structure properly describes the process in its region of validity is accepted with an error probability α, if the estimated variance does not exceed the corresponding confidence interval. Otherwise the hypothesis is rejected and the corresponding local model is replaced by two new local models.

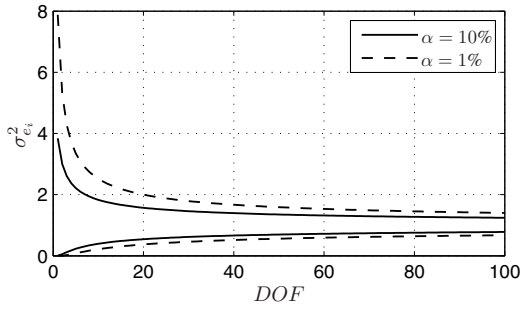

Fig. 4. Upper and lower bounds of the χ^2 distribution

In Fig. 4 the upper and lower bounds of the χ^2 distribution are depicted for $\alpha = 1\%$ and $\alpha = 10\%$, respectively. In the χ^2 distribution the probability α is a good means to control regularisation. Accordingly, a small error probability results in a small number of local models while the robustness of the parameter estimation process is increased. An increased error probability will in turn yield a more accurate description of the process with a higher number of local models while the robustness is decreased (overfitting).

C. Initialisation of new Local Models

The robustness of the training algorithm is closely related to the initialisation of new parameters when the model complexity is increased. Thus the initialisation of new local models, i. e. the consequent parameters $\boldsymbol{\theta}_l$ and $\boldsymbol{\theta}_M$ as well as the weight vector of the most recent split $\boldsymbol{\psi}_{M-1}$, must not depend on a random variables.

The incremental model construction allows a proper initialisation of these parameters: The weight vector $\boldsymbol{\psi}_{M-1}$ of new node is chosen based on the weighted mean and the weighted covariance matrix of the observations with respect to the worst local model. The initialisation of the local model parameters $\boldsymbol{\theta}_l$ and $\boldsymbol{\theta}_M$ is then based on the conventional weighted least squares algorithm.

IV. Example

In order to demonstrate the capabilities of the proposed evolving model tree construction scheme the online training of a complex *dynamic* nonlinear local model network using real measurement data from a state-of-the-art 4-cylinder EURO5 diesel engine is presented.

The inputs into the system are *engine speed* N [rpm] and *main injection mass* Q [mg/stroke]. Exemplarily, the *turbine speed* N_{Turbo} [rpm] is considered as the system output $y(k)$. Accordingly, the input-output dynamics are described by the nonlinear difference equation

$$N_{Turbo}(k) = f\left(\boldsymbol{x}(k)\right)$$

where the dynamic regressor vector in (1) is made up according to

$$\boldsymbol{x}(k) = \begin{bmatrix} 1 \\ Q(k-1) \\ \vdots \\ Q(k-m) \\ N(k-1) \\ \vdots \\ N(k-m) \\ N_{Turbo}(k-1) \\ \vdots \\ N_{Turbo}(k-m) \end{bmatrix}.$$

The dynamic system order for the local models is chosen as $m = 3$.

The dynamic input and output data are depicted in Fig. 5. All in all 5000 data samples are available for the training of the local model network. Here, amplitude modulated pseudo random binary (APRB) signals are used for the input signals in order to ensure proper excitation of the system, see e. g. [6],

[23]. The bandwidth of the input signals is defined by their minimum and maximum hold times which are chosen in consideration of the expected system dynamics.

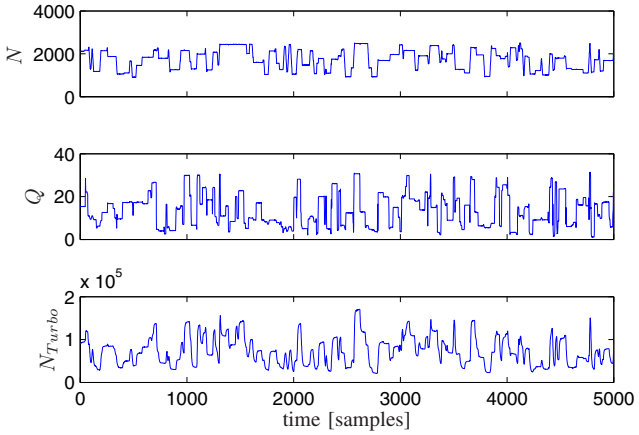

Fig. 5. Measured input and output data

The *initial* local model network with two local models is constructed using the first 1000 samples, see Fig. 6. The partition space is spanned by $N(k-1)$ and $Q(k-1)$ which are the main influence parameters on the highly nonlinear behaviour of the engine. In Fig. 6 a contour plot of the membership functions indicates the region of validity of the two local models. The trajectory of the initial data record is depicted in grey.

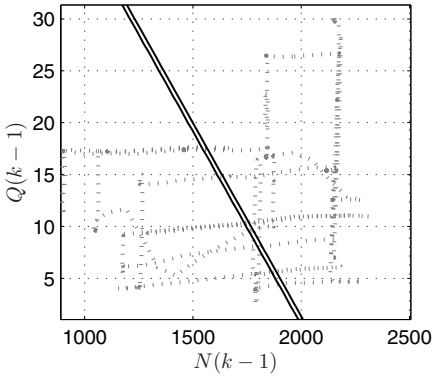

Fig. 6. Initial engine model with 1000 samples

In Fig. 7 the evolvement of the first two local models during the online training procedure is illustrated, c. f. Fig. 6. The validity functions (black) are continuously adapted to the growing data base using the online optimisation algorithm from section III-A. The lower plot in Fig. 7 illustrates how the estimated variances $\sigma^2_{e_i}$ of the two local models evolve as the number of data and the operating range of the LMN increase. Obviously, the estimated variance of the second local model exceeds the upper bound of the χ^2 distribution at some stage. According to section III-B, the second local model is then replaced by two new models in the next iteration step. Their validity functions are indicated by the dashed black contour lines.

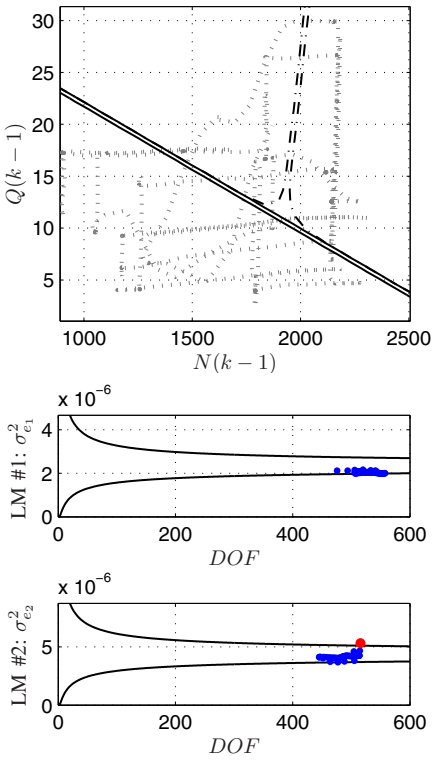

Fig. 7. Online training: Validity functions and χ^2 criterion

The sample-wise online training of the evolving local model tree using the χ^2 splitting rule from section III-B with $\alpha = 1\%$ results in a local model network with seven local models. The final model with the shape and extent of each validity function (black) as well as the training data record (grey) are shown in Fig. 8.

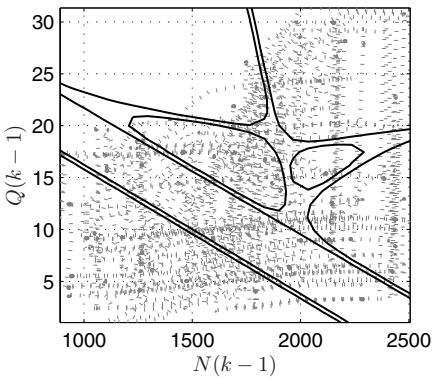

Fig. 8. Final model with 5000 samples and 7 local models

The performance of the local model network obtained from online training is highlighted using a dynamic generalisation data record. In Fig. 9 a section of the measured output and the simulated model output are compared. It is clearly visible that

the LMN accurately describes the nonlinear behaviour of the engine throughout the operating range of the engine.

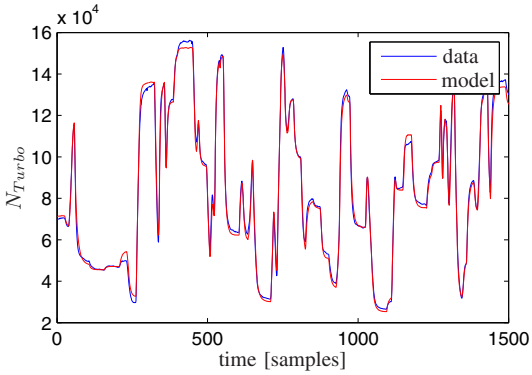

Fig. 9. Simulated model output using generalisation data

In table I the performance of the models obtained from the evolving online training and the classic batch algorithm is indicated by means of the R^2 statistics

$$R^2 = 1 - \frac{\sum_{k=1}^{N} (y(k) - \hat{y}(k))^2}{\sum_{k=1}^{N} (y(k) - \bar{y})^2}, \qquad (13)$$

where $\bar{y}$ is the mean value of all $y(k)$.

R^2	0.99277	0.99353

V. CONCLUSION AND OUTLOOK

In this paper an evolving local model network concept especially suited for engine modelling is presented. Especially in dynamic system identification the computational speed is an important requirement for online training. The incremental model construction allows a proper initialisation of the model parameters in order to increase the robustness while the computational demand is low. A new evolving optimisation algorithm for the online training of the local model network is proposed where the particular choice of the cost function for the split optimisation aims at obtaining locally interpretable models.

A statistically motivated splitting rule is proposed in order to automatically detect when an extension of the model structure is reasonable.

The practical applicability of the evolving local model network is validated by means of real dynamic measurement data from a state-of-the-art 4-cylinder diesel engine.

Rough Set Approach to User Modeling

Binghui Helen Wu

Swhelen21@hotmail.com

***Abstract*—The intelligence of an interactive system is exhibited through the evolution of its intelligent behaviors, namely, its effectiveness in performing tasks and its adaptiveness to both variations of task conditions and different users. Having a good user modeling component in any intelligent interactive system becomes crucial to the performance of that system. We have developed a computational approach to building intelligent tutoring systems (ITS) in conjunction with our framework for ITS [1]. This computational approach employs two exploratory AI techniques—a hybrid knowledge representation model as an implementation mechanism of ITS and a rough set [2] approximation approach to user modeling. In this article, we focus on discussing the rough set approach to user modeling of the system in detail.**

Keywords-rough sets; user modeling; computational approach to knowledge representations; intelligent tutoring systems

I. INTRODUCTION

Research in building intelligent computer assisted learning environments (more often known as intelligent tutoring systems, ITS) has been ongoing for more than 20-25 years. Existing ITS research, including well-known tutoring systems such as Clancey's GUIDON and its revision [3], Anderson's ACT Tutors [4], Johnson's PROUST [5], and many others, have shown that the key feature of tutoring systems is their ability to diagnose students' misconceptions in learning during a tutoring process and, based upon those diagnoses, to provide students with remedial learning. However, many psychological questions underlying learning, teaching and understanding have not received convincing answers. In addition, enormous difficulties in creating a precise machine representation of the students' learning stages and in identifying students' possible misconceptions lend to a diversification of ITS research. Many urged the importance of evaluation of such systems, for example, the special issue on evaluation in IJ. of Artificial intelligence in Education (1993) 4(2/3).

In spite of difficulties in existing ITS research, we believe that tutoring by computers is an attractive alternative to human tutors in providing assistance, both to instructors who are responsible for students' learning and to individual students who are supposed to learn the subject to be taught, especially when human tutors are not available or not willing to spend more time. In fact, one study has shown [6], tutoring by a human instructor–a one-on-one help session to improve an individual student's learning—is more effective than that in a classroom instruction setting.

Aiming at building an effective tutoring system, which is as adaptable to different students and instructors as possible, we have proposed a framework (ATA, i.e., Artificial Teaching Assistant) for ITS [1] based on the constructivist theory of knowledge, learning, and understanding. Constructivism is a model of how learning takes place. It has drawn considerable attention among science education researchers and ITS researchers who aim at building computer based learning environment [7] [8] [9]. In the constructivist view, learning is an active process of constructing a conceptual framework. Although sharing the basic view of learning, different interpretations of this view result in different approaches to science education. Our understanding of constructivist theory is based on Cobern's interpretation [10], in which our ATA framework for ITS reflects.

This ATA framework consists of three models—presentation, question, and test models—attempting to capture the two most important aspects of a tutoring process. One of the two aspects is how the presented knowledge is organized, so that it can be presented automatically and effectively. The other is how questions and tests are to be given to ensure that students have developed a meaningful interpretation of the presented knowledge and can apply it to solve related problems. To exemplify our ATA framework for ITS, we have been implementing a prototyped tutoring system with number systems, a topic in Foundations of Computer Science [11], as its domain. A systematic approach has been developed for the implementation. In this paper, we first give an overview of our computational approach to building ITS, in which a hybrid knowledge representation model (SG, i.e., Graph-Sets) provides both an automated presentation process of domain knowledge and automated interpretation of student learning and/or understanding of the presented knowledge. Then, we present a novel approach to user modeling—rough set approximation—that we have used in the user modeling component of the implementation of our tutoring system.

II. OVERVIEW OF OUR COMPUTATIONAL APPROACH TO ITS

Our hybrid representation model (GS model), which mixes two levels of knowledge representation schemes, subject network—a fully connected, directed, and acyclic graph with a semantic interpretation and "knowledge base"—a two tuple, a universal discourse and a class of relations imposed on the universal set. There are two types of knowledge possessed by the paradigm of our tutoring system: the knowledge of the subject materials to be represented and the knowledge of how to make an effective presentation dynamically based on various student responses during tutoring so that the quality of tutoring can be ensured. Based on these, we use a variation of semantic networks (named subject network), as the coarse grain of representation of domain knowledge; and we use "knowledge base" (coined by Pawlak, see the chapter in [2]), as the fine grain representation of the domain knowledge.

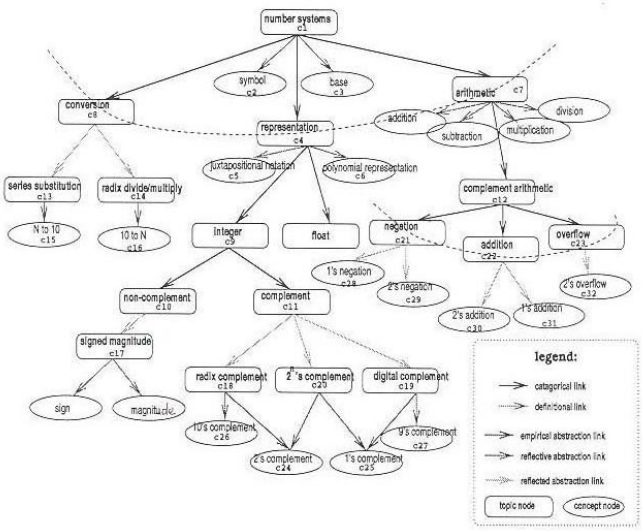

Figure 1: An Example to illustrate the ATA representation model of our framework for ITS (see Appendix for a clear version)

A. Knowledge Representation Scheme I: Subject Network

In semantic networks, knowledge is represented in terms of nodes, which can represent objects, and are connected by links that represent the interrelations among nodes. This graphical form of knowledge representation is most appealing and has long been used in AI systems including ITS [12] [13]. In the context of our tutoring system where abstract knowledge has been chosen as the domain of tutoring materials, naturally, we have adopted this knowledge representation scheme. However, there are two important features that have distinguished our way of using this scheme.

First, as shown in Figure 1, there are two different kinds of nodes: topic and concept, in which knowledge of the subject material has been stored. There are also two kinds of links to capture two kinds of relations among nodes: inclusion and dependency. An inclusion link describes the relation between two nodes in which the destination node always elaborates its source node (i.e., is a subtopic of the topic represented in the source node). On the other hand, a dependency link describes a dependency relation between two nodes with two possibilities. If a topic node depends on a concept node, the concept is used to define the topic node; and, if a dependency link exists between two topic nodes, the source node would be the prerequisite topic of the destination node. For example (see Figure 1), the topic, *number systems*, can be defined using concepts, *symbol* and *base* (dependency) and can be elaborated with subtopics, *representation*, *arithmetic*, and conversion of numbers with different bases (inclusion). Further, in our number systems example, in order to introduce the subtopic *conversion* (between numbers with different bases), we need to have introduced how a number is represented (*representation*). Therefore, the relation between number representation and number conversion is a dependency relation. Also, note that both topic and concept nodes are used to store knowledge in a subject network; they are both literally concepts. The difference between the two, besides their names, is that the concept in a concept node in a subject network is atomic in the sense that it doesn't need to be further elaborated. Therefore, concept nodes are minimal elements of subject graphs.

Second, in addition to the nodes and links described above, special kinds of nodes depicted in the dashed notations and named supplementary nodes, are utilized in the subject graph to represent supplementary material as options for students who desire to know more and learn further about the subject. A supplementary node may be either a topic or concept node. Continuing with our example, since the subtopic conversion mainly provides a better understanding of numbers, it may not be necessary to teach this subtopic if we present the topic, number systems, in connection with digital computers. Thus, we define the subtopic as a supplementary material to students' learning of number systems.

Overall, the knowledge representation scheme described above provides not only a way of establishing a network of subject material, but also an automatic presentation procedure: that is, an automatic scheme for traversing nodes by following links which may be optionally set by a user (an instructor). Now the problem left to be investigated is how can we ensure that a student is learning while following through a presentation? We believe that the behaviorist instructional teaching [14] can be effective. Specifically, we use Gagne's nine-significant-event model—recursively utilizing the nine events while instructing: gaining learner's attention, informing learner of objectives, stimulating the recall of prerequisites, presenting stimuli, providing guidance, eliciting performance, providing feedback, assessing performance, and enhancing retention and transfer. Overall, we ask questions while presenting materials and give exercise problems as homework so that we can assess students' performance in their learning. Then, the question is how can we implement this kind of tutoring so that our system can do it effectively?

B. Knowledge Representation Scheme II: Knowledge Base

Pawlak has proposed a formal definition of knowledge in terms of Knowledge Base and its basic property [2]. Directly motivated by his understanding and formalization of "knowledge" and "concepts," we employ his set notations, known as Knowledge Base, as a fine grain representation of the presented knowledge in tutoring systems.

In our representation, concepts in a subject network of a tutoring system used to evaluate students' learning are encoded in questions and problems, which are accessed through interactions between students and the system during tutoring. That is, those of concepts are used for questioning and testing students, and evaluating students' answers. For instance, in our number systems example, there are about 35 concepts, including 11 supplementary concepts used for testing and evaluating students' learning of the subject material; and there are about 50 questions and problems that have been stored in the associated database of the tutoring system, which may be

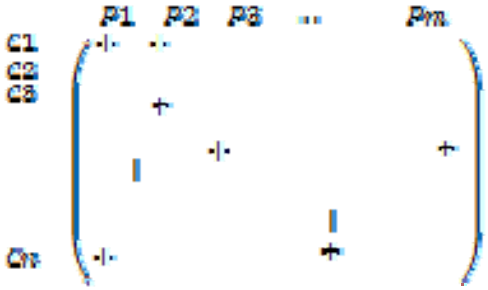
assigned to students as exercises, where each problem embeds several concepts among the fifty. In general, let

$$C=\{c_1, c_2, \cdots, c_n\} \quad (1)$$

be the set of n concepts that are presented in a subject network. Further, let there be m problems in the problem set

$$P=\{p_1, p_2, \cdots, p_m\} \quad (2)$$

that have included these n concepts in the subject network. One way of representing such knowledge is to use n by m matrix as the following.



In this matrix, a cell is checked means that the concept identified by the row of that cell is embedded in the problem identified by the column of that cell. Further, a student's answer to the problem can be checked against these concepts. We then keep track of students' answers to problems, which should be a reflection of their understanding of those concepts.

Although we have found a method to represent subject material (the use of GS-model) and student learning stages (eliciting performance of student's learning of each concept) mechanically and to test and evaluate students' learning through their answering questions and solving problems, there are many possible kinds of uncertainties inherent in this paradigm of tutoring.

III. User Modeling to Cope with Uncertainties

We have identified two kinds of uncertainties, namely, vagueness and incomplete information. Vagueness may exist in the methods of evaluating students' answers and in the answers that students give to problems. First, as to the methods of evaluating students' answers, it is likely that relations between concepts may not be simple, but instead, hierarchical. For example, in the subject domain of our tutoring system, complement is an important number representation in digital computers, which provides uniform computation for arithmetic operations of both positive and negative numbers. There are two variations of this representation, radix and digit complements. Complement, radix complement, and digit complement are considered to be different concepts in our representation model. Obviously, they are closely related. That is, one's understanding of radix complement may imply his understanding of complement and partial understanding of digit complement. Generally depending on how an instructor would view these related concepts, the subject material in a tutoring system could be rearranged with significant differences, so can problems to test students' mastery level to those concepts.

Second, as to the students' answer, again according to the behaviorist model of understanding students' learning, if a students' answer to a problem is incorrect, generally, we infer that the student has not yet mastered the concept(s) that the problem tries to test. However, the information on the cause of students' wrong answers is somewhat incomplete (perhaps, it would be impossible to obtain it fully), and may result from students' psychological factors, their mental states during a tutoring session. Simply presenting the tutoring material again to students may not be an effective remedial learning. Instead, testing students with more problems and approximating their answers could be a better solution. This means that more flexible ways of evaluating students' answers may be desirable or even necessary.

Motivated by seeking how to build an accurate user model, we have explored the rough set formalism and adopted it in the user-modeling component of our tutoring system to compensate for these uncertainties.

A. The Rough Set Approximation

Pawlak has succinctly described [15]:

"In the rough set theory each vague concept is replaced by a pair of precise concepts called its lower and upper approximations; the lower approximation of a concept consists of all objects which surely belong to the concept, whereas the upper approximation of the concept consists of all objects which possibly belong to the concept." (p. 73 in [2])

Corresponding to his description of vague concept, we have here the vagueness of evaluating students' learning and the vagueness of understanding of the relations between concepts depending upon instructors' preference.

Formally, let U be a set of universe of discourse (called universe); let **R** be a set of equivalence relations imposed on the universe U.

The Knowledge Base K is defined as K = (U, **R**); and the concept X in K is defined as a subset of U, i.e., $X \subseteq U$.

Further, the upper approximation of the concept X in K under a given equivalence relation **R** is defined as

$$\overline{X_R} = \{\, x : [x]_R \cap X \neq 0 \,\} \quad (3)$$

and the lower approximation of the concept X is defined as

$$\underline{X_R} = \{ x : [x]_R \subseteq X \} \quad (4)$$

Here $[x]_R$ represents the equivalence class of x under the given relation R. If $\overline{X}_R = \underline{X}_R$, then the concept X is considered to be precise; otherwise, we say the concept is vague. For a vague concept, these two approximations under the given relation in the Knowledge Base K can be calculated and obtained.

For example, as we have previously written, let (1) be the set of n concepts that are presented in a subject network. An interrelationship among concepts can be expressed as an equivalence relation (a partition). Then, there are many

possible partitions to form equivalence classes on the set C. Further, because there are m problems in the problem set (2) that have included these n concepts in the subject network, there should be various combinations for an instructor to assign a student problems according to the instructor's preference (expressed in his way of partitioning concepts in the subject network) and using this partition, problems are assigned. Further, an evaluation of the students' answers involving each concept can be obtained. Among the possible answers that a student may give, an evaluation based on the rough set approximation may be performed.

In our tutoring system, specifically, in one of the subject networks of the tutoring system, we can presumably represent all concepts that we would like students to learn with the possibility of varying granularity level of each node; and we also can select sufficient problems to embed these concepts, and for students to solve. Formally, let Pi be a subset of the problem set P, that is,

$$P = \cup P_i,\ i \in 1,2,\cdots,m \tag{5}$$

in the subject network. Let C_i be a subset of the concept set C, that is,

$$C = \cup C_i,\ i \in 1,2,\cdots,n \tag{6}$$

in the subject network. We can impose relations between P and C functionally as

$$f_{P_i} : P_i \to C \text{ where } i \in 1,2,\cdots,l \tag{7}$$

and each of these l functions is subjective; and

$$f_{C_i} : C_i \to P \text{ where } i \in 1,2,\cdots,k\ ; \tag{8}$$

and it (f_{C_i}) indicates that, given a group of concepts, a corresponding set of problems can be selected to test students' learning of this group of concepts. PC (Note that $P_i \in 2^P$ and $C_i \in 2^C$.) Providing the mechanism based on the rough set theory, our system allows instructors to group concepts (C_i) and to select problems (P_i) differently so that the evaluation of students' answers to problems can vary according to instructors' preferences. Our objective here is to find good selection algorithms such that the vagueness in ensuring and evaluating students' learning in the tutoring processes will be minimized.

B. Comparison with Other Approximation Approaches

Katz et al.[16] have proposed using fuzzy probabilistic variables to measure performance conditions when students are learning with their tutoring system. More recently, Kavcic [19] has conjectured with fuzzy and probabilistic user modeling. In fact, probability theory [17] and fuzzy set theory [18] are popularly used in approximate reasoning. However, the advantage of the rough set approximation over these two in our case is that the numerical value of imprecision is calculated according to a pre-defined formula which is based on the fundamental concepts used to express imprecision of knowledge. For example, Pawlak has proposed one numerical calculation of the rough set imprecision, namely,

$$a_R = \frac{card\ \underline{R}}{card\ \overline{R}} \tag{9}$$

where card denotes the cardinality of sets ($\overline{R}$ or $\underline{R}$). To illustrate this point, we use a simple example as follows. Let there be 10 concepts that have been chosen to be presented to students. One instructor may partition these 10 concepts as

$$[c_1]_R = \{c_1, c_2, c_3\ \}, \tag{10}$$

$$[c_4]_R = \{\ c_4, c_5\ \}, \tag{11}$$

$$[c_6]_R = \{\ c_6\ \}, \tag{12}$$

$$[c_7]_R = \{\ c_7, c_8\ \}, \tag{13}$$

$$[c_9]_R = \{\ c_9, c_{10}\ \}, \tag{14}$$

That means that concepts in the same equivalent class are substitutable. Suppose one student has mastered the following concepts:

$$\{c_1, c_2, c_4, c_6, c_7, c_9, c_{10}\ \}; \tag{15}$$

Then the upper approximation of his performance under the given relation is

$$\{c_1, c_2, c_3, c_4, c_5, c_6, c_7, c_8, c_9, c_{10}\ \}; \tag{16}$$

while the lower approximation of his performance is

$$\{c_6, c_9, c_{10}\ \} \tag{17}$$

Consequently, the accuracy using Pawlak's calculation would be $2/5$. On the other hand, the fuzzy probability variables in [16] are obtained by expert estimations without a predefined membership function. As a result, the inconsistency of human performance would bias the approximation processes inevitably.

IV. CONCLUSION AND FURTHER INDICATION

We have developed the rough set approach to user modeling under our ATA framework for ITS and our hybrid knowledge representation model (GS model) and implemented it in the user modeling component of our tutoring system. Theoretically, our development approaches are based on the constructivist understanding of scientific knowledge [9] [10] and the constructivist view of learning mathematical knowledge [8]. After we have formulated our hybrid representation model (GS model), the rough set approximation

fits well in the implementation of our tutoring system. As we have briefly described, under the ATA framework, GS model provides an automated presentation mechanism (both initial and remedial presentations). Thus, the rough set approach can be used on top of the model to make the tutoring process more adaptable.

Our intention has been using exploratory AI approaches to build a tutoring system with observable intelligent behavior in its performance. Other important factors confronted in our implementation have been interface design issues. These issues may contribute to user modeling, and could be crucial to the performance of our system as well. As we have tried to show in this article, our automation mechanism is based on the high consensus approach—i.e., providing questions with multiple choices, and exercises that have solutions with well-defined steps— in evaluating students' learning. Wasilewska has recently formulated Knowledge Systems [20] based on Pawlak's Knowledge base in the context of data mining. It can also be applied to the user modeling component of our ITS. We strongly believe that with these exploratory AI approaches—i.e., the hybrid representation model and the rough set approximation—our tutoring system has had a lot to offer to ITS developers and will have a significant potential in the development of ITS.

***Abstract*—Support vector regression (SVR) employs the support vector machine (SVM) to tackle problems of function approximation and regression estimation. SVR has been shown to have good robust properties against noise. Besides, in SVR, outliers may also possibly be taken as support vectors. Such an inclusion of outliers in support vectors may lead to seriously overfitting phenomena. The rough set theory is successes to deal with imprecise, incomplete or uncertain for information system. In this paper, a novel regression approach, termed as the Rough Margin Support Vector Regression (RMSVR) network, is proposed to enhance the robust capability of SVR. The basic idea of the approach is to adopt the concept of rough sets to construct the model obtained by SVR and fine tune it with a robust learning algorithm. Simulation results of the proposed approach have shown the effectiveness of the approximated function in discriminating against outliers.**

Keywords-support vector regression(SVR); outlier; rough sets; robust learning

I. INTRODUCTION

The support vector machine (SVM) is a universal approach for solving the problems of multidimensional function estimation. Those approaches are all based on the Vapnik–Chervonenkis (VC) theory [1-2]. When SVM is employed to tackle the problems of function approximation and regression estimation, the approaches are often referred to as the support vector regression (SVR) [3]. The SVR type of function approximation is very effective, especially for the case of having a high-dimensional input space. Another important advantage for using SVR in function approximation is that the number of free parameters in the function approximation scheme is equal to the number of support vectors. Such a number can be obtained by defining the width of a tolerance band. Thus, the selection of the number of free parameters can be directly related to the approximation accuracy and does not have to depend on the dimensionality of the input space or other factors as that in the cases of multilayer feedforward neural networks.

Outliers may occur due to various reasons, such as erroneous measurements or noisy phenomenon appearing in the tail portion of some noise distribution functions. When the obtained observations contain noise or outliers, the learning process being unaware of those situations may try to fit those unwanted data and this behavior may lead to a corrupted approximation function. This phenomenon is often called overfitting [4-5]. In [6], SVR has been shown to have better robust properties for various signal-to-noise ratios. In [7], SVR has also been shown to have excellent performance for both the ε -insensitive function and Huber's robust function matching the correct type of noise in an application of time series prediction. Besides, a general cost function for SVR has also been proposed in considering error distributions [8]. In [9], the SVM with weighted least square (LS-SVM) is proposed to overcome the effects of outliers. However, when the parameters in those approaches are not properly chosen, the final results may be affected by its parameters. This property has also been mentioned in [9]. The selection of parameters in SVR is not straightforward. In [10], a robust SVR (RSVR) network is proposed to enhance the robust capability of SVR. The basic idea of the approach is to adopt the concept of traditional robust statistics to fine tune the model obtained by SVR.

In the last two decades, rough sets and fuzzy sets turned out to be two contemporary progresses in analyzing inexact, imprecise, uncertain, or vague knowledge. The former captures the distinct aspect of indiscernibility in knowledge, while the latter describes the inherent feature of vagueness in linguistics and decision-making. The rough set theory proposed by Pawlak [11-12] is a mathematical theory dealing with uncertainty in data. Rough sets rely on the notion of lower and upper approximations of a set and are applied to rough fuzzy control [13], modeling, system identification[14] , discovery of discussion rules from experimental data [15] and clustering [16-17]. Recently, combining both rough and SVM [18-24], Lingras [19] proposed a rough set approach to SVM classification removes the necessity of exact classification and is especially useful when dealing with noisy data. By utilizing the boundary region in rough sets shorten the training time and reduced storage requirements compared to the conventional techniques. In [20] proposed a so-call RST–SVM, the redundant attributes in multi-attribute information table can be reduced by RST approach, is utilized as a preprocessor to improve business failure prediction capability by SVM. Asharaf [18] incorporates rough set theoretic flavor in support vector clustering paradigm to achieve soft clustering. The user-defined parameters allow to control the extent of softness by controlling the width of boundary region and number of outliers. Chen [21] proposed fuzzy transitive kernels based fuzzy rough sets, and then reformulated hard margin support vector machines into fuzzy rough set based SVMs (FRSVMs)

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

with new constraints in which the memberships are taken into account. It has certain capacity to deal with noise. In [22], a called rough support vector regression (RSVR), is proposed to improve the modeling of rough patterns. rough insensitive loss function by applying separate SVR for patterns of lower and upper values. The main advantage of rough-SVR was that it almost never over-predicted the upper values. Based on *v*-SVM(SVR) [25], Zhang [23] gave a rough margin based support vector machine for classification to escape from the overfitting problem due to outliers. In [24] focus on the rough margin based *v*-SVR which constructs the rough margin with double tolerance bands. In this paper, a novel regression approach, termed as the Rough Margin Support Vector Regression (RMSVR) network, is proposed to enhance the robust capability of SVR. The basic idea of the approach is to adopt the concept of rough sets to construct the model obtained by SVR and fine tune it with a robust learning algorithm. Simulation results of the proposed approach have shown the effectiveness of the approximated function in discriminating against outliers.

The reminder of this paper is outlined as follows. Section II describes the concept of rough sets and the fundamental ideas for SVR. In Section III, the RMSVR network is proposed and its learning process is introduced. Section IV gives experimental results. Concluding remarks are given in Section V.

II. SUPPORT VECTOR REGRESSION AND ROUGH SETS

A. Support vector regression

A function approximation problem can be formulated as to obtain a function from a set of observations $\{(\vec{x}_1, y_1),(\vec{x}_2, y_2),...,(\vec{x}_N, y_N)\}$ with $\vec{x}_i \in R^m$ and $y_i \in R$, where N is the number of training data, $\vec{x}_i$ is the i-th input vector, and y_i is the desired output for the input $\vec{x}_i$. Based on the SVM theory, SVR is to approximate the given observations in an m-dimensional space by a linear function in another feature space F. The function in SVR is of the form

$$f(\vec{x}, \vec{w}) = \langle \vec{w}, \Phi(\vec{x}) \rangle + b \tag{1}$$

where $\langle \cdot, \cdot \rangle$ is an inner product defined on F, $\Phi(\cdot)$ is a nonlinear mapping function from R^m to F, $\vec{w} \in F$ is a weight vector to be identified in the function, and b is a threshold. Usually, the considered cost function [26] is

$$R_{SV}[f] = R_{emp}[f] + C \cdot \|\vec{w}\|^2 \tag{2}$$

where $R_{emp}[f] = \frac{1}{N}\sum_{i=1}^{N} L(y_i - f(\vec{x}_i, \vec{w})) = \frac{1}{N}\sum_{i=1}^{N} L(e_i)$ [27], $L(y - f(\vec{x}, \vec{w}))$ is the loss function measuring the error between y and the estimated output $f(\vec{x}, \vec{w})$ for a given input , and $C > 0$ is a regular constant. In traditional SVR, the ε-insensitive function is used as the loss function in (2).

It was shown in [2] that the solution of the above problem can be expressed in terms of support vectors $\vec{w} = \sum_{i=1}^{N} \theta_i \Phi(\vec{x}_i)$, and the function f is then written as.

$$f(\vec{x}, \vec{w}) = \sum_{i=1}^{N} \theta_i \langle \Phi(\vec{x}_i), \Phi(\vec{x}) \rangle + b \tag{3}$$

In (3), the inner product $\langle \Phi(\vec{x}_i), \Phi(\vec{x}) \rangle$ in the feature space is usually considered as a kernel function [28]. The kernel function determines the smoothness properties of solutions and should reflect a prior knowledge on data. The choice of the kernel function is usually left for users. The coefficients θ_i s in (3) can be solved by quadratic programming methods with suitable transformation of the above problem into constraint optimization problems In (3), the constant b is unknown. Various forms can be found in the literature [6].

According to the SVM theory, SVR has the advantage of self-determining its structure. Hence, there are no initialization problems for SVR. For training data sets with certain noise distributions, SVR also has shown excellent performance under the ε-insensitive function or Huber's robust function [3,5,7]. However, the robust effects against training data sets with outliers are not obvious in SVR.

B. Rough sets

The theory of rough sets [11-12] has recently emerged as another major mathematical tool for managing uncertainty that arises from granularity in the domain of discourse—that is, from the indiscernibility between objects in a set. The intention is to approximate a rough (imprecise) concept in the domain of discourse by a pair of exact concepts, called the lower and upper approximations. These exact concepts are determined by an indiscernibility relation in the domain, which, in turn, may be induced by a given set of attributes ascribed to the objects of the domain. The lower approximation is the set of objects definitely belonging to the vague concept, whereas the upper approximation is the set of objects possibly belonging to the same. A rough set X is characterized by its lower and upper approximations $\underline{B}X$ and $\overline{B}X$, respectively, with the following properties.

1) An object $\vec{x}_k$ can be part of at most one lower approximation.
2) If $\vec{x}_k \in \underline{B}X$ of cluster X, then simultaneously $\vec{x}_k \in \overline{B}X$.
3) If $\vec{x}_k$ is not a part of any lower approximation, then it belongs to two or more upper approximations.

III. ROUGH MARGIN SUPPORT VECTOR REGRESSION ALGORITHM

A novel approach, termed as Rough Margin Support Vector Regression (RMSVR) Algorithm, is proposed. Support vector regression (SVR) [3] which is constructed by minimizing Vapnik's ε-insensitive loss function residuals between the outputs of SVR and the target values and the

model complexity. Instead of selecting an appropriate ε, Schölkopf et al [25] proposed a *v*-support vector regression (*v*-SVR), which introduces a new parameter *v* which can control the number of support vectors and training errors without defining ε a prior. They proved that *v* is an upper bound on the fraction of margin errors and lower bound of the fraction of support vectors.

In [24] focus on the rough margin based *v*-SVR, which constructs the rough margin with double ε instead of single ε for *v*-SVR such as Fig.1. Following the rough theory, ε_l and ε_u is the lower margins and the upper margins, respectively. The regions between those two margins are equivalent to the boundary regions; the region inside the lower margins is equivalent to the positive region; and the regions outside the upper margins are equivalent to the negative regions. When the datum lies in the positive region, it is regarded as non-support vector. The datum lying in the boundary and negative regions are all support vectors. The farther the datum deviates from the target function, the more important it is, so it emphasizes the residuals introduced by the data lying in the negative regions. Although the experimental results on benchmark datasets have been conformed the effectiveness of this idea, but if the outliers exist that will result in overfitting phenomena. In our approach, the datum lying in the boundary regions are considered as support vectors, i.e. ε_l and ε_u is the lower bound and upper bound of the fraction of support vectors, respectively. The datum lying in negative regions are viewed as outliers.

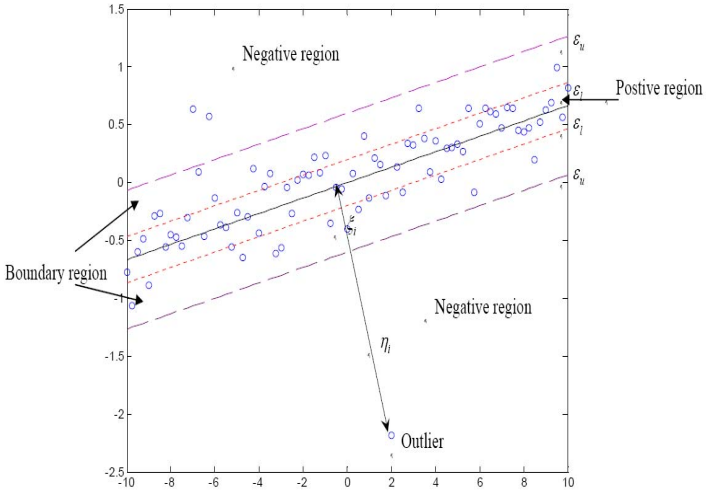

Fig.1 Rough margin SVR

Similar to the classical *v*-SVR and rough *v*-SVR, the primal problem can be described as:

$$\min_{\vec{w},\varepsilon_l,\varepsilon_u,\xi_i,\xi_i^*,\eta_i,\eta_i^*} \frac{1}{2}\|\vec{w}\|^2 + C\left(v\left(\varepsilon_l+\delta^b\varepsilon_u\right)+\frac{1}{l}\sum_{i=1}^{l}\left(\xi_i+\xi_i^*\right)+\frac{\delta^n}{l}\sum_{i=1}^{l}\left(\eta_i+\eta_i^*\right)\right) \quad (4)$$

subject to

$$\begin{aligned}
&\left(\vec{w}\cdot\Phi\left(\vec{x}_i\right)+b\right)-y_i \le \varepsilon_l+\xi_i+\eta_i,\\
&y_i-\left(\vec{w}\cdot\Phi\left(\vec{x}_i\right)+b\right) \le \varepsilon_l+\xi_i^*+\eta_i^*,\\
&0\le\xi_i\le\varepsilon_u-\varepsilon_l,\ \ 0\le\xi_i^*\le\varepsilon_u-\varepsilon_l,\\
&\eta_i\ge 0,\ \ \eta_i^*\ge 0,\ \ \varepsilon_l\ge 0,\ \ \varepsilon_u\ge 0,
\end{aligned}$$

The Lagrange function is defined as

$$\begin{aligned}
L=&\frac{1}{2}\|\vec{w}\|^2+C\left(v\left(\varepsilon_l+\delta^b\varepsilon_u\right)+\frac{1}{l}\sum_{i=1}^{l}\left(\xi_i+\xi_i^*\right)+\frac{\delta^n}{l}\sum_{i=1}^{l}\left(\eta_i+\eta_i^*\right)\right)\\
&-\sum_{i=1}^{l}\alpha_i\left(\varepsilon_l+\xi_i+\eta_i+y_i-\left(\vec{w}\cdot\Phi\left(\vec{x}_i\right)+b\right)\right)\\
&-\sum_{i=1}^{l}\alpha_i^*\left(\varepsilon_l+\xi_i^*+\eta_i^*-y_i+\left(\vec{w}\cdot\Phi\left(\vec{x}_i\right)+b\right)\right)\\
&-\sum_{i=1}^{l}\beta_i\left(\varepsilon_u-\varepsilon_l-\xi_i\right)-\sum_{i=1}^{l}\beta_i^*\left(\varepsilon_u-\varepsilon_l-\xi_i^*\right)\\
&-\sum_{i=1}^{l}\gamma_i\xi_i-\sum_{i=1}^{l}\gamma_i^*\xi_i^*-\sum_{i=1}^{l}\sigma_i\eta_i-\sum_{i=1}^{l}\sigma_i^*\eta_i^*-\lambda_l\varepsilon_l-\lambda_u\varepsilon_u
\end{aligned} \quad (5)$$

where $\alpha_i\ge 0,\alpha_i^*\ge 0,\beta_i\ge 0,\beta_i^*\ge 0,\gamma_i\ge 0,\gamma_i^*\ge 0,\sigma_i\ge 0,\sigma_i^*\ge 0$, $\lambda_l\ge 0$, $\lambda_u\ge 0$ are Lagrangian multipliers. According to KKT conditions and then the dual problem can be written as

$$\min_{\alpha_i,\alpha_i^*}\ \frac{1}{2}\sum_{i,j=1}^{l}\left(\alpha_i-\alpha_i^*\right)\left(\alpha_j-\alpha_j^*\right)K(\vec{x}_i,\vec{x}_j)-\sum_{i=1}^{l}\left(\alpha_i-\alpha_i^*\right)y_i \quad (6)$$

subject to

$$\begin{aligned}
&\sum_{i=1}^{l}\left(\alpha_i-\alpha_i^*\right)=0\\
&\alpha_i,\alpha_i^*\in\left[0,\delta_n\frac{C}{l}\right]\\
&\sum_{i=1}^{l}\left(\alpha_i+\alpha_i^*\right)\le\left(1+\delta_b\right)Cv
\end{aligned}$$

The regression estimate then takes the form,

$$f(x)=\sum_{i=1}^{l}\theta_i K(\vec{x}_i,\vec{x}_j)+b, \quad (7)$$

where $\theta_i=\alpha_i-\alpha_i^*$ and $K(\vec{x}_i,\vec{x}_j)$ is a kernel function.

We let $v\ge 0,\delta^b\ge 0,\delta^n\ge 0$. If $\delta^b=0,\delta^n=1$, RMSVR is equivalent to the classical *v*-SVR. In other word, let $\delta^b=1,\delta^n\ge 1$, RMSVR becomes the rough *v*-SVR. In this function approximation approach, we select $\delta^b>1$ to emphasize those support vectors lying in the boundary regions, and select $\delta^n<1$ give the penalty to the datum lying in negative regions. Hence, *b* can be computed as:

$$\begin{aligned}
b=\frac{1}{2}\Bigg\{&\min_{i\notin NG}\left(y_i-\sum_{i=1}^{N}\left(\alpha_j-\alpha_j^*\right)K(\vec{x}_i,\vec{x}_j)\right)\\
&+\max_{i\notin NG}\left(y_i-\sum_{i=1}^{N}\left(\alpha_j-\alpha_j^*\right)K(\vec{x}_i,\vec{x}_j)\right)\Bigg\}
\end{aligned} \quad (8)$$

where NG expressed the datum lying in negative regions.

The initial phase is to determine the network structure and the corresponding initial network weights through the RMSVR approach. In this paper, the kernel function is chosen as Gaussian function and defined as

$$K(\vec{x},\vec{x}_i)=\exp\left[-\left\|\vec{x}-\vec{x}_i\right\|^2/2\tau^2\right] \quad (9)$$

where is τ a constant. After applying the RMSVR approach, an initial network is obtained which has been with a level of accuracy against outliers. Furthermore, to improve the accuracy, it should to adjust those weights by the robust learning approach. A robust learning algorithm called ARBP [5] is proposed, in this algorithm, it is simply embedding an annealing process into the learning process, and a deterministic annealing process is used to replace the scale estimator. Based on this idea, the robust cost function of ARBP is defined as:

$$E_{ARBP}=\sum_{i=1}^{l}\chi\left(e_k,\kappa(\tau)\right), \quad (10)$$

where $\chi(\cdot)$ is the loss function. $e_k=y_k-\hat{y}_k$ .The annealing schedule, $\kappa(\tau)$ is usually selected to decrease toward zero as the epoch number increases to infinite; that is $\lim_{\tau\to\infty}\kappa(\tau)=0$.

In the learning algorithm, $\vec{\theta}$ can be updated as

$$\vec{\theta}(t+1)=\vec{\theta}(t)+\Delta\vec{\theta}(t) \quad (11)$$

with

$$\Delta\vec{\theta}(t)=\varsigma\frac{\partial E_{ARBP}(t)}{\partial\vec{\theta}}, \quad (12)$$

where ς is the learning constant.

The proposed Algorithm is described in the following:

[Step 1] Initialize the RMSVR structure with the given kernel functions, the loss function, and the constant C,v,δ^b,δ^n .

[Step 2] For each training pattern, compute the estimated result by Equ.(7) and its error.

[Step 3] Update the weight vector incrementally by (11) and (12).

[Step 4] Compute the robust cost function defined by (10).

[Step 5] If the termination conditions are not satisfied, then go to Step 2; otherwise, terminate the learning process.

IV. Simulation Example

A sinc function is considered and defined as

$$y=\frac{\sin(x)}{x},\ -10\le x\le 10 .$$

80 input-output data are used. In this example, outliers are added artificially by moving some points away from designated locations. The parameters selected as $\tau=3, C=0.5$. Based on the above procedure, the approximated results of RMSVR are presented in Fig. 1 and RMSVR with robust learning are shown as Fig.2. It can be found that the proposed RMSVR can reduce the overfitting phenomena.

V. Conclusion

Rough set theory turned out to be particularly adequate for the analysis of various types of data with inexact, uncertain or vague knowledge. In this paper, a novel regression approach, termed as the Rough Margin Support Vector Regression (RMSVR) network, is proposed to enhance the robust capability of SVR. The basic idea of the approach is to adopt the concept of rough sets to construct the model obtained by SVR and fine tune it with a robust learning algorithm. Simulation results of the proposed approach have shown the effectiveness of the approximated function in discriminating against outliers.

***Abstract*—This study presents an efficient immune symbiotic evolution learning algorithm for the compensatory neural fuzzy network (CNFN). The proposed immune symbiotic evolution learning method (ISEL) includes three major components - initial population, subgroup symbiotic evolution and immune system algorithm. The advantage of the proposed ISEL method are that the subgroup symbiotic evolution method uses the subgroup-based population to evaluate the fuzzy rules locally and the adopted immune system algorithm can accelerate the search and increase global search capacity. Finally, the simulation results have shown that the proposed CNFN-ISEL can outperform other methods.**

Keywords- Compensatory fuzzy operator; neural fuzzy network; symbiotic evolution; immune system algorithm ; control problems.

I. INTRODUCTION

Many researchers have developed GAs to implement fuzzy systems and neural fuzzy networks in order to automate the determination of parameters and structures [1]-[3]. Unfortunately, the number of fuzzy rules (i.e., the length of each chromosome in the GA) increased exponentially as the number of inputs increased. However, such GAs encounter some important issues: 1) the input space is partitioned into a grid; 2) the number of fuzzy rules is determined by trial and error or by a expert system; 3) a fuzzy system was encoded into a chromosome; and 4) the rate of convergence of the evolution process is low.

This study presents an efficient immune symbiotic evolution learning algorithm (ISEL) for the compensatory neural fuzzy network. The proposed compensatory neural fuzzy network (CNFN) is based on our previous research [4]. The immune symbiotic evolution learning method (ISEL) includes three major components - initial population, subgroup symbiotic evolution and immune system algorithm. First, the self-clustering algorithm that determines proper input space partitioning and finds the mean and variance of the membership function and the number of rules, is applied to the initial population. Second, the subgroup symbiotic evolution method in which each sub-antibody represents a single fuzzy rule differs from traditional GAs. A fuzzy system with *R*-rules is constructed by selecting and combining *R* sub-antibodies from a given population, and allowing the evolution of the rule itself. Third, the immune system algorithm uses the clonal selection principle to cancel antibodies between others of high similar degree, and these antibodies, after the process, will be of higher quality, accelerating the search and increasing the global search capacity.

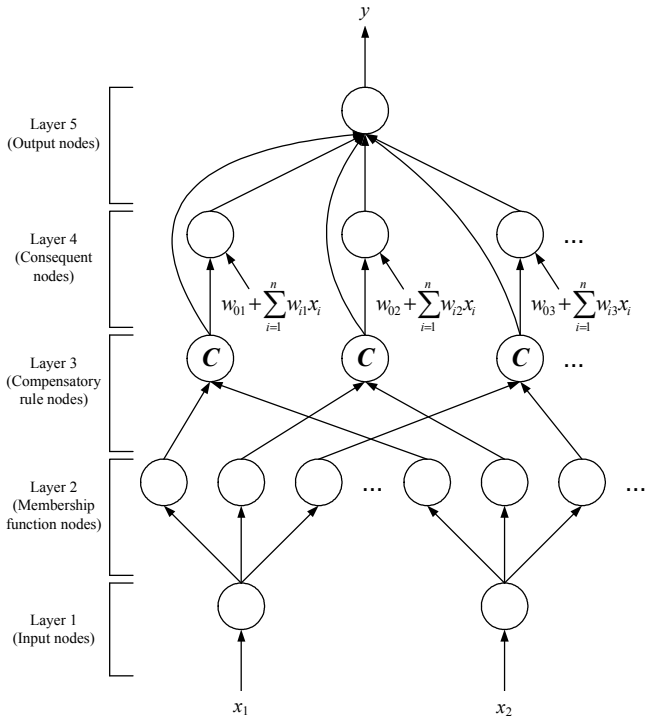

Figure 1. Structure of the proposed CNFN.

II. STRUCTURE OF COMPENSATORY NEURAL FUZZY NETWORK

The section describes the compensatory neural fuzzy network (CNFN) [4]. Compensatory operators are used to optimize fuzzy logic reasoning and to select optimal fuzzy operators. Therefore, an effective neural fuzzy network should be able not only to adaptively adjust fuzzy membership functions but also to dynamically optimize adaptive fuzzy operators. Figure 1 shows the structure of the CNFN.

The CNFN realizes a fuzzy model in the following form.

$$\text{Rule}-j: \quad \text{IF}\left[x_1 \text{ is } A_{1j} \text{ and } x_2 \text{ is } A_{2j} \ldots \text{and } x_i \text{ is } A_{ij} \ldots \text{and } x_N \text{ is } A_{Nj}\right]^{1-\gamma_j+\frac{\gamma_j}{N}} \quad (1)$$
$$\text{THEN } y' \text{ is } w_{0j}+w_{1j}x_1+w_{2j}x_2+\ldots+w_{ij}x_i+\ldots w_{Nj}x_N$$

where x_i is the input variable; y' is the output variable; A_{ij} is the linguistic term of the precondition part; $\gamma_j \in [0,1]$ is the

compensatory degree, and w_{0j} and w_{ij} are the corresponding parameters of consequent part.

III. An Immune Symbiotic Evolution Learning for the CNFN

This section describes an immune symbiotic evolution learning method (ISEL) for constructing the CNFN. The ISEL method comprises of three major components - initial population, subgroup symbiotic evolution and immune system algorithm. First, the initial population uses the self-clustering algorithm that determines proper input space partitioning and finds the mean and variance of the Gaussian membership function and the number of rules. Second, in traditional symbiotic evolution, all rules generally evolve together; however, in the subgroup symbiotic evolution method, each rule evolves separately. Third, the immune system algorithm uses the clonal selection principle to accelerate the search and increase global search capacity. Figure 2 presents the immune symbiotic evolution learning of the CNFN.

A. Initial Population

This subsection introduces the production of initial population, covering the coding and initialization steps. The coding step involves the membership functions and the fuzzy rules of a fuzzy system that represent sub-antibodies and are suitable for subgroup symbiotic evolution. The initialization step assigns the population values before the evolution process begins.

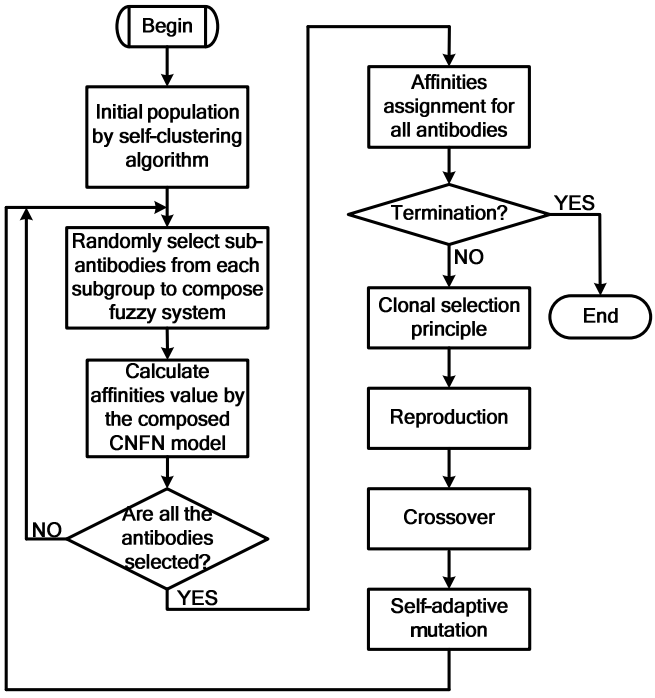

Figure 2. Flowchart of the proposed ISEL method.

1) Coding Step

The first step in ISEL method is the coding of a fuzzy rule into a sub-antibody. Figure 3 shows an example of a fuzzy rule coded into a sub-antibody where *i* and *j* are the *i*th dimension and the *j*th rule. Figure 3 describes a fuzzy rule given by Eq. (1), where m_{ij} and σ_{ij} are the mean and variance of a Gaussian membership function, respectively; c_j and d_j are compensatory parameters, and w_{ij} is the corresponding parameter of the consequent part associated with the *j*th rule node.

Sub-antibody

m_{1j}	σ_{1j}	m_{2j}	σ_{2j}	.....	m_{ij}	σ_{ij}	.....	c_j	d_j	w_{0j}	w_{1j}	w_{2j}	.....	w_{ij}	.....

Figure 3. Coding a fuzzy rule into a sub-antibody in subgroup symbiotic evolution.

2) Initialization Step

Before the ISEL method is designed, the individuals that will constitute an initial population must be created. In this study, the initial population was created according to the range of the mean and variance of the membership function, which were computed by the self-clustering algorithm (SCA) method [5]. The following formulations show the generation of the initial population.

Mean: $Sub\text{-}antibody[index] = m_{ij} + random[0,1] \times \sigma_{ij}$
where $index=1,3,\ldots,2\times N\text{-}1$

Variance: $Sub\text{-}antibody[index] = 4 \times random[0,1] \times \sigma_{ij}$
where $index=2,4,\ldots,2\times N$

Other parameters: $Sub\text{-}antibody[index] = random[-1,1]$
where $index>2\times N$

where *index* is the site of a sub-antibody; m_{ij} and σ_{ij} are the mean and variance, respectively of the Gaussian membership function of the *j*th rule of the *i*th input variable. The size of the population depends on the complexity of the problem. Many experiments showed that the population size of 20 is most effective. Besides the population size, other parameters must be set. This is the number of fuzzy systems to be formed and evaluated in each generation. The crossover rate, and the mutation rate and these parameters also depend on the complexity of the problem.

B. Subgroup Symbiotic Evolution

This subsection presents a novel method of subgroup symbiotic evolution. As described above, in the subgroup symbiotic evolution, the affinity value of a rule (a sub-antibody) is computed as the sum of the affinity values of all the feasible combinations of that rule with all other randomly selected rules, and then dividing this sum by the total number of combinations. Figure 4 shows the structure of the sub-antibody in the subgroup symbiotic evolution. The stepwise assignment of the affinity value is as follows.

Step 0: Divide the rules into subgroups of size *ps*.

Step 1: Randomly select *R* fuzzy rules (sub-antibody) from each of the above subgroups, and compose the fuzzy system using these *R* rules.

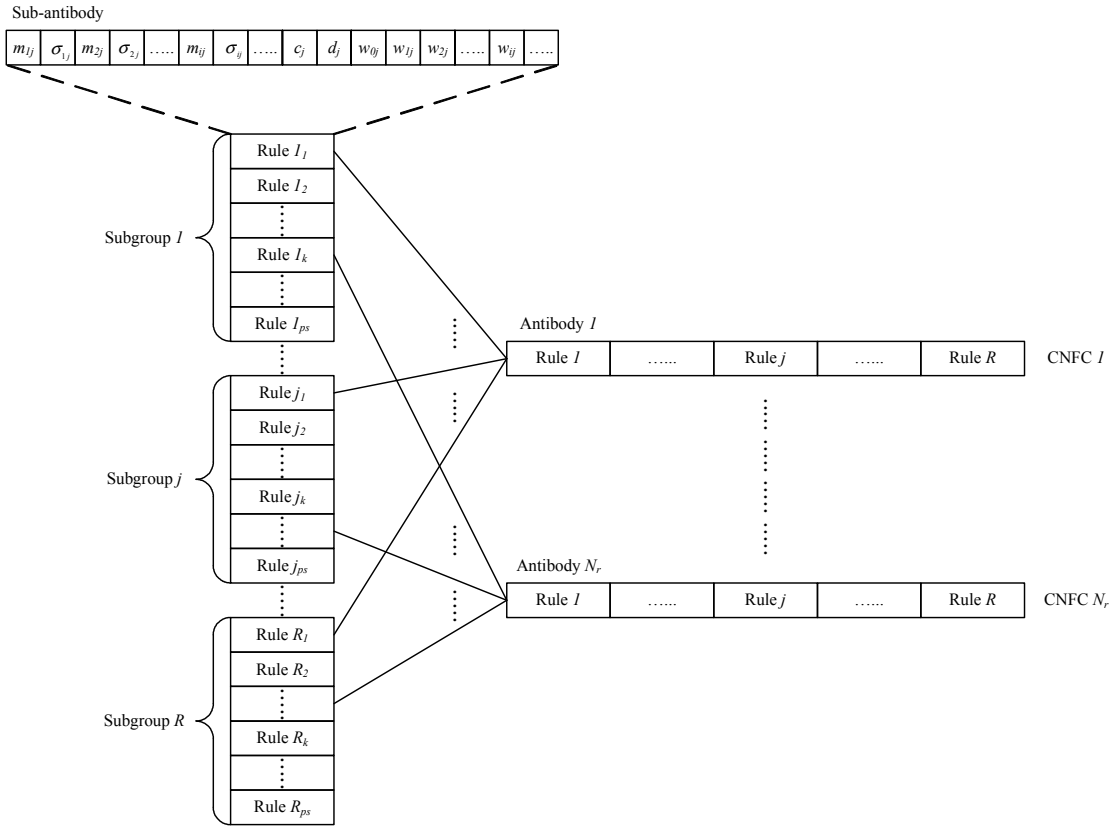

Figure 4. Structure of sub-antibody in subgroup symbiotic evolution.

Step 2: Calculate affinities of the antibodies using the CNFN thus composed. In this study, the affinity value is given by the follow formula;

$$Affinity\ value = \frac{1}{1+\sqrt{\frac{1}{N_t}\sum_{k=1}^{N_t}\left(y_k - y_k^d\right)^2}} \qquad (2)$$

where y_k represents the *kth* model output; y_k^d represents the desired output, and N_t represents the number of input data.

Step 3: Divide the affinity value by R and accumulate the divided affinity value to the affinity record of the R selected rules with their recorded affinity values initially set to zero.

Step 4: Repeat the above steps until each rule (sub-antibody) in each subgroup has been selected a sufficient number of times, and record the number of fuzzy systems to which each sub-antibody has contributed.

Step 5: Divide the accumulated affinity of each sub-antibody by the number of times it has been selected.

Step 6: Sort these sub-antibodies in each subgroup in order of decreasing affinity.

C. Immune System Algorithm

This subsection introduces the implementation of the immune system algorithm that is based on the clonal selection principle, the reproduction step, the crossover step and the self-adaptive mutation step.

1) Clonal Selection Principle

The antibodies of this immune system that eliminate the antigen should exhibit at least a minimal threshold of diversity. Accordingly, the diversity operator is applied to these antibodies such that those between others of high similar degree are canceled, guaranteeing and improvement in quality. This process is called clonal selection principle. Therefore, if the affinity between two antibodies exceeds the suppression threshold Th_{aff}, then these two antibodies are called similar. Now, the subgroup is assumed to be composed of *ps* sub-antibodies with L genes, as shown in Fig. 5.

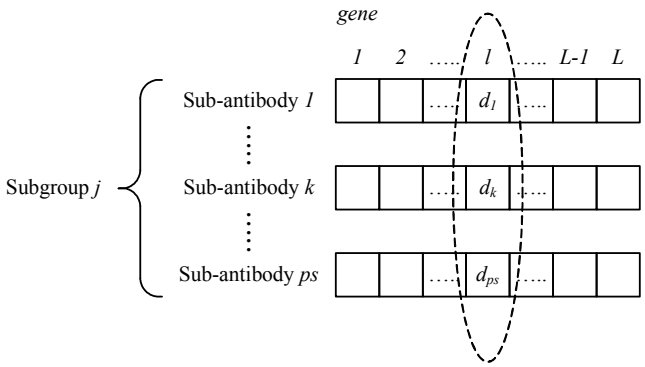

Figure 5. Composition of subgroup with these sub-antibodies.

Information theory yields the entropy value $EV_l(ps)$ of the lth gene in this jth subgroup:

$$EV_l(ps) = \sum_{k=1}^{ps} -P_{kl} \log P_{kl} \quad (3)$$

where P_{kl} is the probability of the kth allele from the lth gene, and $P_{kl} = 1/\left(1 + \left\| d_k - d_{k'} \right\|\right)$ is defined, where d_k and $d_{k'}$ are the genes of the kth and the k'th sub-antibody, respectively. The diversity of the genes is calculated using Eq. (3). If all alleles of the lth gene are of the same form, then the entropy value $EV_l(ps)$ will be zero.

The average entropy value *EV(ps)* of diversity is also given as follows;

$$EV(ps) = \frac{\sum_{l=1}^{L} EV_l(ps)}{L} \quad (4)$$

where L is the size of the gene in a sub-antibody. Equation (4) yields the diversity of the sub-antibody pool in terms of the entropy. Two affinity expression are considered in the proposed approach. The first explains the relationships between the antibody and the antigen, and is given by Eq. (2). The second describes the degree of association between sub-antibodies. The following equation computes the affinity between sub-antibodies;

$$Affinity_Ab_{kk'} = \frac{1}{1 + EV(2)} \quad (5)$$

where $Affinity_Ab_{kk'}$ is the affinity between two sub-antibodies k and k', and *EV(2)* is the entropy of only the sub-antibodies k and k'. This affinity is constrained from zero to one. When *EV(2)* is zero, the genes of the kth sub-antibody and the k'th sub-antibody are the same. Therefore, the clonal selection principle is that if the $Affinity_Ab_{kk'}$ exceeds Th_{aff}, then the sub-antibody should be canceled. Reproduction, crossover and mutation steps follow, according to the flowchart presented in Fig. 6.

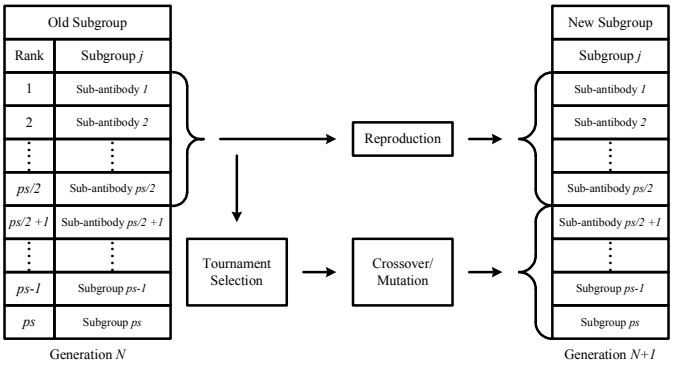

Figure 6. Flowchart of reproduction, crossover and mutation steps.

2) Reproduction Step

Reproduction is a process in which sub-antibody strings are copied according to their affinity values. This process is an artificial version of natural selection. This study uses the roulette-wheel selection method [6] - a simulated roulette is spun - in this reproduction step. The best performing sub-antibodies in the top half of the subgroup evolves to the next generation. The other half is generated to perform crossover on sub-antibodies in the top half of the parent generation.

3) Crossover Step

Reproduction directs the search toward the best existing sub-antibodies but does not create any new sub-antibodies. In nature, an offspring has two parents and inherits genes from both. The main operator working on the parents is the crossover operator, the operation of which occurred for a selected pair with a crossover rate that was set to 0.5 in this study. Therefore, the new sub-antibodies are principally generated by crossover. In this process, the first step is to select two sub-antibodies for crossover. Two sub-antibodies for crossover are selected by tournament selection [6] on the top half of the best-performing sub-antibodies. Tournament selection shown in Fig.7 randomly selects three sub-antibodies in each subgroup, and the sub-antibody with the best affinity is adopted as the designated sub-antibody. The other designated sub-antibody is selected in the same way. Two new sub-antibodies are generated by performing crossover on the selected designated sub-antibodies.

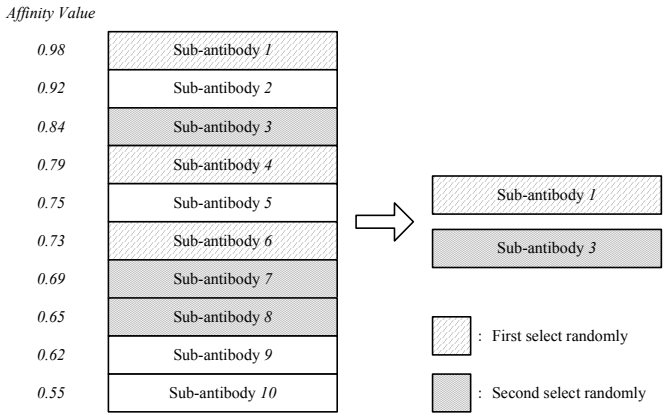

Figure 7. Tournament selection.

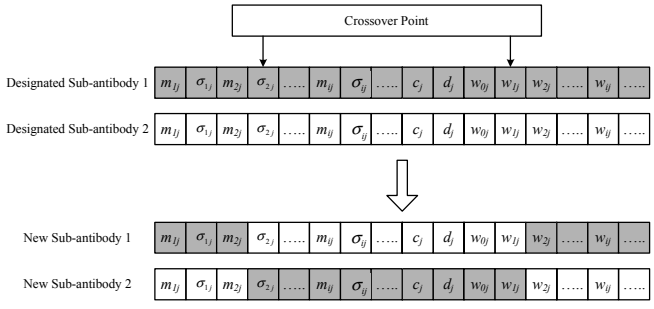

Figure 8. Two-point crossover.

In the second step, the two designated sub-antibodies are crossed and separated using a two-point crossover, as shown in Fig. 8, in which new sub-antibodies are created by exchanging the gene between the selected sites of the two designated sub-antibodies. In the crossover step, we also keep the same number of sub-antibodies in the other half of the population for each subgroup. After this operation, the new sub-antibodies replace the designated sub-antibodies with poor performances.

4) Self-Adaptive Mutation Step

After reproduction and the crossover step yielded new strings, no new information is introduced to the subgroup at the site of a sub-antibody. As a source of new sites, mutation

should be used sparingly because it is a random search operator. In the following simulations, a mutation rate was set to 0.3. Mutation is an operator that randomly alters the allele of a gene. The self-adaptive mutation adopted in the immune system algorithm yields high diversity. The sub-antibody suffers from a mutation to avoid falling in a local optimal solution and to ensure the searching capacity of approximate global optimal solution. The self-adaptive mutation with real-valued representation can be used to produce mutants by adding a number randomly selected from some interval to a given antibody. Figure 9 shows the self-adaptive mutation of a sub-antibody. The mutation value is generated according to Eq. (6). Following self-adaptive mutation, a new sub-antibody can be introduced into the population.

$$SAb[index] = \begin{cases} SAb[index] + (\max(SAb[:]) - SAb[index]) \times \lambda, \text{if } \alpha > 0.5 \\ SAb[index] + (\min(SAb[:]) - SAb[index]) \times \lambda, \text{if } \alpha \le 0.5 \end{cases} \quad (6)$$

where $\lambda = \beta \times (t/T)^{\beta}$, $\alpha, \beta \in [0,1]$ are random values; *index* represents the gene in a sub-antibody (*SAb*); t is the tth generation, and T is the maximum number of generations.

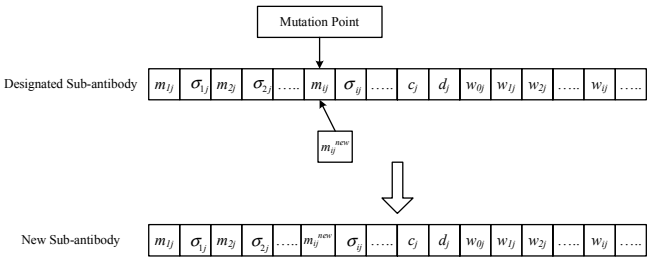

Figure 9. Self-adaptive mutation.

TABLE I. INITIAL PARAMETERS BEFORE TRAINING.

Parameter	Value
Size of Subgroup (*ps*)	20
Crossover Rate	0.5
Mutation Rate	0.3
Threshold of Affinity (Th_{aff})	0.95
Coding Type	Real Number

IV. ILLUSTRATIVE EXAMPLES

This study evaluated the performance of the proposed compensatory neural fuzzy network using immune symbiotic evolution learning algorithm (CNFN-ISEL) for nonlinear control systems. This section presents several examples and compares the performance with that of other neural fuzzy networks using symbiotic evolution (NFN-SE) [7], [8]. In the nonlinear control system problems, CNFN-ISEL is adopted to design controllers in four simulations - multi-input single-output plant control, multi-input multi-output plant control [9] and backing up the truck [10]. Table I presents the initial parameters before training used in the four computer simulations.

Example 1: Multi-input Single Output (MISO) Control

The controlled plant is the same as that used elsewhere [9], and is described by

$$y_p(k+1) = f[y_p, y(k-1)] + u(k) \quad (23)$$

where $f[y_p, y(k-1)] = \dfrac{y_p(k)y_p(k-1)[y_p(k)+2.5]}{1+y_p^2(k)+y_p^2(k-1)}$.

In designing the CNFN, the desired output y_r is specified by the following 250 pieces of data;

$$y_r(k+1) = 0.6y_r(k) + 0.2y_r(k-1) + r(k) \quad (24)$$

where $r(k) = 0.5\sin(2\pi k/45) + 0.2\sin(2\pi k/15) + 0.2\sin(2\pi k/90)$.

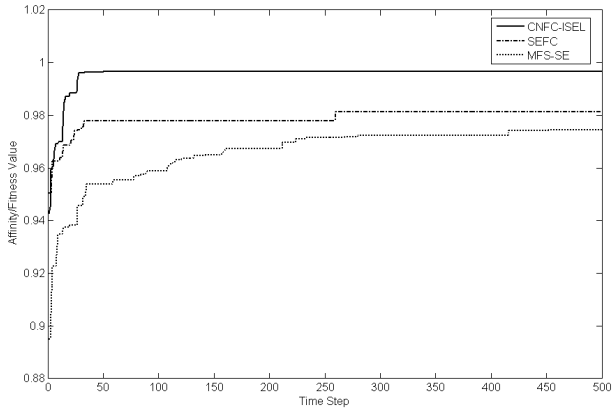

Figure 10. Learning curves of best performance of the CNFN-ISEL, SEFC and MFS-SE in Example 1.

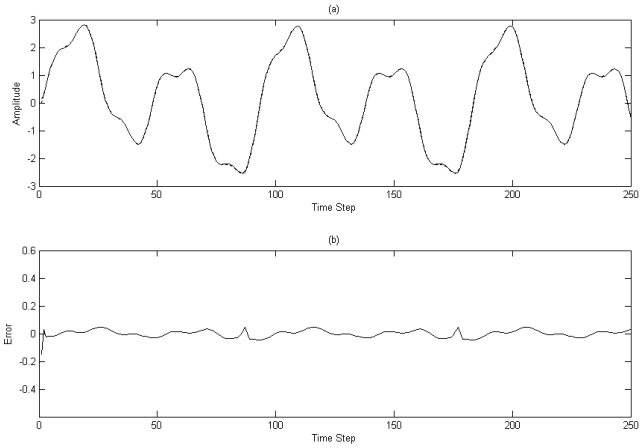

Figure 11. (a) Desired (solid line) and model (dotted line) output generated by CNFN designed with ISEL in Example 1. (b) Errors of proposed CNFN-ISEL.

The inputs to the CNFN are $y_p(k)$, $y_p(k+1)$, $y_r(k)$ and $y_r(k+1)$ and the output is $u(k)$. For the self-clustering algorithm (SCA), we chose the parameter D_{thr}=0.85 and then four rules are generated by SCA in CNFN; hence, R=4, and the number of total parameters is 60. Accordingly, the number of genes is also 15 in each subgroup. Figure 10 plots the learning curves of the best performance of the CNFN-ISEL for the affinity/fitness value, the symbiotic evolution of the fuzzy controller (SEFC) [7] and the Mamdani-type fuzzy system using the symbiotic evolution algorithm (MFS-SE) [8], after the learning process of 500 generations. Figure 11 (a) plots the control results of the desired output and the model output after a learning process of 500 generations. Figure11 (b) shows the errors of the proposed method. Table II presents the best and averaged affinity/fitness

values after 500 generations of training. The comparison indicates that the best and averaged affinity/fitness values of CNFN-ISEL are better than those obtained using other methods.

TABLE II. PERFORMANCE COMPARISONS WITH CNFN-ISEL, SEFC AND MFS-SE IN EXAMPLE 1.

Method	CNFN-ISEL	SEFC [7]	MFS-SE [8]
Affinity/Fitness Value (Ave)	0.9916	0.9793	0.9655
Affinity/Fitness Value (Best)	0.9961	0.9802	0.9745

Example 2: Multi-input Multi-output (MIMO) Control

In this example, the MIMO plants [9] to be controlled are described by the equations

$$\begin{bmatrix} y_{p1}(k+1) \\ y_{p2}(k+1) \end{bmatrix} = \begin{bmatrix} 0.5\dfrac{y_{p1}(k)}{1+y_{p2}^2(k)} \\ 0.5\dfrac{y_{p1}(k)y_{p2}(k)}{1+y_{p2}^2(k)} \end{bmatrix} + \begin{bmatrix} u_1(k) \\ u_2(k) \end{bmatrix}. \quad (25)$$

The controlled outputs should follow the desired output yr1 and yr2 as specified by the following 250 pieces of data;

$$\begin{bmatrix} y_{r1}(k) \\ y_{r2}(k) \end{bmatrix} = \begin{bmatrix} \sin(k\pi/45) \\ \cos(k\pi/45) \end{bmatrix}. \quad (26)$$

The inputs of the CNFN are $y_{p1}(k)$, $y_{p2}(k)$, $y_{r1}(k)$ and $y_{r2}(k)$, and the outputs are $u_1(k)$ and $u_2(k)$. For the self-clustering algorithm (SCA), we chose the parameter D_{thr}=1 and then six rules generated by SCA in CNFN, R=6. Therefore, the total number of parameters is 120 and the number of genes is 20 in each subgroup.

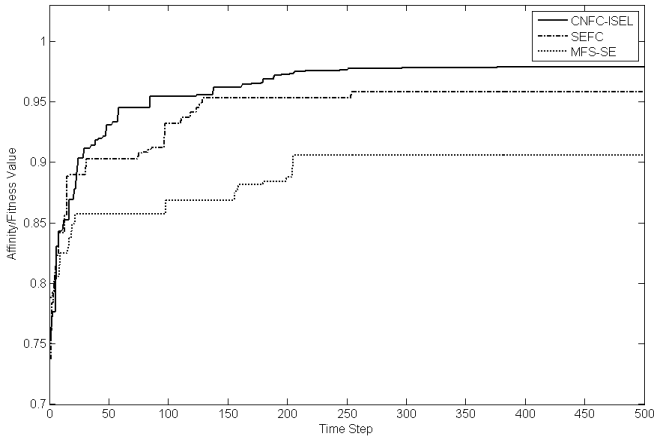

Figure 12. Learning curves of best performance of the CNFN-ISEL, SEFC and MFS-SE in Example 2.

Figure 12 plots the learning curves of the best performance of the CNFN-ISEL model for the affinity/fitness value, the symbiotic evolution of the fuzzy controller (SEFC) [7] and the Mamdani-type fuzzy system using symbiotic evolution algorithm (MFS-SE) [8], after the learning process of 500 generations. To demonstrate the control result, Figures 13(a) and (b) plot the control results of the desired output and the model output after the learning process of 500 generations. Figures 13 (c) and (d) show the errors of the proposed method. Table III presents the best and averaged affinity/fitness values after 500 generations of training. The comparison indicates that the best and averaged affinity/fitness values of CNFN-ISEL are better than those of other methods.

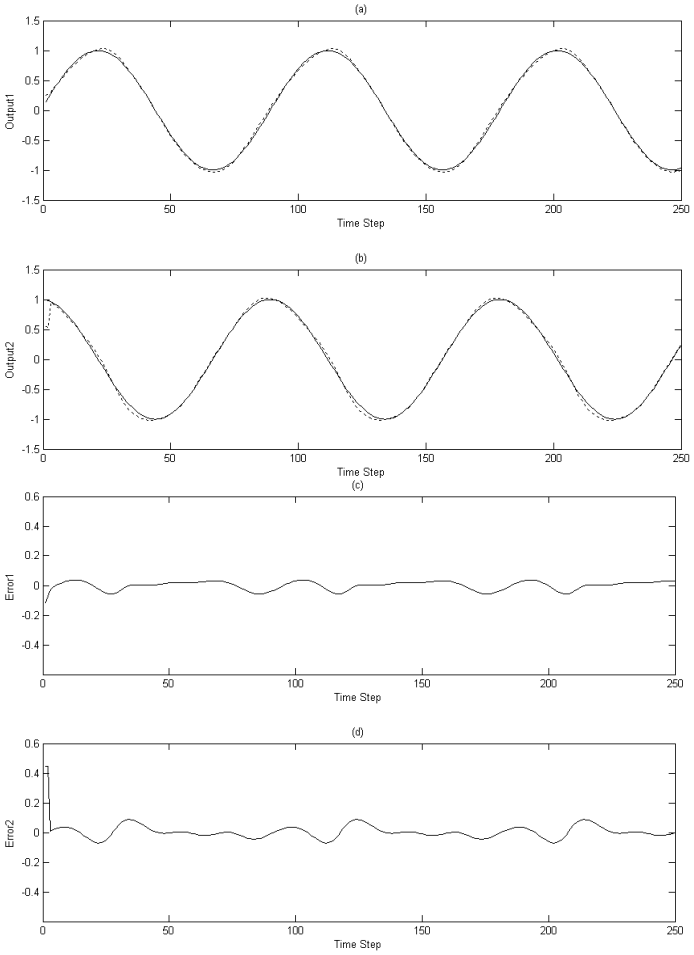

Figure 13. Desired (solid line) and model (dotted line) output generated by CNFN designed with ISEL in Example 1. (a) Output 1. (b) Output 2. Errors of proposed CNFN-ISEL for (c) output 1 and (d) output 2.

TABLE III. COMPARISON OF PERFORMANCE OF CNFN-ISEL, SEFC AND MFS-SE IN EXAMPLE 2.

Method	CNFN-ISEL	SEFC [7]	MFS-SE [8]
Affinity/Fitness Value (Ave)	0.9721	0.9553	0.8503
Affinity/Fitness Value (Best)	0.9786	0.9581	0.8560

Example 3: Control of Backing Up the Truck

Backing a truck into a loading dock is difficult. It is a nonlinear control problem for which no traditional control method exists [10]. Figure 14 shows the simulated truck and loading zone. The truck position is exactly determined by three state variables ϕ, x and y, where ϕ is the angle between the truck and the horizontal, and the coordinate pair (x, y) specifies

the position of the center of the rear of the truck in the plane. The steering angle θ of the truck is the controlled variable. Positive values of θ represent clockwise rotations of the steering wheel and negative values represent counterclockwise rotations. The truck is placed at some initial position and is backed up while being steered by the controller. The objective of this control problem is to use backward only motions of the truck to make the truck arrive in the desired loading dock (x_{desired}, y_{desired}) at a right angle (ϕ_{desired}=90°). The truck moves backward as the steering wheel moves through a fixed distance (*df*) in each step. The loading region is limited to the plane [0,100] × [0,100].

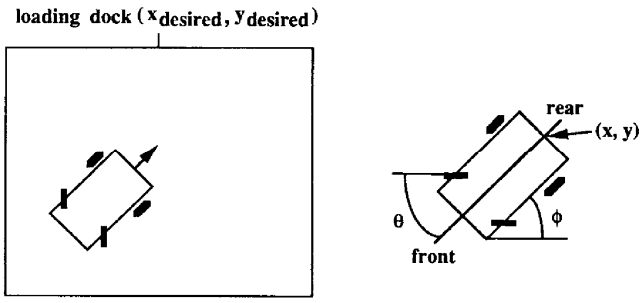

Figure 14. Diagram of simulated truck and loading zone.

The input and output variables of the CNFN must be specified. The controller has two inputs, truck angle ϕ and cross position *x*. When the clearance between the truck and the loading dock is assumed to be sufficient, the *y* coordinate is not considered as an input variable. The output of the controller is the steering angle θ. The ranges of the variables *x*, ϕ and θ are as follows.

$$0 \le x \le 100 \tag{27}$$

$$-90° \le \phi \le 270° \tag{28}$$

$$-30° \le \theta \le 30° \tag{29}$$

The equations of backward motion of the truck are,

$$\begin{aligned} x(k+1) &= x(k) + d_f \cos\theta(k) + \cos\phi(k) \\ y(k+1) &= y(k) + d_f \cos\theta(k) + \sin\phi(k) \\ \phi(k+1) &= \tan^{-1}\left[\frac{l\sin\phi(k) + d_f \cos\phi(k)\sin\theta(k)}{l\cos\phi(k) - d_f \sin\phi(k)\sin\theta(k)}\right] \end{aligned} \tag{30}$$

where *l* is the length of the truck. Equation (30) yields the next state from the present state.

Learning involves several attempts, each starting from an initial state and terminating when the desired state is reached; the CNFN is thus trained. For the self-clustering algorithm (SCA), we chose the parameter D_{thr}=0.45. After SCA learning, 13 fuzzy logic rules are generated and the parameters of the membership functions are determined. Hence, the total number of parameters is 117 and the number of genes is 9 in each subgroup. The training process continues for 500 generations. The affinity of the CNFN is approximately 0.95587 and the learning curve of CNFN is compared with those obtained using various existing models [7], [8], as shown in Fig. 15. Figures 16(a)-(b) plot the trajectories of the moving truck controlled by the CNFN, starting at initial positions (*x*, *y*, ϕ) = (a) (10 ,20 ,150°) and (b) (70, 20, -30°), after the training process has been terminated. The considered performance indices include the best affinity/fitness and the average affinity/fitness value. Table IV compares the results. According to these results, the proposed CNFN-ISEL outperforms various existing models.

Affinity/Fitness Value (Best)	0.9558	0.9516	0.9398

V. CONCLUSION

This study proposes an efficient immune symbiotic evolution learning algorithm for the compensatory neural fuzzy network. The immune symbiotic evolution learning method (ISEL) includes three major components - initial population, subgroup symbiotic evolution and immune system algorithm. However, the self-clustering algorithm, an evolution of the rule itself, the clonal selection principle of antibodies, and self-adaptive mutation are achieved by ISEL method. Moreover, the proposed CNFN-ISEL obtains better simulation results than alternative models in some circumstances, for example achieving faster learning and higher design accuracy in many nonlinear control problems.

***Abstract*—A hybrid learning algorithm is proposed to train fuzzy neural networks (FNNs) for identifying a time-delay chaotic system with outliers. In the proposed algorithm, integrating support vector regression (SVR) and annealing robust time-varying learning algorithm (ARTVLA) to optimize FNNs. In the evolutionary procedure, first, SVR is adopted to determine the number of hidden layer nodes and the initial structure of the FNNs. After initialization, ARTVLA with nonlinear time-varying learning rate is then applied to train FNNs. In ARTVLA, the determination of the learning rate would be an important work for the trade-off between stability and speed of convergence. A computationally efficient optimization method, particle swarm optimization (PSO) method, is adopted to simultaneously find optimal learning rates. Due to the advantages of SVR and ARTVLA (SVR-ARTVLA), the proposed FNNs (SVR-ARTVLA-FNNs) have good performance for identifying a time-delay chaotic system: Mackey Glass system with outliers. Simulation results are illustrated the effectiveness and feasibility of the proposed SVR-ARTVLA-FNNs.**

Keywords-fuzzy neural networks; support vector regression; time-delay chaotic system; annealing robust time-varying learning algorithm; particle swarm optimization

I. INTRODUCTION

A chaotic system is a nonlinear deterministic system that has some special features of sensitive dependence on initial conditions and unstable bounded trajectories in the phase space. Control and synchronization of chaotic systems have been investigated in various fields during recent years [1-3]. Due to their characteristics sensitivity to initial conditions, chaotic systems are not easy to identify. Recently, some researchers have endeavored to improve the identification of chaotic time series [4-6].

In the field of artificial intelligence, a fuzzy system using the human-like reasoning and expert knowledge can model complex nonlinear process characterized with ill-defined and uncertain factors. However, a fuzzy system lacks the learning capacity, it is difficult to fine tune fuzzy rules and membership functions from the training data. Neural networks have learning, adaption, and nonlinear mapping capacities, but the mapping rules in the networks is hard to understand. Therefore, FNNs combine the benefits of fuzzy logic and neural network, which is a popular research topic in system identification and control [7-9]. However, the number of fuzzy rule in the simplified fuzzy inference system and the initial parameters of FNNs are difficult to determine.

Recently, SVR [10] incorporated with FNNs has become a popular research topic. In this article, in order to overcome the above problems of training FNNs, first, an SVR method with Gaussian kernel function is adopted to determine the initial structure of the FNNs for identifying nonlinear systems [11, 12]. After initialization, an annealing robust concept in [12, 13] with ARTVLA is then applied to train the FNNs (ARTVLA-FNNs), in which PSO method is adopted to find optimal learning rates during learning procedure. A time-delay chaotic system will be given to illustrate the feasibility and efficiency of the proposed SVR-based ARTVLA-FNNs (SVR-ARTVLA-FNNs) for system identification of the Mackey Glass system.

II. ARCHITECTURE OF FUZZY NEURAL NETWORKS

A. Identification of Chaotic Time series

Let $\{\boldsymbol{x}\}$ be a chaotic system with time delay generated by an m-dimensional nonlinear dynamical system. According to Takens's delay embedding theorem [14], an embedding of

chaotic attractors can be obtained by constructing delay vectors

$$x(t+\tau) = f(x(t), x(t-\tau), x(t-2\tau), \cdots, x(t-(m-1)\tau)), \quad (1)$$

where $[x(t-\tau), x(t-2\tau), \cdots, x(t-(m-1)\tau)]$ is a proper vector, τ is the time-delay parameter, and m is the embedding parameter. If m is large enough, there exists a smooth function $f(\cdot)$ [15].

In this paper, the FNN will be applied to identify nonlinear systems due to the advantages of the self-learning ability of neural networks and the adaptive ability of fuzzy logic. The current output can be expressed as

$$\hat{x}_k(t+1) = \sum_{i=1}^{r} w_{ik} \exp\left(-\frac{(\boldsymbol{x} - b_i)^2}{2a_i^2} \right) \quad \text{for } k = 1, 2, \ldots, p, \quad (2)$$

where $\boldsymbol{x} = [x(t), x(t-1), \cdots, x(t-n)]$ is the input vector to FNNs, w_{ik} is the synaptic weight of the ith fuzzy rule for the kth FNN output, a_i and b_i are the widths and the centers of the ith membership function for all input data $\boldsymbol{x}$, respectively.

B. Fuzzy Neural Networks Model

The proposed architecture of FNNs is depicted in Fig. 1. It is a four-layered network structure that consists of input, membership function, inference rule, and output layers. In the FWNNs, a wavelet function is adopted as the membership function. Generally, the fuzzy rule of FNNs is expressed as

$$R_i: \text{IF } x_1 \text{ is } A_{i1} \text{ and } \ldots \text{ and } x_n \text{ is } A_{in},$$
$$\text{THEN } \hat{y}_{i1} = w_{i1} B_i \text{ and } \ldots \text{ and } \hat{y}_{ik} = w_{ik} B_i, \quad (3)$$

where R_i is the ith fuzzy rule, $1 \le i \le r$, x_j is the jth input, $1 \le j \le n$, y_{ik} is the kth output contributed by the ith fuzzy rule, $1 \le k \le p$, A_{ij} is the membership function for the ith fuzzy rule of the jth input characterized by a wavelet function, w_{ik} is the synaptic weight of the ith inference rule for kth system output, and B_i is the constant consequent of the ith fuzzy rule. The semantic meaning and operation function of the nodes in each layer are described as follows：

***Layer* 1** (input layer): In this layer, the number of nodes is equal to the number of input variables. These nodes are used to transmit the input linguistic values to the next layer directly.

***Layer* 2** (membership function layer): In this layer, each node corresponds to one input linguistic term in Layer 1. In other words, the membership value specifying the degree to which an input value belongs to a fuzzy set is calculated in this layer. To describe the linguistic terms, Gaussian function representing fuzzy membership functions is adopted as

$$\mu_{ij}(x_j) = \exp\left(-\frac{(x_j - b_{ij})^2}{2a_{ij}^2} \right), \quad (4)$$

where a_{ij} and b_{ij} for $i = 1, 2, \ldots, r$, $j = 1, 2, \ldots, n$ are the dilation and the translation of the ith wavelet membership function for the jth input variable x_j, respectively.

***Layer* 3** (inference rule layer): Each node represents one fuzzy rule in this layer. The AND (min) operation is applied to calculate the output of each node. That is, product inference method is used to determine the firing strength of each node. Each inference rule can be expressed as

$$B_i = \prod_{j=1}^{n} \mu_{ij}(x_j) \quad \text{for } i = 1, 2, \ldots, r, \quad (5)$$

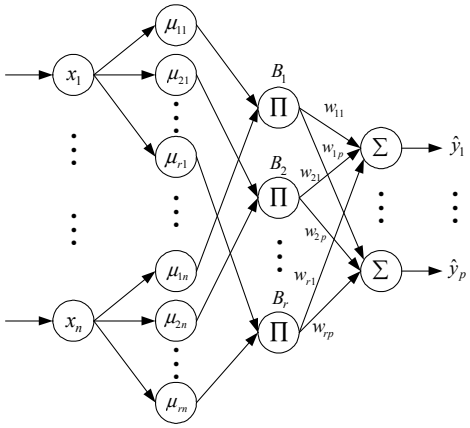

Figure 1. The architecture of fuzzy neural networks (FNNs).

***Layer* 4** (output layer): In this layer, each node represents an individual output of the FNN by using a simple weighted sum. The mathematic function of the kth output is shown as

$$\hat{y}_k = \sum_{i=1}^{r} w_{ik} B_i = \sum_{i=1}^{r} w_{ik} \prod_{j=1}^{n} \exp\left(-\frac{(x_j - b_{ij})^2}{2a_{ij}^2} \right), \quad (6)$$

where $\hat{y}_k$ for $k = 1, 2, \ldots, p$ is the kth FNN output.

It is very difficult, if not impossible, to solve the above problem directly. In usual cases, the initial values of r, w_{ik}, b_{ij}, and a_{ij} are chosen first. Then a training algorithm is applied to FNNs to search for the optimal combination of these values in an iterative manner. However, as mentioned above, there is no way to choose these initial values systematically. Therefore, in the following section, an SVR approach will be proposed to serve for this purpose.

III. SVR-ARTVLA-FNNS BASED ON PSO

A. SVR-Based Initial Structure of FNNs

When approximating an unknown function, SVR method can be adopted to build the initial structure of FNNs [10]. Meanwhile, assume that a set of basis functions, $g_l(\mathbf{x})$, $l = 1, 2, \cdots, L$, is given. Then the problem of function

approximation is transformed into finding the parameters of the following basis linear expansion

$$f(\mathbf{x},\boldsymbol{\theta}) = \sum_{l=1}^{L} \theta_l g_l(\mathbf{x}) + bias\,, \tag{7}$$

where $\boldsymbol{\theta} = (\theta_1, \theta_2, \cdots, \theta_L)$ is a parameter vector to be identified and *bias* is a constant to be determined.

From SVR method, one can find that the solution is to find $f(\mathbf{x},\boldsymbol{\theta})$ in (7) that minimizes

$$R(\boldsymbol{\theta}) = \frac{1}{N}\sum_{j=1}^{N} L_\varepsilon(y_1^{(j)} - f(\mathbf{x}^{(j)}, \boldsymbol{\theta}))\,, \tag{8}$$

subject to the constraint

$$\|\boldsymbol{\theta}\|^2 < C\,, \tag{9}$$

where $L_\varepsilon(\cdot)$ is the ε-insensitive loss function defined as

$$L_\varepsilon(e) = \begin{cases} 0 & \text{for } |e| \le \varepsilon \\ |e| - \varepsilon & \text{otherwise} \end{cases} \tag{10}$$

for some nonnegative number ε.

Vapnik [10] has applied the kernel function $K(\mathbf{x}_r, \mathbf{x}_s)$ to replace the inner product of basis functions $g_l(\mathbf{x}_r)$ and the Lagrange multiplier method has been adopted to minimize (8). Then the dual optimization problem can be expressed as follows:

$$\begin{aligned} \text{Min } Q(\alpha, \alpha^*) = \varepsilon\sum_{r=1}^{N}(\alpha_r + \alpha_r^*) - \sum_{r=1}^{N} y_r(\alpha_r - \alpha_r^*) \\ + \frac{1}{2}\sum_{r,s=1}^{N}(\alpha_r^* - \alpha_r)(\alpha_s^* - \alpha_s)K(\mathbf{x}_r, \mathbf{x}_s), \end{aligned} \tag{11}$$

subject to the constraint

$$\sum_{r=1}^{N}\alpha_r^* = \sum_{r=1}^{N}\alpha_r\,,\ 0 < \alpha_r^*, \alpha_r < C \tag{12}$$

and the solution is in the form of the following linear expansion of kernel functions

$$f(\mathbf{x}, \alpha, \alpha^*) = \sum_{l=1}^{L}(\alpha_l^* - \alpha_l)K(\mathbf{x}, \mathbf{x}_l) + bias\,. \tag{13}$$

Note that some of $(\alpha_l^* - \alpha_l)$'s are not zeros and the corresponding vectors $\mathbf{x}_l$'s are called *support vectors* (SVs).

The Gaussian function is used as the kernel function, then (13) can be rewritten as

$$f(\mathbf{x},\lambda) = \sum_{l=1}^{\#SV}\lambda_l \exp\left(-\frac{\|\mathbf{x} - \mathbf{x}_l\|^2}{2\sigma_l^2}\right) + bias\,, \tag{14}$$

where $\#SV$ is the number of SVs, $\lambda_l = (\alpha_l^* - \alpha_l) \neq 0$, and $\mathbf{x}_l$ denotes SVs. Comparing (14) with (2), *#SV*, *l*, λ_l, $\mathbf{x}_l$, and σ_l in (14) can be regarded as the *r*, *i*, w_{ik}, b_i, and a_i in (2), respectively.

B. ARTVLA-Based FNNs

With an initial structure, a learning algorithm must be established to train FNNs. In the training procedure of the proposed FNNs, the annealing concept in the cost function of robust back-propagation learning algorithm was adopted to overcome the existing problems in robust back-propagation learning algorithm, such as slow convergence rate and getting into local minimum. A cost function for the ARTVLA is defined here as

$$J_k(h) = \frac{1}{N}\sum_{j=1}^{N}\rho\left[e_k^{(j)}(h); \beta(h)\right] \text{ for } k = 1, 2, \cdots, p\,, \tag{15}$$

where

$$\begin{aligned} e_k^{(j)}(h) &= y_k^{(j)} - \hat{f}_k(\mathbf{x}^{(j)}) \\ &= y_k^{(j)} - \sum_{i=1}^{L} w_{ik}\exp\left(-\frac{\|\mathbf{x}^{(j)} - b_i\|^2}{2a_i^2}\right), \end{aligned} \tag{16}$$

h is the epoch number, $e_k^{(j)}(h)$ is the error between the *k*th desired output and the *k*th output of FNNs at epoch *h* for the *k*th input-output training data in a nonlinear system, $\beta(h)$ is a deterministic annealing schedule acting like the cut-off point, and $\rho(\cdot)$ is a logistic loss function defined as

$$\rho[e_k^{(j)}; \beta] = \frac{\beta}{2}\ln\left[1 + \frac{(e_k^{(j)})^2}{\beta}\right] \text{ for } k = 1, 2, \cdots, p\,. \tag{17}$$

Based on the gradient-descent kind of learning algorithms, the synaptic weights w_{ik}, the centers b_i, and the widths a_i of Gaussian functions are updated as

$$\Delta w_{ik} = -\eta_{w_k}\frac{\partial J_k}{\partial w_{ik}} = -\frac{\eta_{w_k}}{N}\sum_{j=1}^{N}\varphi_k(e_k^{(j)}; \beta)\frac{\partial e_k^{(j)}}{\partial w_{ik}}\,, \tag{18}$$

$$\Delta b_i = -\eta_b\frac{\partial J_k}{\partial b_i} = -\frac{\eta_b}{N}\sum_{j=k}^{p}\sum_{j=1}^{N}\varphi_k(e_k^{(j)}; \beta)\frac{\partial e_k^{(j)}}{\partial b_i}\,, \tag{19}$$

$$\Delta a_i = -\eta_a\frac{\partial J_k}{\partial a_i} = -\frac{\eta_a}{N}\sum_{k=1}^{p}\sum_{j=1}^{N}\varphi_k(e_k^{(j)}; \beta)\frac{\partial e_k^{(j)}}{\partial a_i}\,, \tag{20}$$

$$\varphi_k(e_k^{(j)}; \beta) = \frac{\partial\rho(e_k^{(j)}; \beta)}{\partial e_k^{(j)}} = \frac{e_k^{(j)}}{1 + (e_k^{(j)})^2 / \beta(h)}\,, \tag{21}$$

where η_{w_k}, η_b, and η_a are the learning rates for the synaptic weight w_{ik}, $k = 1, 2, \cdots, p$, the center b_i, and the width a_i, respectively; $\varphi(\cdot)$ is usually called the influence function. In the ARTVLA, the annealing schedule $\beta(h)$ has the properties:

(A) β_{initial}, $\beta(h)$ for the first epoch, has large values;

(B) $\beta(h) \to 0^+$ for $h \to \infty$;

(C) $\beta(h) = \kappa / h$ for any h epoch, where κ is a constant.

When the learning rates are constant in (18) to (10), the work for selecting an appropriate learning rate is tedious; moreover, there exists a tendency to get stuck in a near-optimal solution or to converge slowly. To overcome the stagnation in searching a globally optimal solution, an ARTVLA is proposed to approach the optimal solution closely in this paper. In the learning procedure, considering the search space, a large learning rate is selected at the beginning. Once the algorithm is found to converge more and more towards the optimum, the evolution process is gradually converted to a finer and finer tuning by a smaller learning rate in later epochs. Then, in the ARTVLA, a nonlinear time-varying evolution concept is adopted over iterations, in which the learning rates η_w, η_b, and η_a with a high value $\eta_{\max}$ and nonlinearly decreases to $\eta_{\min}$ at the maximal number of epochs, respectively. This means that the mathematical expressions are given as shown as

$$\eta_w = \eta_{\min} + \left(1 - \frac{h}{epoch_{\max}}\right)^{pw} (\eta_{\max} - \eta_{\min}), \tag{22}$$

$$\eta_b = \eta_{\min} + \left(1 - \frac{h}{epoch_{\max}}\right)^{pb} (\eta_{\max} - \eta_{\min}), \tag{23}$$

$$\eta_a = \eta_{\min} + \left(1 - \frac{h}{epoch_{\max}}\right)^{pa} (\eta_{\max} - \eta_{\min}), \tag{24}$$

where $epoch_{\max}$ is the maximal number of epochs and h is the current number of epochs. In the updated procedure, appropriate functions for the learning rate η_w, η_b, and η_a can promote the performance of FNNs. However, simultaneously determining the optimal combination of *pw*, *pb*, and *pa* is a time-consuming work. An efficient evolutionary algorithm, PSO, will be adopted to determine the optimal solution (*pw*, *pb*, *pa*).

C. Particle Swarm Optimization

PSO is a population-based stochastic searching technique developed by Kennedy and Eberhart [16]. It is similar to the continuous genetic algorithms, in which it begins with a random population matrix and searches for the optimum by updating generations. However, the PSO has no evolution operations such as crossover and mutation. The potential of this technique makes it be a powerful optimization tool which has been successfully applied to many fields. Nowadays PSO has been developed to be real competitors with other well-established techniques for population-based evolutionary computation [17-19].

In this paper, the PSO method is adopted to find the optimal combination (*pw*, *pb*, *pa*) of learning rates in (22) to (24) for system identification. When applying the PSO method, possible solutions must be encoded into particle positions and a fitness function must be chosen. In the system identification, the goal is to minimize the error between the desired outputs and the trained outputs. Therefore, the root mean squares error (*RMSE*) should be used to define a fitness function. This means that the fitness function will be defined as

$$RMSE = \sqrt{\frac{1}{N}\sum_{j=1}^{N}\left(y^{(j)} - \hat{y}^{(j)}\right)^2}, \tag{25}$$

where $y^{(j)}$ is the desired output, $\hat{y}^{(j)}$ is the trained output for *N* sampling data.

IV. Simulation Results

In the identification scheme of a chaotic system, training input-output data are obtained by feeding a time series $[x(t), x(t-\tau), x(t-2\tau), \cdots, x(t-(m-1)\tau)]$ to the system and to predict its corresponding output $x(t+\tau)$ Then subject to the same input data, the objective of identification is to construct an SVR-ARTVLA-FNNs model based on PSO method, which produces an output $\hat{x}(t+\tau)$ to approximate $x(t+\tau)$ as closely as possible.

In this section, a time-delay chaotic system with outliers is used to verify the feasibility of the proposed SVR-ARTVLA-FNNs. When applying the proposed algorithm, the population size, the maximal iteration number, and the maximal epoch number are chosen to be 30, 200, and 500, respectively. As for the parameters in PSO, the best ranges were presented [19]. The variables *pw* *pb* and *pa* in learning rate functions (22) through (24) are all chosen as real numbers in the range $[0.1, 5]$. In PSO, the particles are updated by linearly time-varying evolutionary algorithm in [19]. Meanwhile, the values of $\eta_{\max}$ and $\eta_{\min}$ are set as 1.0 and 0.01, respectively. To evaluate the performance of the proposed FNNs, *RMSE* of the training data is adopted as

$$RMSE = \sqrt{\frac{1}{N}\sum_{j=1}^{N}\left(x_j(t) - \hat{x}_j(t)\right)^2}, \tag{26}$$

where $x_j(t)$ is the desired output of the chaotic time series, $\hat{x}_j(t)$ is the trained output of the proposed FNNs.

***Example*:** A typical chaotic system, Mackey Glass time-delay series, is considered as an example described as follows [6]:

$$x = \frac{px(t-\tau)}{1 + x^r(t-\tau)} - qx(t), \tag{27}$$

where $p = 0.2$, $q = 0.1$, $r = 10$, τ is the time-delay parameter. If $\tau \geq 17$, the time series show the chaotic phenomenon. To compare with [6, 20], the time series are chosen as

$$x(t+6) = f(x(t), x(t-6), x(t-12), x(t-18\tau)), \qquad (28)$$

where $x(t)$, $x(t-6)$, $x(t-12)$, and $x(t-18)$ are the inputs of the proposed FNNs; $x(t+6)$ is the output of the FNNs.

In the simulation, 1000 time-delay series are generated from (27) with initial value $x(0) = 1.2$. The former 500 data are selected as the training data for identifying the Mackey Glass system shown in Fig. 2. Assume that the membership function is Gaussian function and initial structures are obtained by an ε-SVR approach, in which the parameters are set as $C = 10$, $\varepsilon = 0.3775$ in (9) and (10).

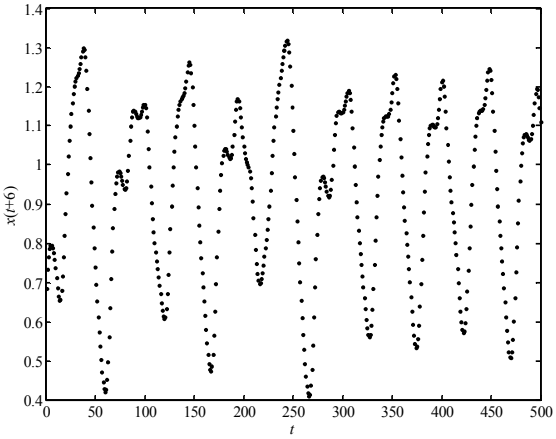

Figure 2. Training data without outliers for identifying time-delayMackey Glass system.

Problem 1:

The training data with no outliers are fed into the FNNs. The initial values of w_{ik}, b_i, and a_i in (2) can be determined by ε-SVR approach. Meanwhile, the number of fuzzy rules is obtained as 23.

Based on the above initial structure of FNNs, ARTVLA with nonlinear learning rates to train the SVR-FNNs, in which the optimal learning rates are determined by PSO method. Then, the optimal sets (pw, pb, pa) in (22) to (24) are obtained as (4.241218, 2.050131, 3.700988). Meanwhile, the final value of *RMSE* with ARTVLA-FNNs is found to be 0.005886. With the optimal learning rates, the errors of training data after 500 epochs are illustrated in Fig. 3.

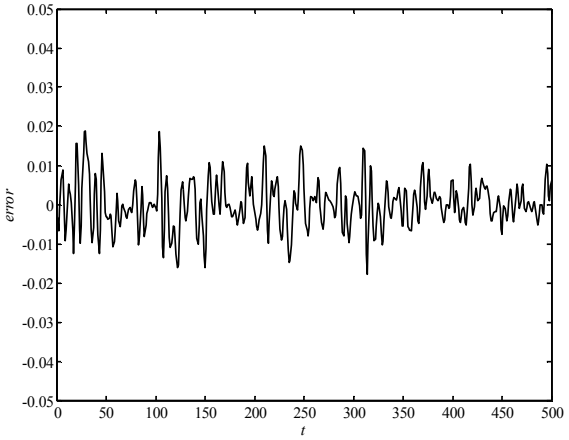

Figure 3. The plots of $error = x(t) - \hat{x}(t)$ for 500 training data without outliers after 500 training epoch.

Problem 2:

The training data with 10 artificial outliers shown in Fig. 4 are fed into the FNNs. The initial values of w_{ik}, b_i, and a_i in (2) can be determined by ε-SVR method. Meanwhile, the number of fuzzy rules is obtained as 25.

Based on the above initial structure of FNNs, ARTVLA with nonlinear learning rates to train the SVR-FNNs, in which the optimal learning rates are determined by PSO method. Then, the optimal sets (pw, pb, pa) in (22) to (24) are obtained as (2.306907, 0.979595, 2.961404). Meanwhile, the final value of *RMSE* with ARTVLA-FNNs is found to be 0.007477. With the optimal learning rates, the errors of training data after 500 epochs are illustrated in Fig. 5.

From the above results, the feasibility of the ARTVLA-FNNs has been confirmed. The final *RMSEs* of the proposed FNNs and other FNNs of [6] are shown in Tables I. From the results, show that the proposed ARTVLA-FNNs can overcome the outliers and get a good performance for training data. Moreover, the comparison of *RMSE* with other NNs for Mackey-Glass time series without outliers after 500 training epochs is shown in Table II, in which the superiority of the proposed ARTVLA-FNNs can be verified.

V. CONCLUSIONS

This paper presents the integrating SVR and ARTVLA to train FNNs for identification of a time-delay chaotic system. With the initial structure of the FNNs using SVR method, the nonlinear time-varying learning rates are simultaneously determined by PSO method to perform the ARTVLA. Then the optimal FNNs are obtained to identify the Mackey-Glass chaotic system. From the simulation results, one can conclude that the proposed SVR-ARTVLA-FNNs using PSO method have good performance for identification of the time-delay series system. Meanwhile, the superiority of the proposed ARTVLA-FNNs with nonlinear learning rates over the other NNs for identification has been verified. The proposed SVR-ARTVLA-FNNs can be further extended to identify more complex chaotic systems.

Abstract—**In this paper, a novel data clustering algorithm based on the *subtractive clustering* (SC) algorithm and a new validity index are proposed. The SC algorithm is a simple method for data clustering; however, it has two problems which must be overcome. The first problem is such that the cluster centers found by SC are taken from data with the highest potential values, but that this data may not be the real cluster centers. The second problem is such that the cluster number generated by the SC algorithm is influenced by a predefined parameter. The proposed algorithm is based on distance relations between data and centers and is designed to ascertain the real centers generated by the SC algorithm. In addition, a novel robust cluster index is proposed to identify the real cluster number generated by SC algorithm.**

Keywords- validity index, subtractive clustering (SC) algorithm, clustering algorithm

1. INTRODUCTION

In classical set theory, the membership of datum to a set is assigned using a value of 0 or 1. Let $\mu_A(x)$ denote the membership value of x belonging to cluster A (or set A). If one datum x belongs to cluster A, the membership value $\mu_A(x)$ is 1, otherwise, its value is 0; this clustering method is called hard partition. However, in practical applications, there are ambiguities found in the data set such that some data may or may not be partitioned into one cluster. In this situation, the membership value $\mu_A(x)$ of x is assigned to a range of [0,1]; this method is called *soft partition*. The fuzzy clustering algorithm based on fuzzy set theory is the most well known soft partition method. In the context of a fuzzy set, a value close to 1 for $\mu_A(x)$ denotes a high degree of membership, while a value close to 0 denotes a low degree of membership. Numerous successful applications of fuzzy clustering have been proposed, such as handwritten digit recognition [1], function approximation [2][3][4], and image processing [5].

There have been numerous fuzzy clustering methods proposed in the literature [6]-[11]. The fuzzy c-means algorithm (FCM) [7][8] has become the most popular fuzzy clustering approach for both theoretical and practical applications in recent decades. However, the FCM algorithm has two disadvantages: (1) the number of clusters has to be known in advance but, in many applications, this knowledge is often not available; (2) when the data training contains outliers, the resultant centers are always influenced by outliers. To overcome the first disadvantage, the results of the analyses pertaining to different numbers of clusters have to be compared to each other using a validity function in order to ascertain an optimal cluster number. As regards the second disadvantage, when the training data contains noise/outliers, the results obtained by FCM are always affected by noise/outliers.

2. A New Clustering Algorithm

The *mountain method* (MM) proposed by Yager and Filev in 1994 [12] is an effective and simple method for identifying the cluster center of the sampling data. The mountain method divides data space into several intervals to construct grids and then evaluates its energies by substituting the distance from the grid to the data points into the objective exponential function in order to determine the approximated cluster centers at the grid with the maximum energy.

Let $X=\{x_1,x_2,\ldots,x_n\}$ be a set of n vectors in a d-dimensional feature space, that is, $x_i \in \Re^d$ is a vector, and x_{kj} denotes the j-th coordinate of the k-th data point, where $k = 1,2,\ldots, n$ and $j = 1,2,\ldots, d$.

The MM for data clustering is divided into three steps:

Step1: first, the mountain function involves constructing a grid on the data space where the intersections of the grid lines are considered to be candidates for the cluster centers.

Step2: the second step entails constructing a mountain function representing a data energy measurement. The value of the mountain function at grid node N_i is calculated by:

$$M(N_i) = \sum_{k=1}^{n} \exp(-\alpha \cdot d(x_k, N_i)), \qquad (1)$$

where α is an application-specific positive constant and $d(x_k,N_i)$ is the distance between the data point x_k and the grid node N_i. The value of the mountain function can be seen to represent the potential ability of any of the grid nodes to be a cluster center. The higher mountain function value of the data is selected as the cluster center.

Step 3: the third step involves an iterative selection of the next cluster centers and a sequential deconstruction of the mountain function value. In each iterative process, the grid node that has the largest energy is selected as the cluster center and the energies of the remaining grid nodes must be eliminated in order to identify the next one. Let N_k^* , $k=1,2,\ldots,c_{max}$, denote the grid node that

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

has the maximal value of the mountain function at the k-th iteration. The maximal value of the mountain function M_k^* is denoted as:

$$M_k^* = \max_i M_k(N_i) \quad (2)$$

The new modified value of the mountain function is defined as follows:

$$M_{k+1}(N_i) = M_k(N_i) - M_k^* \times e^{-\beta d(N_i - N_k^*)} \quad (3)$$

Where β is a predefined positive constant. The MM continually produces new cluster centers and reduces the value of the mountain function until the level of the current maximum M_k^* compared with the original maximum M_1^* becomes too low.

Although the mountain method is a simple method for data clustering and has robust properties against outliers and noise, it has a notable problem that must be overcome. That is, because the mountain function calculates its energies on the grid nodes, the grid nodes and computational loads increase exponentially as the dimensions increase. In 1994, Chiu [13] modified the mountain method to construct a potential function for calculating the clustering center of the sampling data. The proposed method is also called the subtractive clustering (SC) algorithm. In the SC algorithm, the data points are likened to energy sources. The potential generated by each feature point has a peak value at the location of the data point which decreases rapidly at any point away from the data point [14]. The potential of each data point x_i is defined as:

$$P(x_i) = \sum_{k=1}^{n} \exp(-\alpha \cdot d(x_i, x_k)), \quad (4)$$

where $\alpha = \frac{4}{r_a}$, and r_a is a positive constant that is effectively the radius defining a neighborhood. In Equation (4), the total potential of any data point x_i is defined as the sum of the potentials contributed by each data point at x_k. It is reasonable to assume that the peaks of the total potential function correspond to cluster prototypes and that the valleys correspond to the decision boundaries between the clusters [14].

After the potential of each data point is obtained, the data point with the highest potential is selected as the first cluster center. Assume x_1^* is the first cluster center and its potential value is p_1^*. Then, the potential of each data point can be revised by:

$$P(x_i) = P(x_i) - p_1^* e^{-\beta d(x_i, x_1^*)}, \quad (5)$$

where $\beta = \frac{4}{r_b}$, and r_b is a positive constant which is effectively the radius defining a neighborhood that will have measurable reductions in potential. In [13], a good choice for r_b is 1.5 r_a. To find the next cluster center, x_2^*, the new revised potential is maximized and the effects of this cluster center are again removed. The process is repeated until a given threshold for the potential is obtained so that:

$$\frac{p_j^*}{p_1^*} < \delta. \quad (6)$$

In the above equation, δ is a given threshold. The choice of δ is an important factor affecting the clustering results; if δ is too large, then too few data points will be accepted as cluster centers and if δ is too small, then too many cluster centers will be generated [13].

There are two problems that must be overcome: (1) the SC algorithm assumes that the clustering center is x_i^* obtained by the i^{th} iteration. However, the x_i^* may be a rough cluster center which does not represent the actual cluster center; (2) there is no index to indicate what the optimal number of clusters for a data set is. For overcoming the first problem, this paper proposes a new algorithm based on distance measurements to identify the actual cluster centers. For overcoming second problem, this paper proposes a new validity index for the SC algorithm to indicate the goodness of the partitions in various cluster numbers. The proposed validity index combines the compactness in each cluster, the separation between clusters, and the correct ratio of data being properly partitioned into clusters to whole data set.

Let x_i^*, $i = 1,2,\ldots,c_{max}$ are the cluster centers obtained by the SC algorithm, the distance relation between the centers x_i^* and data x_j is defined by the following equation:

$$D_{ij} = \exp(-\alpha \| x_j - x_i^* \|^2), i = 1, 2, \ldots, c_{\max}, j = 1, 2, \ldots, n, \quad (7)$$

where $\|x_j - x_i^*\|$ represents the Euclidean distance between x_j and x_i^* and where α is a constant defined in Equation (4). The value of D_{ij} indicates the distance relationship between x_j and x_i^*. In other words, for a cluster center x_i^*, any data x_j that has high value of D_{ij} indicates that this data x_j is close to the cluster i. Set N_ϵ denotes the number of data which has $D_{ij} \geq \epsilon$, where $\epsilon \geq 0$ is a constant. In this paper, ϵ is set to 0.5. The new center of cluster i is defined by the following equation:

$$v_i = \frac{\sum_{k=1}^{N_\varepsilon} x_k^i}{N_\varepsilon}, \quad (8)$$

where x_k^i are the data which have $D_{ik} \geq \epsilon$. In Equation (8), v_i is the mean of data close to cluster i. In each iterative epoch of the SC algorithm, when a new rough cluster center x_i^* is found, Equation (8) is adopted to evaluate the real cluster center; the potential of the data point can be revised by:

$$P(x_k^i) = P(x_k^i) - p_i^* e^{-\beta d(x_k^i, v_i)}. \quad (9)$$

The differences between the proposed method and the original SC algorithm are such that: (1) the cluster centers obtained by the proposed method provide a more accurate real cluster center than the cluster centers obtained by the SC algorithm; and (2), in each iterative epoch of the proposed method, the revised potential of Equation (9) uses relative data, x_k^i, that is close to the cluster center *i*, while the revised potential of the SC algorithm in Equation (5) uses all sampling data. That is to say that the proposed method requires less computation of data than SC algorithm.

3. A ROBUST VALIDITY INDEX

A *validity index* is a function which assigns to the output of the clustering algorithm a value to measure the qualities of the partitions provided by the output. The cluster number of SC algorithm is determined in Equation (6) but it is not used for evaluating the fitness of partitions obtained through fuzzy clustering. The validity index for finding an optimal *c,* denoted c^*, which can completely describe the data structure, has become the most studied topic in cluster validity. Several popular validity indexes are reviewed in [15][16].

The partition coefficient (PC) index proposed by Bezdek [17] in 1974 was the first index for the FCM algorithm. et $X=\{x_1,x_2,\ldots x_n\} \subset \Re^d$ be a data set in a *d*-dimensional feature space and μ_{ik} be the membership value of data x_i belonging to cluster *k*. The PC index is defined as:

$$\mathrm{PC}(c) = \frac{1}{n}\sum_{k=1}^{c}\sum_{i=1}^{n}(\mu_{ik})^2 , \quad (10)$$

$$\text{and} \quad \sum_{k=1}^{c}\mu_{ik} = 1, \quad \frac{1}{c} \le PC(c) \le 1 .$$

As regards a clustering algorithm for the partitioning of a data set, the optimal cluster number occurs when the PC (*c*) is at maximal value. The core idea of the PC index is such that the optimal cluster number occurs when the data are most unambiguously partitioned into clusters. The disadvantage of the PC index is that it only considers the fuzzy membership degree μ_{ik} for each cluster without considering the structure of the clusters.

The other index proposed by Bezdek is the partition entropy (PE) index [17][18]. The PE index is defined as:

$$PE(c) = -\frac{1}{n}\sum_{k=1}^{c}\sum_{i=1}^{n}\mu_{ik}\log_a(\mu_{ik}) , \quad (11)$$

where *a* is the base of the logarithm and the range of the PE(c) is $[0, \log_a(c)]$. For finding an optimal c^*, we solve min $_{2\le c\le c_{\min}}$ PE(c) to produce the best clustering performance for a data set. The disadvantage of the PE index is analogous to the PC index, i.e., the PE index will take the minimum value on every hard partition. These two indexes only evaluate the fuzziness and do not consider the data structure of the clusters.

The Xie and Beni (XB) index [19], combined compactness and separation properties, is defined as follows:

$$XB(c) = \frac{\sum_{k=1}^{c}\sum_{i=1}^{n}\mu_{ik}^2 \,\| x_i - v_k \|^2}{n \times min_{i\ne j}(\| v_i - v_j \|)} . \quad (12)$$

Where v_i and v_j represent the centers of cluster *i* and *j*, respectively, while $\|v_i - v_j\|$ represents the Euclidean distance between v_i and v_j. In Equation (12), the numerator indicates the compactness of the fuzzy partition while the denominator indicates the strength of the separation between clusters [20]. A small value in the numerator of the XB index represents a high level of compactness, while a high value in the denominator denotes good separation between clusters. Hence, the lowest $\mathrm{XB}(c), 2 \le c \le c_{\max}$ indicates the optimal cluster number for a data set *X*. However, the separation measurement of the XB index adopts the minimal distance between cluster centers; when cluster number *c* is close to the candidate of the data set, the XB index decreases to the lowest value.

The Fukuyama and Sugeno (FS) index [21] is another index which combines the properties of compactness and separation measurements. The FS index is defined as follows:

$$\mathrm{FS(c)} = \sum_{i=1}^{n}\sum_{k=1}^{c}(\mu_{ik})^m \| x_i - v_k \|^2 - \sum_{k=1}^{c}\left\{\left[\sum_{i=1}^{n}(\mu_{ik})^2\right]\cdot\| v_k - \bar{v}\|\right\}, \quad (13)$$

where $1 < m < \infty$, and $\bar{v} = \frac{1}{c}\sum_{i=1}^{c} v_i$ represents the mean of the cluster centroids. In Equation (13), the first term represents the geometrical compactness of the clusters and the second term indicates the separation between the clusters. When *m* is 2, the first term of the FS index equals the numerator of the XB index. The second term of the FS index is used for the separation measurements. The optimal cluster number is obtained by solving $\min_{2\le c\le n-1} FC(\mathrm{c})$.

The I-index was proposed by Maulik and Bandyopadhyay [22] in 2002. The I-index is defined as:

$$I(c) = \left(\frac{1}{c}\times\frac{E_1}{E_c}\times D_c\right)^2 . \quad (14)$$

Where

$$E_c = \sum_{i=1}^{n}\sum_{j=1}^{c}\mu_{ij}\| x_i - v_j \| , \quad (15)$$

and

$$D_c = \max_{i,j=1}^{c}\| v_i - v_j \| . \quad (16)$$

To find the optimal c^*, the authors tried to solve the max $_{2\le c\le c_{\max}}$ I(c) in order to obtain the best clustering performance for the data set.

In real applications, data domains are often affected by noises and outliers. The resultant partitions obtained by clustering algorithms are consistently affected by those variables and, surprisingly, there has been little discussion in

the literature about the influence of noises and outliers on validity indexes. In this paper, a novel robust validity index is proposed to indicate the adequacy of partitions in a data set with regard to noise and outliers.

Let $X=\{x_1,x_2,\ldots,x_n\} \subset \Re^d$ be a data set in a d-dimensional feature space and $W=\{w_{ik} \mid 0 \le w_{ik} \le 1\}$, $1 \le i \le n, 1 \le k \le c$ be a matrix, where w_{ik} is the membership degree of x_i belonging to cluster k, and $v=\{v_1, v_2, \ldots, v_c\}$ is a set of the cluster centers, where $v_k \in \Re^d$. The w_{ik} is defined by:

$$w_{ik} = \exp(-\frac{\| x_i - v_k \|^2}{\rho^2}), \quad (17)$$

where $\|x_i - v_k\|$ represents the Euclidean distance between x_i and v_k, and ρ is the width of the Gaussian function. In the proposed method, $\rho = \sqrt{\alpha}$, where α is defined by Equation (4). Let F represent a fuzzy set of data x_i belonging to cluster k. Hence, F can be characterized by Equation (17). An α- cut of a fuzzy set F is a crisp set F_α that contains all the elements in X which have membership values in F greater than or equal to α, that is:

$$F_\alpha = \{x_i \in X | w_{ik} \ge \alpha\} \quad (18)$$

This paper assumes that $\alpha = 0.5$ and that Γ represents the number of data satisfying $w_{ik} \ge \alpha$, that is:

$$\Gamma = |F_{0.5}|, \quad (19)$$

where $|\ |$ is the number of elements in a set. When a data x_i closes to cluster k, then w_{ik} is greater than or equal to 0.5 and x_i can be partitioned into cluster k. Hence, this paper defines a parameter τ named *partitioned index* to indicate the ratio of data that has been properly partitioned to all data. Thus, τ is defined as:

$$\tau = \frac{\Gamma}{|X|}. \quad (20)$$

For indicating the fitness of the number of partitions in a data set with noises and outliers, this paper combines compactness, separation, and τ properties to propose a new validity index, CSα, as follows:

$$CS\alpha(c) = (\frac{1}{\tau \times D_{\min}}) \times com. \quad (21)$$

Where,

$$D_{\min} = \min_{i \ne j} (\| v_i - v_j \|), \quad (22)$$

$$com = (\frac{1}{n^2} \sum_{k=1}^{c} \sum_{i=1}^{n} \mu_{ik}^2 \| x_i - v_k \|^2 \times \sum_{k=1}^{c} \sum_{i=1}^{n} \mu_{ik} \| x_i - v_k \|), \quad (23)$$

and,

$$\sum_{k=1}^{c} \mu_{ik} = 1. \quad (24)$$

To find the optimal number of clusters, this paper solves the $\min_{2 \le c \le c_{max}} CS\alpha$. The CSα is subject to three factors: $\frac{1}{\tau}$, $\frac{1}{D_{\min}}$, and *com*.

4. Experimental Results

In this section, two data sets are used to show that the validity index proposed in this paper outperforms other indexes proposed in the literature. For all experiments undertaken in this paper, it is reasonable to regard the square root of n as the upper limit of the optimal number of clusters [23], that is $c_{max} = \sqrt{n}$, where n is the candidate of data set.

Example 1: this example is used to test the performance of various indexes for a data set without noise. Fig. 1(a) shows a data set made up of four clusters and the stars denote the cluster centers obtained by the proposed method. Each cluster has fifty data points, hence, the $c_{max} = \sqrt{200} = 14$. Figs. 1(b)-(f) show the results obtained by PE, XB, FS, I-index and CSα, respectively. The results show that the XB, FS, I-index and CSα indexes can correctly indicate the cluster number of this data set, but the PE index indicate that the optimal numbers of clusters is two. This result shows that the XB, FS, I-index and CSα indexes performe equally as well, but that PE did not have good performance.

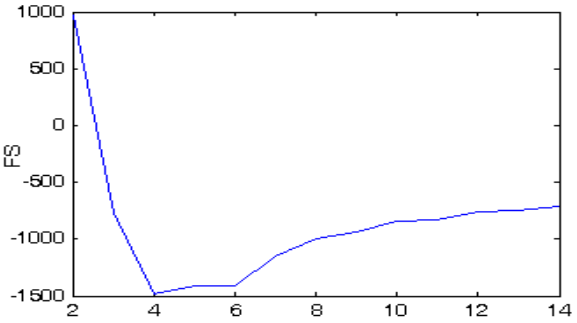
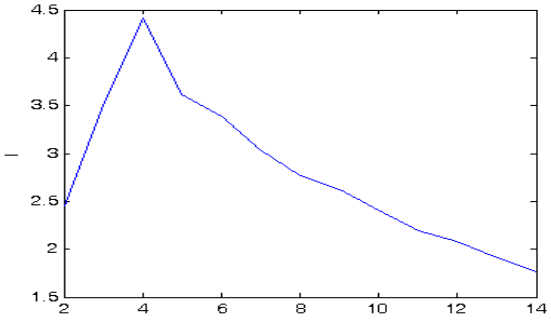
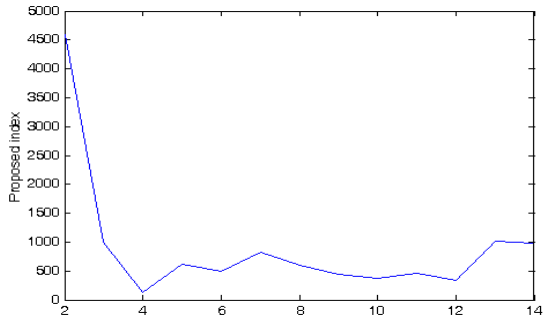
(c)



(d)



(e)



(f)

Fig.1: A data set contains four clusters.

Example 2: In this experiment, 100 noises are added to the data set used in Example 1 to test the proposed clustering and validity index. Fig. 2(a) shows the data set containing three clusters and noises and stars denote the cluster centers obtained by the proposed clustering algorithm. The performances of various indexes for this data set are shown in Figs. 2(b)-(f). The results show that only the proposed index can correctly indicate the optimal number of clusters. The PE, XB, FS, and I-index obtain the optimal number of clusters at two clusters.

5. Conclusions

In this paper, a novel data clustering algorithm based on the SC algorithm and a new validity index are proposed. The proposed clustering algorithm adopts the distance relations between data points and cluster centers obtained by using the SC algorithm to evaluate real cluster centers. In addition, a new validity index composed of compactness, separation, and a partitioned index is proposed to measure the fitness of various cluster numbers. Two examples show that the proposed clustering algorithm can obtain correctly the cluster centers, and the proposed index can indicate correctly the cluster numbers of data set with noises.

***Abstract*—A nonlinear multi-regression based on fuzzy integral (NAFI) model that include outliers under inherent interaction among feature attributes is considered in this paper. The modeling of the proposed model is also performed via a modified algorithm base on particle swarm optimization with quantum-behavior (MQPSO) and the high breakdown value estimator, least trimmed squares (LTS). That is, we successfully integrate mechanisms of the genetic algorithm and the simulated annealing into the QPSO algorithm to estimate parameters of the NAFI model; meanwhile, the LTS estimator is also introduced to filter out outliers. From simulation results, the proposed MQPSO algorithm with LTS estimator (named QPSO-GS) readily corrects the deviation caused by outliers and swiftly achieves convergences on estimating the parameters of the proposed NAFI model with outliers.**

Keywords- Fuzzy integral; nonlinear multi-regression based on fuzzy integral; particle swarm optimization with quantum-behavior; least trimmed squares.

I. INTRODUCTION

In the modern world, to accomplish an optimal decision in aeronautics, economics, industry, science, manufacturing, traffic control, and many other military and civilian applications extremely depend on useful and crucial information which is drawn from messages or data via transformation, classification and/or other procedure. Therefore, multi-sensor systems providing these messages or data are becoming increasingly important in meeting the goal of optimal decision-making. Besides, a feasible model to elaborate on information fusion and a soft computing technique to perform the heavy computations are also critical.

Within the consideration to a feasible model, traditionally, the most common forms are the weighted average model and the linear regression model. These models are all linear and must assume that there is no interaction among feature attributes (i.e. inputs). However, in many real-world systems, the inherent interaction among feature attributes must be considered circumspectly and these kinds of systems are essentially non-additive systems. Hence, a nonlinear multi-regression based on fuzzy integral (NAFI) model with respect to non-additive set function is a powerful consideration to cope with these kinds of systems. In general, Choquet integral is the most frequent form of the fuzzy integral and there are a few literatures have been proposed [1-4]. Liu et al. [1] proposed a NAFI model derived from one of the following three kinds of fuzzy supports, that is, the bespoke fuzzy support, the sample relative fuzzy support and the response correlative fuzzy support. This model deals with the interaction among feature attributes based on the correlation in statistics. Wang et al. proposed the original [2] and weighted [3-4] NAFI model to deal with the information with numerical and categorical feature attributes, respectively. In fact, the weighted NAFI model is the generalized form of the original one. In these two models, the interaction among the feature attributes toward the objective attributes (i.e. outputs) is described as non-additive set functions and is practically deferent from the co-relationship in the statistics. The problem that exactly finds out these parameters is an essential optimization problem and the basic idea is making the residuals as small as possible. Residuals here are defined as the difference between what is actually observed and what is estimated. To minimize residuals, the well-known tool, Least Square (LS) method is introduced and always makes a remarkable estimation in the circumstance that all attributes are uncontaminated with outliers. Unfortunately, these feature and objective attributes are usually subject to outliers in the real world applications. That is, outliers may occur due to various reasons, such as erroneous measurements or the data with a heavy-tailed distribution functions. Whenever the outliers exist, they make a serious deviation of what is estimated all the time. Within outlier detection literatures [5-7], the least trimmed squares (LTS) estimator which possesses not only high breakdown value but also several advantages over the other methods is the most popular form to eliminate effects caused by outliers. In this study, therefore, we focus our efforts on the LTS estimator to eliminate the inference from outliers.

Subsequent to confirming the feasible model and previous analysis, to efficiently and swiftly estimate parameters satisfying appointed criteria from observations, a timesaving soft computing technique is necessary for the information fusion system with contaminated attributes. In literatures, there are many outstanding soft computing techniques qualify for this work; they are neural network [8], genetic algorithm (GA) [9], hybrid learning [10], etc. Particle swarm optimization with quantum-behavior (QPSO) which is an improved type on the traditional particle swarm optimization (PSO) would be one of the powerful choices [11-12]. The QPSO algorithm behaves

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

high performance in single mode systems, because of the property of swift convergence. However, particles usually fall into local extreme state in multimode optimization systems and then take on the premature phenomenon. In order to overcome these defects, we proposed a QPSO algorithm with elitist crossover mechanism of the GA (named MQPSO) in our previous work [13] and performed a superior performance. In this paper, we improve the MQPSO algorithm to manipulate systems with outliers which make serious deviations. That is, the mechanism of the LTS estimator is introduced to eliminate deviation caused by outliers and enhance robustness of the MQPSO, and it is named QPSO-GS. The significant improvement is that the QPSO-GS algorithm combines the concepts of the GA and the simulated annealing (SA) within the QPSO algorithm to achieve global search and overcome prematurity in optimal process, respectively; meanwhile, the LTS estimator is also performed to eliminate the inference from outliers. In order to verify the proposed QPSO-GS algorithm, a numerical example is also performed in this study. From the results of experiment, the proposed QPSO-GS algorithm is able to make a reasonable estimation on parameters of the NAFI model and then, quite precise objective attributes are also acquired.

The rest of paper is organized as follows: in Section II, the NAFI model is proposed. Section III, the least trimmed square estimator and the QPSO algorithm are briefly described. Next, we propose the QPSO-GS algorithm in detail. Section V, the numerical simulation results are demonstrated and then the paper is concluded in Section VI.

II. CHARACTERIZATION OF THE NAFI MODEL

In traditional linear aggregations, the most frequent model to describe the relation between feature attributes X and objective attribute Y is the Lebesgue-like integral [14]. However, in many real-world systems, the inherent interaction among feature attributes must be considered circumspectly. Hence, to reasonably describe the inherent interaction among feature attributes, Wang and Klir [15-16] proposed a regular non-additive set function μ defined on the power set of feature attributes and named fuzzy measure (FM). The formal definition of the FM can be express as

$$\mu(\varnothing)=0,\ \mu(X)=1,\ \varnothing\in P(X), \tag{1}$$

$$A\in P(X),\ B\in P(X), \text{ and } A\subset B\Rightarrow \mu(A)\le\mu(B). \tag{2}$$

Besides, a fuzzy integral is also introduced to aggregate the feature attributes. That is, whenever we deal with information fusion systems where information possesses inherent interaction, the fuzzy integral with respect to the FM is the most reasonable tools. In practical applications, there are many kinds of fuzzy integrals such as Choquet integral [17], Sugeno integral [18] and Wang integral [19], and so on. Considering simplicity and accuracy, the Choquet integral is the most frequent form and then, the Choquet integral with respect to the FM is defined as follows

$$\int f d\mu=\int_0^{\infty}\mu(F_\alpha)d\alpha, \tag{3}$$

where f is non-negative measureable function with n-dimensions on X, and $F_\alpha=\{x\mid f(x)\ge\alpha, x\in X\}$, $\alpha\in[0,\infty)$, is called the α-cut set of function f. Since X is a finite set, in this work, and the value of measureable function f can be sorted as

$$\min_{1\le i\le n} f(x_i)=f(x_1^*)\le\cdots\le f(x_n^*)=\max_{1\le i\le n} f(x_i), \tag{4}$$

where $\{x_1^*,x_2^*,\cdots,x_n^*\}$ is a permutation of $\{x_1,x_2,\cdots,x_n\}$. Then, the discrete type of Choquet integral with respect to the FM defined above can be express as

$$\int f d\mu=\sum_{i=1}^{n}\left(f(x_i^*)-f(x_{i-1}^*)\right)\cdot\mu(\{x_i^*,\cdots,x_n^*\}). \tag{5}$$

In addition, to deal with observations with categorical attributes, i.e., these feature attributes have only finitely many states, and numerical attributes, simultaneously, the NAFI model which indicates the relation between hybrid attributes and objective attributes can be expressed by the following formula [4]

$$y=c+q\cdot\int(\omega\cdot f)d\mu+er, \tag{6}$$

where c and q are constants, $\int f d\mu$ is the Choquet integral of function f with respect to the FM μ, vector $\omega=(\omega_1,\omega_2,\cdots,\omega_n)$ is an n-dimensional weighting vector which is used for coping with categorical attributes, i.e. vector ω is used for balancing the units among various attributes and satisfies the following constrain

$$0<\omega_i\le 1 \text{ and } \max_{1\le i\le n}\omega_i=1,\ i=1,2,\cdots,n. \tag{7}$$

In the NAFI model, totally, there are 2^n+n unknown parameters and increase exponentially with the dimension of feature attributes. In order to complete the NAFI model, these parameters have to be determined in advance. That is so called the learning state or the training state of the NAFI model. In this state, associating (6) with available observations constitute an over-determined system with Choquet integral. Thus, the analytic solution of the model parameters cannot be exact figured out. Furthermore, constants c and q are essential of difference from the other parameters which are governed by the Choquet integral. Therefore, the dual optimization procedures must be performed, simultaneously; meanwhile, the performance index of optimization J (called fitness function) is also introduced and expressed as

$$J=\text{Min}\left\{\sum_{j=1}^{k}\left(y_j-c-q\cdot\int(\omega\cdot f_j)d\mu\right)^2\right\}, \tag{8}$$

where k is the length of available observations for the training state. Because the kernel of the performance index of optimization is the LS estimator, it usually suffers from outliers in real world systems. Fortunately, there are many high breakdown value regression estimators have been proposed to

eliminate the effect of outliers [6-7]. For the reason of simplicity and efficiency, the least median of squares (LMS) and the LTS are the most popular regression estimators in scientific applications. Furthermore, the LTS estimator possesses not only the same breakdown value as LMS, but also several merits: for instance, its objective function is smoother; its statistical efficiency is better, and so on. Therefore, we focus the treatment of outliers on LTS method and then the fitness function J is revised as the form

$$J = \text{Min}\left\{\sum_{j=1}^{h}\left(y_j^* - c - q\cdot\int(\omega\cdot f_j^*)d\mu\right)^2\right\}, \qquad (9)$$

where y_j^* and f_j^* are a permutation of observations under the best model parameters and h is a trimmed parameter of the LTS estimator. The block diagram of the proposed structure for the training state and information fusion systems are shown in Fig. 1. Where the block named QPSO-GS receives the differences of objective attributes between observations and estimations when the terminative criterion is not satisfied yet, and then the parameters of the NAFI model are updated base on these differences; meanwhile, in the LTS block used for filtering out these atypical observations, the trimmed parameter h is also revised by the global optimal parameters so far.

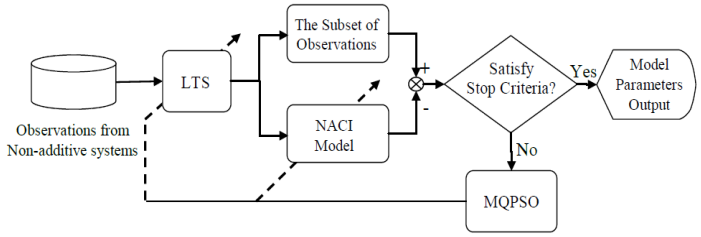

Figure 1. Block diagram of the proposed structure for the parameters estimation of the NACI model via MQPSO and LTS.

III. THE LTS ESTIMATOR AND THE QPSO ALGORITHM

In robust regression analysis [6], the LTS estimator is formulated as

$$\text{Min}\left\{\sum_{i=1}^{h} r^2(d_i)\right\},\ r^2(d_1)\le\cdots\le r^2(d_h)\le\cdots\le r^2(d_k), \quad (10)$$

where d_i is the i_{th} observation, $r^2(d_i)$ is the i_{th} squared residual, k is the length of observations and h is the number of data points which are not trimmed from the data set. The maximum tolerance of the LTS estimators to outliers (named Maximum Breakdown Point) for any equi-variant regression estimator satisfies

$$\text{Breakdown Point} \le \frac{1}{k}\left(\left((k-\zeta)/2\right)+1\right), \qquad (11)$$

where ζ is the dimension of variables. Intuitively, 50% is the upper bound that can be expected and it is actually attained for $h=(k+\zeta+1)/2$. In theorem, the solution of (10) always exists. Of course, one can achieve the optimal solution by performing $C(k,h)$ ordinary least square problems for all subsets of $\{1,2,\cdots,k\}$ with h elements and selecting the best one among all candidates. Obviously, it is laborious and impractical for real world systems with large observations. In order to cope with a great deal of observations, the FAST-LTS method was been proposed [7]. The major distinguishing features are the initial h-subset, the C-step and the nested extensions. By and large, the initial h-subset is a preselecting mechanism to confirm that a clean h-subset $\{d_1,d_2,\cdots,d_h\}$ drawn from all observations can be attained and the C-step is a recursive procedure and used for increasing accuracy of the estimated model parameters. For a small to moderate data size k, these two procedures work well and do not take much time. When observations are large enough, the procedure named nested extension is introduced to avoid the heavy computation.

After drawing observations without contaminations, a proper soft computing technique is essential and can help us to efficiently estimate parameters of the NAFI model. The QPSO algorithm is one of these soft computing techniques, and possesses a significant ability of global and local search. In the QPSO algorithm, particles move in a quantum multi-dimensional space, the state of particles is usually depicted by normalized wave function $\Psi(\rho,t)$, i.e., the probability amplitude of position where particles are presence; and the wave function satisfies the constrain

$$\int_{\text{whole space}}\left|\Psi(\rho,t)\right|^2 d\rho = 1, \qquad (12)$$

where ρ is the n-dimensional coordinates. That is, a single particle with mass m is subjected to the influence of a potential field $V(\rho,t)$ in the quantum space and the wave function is governed by the Schrödinger equation:

$$i\hbar\frac{\partial}{\partial t}\Psi(\rho,t) = -\frac{\hbar^2}{2m}\nabla^2\Psi(\rho,t) + V(\rho,t)\Psi(\rho,t), \quad (13)$$

where $\hbar$ is the Planck constant and ∇^2 is the Laplacian operator. In the environment with potential field, the particles are then attracted to the center of potential field through the optimization process, and such attraction leads to the global optimum. Base on the assumption that the attractive potential field is time-independent (called stationary state); the solution of the time-independent Schrödinger equation has the form [20]

$$\Psi(\rho,t) = \varphi(\rho)\cdot\exp(-i\omega t), \qquad (14)$$

where ω has the dimensions of an angular frequency. In theorem, any type of potential well can describe this system which is bounded and attracted by a potential field, but the simplest one is the Delta Potential Well and the potential field is given by

$$V(\rho) = -\gamma\delta(\rho), \qquad (15)$$

where γ is a positive number proportional to the "depth" of the potential well. For the sake of simplicity, the solution of time-independent Schrödinger equation for this system in one dimensional space is considered and expressed as

$$Q(z) = |\varphi(z)|^2 = \frac{1}{L} e^{-\frac{2|z|}{L}},\ L = \frac{\hbar^2}{m\gamma}, \tag{16}$$

where $Q(z)$ is the probability density function for measuring a particle's state and L is the characteristic length of Delta Potential Well which specifies the search scope of a particle. In order to obtained the precise position of particles, Monte Carlo Method is used for simulating the procedure that the quantum state collapses to the classic state, and the particle's position can be expressed as

$$\varphi_i = pf^{cnt}(i) \pm L/2 \cdot \ln\left(1/u\right),\ i = 1,2,\cdots,NP, \tag{17}$$

where NP is the number of particles in a population, u is random number uniformly distribute on $[0,1]$ and pf^{cnt} is the center of potential field which is proposed by Clerc and Kennedy [21] and defined as

$$pf^{cnt}(i) = \frac{\left(c_1 \cdot p_i^{loc} + c_2 \cdot p^{gol}\right)}{\left(c_1 + c_2\right)},\ i = 1,2,\cdots,NP, \tag{18}$$

where c_1 , c_2 are constriction coefficients and p_i^{loc} , p^{gol} are the best position of the i_{th} particle and the global best position found so far. In order to improve performance of the QPSO algorithm, Sun et al [12] employ a Mean Best Position (*mbest*) to evaluate parameter *L*. However, to extend the global search of the QPSO algorithm, the *mbest* is modified and then these two parameters can be expressed as the following form

$$mbest = \left[\sum_{i=1}^{NP} \frac{\phi_{i,1}}{NP}, \sum_{i=1}^{NP} \frac{\phi_{i,2}}{NP}, \cdots, \sum_{i=1}^{NP} \frac{\phi_{i,n}}{NP}\right], \tag{19}$$

$$L = 2 \cdot \beta \left| mbest - \varphi_i \right|, \tag{20}$$

where β is a creative coefficient which is used to adjust the convergent speed of individual particle and the performance of the QPSO algorithm.

IV. THE QPSO-GS ALGORITHM

Within empirical applications, however, the QPSO algorithm usually represents stagnating phenomenon for searching the global optimal solution in multi-mode problems and systems; meanwhile, it is also strongly influenced by the creative coefficient β . In order to improve these defects, a nonlinearly updating mechanism of the creative coefficient β and instantaneously monitoring the convergence of optimization procedure are introduced. The nonlinearly revising mechanism which is similar to the SA is expressed as the form

$$\beta = \beta_{ini} - \Delta\beta \cdot (1 + \exp(-(\Delta fit)))^{-1}, \tag{21}$$

where $\Delta\beta$ is step length of β , Δfit is the changing rate of optimal estimation so far and β_{ini} is the initial value of β .

The other improvement of the proposed QPSO-GS algorithm is the mechanism to overcome prematurity. Inspired by these mechanisms of mutation and elite crossover in the GA, an index of conquering stagnation (named *ECM* which is an abbreviation of elite crossover and mutation) is used for monitoring the status of optimization procedure. That is, during the optimization procedure, the QPSO-GS algorithm preserves each different p^{gol} ; meanwhile, the index of conquering stagnation, *ECM* is set to zero whenever p^{gol} is updated. Of course, the *ECM* increases by one whenever p^{gol} is unchanged. Before finishing current iteration, the QPSO-GS algorithm makes a judgment whether *ECM* exceeds the specific criteria. If it is true, the QPSO-GS algorithm lets the new population be these collected p^{gol} instead of original population (all/or these worse particles) and sets the *ECM* to zero, instantaneously.

Because the kernel of estimating fitness is the LS estimator, the MQPSO algorithm presents superior performances for estimating parameters for observations without outliers in our previous work. However, the MQPSO algorithm always makes a serious deviation in the contaminated circumstance. Hence, the LTS estimator is introduced to sieve out the observations without contamination and the proposed QPSO-GS algorithm is detailed below:

Step 1: Perform the LTS estimator to sieve out these *h* observations without contamination.

Step 2: Randomly initialize the population of particles with dimension $2^n - 2 + n$ and then, evaluate their fitness values by (9).

Step 3: Sort particles according to their fitness values and then initialize p_i^{loc} , p^{gol} .

Step 4: Calculate pf^{cnt} , *mbest* and *L* by (18), (19) and (20), respectively.

Step 5: Select (22) or (23) with randomly probability to update φ_i .

$$\varphi_{i+1} = pf^{cnt}(i) + \beta \cdot \left\| mbest - \varphi_i \right\| \cdot \ln(1/u), \tag{22}$$

$$\varphi_{i+1} = pf^{cnt}(i) - \beta \cdot \left\| mbest - \varphi_i \right\| \cdot \ln(1/u). \tag{23}$$

Step 6: Evaluate the fitness values of all particles by (9).

Step 7: According to evaluation in Step 6, update p_i^{loc} .

Step 8: Check over whether the maximum iteration is reached or the terminative criterion is satisfied? If yes, go to Step 11, else perform next Step.

Step 9: Check over whether p^{gol} is updated? If p^{gol} is updated, sets *ECM* to 0 and perform the LTS

procedure, then go to Step 4. If p^{gol} is unchanged, increase ECM by 1 and perform next Step.

Step 10: Check over whether the maximum ECM is reached? If yes, let these collected p^{gol} instead of φ_{i+1} and go to Step 4, else keep φ_{i+1} and go to Step 4.

Step 11: Check over whether p^{gol} should be updated and then output results.

V. Numerical Simulation and Results

To demonstrate and verify the effectiveness and feasibility of the proposed systems are shown in Figure 1, an artificial observation profile which simulates 4 continuous sampling data with outliers is made to estimate the model parameters by associating the proposed QPSO-GS algorithm based on the NAFI model. All simulations are implemented in the Matlab environment and conducted on Intel Core 2 Duo CPU P8400, 4GB Ram capacity PC.

Example 1: The original model parameters are set as: c=4, q=1.5, μ = { 0.22, 0.3, 0.45, 0.28, 0.42, 0.49, 0.6, 0.25, 0.45, 0.52, 0.62, 0.74, 0.82, 0.88,1 } , w = { 0.3, 0.26, 1, 0.48 } . Then, we randomly create 400 4-dimensional feature attributes with 10% random contamination (marked with shadows) to produce training data as shown in Table I, where y_{true} and y_{cont} are the original and contaminated objective attributes, respectively. After performing the proposed QPSO-GS algorithm for many times, the average results of estimating model parameters are shown in Tables II, where y_{esti} is the estimated objective attributes, p_{esti} and p_{true} are the contaminated and original model parameters, respectively. In addition, we also show plots of the training data and estimated results in Figures 2~3. In this Example, the terminative criteria of program are maximum iterations which reach 1500 times or the mean square error which is less than 10^{-4}. From Table II and Figures 2~3, these estimated results almost the same as original objective attributes and these estimated model parameters are really precise. That is, the QPSO-GS algorithm is able to efficiently filter out outliers from observations. That is, the proposed QPSO-GS readily corrects the deviation caused by outliers and swiftly achieves convergences on estimating the parameters of the proposed NAFI model with outliers.

VI. Conclusions

In this paper, the NAFI model association with the QPSO-GS algorithm is considered and developed to deal with a non-additive system with outliers. Whenever atypical observations are presence, the estimation method of parameters based on the LS estimator is no longer feasible. Therefore, there is an excellently alternative ways to replace the LS estimator with the LTS estimator. That is, we successfully integrate mechanisms of the GA and the SA into the QPSO algorithm to estimate parameters of the NAFI model with outliers; meanwhile, the LTS estimator is also introduced to filter out outliers. From the simulation results, the proposed QPSO-GS algorithm can precisely estimate parameters of the NAFI model for observations contaminated with outliers; meanwhile, it still maintains high coincidence between the estimated and original objective attributes.

***Abstract*—The purpose of this paper is to deal with the problem of least-squares multiple regression with fuzzy data. The constant regression coefficient is assumed to be symmetric triangular, and other coefficients are real (crisp). By applying symmetric triangular approximations of fuzzy numbers, a new method for computing the regression coefficients is proposed. The new method is efficient and easy to determine the coefficients.**

***Index Terms*—fuzzy linear regression, symmetric triangular approximation, least-squares estimates.**

I. Introduction

An arbitrary fuzzy number $\tilde{A}$ can be represented by an ordered pair of left continuous functions $[A^l(\alpha), A^u(\alpha)]$, $0 \leq \alpha \leq 1$, which both satisfy the following conditions:

1) A^l is increasing on [0,1],
2) A^u is decreasing on [0,1],
3) $A^l(1) \leq A^u(1)$.

Let $\mathbb{R}$ and $F(\mathbb{R})$ denote the sets of all real numbers and fuzzy numbers, respectively. In this paper, we always place a $\sim$ over a letter to denote a fuzzy number, for example $\tilde{X}_i$, $\tilde{A} \in F(\mathbb{R})$ and $a, \tau, \sigma \in \mathbb{R}$. Let $\tilde{A}$ and $\tilde{B} \in F(\mathbb{R})$. The Euclidean distance between $\tilde{A}$ and $\tilde{B}$ is defined as

$$\mathrm{d}(\tilde{A}, \tilde{B}) = \Big[\int_0^1 (|A^l(\alpha) - B^l(\alpha)|^2 + |A^u(\alpha) - B^u(\alpha)|^2) \mathrm{d}\alpha \Big]^{\frac{1}{2}}.$$

Given fuzzy vectors $\vec{\tilde{Y}} = (\tilde{Y}_1, \ldots, \tilde{Y}_n)$ and $\vec{\tilde{X}}_i = (\tilde{X}_{i1}, \ldots, \tilde{X}_{in}) \in F(\mathbb{R})^n$, $1 \leq i \leq m$, the problem of fuzzy linear regression analysis is to find the regression coefficients $\tilde{A}_i \in F(\mathbb{R})$, $0 \leq i \leq m$, which minimize the observation error

$$\begin{aligned} &\mathrm{d}^2(\vec{\tilde{Y}}, \tilde{A}_0 \vec{1} + \tilde{A}_1 \vec{\tilde{X}}_1 + \cdots + \tilde{A}_m \vec{\tilde{X}}_m) := \\ &\sum_{j=1}^{k} \mathrm{d}^2(\tilde{Y}_j, \tilde{A}_0 + \tilde{A}_1 \tilde{X}_{1j} + \cdots + \tilde{A}_m \tilde{X}_{mj}), \end{aligned} \tag{1}$$

where $\vec{1} := (1, \ldots, 1)$.

In 1982, Tanaka et al. [21] first examined fuzzy regression analysis with real independent (or explanatory) and fuzzy dependent (or response) variables, in which the regression coefficients are assumed to be symmetric triangular fuzzy numbers. Afterwards, many scholars studied this type fuzzy regression analysis by generalizing the coefficients to more general fuzzy numbers [2], [6], [8], [9], [10], [14], [16], [18], [19], [22]. In 1992, Sakawa and Yano [20] considered fuzzy linear regression models with fuzzy data, that means the independent variables and dependent variable are all fuzzy numbers. Subject to the regression coefficients are all real, the least-squares estimation was further studied by Diamond [4], and the existence was proved by Kratschmer [17]. In 1992, Bardosy et al. [11] presented normal equations systems depended on signs of regression coefficients to estimate the regression coefficients. And, in 2002 Kao and Chyu [12] proposed a two-stage method. Most of the recent approaches have to consider optimization cones, then determine the regression coefficients by comparing observation errors of these possible estimators. It will take a lot of time to find the best one. An iterative algorithm (numerical method) was proposed by Bargiela et al. [1]. In 2009, Yeh [27] showed that the multiple regression problem can be replaced with a 0-1 programming problem. Furthermore, he proposed a formula for computing the regression coefficients in one-variable models (see the following Theorem 5). For more general case that the constant coefficient is fuzzy, Diamond and Korner [5] generalized their previous results via Hukuhara difference. Wunsche and Nather [23] turned to study on the restriction that the data are of normal distributions. Chen and Hsueh [3] used the least-squares method to determine regression coefficients in multiple-variable models. There are also many other contributions to this type [2], [8], [9], [13], [15], [18].

This paper is organized as follows. In Section 2, we introduce the mean of fuzzy numbers. In Section 3, we present an formula for solving the regression model whose regression coefficients are all real. The present formula is simple and clear. In Section 4, we completely solve the regression problem whose constant coefficient is assumed to be symmetric triangular. In Section 5, we work on the example designed by Sakawa and Yano. It is shown that our estimator is better than the previous.

II. The mean of fuzzy numbers

Let $\tilde{Z}_i$, $1 \leq i \leq n$ be fuzzy numbers. We define the *mean* of $\tilde{Z}_i$ as follows

$$E(\tilde{Z}) = \frac{1}{n} \sum_{i=1}^{n} \tilde{Z}_i. \tag{2}$$

Theorem 1. *Let $\tilde{Z}_i$, $1 \leq i \leq n$ be fuzzy numbers. Then,*

$$\sum_{i=1}^{n} \mathrm{d}^2(\tilde{Z}_i, \tilde{A}) = \sum_{i=1}^{n} \mathrm{d}^2(\tilde{Z}_i, E(\tilde{Z})) + n\mathrm{d}^2(E(\tilde{Z}), \tilde{A}),$$

for each $\tilde{A} \in F(\mathbb{R})$.

Let $\tilde{A} = [A^l(\alpha), A^u(\alpha)]$ and $\tilde{B} = [B^l(\alpha), B^u(\alpha)] \in F(\mathbb{R})$. The *vector difference* between $\tilde{A}$ and $\tilde{B}$ is described as follows

$$\tilde{A} \ominus \tilde{B} := [A^l(\alpha) - B^l(\alpha), A^u(\alpha) - B^u(\alpha)].$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

The vector difference between $\tilde{A}$ and $\tilde{B}$ may not belong to $F(\mathbb{R})$. For example,

$$[\alpha, 2-\alpha] \ominus [2\alpha, 2] = [-\alpha, -\alpha] \notin F(\mathbb{R}).$$

Notice that, we can still compute the distance $\mathrm{d}(\tilde{A}, \tilde{B})$, defined in Section 1, even if $\tilde{A} = [A^l(\alpha), A^u(\alpha)]$ and $\tilde{B} = [B^l(\alpha), B^u(\alpha)] \notin F(\mathbb{R})$.

Theorem 2. *Let $\vec{\tilde{Y}} = (\tilde{Y}_1, \ldots, \tilde{Y}_n)$ and $\vec{\tilde{X}} = (\tilde{X}_1, \ldots, \tilde{X}_n) \in F(\mathbb{R})^n$ be fuzzy vectors. Then,*

$$\mathrm{d}^2(\vec{\tilde{Y}}, \tilde{A}\vec{1} + b\vec{\tilde{X}}) = \sum_{i=1}^{n} \mathrm{d}^2(\tilde{Y}_i \ominus E(\tilde{Y}), b\tilde{X}_i \ominus bE(\tilde{X})) + n\mathrm{d}^2(E(\tilde{Y}) \ominus bE(\tilde{X}), \tilde{A}),$$

for each $\tilde{A} \in F(\mathbb{R})$ and each $b \in \mathbb{R}$.

III. A FORMULA FOR COMPUTING REAL REGRESSION COEFFICIENTS

In this section, we are going to study fuzzy regression analysis with real regression coefficients, that is to find $a, b \in \mathbb{R}$ minimizing the observation error

$$\mathrm{d}^2(\vec{\tilde{Y}}, a\vec{1} + b\vec{\tilde{X}}),$$

where $\vec{\tilde{Y}} = (\tilde{Y}_1, \ldots, \tilde{Y}_n)$ and $\vec{\tilde{X}} = (\tilde{X}_1, \ldots, \tilde{X}_n)$ are given data.

Let $\tilde{A} \in F(\mathbb{R})$ and Ω be a closed convex subset of $F(\mathbb{R})$. Then, an element $P_\Omega(\tilde{A}) \in \Omega$ is called the *best approximation* of $\tilde{A}$ in Ω if

$$\mathrm{d}(\tilde{A}, P_\Omega(\tilde{A})) \le \mathrm{d}(\tilde{A}, \tilde{X}), \quad \forall \tilde{X} \in \Omega.$$

If we set $\Omega = \mathbb{R}$ (i.e. each $\tilde{A} \in \Omega$ is real), then

$$P_{\mathbb{R}}(\tilde{A}) := \int_0^1 A^c(\alpha)\, d\alpha.$$

Proposition 3. *Let $\tilde{A}, \tilde{B} \in F(\mathbb{R})$ and $a, b \in \mathbb{R}$. Then,*

$$P_{\mathbb{R}}(a\tilde{A} + b\tilde{B}) = aP_{\mathbb{R}}(\tilde{A}) + bP_{\mathbb{R}}(\tilde{B}),$$
$$P_{\mathbb{R}}(a\tilde{A} \ominus b\tilde{B}) = aP_{\mathbb{R}}(\tilde{A}) - bP_{\mathbb{R}}(\tilde{B}),$$

and

$$\mathrm{d}^2(\tilde{A}, a) = \mathrm{d}^2(\tilde{A}, P_{\mathbb{R}}(\tilde{A})) + |P_{\mathbb{R}}(\tilde{A}) - a|^2.$$

From Theorem 2 we find

$$\mathrm{d}^2(\vec{\tilde{Y}}, a\vec{1} + b\vec{\tilde{X}}) = \sum_{i=1}^{n} \mathrm{d}^2(\tilde{Y}_i \ominus E(\tilde{Y}), b\tilde{X}_i \ominus bE(\tilde{X})) + n\mathrm{d}^2(E(\tilde{Y}) \ominus bE(\tilde{X}), a).$$

Consequently, by Proposition 3 we have

$$\begin{aligned} &\mathrm{d}^2(E(\tilde{Y}) \ominus bE(\tilde{X}), a) \\ &\ge \mathrm{d}^2(E(\tilde{Y}) \ominus bE(\tilde{X}), P_{\mathbb{R}}(E(\tilde{Y})) - bP_{\mathbb{R}}(E(\tilde{X}))). \end{aligned}$$

Hence, to minimize $\mathrm{d}^2(\vec{\tilde{Y}}, a\vec{1} + b\vec{\tilde{X}})$ we must choose that

$$a = P_{\mathbb{R}}(E(\tilde{Y})) - bP_{\mathbb{R}}(E(\tilde{X})),$$

and then we have

$$\begin{aligned} &\mathrm{d}^2(\vec{\tilde{Y}}, a\vec{1} + b\vec{\tilde{X}}) \\ =&\mathrm{d}^2(\vec{\tilde{Y}}, [P_{\mathbb{R}}(E(\tilde{Y})) - bP_{\mathbb{R}}(E(\tilde{X}))]\vec{1} + b\vec{\tilde{X}}) \\ =&\sum_{i=1}^{n} \mathrm{d}^2(\tilde{Y}_i \ominus P_{\mathbb{R}}(E(\tilde{Y})), b\tilde{X}_i \ominus bP_{\mathbb{R}}(E(\tilde{X}))). \end{aligned}$$

Recall that every closed interval can be represented by its center and radius (half width). For instance, the center of $[A^l(\alpha), A^u(\alpha)]$ is

$$A^c(\alpha) := \frac{A^l(\alpha) + A^u(\alpha)}{2}, \tag{3}$$

and the radius of $[A^l(\alpha), A^u(\alpha)]$ is

$$A^r(\alpha) := \frac{A^u(\alpha) - A^l(\alpha)}{2}. \tag{4}$$

That means we can use the symbol

$$[A^c(\alpha), A^r(\alpha)]_{CR}$$

to rewrite the fuzzy number $\tilde{A} = [A^l(\alpha), A^u(\alpha)]$, which is called the CR-*representation* of $\tilde{A}$, see [24].

Proposition 4 (Proposition 1, [27])**.** *Let*

$$\tilde{A} = [A^c(\alpha), A^r(\alpha)]_{CR} \quad \textit{and} \quad \tilde{B} = [B^c(\alpha), B^r(\alpha)]_{CR}$$

be fuzzy numbers with CR*-representations, and $a \in \mathbb{R}$. Then the addition and scalar multiplication of fuzzy numbers can be described as follows:*

$$\tilde{A} + \tilde{B} = [A^c(\alpha) + B^c(\alpha), A^r(\alpha) + B^r(\alpha)]_{CR}$$

and

$$a\tilde{A} = [aA^c(\alpha), |a|A^r(\alpha)]_{CR},$$

respectively. Moreover,

$$(\sum_i a_i\tilde{X}_i)^c(\alpha) = \sum_i a_i\tilde{X}_i^c(\alpha)$$

and

$$(\sum_i a_i\tilde{X}_i)^r(\alpha) = \sum_i |a_i|\tilde{X}_i^r(\alpha),$$

for all $\tilde{X}_i \in F(\mathbb{R})$ and $a_i \in \mathbb{R}$.

For each fuzzy vector $\vec{\tilde{Z}} = (\tilde{Z}_1, \ldots, \tilde{Z}_n)$, where

$$\tilde{Z}_j = [Z_j^c(\alpha), Z_j^r(\alpha)]_{CR}, \quad 1 \le j \le n,$$

are represented with CR-representations, define two real functional vectors as follows:

$$\vec{Z}^c := (Z_1^c(\alpha), \ldots, Z_n^c(\alpha))$$

and

$$\vec{Z}^r := (Z_1^r(\alpha), \ldots, Z_n^r(\alpha)).$$

Recall that, for any two real vector functions $\vec{f} = (f_1, \ldots, f_n)$ and $\vec{g} = (g_1, \ldots, g_n)$ the *inner product* of $\vec{f}$ and $\vec{g}$ is

$$\langle \vec{f}, \vec{g} \rangle := \sum_{i=1}^{n} \int_0^1 f_i(x) g_i(x)\ dx. \tag{5}$$

Now, let $\vec{\tilde{X}} = (\tilde{X}_1, \ldots, \tilde{X}_n)$ and $\vec{\tilde{Y}} = (\tilde{Y}_1, \ldots, \tilde{Y}_n) \in F(\mathbb{R})^n$. Define

$$\begin{aligned}
S^c_{xx} &:= \langle \vec{X}^c - P_{\mathbb{R}}(E(\tilde{X}))\vec{1}, \vec{X}^c - P_{\mathbb{R}}(E(\tilde{X}))\vec{1} \rangle,\\
S^c_{xy} &:= \langle \vec{X}^c - P_{\mathbb{R}}(E(\tilde{X}))\vec{1}, \vec{Y}^c - P_{\mathbb{R}}(E(\tilde{Y}))\vec{1} \rangle,\\
S^r_{xx} &:= \langle \vec{X}^r, \vec{X}^r \rangle,\\
S^r_{xy} &:= \langle \vec{X}^r, \vec{Y}^r \rangle.
\end{aligned}$$

It is easy to verify $S^c_{xx} \geq 0$, $S^r_{xx} \geq 0$, and $S^r_{xy} \geq 0$.

Theorem 5 (Theorem 6, [27]). *Let $\vec{\tilde{Y}}$ and $\vec{\tilde{X}} \in F(\mathbb{R})^n$, and let $(-1)^s$ denote the sign of S^c_{xy}. If $S^c_{xx} + S^r_{xx} \neq 0$, then the regression coefficients can be computed by the following formula*

$$b = (-1)^s (|S^c_{xy}| + S^r_{xy})(S^c_{xx} + S^r_{xx})^{-1}, \tag{6}$$

$$a = P_{\mathbb{R}}(E(\tilde{Y})) - bP_{\mathbb{R}}(E(\tilde{X})). \tag{7}$$

IV. A theorem for more general regression model

Let Δ denote the set of all symmetric triangular fuzzy numbers. In this section, we are going to study fuzzy regression model whose constant regression coefficient is symmetric triangular, that is to find $\tilde{A} \in \Delta$ and $b \in \mathbb{R}$ minimizing the observation error

$$\mathrm{d}^2(\vec{\tilde{Y}}, \tilde{A}\vec{1} + b\vec{\tilde{X}}).$$

For each $\tilde{A} \in F(\mathbb{R})$, an element $P_\Delta(\tilde{A}) \in \Delta$ is called the *symmetric triangular approximation* of $\tilde{A}$ if

$$\mathrm{d}(\tilde{A}, P_\Delta(\tilde{A})) \leq \mathrm{d}(\tilde{A}, \tilde{X}), \quad \forall \tilde{X} \in \Delta.$$

In [28], the author proved that:

Proposition 6. *Let $\tilde{A} \in F(\mathbb{R})$. Then, its the symmetric triangular approximation $P_\Delta(\tilde{A}) = [\tau, \sigma]_{CR}$ can be computed by the following formula*

$$\tau = \tau(\tilde{A}) := \int_0^1 A^c(\alpha)\ d\alpha, \tag{8}$$

$$\sigma = \sigma(\tilde{A}) := 3\int_0^1 A^r(\alpha)(1-\alpha)\ d\alpha. \tag{9}$$

It is easy to verify that

$$\tau(a\tilde{A}) = a\tau(\tilde{A})$$

$$\sigma(a\tilde{A}) = |a|\sigma(\tilde{A})$$

for all $\tilde{A} \in F(\mathbb{R})$ and $a \in \mathbb{R}$. For more general approximations of fuzzy numbers, we refer to [7], [25], [26], [29], [30].

Proposition 7. *Let $\tilde{A}, \tilde{B} \in F(\mathbb{R})$ and $a, b \in \mathbb{R}$. Then,*

$$P_\Delta(a\tilde{A} + b\tilde{B}) = aP_\Delta(\tilde{A}) + bP_\Delta(\tilde{B}),$$

$$P_\Delta(a\tilde{A} \ominus b\tilde{B}) = aP_\Delta(\tilde{A}) \ominus bP_\Delta(\tilde{B}). \tag{10}$$

Furthermore,

$$\mathrm{d}^2(\tilde{A}, \tilde{X}) = \mathrm{d}^2(\tilde{A}, P_\Delta(\tilde{A})) + \mathrm{d}^2(P_\Delta(\tilde{A}), \tilde{X}), \forall \tilde{X} \in \Delta. \tag{11}$$

Let $\tilde{A} \in \Delta$. From Theorem 2 we find

$$\begin{aligned}
&\mathrm{d}^2(\vec{\tilde{Y}}, \tilde{A}\vec{1} + b\vec{\tilde{X}}) =\\
&\sum_{i=1}^{n} \mathrm{d}^2(\tilde{Y}_i \ominus E(\tilde{Y}), b\tilde{X}_i \ominus bE(\tilde{X})) + n\mathrm{d}^2(E(\tilde{Y}) \ominus bE(\tilde{X}), \tilde{A}).
\end{aligned}$$

Consequently, by Proposition 7 we have

$$\begin{aligned}
&\mathrm{d}^2(E(\tilde{Y}) \ominus bE(\tilde{X}), \tilde{A}) \qquad \text{(by Eq.(10))}\\
&\geq \mathrm{d}^2(E(\tilde{Y}) \ominus bE(\tilde{X}), P_\Delta(E(\tilde{Y}) \ominus bE(\tilde{X}))) \qquad \text{(by Eq.(11))}\\
&= \mathrm{d}^2(E(\tilde{Y}) \ominus bE(\tilde{X}), P_\Delta(E(\tilde{Y})) \ominus bP_\Delta(E(\tilde{X}))).
\end{aligned}$$

Hence, if $P_\Delta(E(\tilde{Y})) \ominus bP_\Delta(E(\tilde{X})) \in \Delta$, we only choose

$$\tilde{A} = P_\Delta(E(\tilde{Y})) \ominus bP_\Delta(E(\tilde{X}))$$

and then we have

$$\begin{aligned}
&\mathrm{d}^2(\vec{\tilde{Y}}, \tilde{A}\vec{1} + b\vec{\tilde{X}})\\
=&\sum_{i=1}^{n} \mathrm{d}^2(\tilde{Y}_i \ominus P_\Delta(E(\tilde{Y})), b\tilde{X}_i \ominus bP_\Delta(E(\tilde{X}))).
\end{aligned} \tag{12}$$

Thus, the rest is to find $b \in \mathbb{R}$ which minimizes the above value (i.e. Eq.(12)). But in general case, it may happen

$$P_\Delta(E(\tilde{Y})) \ominus bP_\Delta(E(\tilde{X})) \notin \Delta.$$

Note that, Proposition 7 implies

$$\begin{aligned}
P_\Delta(E(\tilde{Y})) \ominus bP_\Delta(E(\tilde{X})) = \Big[&\tau(E(\tilde{Y})) - b\tau(E(\tilde{X})),\\
&(\sigma(E(\tilde{Y})) - |b|\sigma(E(\tilde{X})))(1-\alpha)\Big]_{CR}
\end{aligned} \tag{13}$$

Hence, we obtain $P_\Delta(E(\tilde{Y})) \ominus bP_\Delta(E(\tilde{X})) \notin \Delta$ if and only if

$$\sigma(E(\tilde{Y})) < |b|\sigma(E(\tilde{X})).$$

Let $\vec{\tilde{X}} = (\tilde{X}_1, \ldots, \tilde{X}_n)$ and $\vec{\tilde{Y}} = (\tilde{Y}_1, \ldots, \tilde{Y}_n)$. Define

$$\begin{aligned}
T^c_{xx} &:= \langle \vec{X}^c - \tau(E(\tilde{X}))\vec{1}, \vec{X}^c - \tau(E(\tilde{X}))\vec{1} \rangle,\\
T^c_{xy} &:= \langle \vec{X}^c - \tau(E(\tilde{X}))\vec{1}, \vec{Y}^c - \tau(E(\tilde{Y}))\vec{1} \rangle,\\
T^r_{xx} &:= \langle \vec{X}^r - \sigma(E(\tilde{X}))(1-\alpha)\vec{1}, \vec{X}^r - \sigma(E(\tilde{X}))(1-\alpha)\vec{1} \rangle,\\
T^r_{xy} &:= \langle \vec{X}^r - \sigma(E(\tilde{X}))(1-\alpha)\vec{1}, \vec{Y}^r - \sigma(E(\tilde{Y}))(1-\alpha)\vec{1} \rangle.
\end{aligned}$$

Note that, by Eq.(5), (8), and (9) it is easy to verify that

$$\begin{aligned}
\langle \vec{X}^c, \tau(E(\tilde{X}))\vec{1} \rangle &= n\tau(E(\tilde{X}))^2,\\
\langle \vec{X}^c, \tau(E(\tilde{Y}))\vec{1} \rangle &= \langle \vec{Y}^c, \tau(E(\tilde{X}))\vec{1} \rangle = n\tau(E(\tilde{X}))\tau(E(\tilde{Y})),\\
\langle \vec{X}^r, \sigma(E(\tilde{X}))(1-\alpha)\vec{1} \rangle &= \frac{n}{3}\sigma(E(\tilde{X}))^2,\\
\langle \vec{X}^r, \sigma(E(\tilde{Y}))(1-\alpha)\vec{1} \rangle &= \langle \vec{Y}^r, \sigma(E(\tilde{X}))(1-\alpha)\vec{1} \rangle\\
&= \frac{n}{3}\sigma(E(\tilde{X}))\sigma(E(\tilde{Y})).
\end{aligned}$$

Hence, we have

$$T^c_{xx} := \langle \vec{X}^c, \vec{X}^c \rangle - n\tau(E(\tilde{X}))^2, \tag{14}$$

$$T^c_{xy} := \langle \vec{X}^c, \vec{Y}^c \rangle - n\tau(E(\tilde{X}))\tau(E(\tilde{Y})), \tag{15}$$

$$T^r_{xx} := \langle \vec{X}^r, \vec{X}^r \rangle - \frac{n}{3}\sigma(E(\tilde{X}))^2, \tag{16}$$

$$T^r_{xy} := \langle \vec{X}^r, \vec{Y}^r \rangle - \frac{n}{3}\sigma(E(\tilde{X}))\sigma(E(\tilde{Y})). \tag{17}$$

Theorem 8. *Input $\vec{\tilde{Y}}$ and $\vec{\tilde{X}} \in F(\mathbb{R})^n$. Suppose that*

$$T^c_{xx} + T^r_{xx} \neq 0.$$

Let $(-1)^t$ denote the sign of T^c_{xy} and

$$\delta^+ := \frac{|T^c_{xy}| + T^r_{xy}}{T^c_{xx} + T^r_{xx}} \tag{18}$$

and

$$\delta^- := \frac{-|T^c_{xy}| + T^r_{xy}}{T^c_{xx} + T^r_{xx}}. \tag{19}$$

Then the regression coefficients can be computed in the following cases:

1) *If $\delta^+ \geq 0$ and $\sigma(E(\tilde{Y})) \geq \delta^+\sigma(E(\tilde{X}))$, then*

$$b = (-1)^t\delta^+, \tag{20}$$

$$\tilde{A} = P_\Delta(E(\tilde{Y})) \ominus bP_\Delta(E(\tilde{X})). \tag{21}$$

2) *If $\delta^+ \geq 0$ and*

$$\delta^+\sigma(E(\tilde{X})) > \sigma(E(\tilde{Y})) \geq \delta^-\sigma(E(\tilde{X})),$$

then set

$$b^{(1)} = (-1)^t\delta^-, \tag{22}$$

$$\tilde{A}^{(1)} = P_\Delta(E(\tilde{Y})) \ominus b^{(1)}P_\Delta(E(\tilde{X})), \tag{23}$$

and applying Theorem 5, by Eqs.(6) and (7) compute real regression coefficients, say $a^{(2)}$ and $b^{(2)}$. Finally, compare the two observation errors

$$\mathrm{d}^2(\vec{\tilde{Y}}, \tilde{A}^{(1)}\vec{1} + b^{(1)}\vec{\tilde{X}}) \quad \textit{and} \quad \mathrm{d}^2(\vec{\tilde{Y}}, a^{(2)}\vec{1} + b^{(2)}\vec{\tilde{X}})$$

and output the best estimators.

3) *If $\delta^+ < 0$ or $\sigma(E(\tilde{Y})) < \delta^-\sigma(E(\tilde{X}))$, then compute real regression coefficients by Theorem 5.*

V. An illustrative example

Example 1 ([1], [2], [8], [13], [18], [20])**.** In order to cross-reference to the previous contributions let's consider the following example designed by Sakawa and Yano [20]:

	$\vec{Y}_i$	$\vec{X}_i$
1.	$[3.5 + 0.5\alpha, 4.5 - 0.5\alpha]$	$[1.5 + 0.5\alpha, 2.5 - 0.5\alpha]$
2.	$[5 + 0.5\alpha, 6 - 0.5\alpha]$	$[3 + 0.5\alpha, 4 - 0.5\alpha]$
3.	$[6.5 + \alpha, 8.5 - \alpha]$	$[4.5 + \alpha, 6.5 - \alpha]$
4.	$[6 + 0.5\alpha, 7 - 0.5\alpha]$	$[6.5 + 0.5\alpha, 7.5 - 0.5\alpha]$
5.	$[8 + 0.5\alpha, 9 - 0.5\alpha]$	$[8 + 0.5\alpha, 9 - 0.5\alpha]$
6.	$[7 + \alpha, 9 - \alpha]$	$[9.5 + \alpha, 11.5 - \alpha]$
7.	$[10 + 0.5\alpha, 11 - 0.5\alpha]$	$[10.5 + 0.5\alpha, 11.5 - 0.5\alpha]$
8.	$[9 + 0.5\alpha, 10 - 0.5\alpha]$	$[12 + 0.5\alpha, 13 - 0.5\alpha]$

By applying Eqs.(3) and (4), represent all fuzzy numbers with CR-representations, as follows:

	$\vec{Y}_i$	$\vec{X}_i$
1.	$[4.0, 0.5(1-\alpha)]_{CR}$	$[2.0, 0.5(1-\alpha)]_{CR}$
2.	$[5.5, 0.5(1-\alpha)]_{CR}$	$[3.5, 0.5(1-\alpha)]_{CR}$
3.	$[7.5, 1.0(1-\alpha)]_{CR}$	$[5.5, 1.0(1-\alpha)]_{CR}$
4.	$[6.5, 0.5(1-\alpha)]_{CR}$	$[7.0, 0.5(1-\alpha)]_{CR}$
5.	$[8.5, 0.5(1-\alpha)]_{CR}$	$[8.5, 0.5(1-\alpha)]_{CR}$
6.	$[8.0, 1.0(1-\alpha)]_{CR}$	$[10.5, 1.0(1-\alpha)]_{CR}$
7.	$[10.5, 0.5(1-\alpha)]_{CR}$	$[11.0, 0.5(1-\alpha)]_{CR}$
8.	$[9.5, 0.5(1-\alpha)]_{CR}$	$[12.5, 0.5(1-\alpha)]_{CR}$

By Eq.(2) we obtain the mean of $\tilde{Y}_i$ is

$$E(\tilde{Y}) = [6.875 + 0.625\alpha, 8.125 - 0.625\alpha].$$

Consequently, by applying Eqs.(3) and (4) the CR-representation of $E(\tilde{Y})$ is

$$E(\tilde{Y}) = [7.5, 0.625(1-\alpha)]_{CR}.$$

In the same way, we obtain

$$\begin{aligned} E(\tilde{X}) &= [6.9375 + 0.625\alpha, 8.1875 - 0.625\alpha] \\ &= [7.5625, 0.625(1-\alpha)]_{CR}. \end{aligned}$$

Now, by Eqs.(8) and (9) we obtain

$$\begin{aligned} &\tau(E(\tilde{X})) = 7.5625, \\ &\sigma(E(\tilde{X})) = 0.625, \\ &\tau(E(\tilde{Y})) = 7.5, \\ &\sigma(E(\tilde{Y})) = 0.625. \end{aligned}$$

Hence, by Eq.(5) and (14)-(17) we obtain

$$\begin{aligned} &T^c_{xx} := 97.71875, \\ &T^c_{xy} := 50.75, \\ &T^r_{xx} := 0.125, \\ &T^r_{xy} := 0.125. \end{aligned}$$

T^c_{xy} is positive, so $(-1)^t = 1$. Consequently, by Eqs.(18) and (19) we obtain

$$\delta^+ = 0.520$$

and

$$\delta^- = -0.517.$$

Since $\delta^+ \geq 0$ and $\sigma(E(\tilde{Y})) \geq \delta^+\sigma(E(\tilde{X}))$, by Eqs.(20) and (21) (Theorem 8, Case 1) we obtain

$$b = (-1)^t\delta^+ = 0.520$$

and

$$\begin{aligned} \tilde{A} &= P_\Delta(E(\tilde{Y})) \ominus bP_\Delta(E(\tilde{X})) \qquad \text{(by Eq.(14))} \\ &= [\tau(E(\tilde{Y})) - b\tau(E(\tilde{X})), \\ &\qquad (\sigma(E(\tilde{Y})) - |b|\sigma(E(\tilde{X})))(1-\alpha)]_{CR} \\ &= [3.5675, 0.3(1-\alpha)]_{CR} \\ &= [3.2675 + 0.3\alpha, 3.8675 - 0.3\alpha] \end{aligned}$$

Table 1. Comparison of the observation errors for previous estimators

			$d^2(\tilde{Y}_i, \tilde{A} + b \odot \tilde{X}_i)$		
	$\vec{X}_i$	$\vec{Y}_i$	D.	C.-H.	Thm. 8
1.	$(1.5, 2, 2.5)$	$(3.5, 4, 4.5)$	0.7344	0.7466	0.7417
2.	$(3, 3.5, 4)$	$(5, 5.5, 6)$	0.0282	0.0273	0.0275
3.	$(4.5, 5.5, 6.5)$	$(6.5, 7.5, 8.5)$	2.3177	2.3265	2.3200
4.	$(6.5, 7, 7.5)$	$(6, 6.5, 7)$	1.0106	0.9965	1.0049
5.	$(8, 8.5, 9)$	$(8, 8.5, 9)$	0.5195	0.5359	0.5267
6.	$(9.5, 10.5, 11.5)$	$(7, 8, 9)$	2.1578	2.1086	2.1352
7.	$(10.5, 11, 11.5)$	$(10, 10.5, 11)$	2.9113	2.9743	2.9403
8.	$(12, 12.5, 13)$	$(9, 9.5, 10)$	0.6648	0.6285	0.6476
Observation errors			10.3443	10.3442	10.3439

Using the data set in Example 1, Diamond [4] obtained the following regression coefficients

$$\tilde{A} = [3.263 + 0.3\alpha, 3.863 - 0.3\alpha],$$
$$b = 0.521.$$

And, Chen and Hsueh [3] obtained

$$\tilde{A} = [3.272 + 0.3\alpha, 3.872 - 0.3\alpha],$$
$$b = 0.521.$$

Table 1 shows that the observation errors corresponding to the above three estimators, where the observation errors are computed by Eq.(1). It is easy to see that our estimators are the best, as follows

$$\tilde{A} = [3.2675 + 0.3\alpha, 3.8675 - 0.3\alpha],$$
$$b = 0.520.$$

VI. Conclusion

In the paper, we apply the CR-representations of fuzzy numbers and symmetric triangular approximations to solve the regression model whose constant coefficient is assumed to be symmetric triangular and other coefficients to be real. The proposed formulae are simple and clear. In the future, one may consider applying more general approximations (such as triangular approximations [30], trapezoidal approximations [7], [26], and symmetric trapezoidal approximations [28]) to solve the following regression model

$$d^2(\vec{\tilde{Y}}, \tilde{A}\vec{1} + b\vec{\tilde{X}}),$$

where $b \in \mathbb{R}$ and $\tilde{A}$ is triangular (trapezoidal or symmetric trapezoidal).

Abstract— **Regression models are well known and widely used as one of the important categories of models in system modeling. In this paper, we extend the concept of fuzzy regression in order to handle real-time implementation of data analysis of information granules. An ultimate objective of this study is to develop a hybrid of a genetically-guided clustering algorithm called genetic algorithm-Fuzzy C-Means (GA-FCM) and a convex hull-based fuzzy regression approach being regarded as a potential solution to the formation of information granules. It is anticipated that the setting of Granular Computing will help us reduce the computing time, especially in case of real-time data analysis, as well as an overall computational complexity. We propose an efficient real-time granular fuzzy regression analysis based on the convex hull approach in which a Beneath-Beyond algorithm is employed to design a convex hull. In the proposed design setting, we emphasize a pivotal role of the convex hull approach, which becomes crucial in alleviating limitations of linear programming manifesting in system modeling.**

Keywords-convex hull, fuzzy regression, Fuzzy C-Means, genetic algorithm, granular computing

I. INTRODUCTION

Nowadays, we witness a significant growth of interest in Granular Computing（GrC) being regarded as a promising vehicle supporting the design, analysis and processing of information granules [1]. With regard of all processing faculties, information granules are collections of entities (elements), usually originating at the numeric level, that are arranged together due to their similarity, functional adjacency and indistinguishability or alike [1]. Given the similarity function to measure the closeness between the samples these data are clustered into certain granules, categories or classes [2]. The process of forming information granules is referred as information granulation.

GrC has begun to play important roles in bioinformatics, pattern recognition, security, high-performance computing and so on in terms of efficiency, effectiveness, robustness as well as a structural representation of uncertainty [3]. Therefore, the needs for sophisticated intelligent data analysis (IDA) tools are highly justifiable when dealing with this type of information.

Ramli *et al.* proposed a real-time fuzzy regression model incorporating a convex hull method, specifically a Beneath-Beyond algorithm [3]. They have deployed a convex hull approach useful in the realization of data analysis in a dynamic data environment. The developed method exhibits good performance as far as computing time and an overall computation complexity are concerned. Fuzzy C-Means (FCM) clustering algorithm, introduced by Dunn in 1973 and generalized by Bezdek in 1981, becomes one of the commonly used techniques of GrC when it comes to the formation of information granules [4] [5]. There has been a great deal of improvements and extensions of this clustering technique. One can refer here to the genetically-guided clustering algorithm called genetic algorithm-FCM (GA-FCM) and proposed by Hall *et al.* It has been shown that the GA-FCM algorithm can successfully alleviate the difficulties of choosing a suitable initialization of the FCM method [6].

Associated with these two highlighted models (that is fuzzy regression and fuzzy clustering), the main objective of this study is to propose an enhancement of the fuzzy regression analysis for the purpose of analysis of information granules. From the IDA perspective, this research intends to augment the model given originally proposed by Bezdek by including the Ramli *et al.*'s approach. It will be shown that such a hybrid combination is capable of supporting real-time granular based fuzzy regression analysis.

In general, the proposed approach helps perform real-time fuzzy regression analysis in presence of information granules. The proposed approach comprises three main phases. First, we use the GA-FCM clustering to granulate the entire data set into a limited number of chunks–information granules. The second phase consists of constructing convex hull polygons for the already formed information granules. Finally, in the last phase, the selected vertices of the constructed convex hull, which covers all information granules, are used to build a fuzzy regressions model. To illustrate the efficiency and effectiveness of the proposed method, a numeric example is presented.

This study is structured as follows. Section 2 serves as a concise and focused review of the fuzzy regression model, convex hull approach, principles of GrC as well as GA-FCM. Section 3 discusses some essentials of fuzzy linear regression

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

augmented by the convex hull approach. Section 4 discusses a processing flow of the proposed approach; a real-time granular-based fuzzy regression models. Section 5 is devoted to a numerical experiment. Finally, Section 6 presents some concluding remarks.

II. SOME RELETED PRILIMINARIES

A. Review of Fuzzy Regression Model

In statistical regression, deviations between observed and estimated values are assumed to be due to the random errors. Regression analysis is one of commonly encountered approaches in describing relationships among the analyzed data. The regression models explain dependencies between independent and dependent variables. The variables, which are used to explain the other variable(s) are called explanatory ones [7].

Although conventional regression has been applied to various applications, problems may arise when we encounter vague relationships between input and output variables in which cases there assumptions made for regression models are not valid any longer. This situation becomes a major reason of a lack of relevance of regression models.

Recall that a standard numeric linear regression model comes in the following form

$$y = a_0 + a_1 x_1 + ... + a_K x_K . \tag{1}$$

As an interesting and useful extension, Tanaka *et al.* [7] introduced an enhancement of the regression model by accommodating fuzzy sets thus giving rise to the term of fuzzy regression or possibilistic regression. The models of this category reflect the fuzzy set based nature of relationships between the dependent and independent variables. The upper and lower regression boundaries in the fuzzy regression are used to quantify the fuzzy distribution of the output values.

As an alternative to the fuzzy specification, an inexact relationship among those dependent and independent variables can be represented via fuzzy linear regression expressed in the following form

$$\widetilde{Y} = \widetilde{A}_0 X_0 + \widetilde{A}_1 X_1 + ... + \widetilde{A}_K X_K = \widetilde{\mathbf{A}}\mathbf{X}^t , \tag{2}$$

where $\mathbf{X} = [X_0, X_1, ..., X_K]$ is a vector of independent variables; $\widetilde{\mathbf{A}} = [\widetilde{A}_0, \widetilde{A}_1, ...\widetilde{A}_K]$ is a vector of fuzzy coefficients represented in the form of symmetric triangular fuzzy numbers and denoted by $\widetilde{A}_j = (\alpha_j, c_j)$. Their membership function is described in the form:

$$u_{\widetilde{A}_j}(a_j) = \begin{cases} 1 - \dfrac{|\alpha_j - a_j|}{c_j}, & : c_j \neq 0, \alpha_j - c_j \le a_j \le \alpha_j + c_j \\ 1, & : c_j = 0, \alpha_j = a_j \\ 0, & : otherwise \end{cases} \tag{3}$$

$$(j = 0, \ldots, K)$$

In addition, from the computational perspective, the estimation of the membership functions of the fuzzy parameters of the regression is concerned with a certain problem of linear programming (LP) [8] [9].

Given the notation used above, (2) can be rewritten as

$$\widetilde{Y}_i = (\alpha_0, c_0) + (\alpha_1, c_1) X_1 + (\alpha_2, c_2) X_2 + ... + (\alpha_K, c_K) X_K \tag{4}$$

where α_j and c_j are the central (modal) value and the spread of triangular fuzzy number, respectively.

Related to the above model (4), we assume that the numeric input and output data are available, while the relation between the input and output data is defined by some fuzzy function in which the distribution of the parameter is governed by the membership functions [10].

By making use of the extension principle, the membership function of the fuzzy number $\widetilde{Y}_i$ comes in the following form

$$u(Y_i) = \begin{cases} 1 - \dfrac{|\, Y_i - \boldsymbol{\alpha}\mathbf{X}_i^t \,|}{\mathbf{c}\,|\,\mathbf{X}_i^t\,|}, & : \mathbf{c}\,|\,\mathbf{X}_i^t\,| \neq 0, \boldsymbol{\alpha}\mathbf{X}_i^t - \mathbf{c}\,|\,\mathbf{X}_i^t\,| \le Y_i \le \boldsymbol{\alpha}\mathbf{X}_i^t + \mathbf{c}\,|\,\mathbf{X}_i^t\,| \\ 1, & : \mathbf{c}\,|\,\mathbf{X}_i^t\,| = 0, \; Y_i = \boldsymbol{\alpha}\mathbf{X}_i^t \\ 0, & : otherwise \end{cases} \tag{5}$$

where $\mathbf{c} = [c_0, c_1, ..., c_K], \boldsymbol{\alpha} = [\alpha_0, \alpha_1, ..., \alpha_K]$ and $\mathbf{c}\,|\,\mathbf{X}_i^t\,| = \sum_{j=0}^{K} c_j \,|\, x_{ij} \,|$, $x_{i0} = 1 : (\forall i = 1, ..., n)$.

Moreover, when we consider an optimization of some objective function, its minimization reduces the total spread of the fuzzy number, $\widetilde{Y}_i$. More specifically we have

$$\underset{\boldsymbol{\alpha},\mathbf{c}}{\text{MIN}} \sum_{i=1}^{n} \mathbf{c}\,|\,\mathbf{X}_i^t\,| = \underset{\boldsymbol{\alpha},\mathbf{c}}{\text{MIN}} \sum_{i=1}^{n} \sum_{j=0}^{K} c_j \,|\, x_{ij} \,| \tag{6}$$

along with the constraints which require that each observation Y_i comes with at least h degree of membership to $\widetilde{Y}_i$, that is $u(Y_i) \ge h \; (i = 1, ..., n),$. This requirement can be expressed in an equivalent form

$$1 - \frac{|\, Y_i - \boldsymbol{\alpha}\mathbf{X}_i^t \,|}{\mathbf{c}\,|\,\mathbf{X}_i^t\,|} \ge h, \qquad \forall i = 1, ..., n \tag{7}$$

The above formulation of the problem leads to the following problem of LP

$$\underset{\boldsymbol{\alpha},\mathbf{c}}{\text{MIN}} \sum_{i=1}^{n} \sum_{j=0}^{K} c_j \,|\, x_{ij} \,| \tag{8}$$

$$\text{subject to } \sum_{j=0}^{K}\alpha_j x_{ij} + (1-h)\sum_{j=0}^{K} c_j \mid x_{ij} \mid \geq Y_i,$$
$$\sum_{j=0}^{K}\alpha_j x_{ij} - (1-h)\sum_{j=0}^{K} c_j \mid x_{ij} \mid \leq Y_i, \qquad (9)$$
$$c_j \geq 0, \quad \alpha_j \in \Re, \quad x_{i0} = 1 \quad (0 \leq h < 1; \quad \forall i = 1,...,n).$$

Additionally, the fuzzy regression model is constructed in such a way so that it "covers" all data points under consideration, cf. [11].

We use the notation $(\tilde{y}_i, \mathbf{x}_i), \tilde{y}_i = (y_i, d_i)$, to denote the fuzzy output data and $\mathbf{x}_i = [x_{i0}, x_{i1}, x_{i2}, ..., x_{iK}]$ $(i = 1,...,n)$ to describe the numeric input data. The notation of $(\boldsymbol{\alpha}, \mathbf{c})$ is used to describe fuzzy coefficients. The development of the fuzzy regression model results in the following LP problem:

$$\underset{\boldsymbol{\alpha},\mathbf{c}}{\text{MIN}} \sum_{i=1}^{n} \mathbf{c} \mid \mathbf{x}_i^t \mid \qquad (10)$$

$$\text{subject to } y_i + L^{-1}(h)d_i \leq \boldsymbol{\alpha}\mathbf{x}_i^t + L^{-1}(h)\mathbf{c} \mid \mathbf{x}_i^t \mid$$
$$y_i - L^{-1}(h)d_i \geq \boldsymbol{\alpha}\mathbf{x}_i^t - L^{-1}(h)\mathbf{c} \mid \mathbf{x}_i^t \mid \qquad (11)$$
$$\mathbf{c} \geq 0 \quad (i = 1,...,n),$$

where $L(u)$ refers to the shape of the membership function of the parameters of the fuzzy regression model while h is a possibility degree expressing to which extent a given datum is "covered" by the model. Based on the above explanation, fuzzy regression becomes the possibilistic model that can be used in the context of possibility theory [12]. Furthermore, it is possible in this formulation of the fuzzy regression model to treat non-fuzzy data with zero width setting the value of, d to 0 as described in the above formulas.

B. Convex Hull Approach

Let us recall that the convex hull of a set S of points while $hull(S)$ is defined to be a minimum convex set containing S. A point $P \in S$ is an extreme point of S if $P \notin hull(S - P)$. In general, if S is finite, then $hull(S)$ are a convex polygon and the extreme points of S are the corners of this polygon. The edges of this polygon are referred to as the edges of the $hull(S)$. Figure 2 illustrates the convex hull realization.

The concept closely related here is the affine hull of a set S in Euclidean space $\Re^K$. It is the smallest affine set containing S, or equivalently, the intersection of all affine sets containing S. Here, an affine set is defined as the translation of a vector subspace. The affine hull $aff(S)$ of S is the set of all affine combinations of elements of S, namely,

$$aff(S) = \{\sum_{j=1}^{K}\alpha_j x_j \mid x_j \in S, \alpha_j \in \Re, \alpha_j \geq 0, \sum_{j=1}^{K}\alpha_j = 1\}. \qquad (12)$$

The Beneath-Beyond algorithm is developed to incrementally build up the convex hull by keeping track of the current convex hull P_i and using an incidence graph [13]. In a nutshell, the Beneath-Beyond algorithm comprises the following steps:

Step_1 : Select and sort points along one direction, say x_1. Let $s = \{p_0, p_1, ..., p_{n-1}\}$ be input points after sorting. Process the points in increasing order.

Step_2 : Take the first n points, which define a facet (*dimensional faces*) as the initial hull.

Step_3 : Let P_i be the point to be added to the hull at the i th stage. Let $p_i = conv(p_0, p_1, ..., p_{i-1})$ be the convex hull polytope built so far. This step includes two kinds of hull updates;

(a) A pyramidal update is done when $p_i \notin aff(p_0, p_1, ..., p_{i-1})$ - when P_i is not on the hyperplane defined by the current hull. A pyramidal update consists of adding a new node representing P_i to the incidence graph and connecting this node to all existing hull vertices by new edges.

(b) A non-pyramidal update is done when the above condition is not met, *i.e.* P_i is in the affine subspace defined by the current convex hull. In this case, faces that are visible from P_i are removed and new facets are created.

C. Review of Granular Computing with Genetic Clustering

As said earlier, GrC is a general computing paradigm that effectively deals with processing information granules. The underlying formalism relies on a way in which information granules are represented; here we may consider set theory, fuzzy sets, rough sets, to name a few of the available alternatives [1] [14].

In this context, FCM arises as a way of formation of information granules represented by fuzzy sets [5]. In essence, the FCM algorithm is developed based on the minimization of the following objective function

$$J_m(U,V) = \sum_{i=1}^{c}\sum_{k=1}^{n}(U_{ik})^m D_{ik}^2(\mathbf{v}_i, \mathbf{x}_k) \qquad 1 \leq i \leq c; 1 \leq k \leq n \qquad (13)$$

where $U \in M_{fcn}$ is a fuzzy partition matrix, $V = (\mathbf{v}_1, \mathbf{v}_2, ..., \mathbf{v}_c)$ is a collection of cluster centers *(prototypes).* $\mathbf{v}_i \in \Re^K$ $\forall i$ and $D_{ik}(\mathbf{v}_i, \mathbf{x}_k)$ is a distance between x_k and the i^{th} prototype while m is a certain parameter known as a fuzzification coefficient, $m > 1$.

The FCM optimizes (13) by iteratively updating the prototypes and the partition matrix. More specifically, we choose some values of c, m and ε (termination condition – a small positive constant), then generate a random a fuzzy partition matrix U^0 and set an iteration index $t = 0$. An iterative process is organized as follows. Given the

membership value $\mu_{ik}^{(t)}$, the cluster centers $\mathbf{v}_i^{(t)}(i=1,\ldots,c)$ are calculated by

$$\mathbf{v}_i^{(t)} = \frac{\sum_{k=1}^{n}(\mu_{ik}^{(t)})^m \mathbf{x}_k}{\sum_{k=1}^{n}(\mu_{ik}^{(t)})^m} \quad for \quad 1 \le k \le n.. \tag{14}$$

Given the new cluster centers $\mathbf{v}_i^{(t)}$, we update the membership values of the partition matrix $\mu_{ik}^{(t)}$

$$\mu_{ik}^{t+1} = \left[\sum_{j=1}^{c} \left(\frac{\left\| \mathbf{x}_k - \mathbf{v}_i^{(t)} \right\|}{\left\| \mathbf{x}_k - \mathbf{v}_j^{(t)} \right\|} \right)^{\frac{2}{m-1}} \right]^{-1} \quad 1 \le j \le c. \tag{15}$$

This process terminates when $\left| U^{(t+1)} - U^{(t)} \right| \le \varepsilon$, or a predefined number of iterations have been reached [15].

We focus here on the practice of genetically-guided clustering algorithm, which proposed by Hall *et al.* in 1999 [6]. Based on Hall *et al.*, in any generation, element i of the population, V_i, a $c \times s$ matrix of cluster centers or prototypes. The initial population of size P is built by some random assignment of real numbers to each of the features of the c cluster centers. The initial values are constrained to be in the range of the attribute to which they are assigned (determined empirically from the experimental data sets) but are otherwise random [6].

In addition, as the cluster centers are to be used by the GA, it becomes necessary to reformulate the objective function for optimization purposes. Expression (13) can be given in terms of distances from the prototypes (as done in the FCM algorithm). As long as $D_{jk}(\mathbf{v}_j, \mathbf{x}_k) > 0 \forall j,k$, $1 \le j \le c; 1 \le k \le n$ we can use the following formula

$$U_{ik} = 1 / \sum_{j=1}^{c} \left(\frac{D_{ik}(\mathbf{v}_i, \mathbf{x}_k)}{D_{jk}(\mathbf{v}_j, \mathbf{x}_k)} \right)^{\frac{2}{m-1}} \quad for \quad 1 \le i \le c; 1 \le k \le n \tag{16}$$

in the calculations of the fuzzy partition matrix. Therefore the reformulated version of the FCM objective function comes in the form

$$R_m(V) = \sum_{k=1}^{n} \left(\sum_{i=1}^{c} D_{ik}^{\frac{1}{1-m}} \right)^{1-m} \quad for \quad 1 \le i \le c; 1 \le k \le n \tag{17}$$

Next we optimize R_m by running a genetically-guided algorithm (GGA). As usual, the important features of the GA-based clustering algorithm relate with the choice of the selection, crossover as well as mutation operators of the genetic optimization; for details one may refer to [6].

Moreover, the complete process of the GGA algorithm is outlined as follows [6].

GGA_1 : Choose m, c and D_{ik}.

GGA_2 : Randomly initialize P sets of c cluster centers. Constrain the initial values within the space defined by the data to be clustered.

GGA_3 : Calculate R_m by using (17) for each population member and apply modified objective function $R_m'(V) = R_m(V) + b \times R_m(V)$, where $b \in [0, c]$ is the number of empty clusters.

GGA_4 : Convert population members to binary equivalents (*using the Gray code*).

GGA_5 : For $i = 1$ to number of generations, Do

i. Used k-fold tournament selection (default $k = 2$) to select $P/2$ parent pairs for reproduction.

ii. Complete a two-point crossover and bitwise mutation for each feature of the parent pairs.

iii. Calculate R_m by using (17) for each population member and apply modified objective function $R_m'(V) = R_m(V) + b \times R_m(V)$, where $b \in [0, c]$ is the number of empty clusters.

iv. Create a new generation of size P which is selected from the two best members of the previous generation and the best children that are generated by using crossover and mutation.

GGA_6 : Provide the cluster centers to the terminal population with the smallest R_m' value and report R_m'

III. Fuzzy Linear Regression Models with Convex Hull Approach

Ordinarily, the weaknesses of the implementation of the multi-dimensional fuzzy linear regression can be addressed by incorporating the convex hull approach [12]. In the introduced modification, the construction of vertices of the convex hull becomes realized in real-time by using related points (convex points) of the graph. Furthermore, the real-time implementation of the method has to deal with a large number of samples (data). Therefore, each particular analyzed sample stands for a convex point and is possibly selected as a convex hull vertex. Some edges connecting the vertices need to be re-constructed as well.

Recall that the main purpose of fuzzy linear regression is to form the upper and lower bounds of the linear regression model. Both the upper line Y^U and lower line Y^L for fuzzy linear regression are expressed in the form:

$$Y^U = \{A_0 + A_1 x_1 + \ldots + A_K x_K\}^U : \{\mathbf{A}\mathbf{x}_i^t\}^U = \boldsymbol{\alpha}\mathbf{x}_i^t + \mathbf{c}\left|\mathbf{x}_i^t\right| \tag{18}$$

$$Y^L = \{A_0 + A_1 x_1 + \ldots + A_K x_K\}^L : \{\mathbf{A}\mathbf{x}_i^t\}^L = \boldsymbol{\alpha}\mathbf{x}_i^t - \mathbf{c}\left|\mathbf{x}_i^t\right| \tag{19}$$

By using (18) and (19), we convert the problem to a general fuzzy regression that is similar to the one shown below:

(i) Evaluation (objective) function

$$\min_{\boldsymbol{\alpha},\mathbf{c}} \sum_{i=1}^{n}\sum_{j=2}^{K} c_j \left|P_{ij}\right|. \tag{20}$$

(ii) Constraints

$$P_{i1} \in Y_i \Leftrightarrow \begin{cases} P_{i1} \le \alpha_0 + c_0 + \sum_{j=2}^{K} \alpha_j P_{ij} + \sum_{j=2}^{K} c_j \left|P_{ij}\right| \\ P_{i1} \ge \alpha_0 - c_0 + \sum_{j=2}^{K} \alpha_j P_{ij} - \sum_{j=2}^{K} c_j \left|P_{ij}\right| \\ (i = 1,\ldots,n) \end{cases} \tag{21}$$

The above expression can be further rewritten as follows:

$$\begin{aligned} Y^U &= \{Y_i^U \,|\, i = 1,\ldots,n\} \\ Y^L &= \{Y_i^L \,|\, i = 1,\ldots,n\}. \end{aligned} \tag{22}$$

We also arrive at the following simple relationships for P_{i1}

$$P_{i1} \le Y_i^U, \quad P_{i1} \ge Y_i^L \qquad (i = 1,\ldots,n). \tag{23}$$

It is well known that any discrete topology is a topology which is formed by a collection of subsets of a topological space X and the discrete metric ρ on X is defined as

$$\rho(x,y) = \begin{cases} 1 & if\ x \ne y \\ 0 & if\ x = y \end{cases} \tag{24}$$

for any $x, y \in X$. In this case, (X,ρ) is called a discrete metric space or a space of isolated points. According to the definition of discrete topology, expression (23) is rewritten as follows:

$$\begin{aligned} S(Y^U) &= \sum_{j=1}^{K} \{Y_j P_{ij}\}^U \ge 0 \\ S(Y^L) &= \sum_{j=1}^{K} \{Y_j P_{ij}\}^L \le 0 \end{aligned} \tag{25}$$

where we assume that $P_{i1} = 1$.

This formula corresponds to the definition of the support hyperplane. Under the consideration of the range of

$$S \bigcap P \ne \phi \ \text{ and } \ P \subset S^+ \text{ or } P \subset S^-, \tag{26}$$

the following relation is valid:

$$\bigcap S(Y^U) = \bigcap S(Y^L). \tag{27}$$

This is explained by the fact that regression formula Y^U and Y^L are formed by vertices of a convex hull. Therefore, it is apparent that the constructed convex hull polygon or more specifically, its vertices clearly define the as discussed constraints of fuzzy mathematical programming, which were becomes more reliable as well as significant for the subsequent processes.

Recall that the convex hull of a set S of points while $hull(S)$ is defined to be a minimum convex set containing S. A point $P \in S$ is an extreme point of S if $P \notin hull(S - P)$. Hence P denotes the set of points (input samples) and P_C is the set of vertices of the convex hull where $P_C \in P$. Therefore, the convex hull has to satisfy the following relationship:

$$conv(P) = conv(P_C) \tag{28}$$

Let us introduce the following set

$$P_C = \left\{x_{Cl} \in \Re^K \,\middle|\, l = 1,\ldots,m\right\} \subseteq P \tag{29}$$

where m is the number of vertices of the convex hull. Plugging this relationship into (21), we arrive at the following constraints:

$$P_{i1} \in Y_i \Leftrightarrow \begin{cases} P_{i1} \le \alpha_0 + c_0 + \sum_{j=2}^{K} \alpha_j P_{ij} + \sum_{j=2}^{K} c_j \left|P_{ij}\right| \\ P_{i1} \ge \alpha_0 - c_0 + \sum_{j=2}^{K} \alpha_j P_{ij} - \sum_{j=2}^{K} c_j \left|P_{ij}\right| \\ (i = 1,\ldots,m). \end{cases} \tag{30}$$

By using (30), the constraints of the LP of the fuzzy linear regression can be written down in the following manner:

$$y_i \in Y_i \Leftrightarrow \begin{cases} y_i \le \boldsymbol{\alpha}\mathbf{x}_i^t + \mathbf{c}\left|\mathbf{x}_i^t\right| \\ y_i \ge \boldsymbol{\alpha}\mathbf{x}_i^t - \mathbf{c}\left|\mathbf{x}_i^t\right| \\ (i = 1,\ldots,m). \end{cases} \tag{31}$$

Moreover, in order to form a suitable regression model based on the constructed convex hull, the connected vertex points are used as the constraints in the LP formulation of the fuzzy linear regression. Considering this process, the use of

the limited number of selected vertices contributes to the minimized computing complexity associated with the model [1].

IV. A Real-Time Granular Based Fuzzy Regression Models with a Convex Hull Implementation

In what follows, we present a hybrid combination of a fuzzy linear regression analysis based on convex hull algorithm, in particular the Beneath-Beyond algorithm to facilitate a real-time fuzzy regression analysis of granular data implementation. The detailed flow of processing is shown in Figure 1.

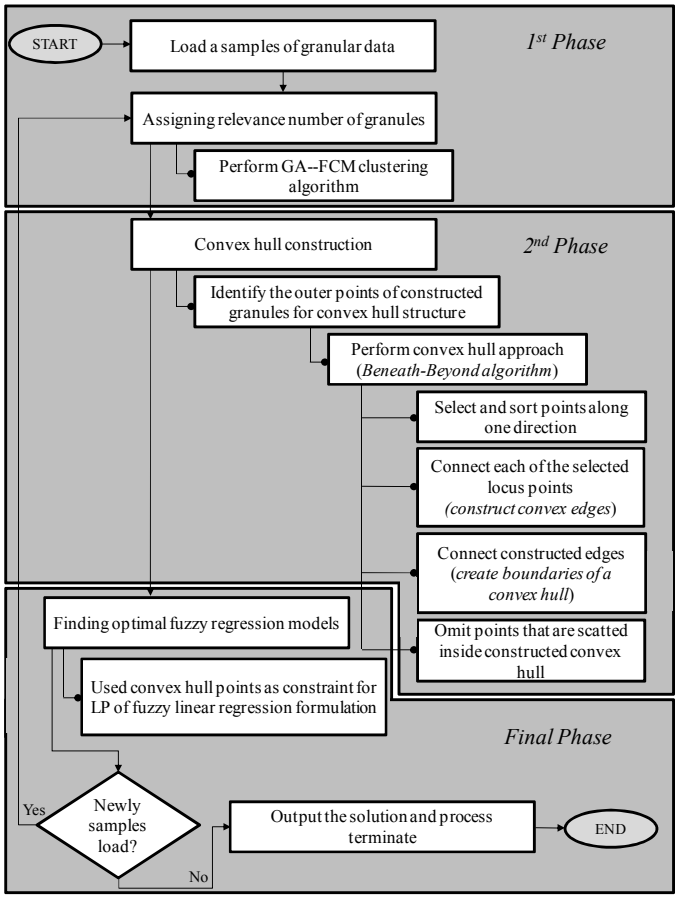

Figure 1. A general flow of processing of the proposed approach.

During the first phase we perform an assigning of appropriate number of granules augmented by GA-FCM clustering algorithm. Then, at the next phase, a construction of convex hull polygon is realized by selecting the outer points among the assigned granules. Therefore, the connection between these selected points (vertices) were became a boundary of the entire analyzed data samples as well as obtained information granules. As a result, with this constructed convex hull, we create the optimal regression lines as realized in the final phase, see Figure 1. In addition, we complete some iterations of the overall procedure considering that more data become available. Say, new samples are provided within a certain time interval, *e.g.*, they could be arriving every 5 or 10 seconds.

In light of the comments made above, it becomes apparent that the quality of granular based fuzzy regression model can be improved by the hybrid combination of fuzzy regression approach with the convex hull approach. The efficiency refers to the computing time as well as the overall computational complexity.

We do not have to consider the complete feature vectors for building regression models; just we utilize the selected vertices which are used for the construction of the convex hull. Therefore, this situation will lead to the decrease of computation load. On the other hand, related to the computational complexity factor for the subsequent iteration, it will only consider the newly added samples of data together with the selected vertices of the previous convex hull. For that reason, this computing scenario will reduce the computational complexity because of the lower number of the feature vectors used for the subsequent processing of regression models [3].

V. A Numerical Example

We present a simple numerical example, which shows the efficiency of the proposed approach in the implementation of real-time granular based fuzzy regression. Below, shows an illustration of real-time data analysis which involve dynamic record/database, see Figure 2. For instant, each of iteration might be having a same amount of newly arrived data. As early mentioned, the size of data were increase along with time spending. We can see here, the volume of data becomes enlarge as regard to the time increased.

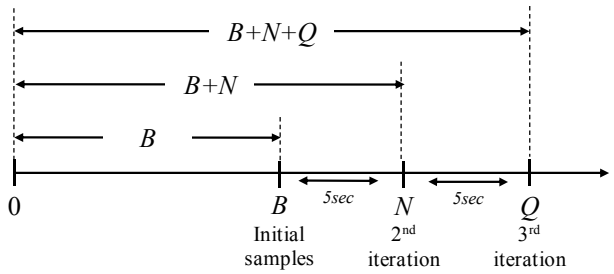

Figure 2. An Illustration of an increasing record/database along with time consumption.

Based on the above figure, we assume that an initial group of samples (*for 1st iteration*) consists of 100 data of the well-known *Iris* data set [11]. Next, considering a distribution of these data, we construct a convex hull polygon, which becomes the boundary of the overall analyzed samples. Among 100 obtained loci points (*clustered feature vectors*), only 11 points were selected as convex hull vertices, see Figure 3. In addition, these selected vertices are located as the outside points of the constructed clusters. By solving the associated LP problem that considered these selected vertices as a part of the constraint portion standing in the problem, we obtained the optimal regression coefficients, see Table I. In addition, we selected $h = 0.05$ to express goodness of fit or compatibility of data and the regression model.

TABLE I. The Center and Width Values of Initial Group of Data Samples

Variables	Center, m_i	Width, c_i
Intercept	2.071	0.163
$C1$	0.612	0.096
$C2$	0.639	0.075
$C3$	-0.412	0.000

Figure 2 shows the obtained feature vectors.

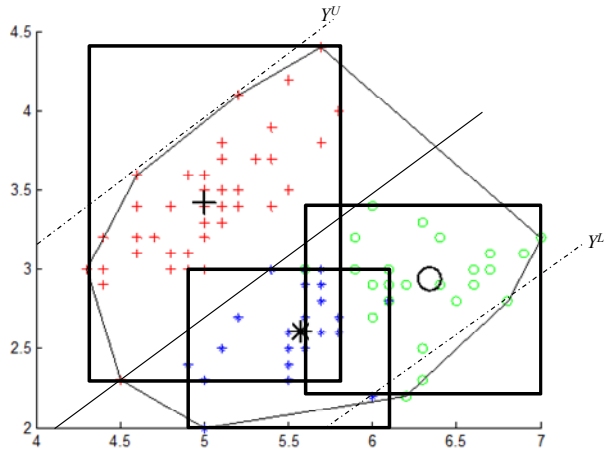

Figure 3. An Ilustration of obtained clustered feature vectors for the initial group of data samples.

To deal with a real-time scenario, we added a group of samples taken from the same data set, which consists of 50 patterns. In this case, we assume that a same as previous parameter setting has been set up and an iteration process has been completed. For this 2nd iteration, only 9 points were considered as convex hull vertices.

Finally, Table II includes the parameters as well as the values of the fuzzy regression which have been obtained and Figure 4 shows the of clustered feature vectors.

TABLE II. CENTER AND WIDTH VALUES OF INITIAL GROUP TOGETHER WITH NEWLY ADDED DATA SAMPLES

Variables	Center, m_i	Width, c_i
Intercept	1.856	0.173
$C1$	0.651	0.102
$C2$	0.709	0.095
$C3$	-0.556	0.000

Let us highlight some essential features related to the time analysis. In general, an increasing number of potential vertices present in the subsequent iterations may not directly influence the required time analysis because some of vertices, which have been previously selected, might be reused in the consecutive iteration. Therefore, this situation might reduce required computing time. Furthermore, due to the decrease in the number of considered vertices, this effect will influence (*reduce*) the computational complexity.

On the other hands, as a supporting evidence for evaluating the performance as well as efficiency of this proposed approach, we use the same set of data samples/parameters and each of experiment was run five times for some other regression approaches; LP approach and fuzzy least-squares regression (FLSR) [16]. Each run presents samples of data sequentially in different order depending on their own procedure. Table III shows the performance of the proposed approach and the remaining regression models in time consumption point of view.

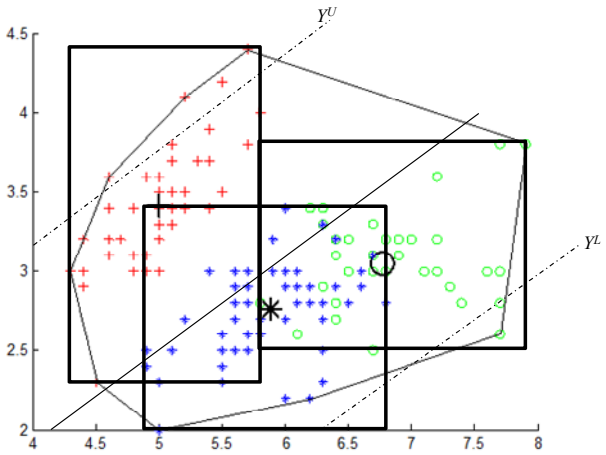

Figure 4. Ilustration of obtained clustered feature vectors for initial group together with newly added data samples.

TABLE III. PERFORMANCE ANALYSIS-TIME CONSUMPTION FACTOR: DETAILS

Model	Iteration	Points Total (*Considered Vertices*)	Time Used (*seconds*)
LP approach	1st iteration	100 (*100*)	0.58
	2nd iteration	150 (*150*)	1.22
FLSR approach	1st iteration	100 (*100*)	0.47
	2nd iteration	150 (*150*)	1.04
Proposed approach	1st iteration	100 (*11*)	0.33
	2nd iteration	150 (*9*)	0.39

Based on above table, we can summarized that, our proposed approach was utilized the minimal time consumption. In addition, noted that, those, LP and FLSR regression approach was not appropriate for dealing with dynamic data analysis. Therefore, these results illustrate the potential of our proposed approach to solve real-time fuzzy regression problem especially for granular computing fields that demand incremental adaptability.

VI. CONCLUDING REMARKS

In this study, we have developed an enhancement of the IDA tool of fuzzy regression in case of information granules. The method first constructs a limited number of information granules and afterwards those granules are processed by running the convex hull-based fuzzy regression. In this way, we have successfully developed a new idea of real-time granular based fuzzy regression models as a modeling alternative to deal with real-world regression problems.

It is shown that information granules are formed as a result of running the genetic version of the FCM called GA-FCM. The second phase of the overall method is completed depending upon the outer plots of the clusters. The sequential flow of processing was carried out to deal with dynamically increasing data set.

Based on the experimental developments, one could note that this approach becomes a suitable design alternative especially when solving real-time fuzzy regression problems with information granules. It works efficiently for real-time data analysis given the reduced processing time as well as the associated computational complexity.

This proposed approach can be applied to real-time fuzzy regression problems in large-scale systems presented in real-world scenarios. In addition, each of selected approach (*GA-FCM and convex hull-based fuzzy regression*) has their own features to be faced with dynamically changes of samples volume within a certain time interval. Therefore, as a result, this extended enhancement or hybrid combination will provide an efficient platform for regression purposes which require only plenty of time as well as reduce computational complexity with lower computing overhead. Although in this paper we dealt with small data sets (*and this was done for illustrative purposes*), it is worth noting that method scales up quite easily.

In further studies, we plan to expand the proposed approach by incorporating some other technologies of soft computing and swarm intelligence.

***Abstract*—A novel approach is introduced to construct a fuzzy regression model when the data available of independent and dependent variables are fuzzy numbers. The approach, consisting on the least-squares method, uses the $\alpha-$level sets of fuzzy observations to estimate the crisp parameters of the model. A competitive study shows the performance and efficiency of the proposed approach with respect to some well-known methods.**

***Keywords*— capability index; fuzzy regression; hydrology; interval arithmetic; least squares method**

I. Introduction

Identification and analysis of the functional relationship between a dependent and some independent variables have made great interest in statistical analysis. Based on such functional relationship, which is called regression model, one can describe and predict the values of the dependent variable using the observations of independent variables.

However, when the data are reported as imprecise quantities we need to develop some soft methods to construct and analyze regression models. Fuzzy set theory provides appropriate tools for modeling regression when imprecise data have been observed. Over the last decades, different approaches to regression modeling have been widely proposed in the statistical literature, focussing on the situation of fuzzy environment. We refer the reader to [3], [4], [8], [12], [13], [15] for some recent works as well as some reviews of the main approaches to regression analysis in fuzzy environment.

In the present work, we investigate the situation in which the data available of independent and dependent variables are fuzzy numbers. We introduce a novel approach to model such a fuzzy data set. In the proposed approach, we apply a squared distance on the space of real intervals. Then, consisting on minimizing the total least-squares of errors, a linear regression model is expressed in terms of interval arithmetic between the α-level sets of fuzzy input-output data at each level of $\alpha \in [0,1]$. The errors are considered based on the differences between the interval-valued data obtained from the α-level sets of the observations and the estimations of the dependent variable. Finally, by aggregating the coefficients obtained from the interval regression model, we estimate the coefficients of the fuzzy regression model. The proposed method is investigated by two numerical competitive examples, which indicate the performance of the proposed model with respect to some well-known models.

The rest of this paper is organized as follows. In the next section, some preliminaries of fuzzy arithmetic that will be used in the sequel are recalled. Section III presents a novel approach to fuzzy regression for fuzzy input output data. In this section, the method of estimation of the parameters of the model is explained. In Section IV, two numerical examples are given to clarify the proposed approach. Finally, in Section V some concluding remarks are made.

II. Preliminaries from fuzzy arithmetic

A fuzzy set $\tilde{A}$ on the universal set $\mathbb{X}$ is defined by its membership function $\tilde{A}(x) : \mathbb{X} \to [0,1]$. Through this paper we will consider that $\mathbb{X} = \mathbb{R}$ (the real line). The α-level set of a fuzzy set $\tilde{A}$ is defined as $A_\alpha = \{x \in \mathbb{R} : \tilde{A}(x) \geq \alpha\}$, $\alpha \in (0,1]$, and $A_0 = \text{closure}\{x \in \mathbb{R} : \tilde{A}(x) > 0\}$. A fuzzy set $\tilde{A}$ of $\mathbb{R}$ is called a fuzzy number if any α-level set of $\tilde{A}$ is a non-empty compact interval, for any $\alpha \in [0,1]$. Such intervals are represented by $A_\alpha = [A_\alpha^l, A_\alpha^u]$.

A specific type of fuzzy number, which is rich and flexible enough to cover most of the applications, is the so-called LR-fuzzy number, denoted by $\tilde{N} = (n, l, r)_{LR}$ with central value $n \in \mathbb{R}$, left and right spread values $l, r \in \mathbb{R}$, decreasing left and right shape functions $L, R : \mathbb{R}^+ \to [0,1]$, with $L(0) = R(0) = 1$. Such LR-fuzzy numbers have the following membership function [16]

$$\tilde{N}(x) = \begin{cases} L(\frac{n-x}{l}) & \text{if} \quad x \leq n, \\ R(\frac{x-n}{r}) & \text{if} \quad x > n. \end{cases}$$

It is easy to see that each α-level set of the LR-fuzzy number $\tilde{N}$ is a closed interval as follows

$$N_\alpha = [n - L^{-1}(\alpha)l, n + R^{-1}(\alpha)r], \quad \alpha \in [0,1].$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

In the special case, where $L(x) = R(x) = max\{0, 1 - |x|\}$, $\tilde{N}$ is called a triangular fuzzy number and is denoted by $\tilde{N} = (n, l, r)_T$.

Algebraic operations on LR-fuzzy numbers are defined based on the interval arithmetic. For our proposes, we recall some definitions and results on this topic [16].

Proposition 2.1: Let $\tilde{M} = (m, l_m, r_m)_{LR}$ and $\tilde{N} = (n, l_n, r_n)_{LR}$ be two LR-fuzzy numbers, and λ be a real number. Then

$$\begin{aligned} \lambda \otimes \tilde{M} &= \begin{cases} (\lambda m, \lambda l_m, \lambda r_m)_{LR} & \text{if} \quad \lambda > 0, \\ \mathcal{I}_{\{0\}} & \text{if} \quad \lambda = 0, \\ (\lambda m, |\lambda| r_m, |\lambda| l_m)_{RL} & \text{if} \quad \lambda < 0, \end{cases} \\ \tilde{M} \oplus \tilde{N} &= (m + n, l_m + l_n, r_m + r_n)_{LR}. \end{aligned}$$

where $\mathcal{I}_A$ represents the indicator function of a crisp set A.

Definition 2.1: Let $I = [i_1, i_2]$ and $J = [j_1, j_2]$ be two intervals, and λ be a real number. Then scaler multiplication and addition of two intervals are defined as follows

$$\begin{aligned} \lambda \otimes I &= \begin{cases} [\lambda i_1, \lambda i_2] & \lambda > 0, \\ \mathcal{I}_{\{0\}} & \lambda = 0, \\ [\lambda i_2, \lambda i_1] & \lambda < 0, \end{cases} \\ I \oplus J &= [i_1 + j_1, i_2 + j_2]. \end{aligned}$$

Definition 2.2: The distance between two intervals $I = [i_1, i_2]$ and $J = [j_1, j_2]$ is defined as

$$\mathcal{D}(I, J) = (i_1 - j_1)^2 + (i_2 - j_2)^2.$$

The reader is refereed to [10] for more on interval arithmetic.

III. Fuzzy regression model

In this section, we investigate the following fuzzy linear regression model

$$\tilde{y}_i = \beta_0 \oplus \beta_1 \otimes \tilde{x}_i, \qquad i = 1, \ldots, n, \tag{1}$$

in which the data $(\tilde{y}_i, \tilde{x}_i)$, $i = 1, \ldots, n$, are fuzzy observations on n statistical units, and the coefficients β_0 and β_1 are crisp values.

In order to estimate the regression coefficients β_0 and β_1, we first transform the fuzzy observations $(\tilde{y}, \tilde{x})$ into a set of interval-valued data obtained from the $\alpha-$level sets of the observations, i.e. $x_\alpha = [x_\alpha^l, x_\alpha^u]$ and $y_\alpha = [y_\alpha^l, y_\alpha^u]$, for any $\alpha \in [0, 1]$. Then, we use the distance $\mathcal{D}$ in Definition 2.2 to minimize the following objective function

$$\begin{aligned} \mathcal{D}(b_0, b_1) &= \sum_{i=1}^{n} \mathcal{D}(y_{i\alpha}, b_0 \oplus b_1 \otimes x_{i\alpha}) \\ &= \sum_{i=1}^{n} \mathcal{D}([y_{i\alpha}^l, y_{i\alpha}^u], b_0 \oplus b_1 \otimes [x_{i\alpha}^l, x_{i\alpha}^u]). \end{aligned}$$

By such a minimization problem we can determine the best values for b_0 and b_1 in the following interval regression model

$$[y_{i\alpha}^l, y_{i\alpha}^u] = b_0 \oplus b_1 \otimes [x_{i\alpha}^l, x_{i\alpha}^u], \qquad i = 1, \ldots, n,$$

which models y_α on x_α at each α-level set, $\alpha \in [0, 1]$.

Note that, the objective function $\mathcal{D}(b_0, b_1)$ represents the sum of squared errors between the observed and estimated values of the $\alpha-$level sets of dependent variable. Now, concerning the sign of b_1, we have the two following expressions for the objective function

$$\begin{aligned} \mathcal{D}^+(b_0, b_1) &= \sum_{i=1}^{n} [(y_{i\alpha}^l - b_0 - b_1 x_{i\alpha}^l)^2 \\ &\qquad + (y_{i\alpha}^u - b_0 - b_1 x_{i\alpha}^u)^2] \quad b_1 \geq 0. \\ \mathcal{D}^-(b_0, b_1) &= \sum_{i=1}^{n} [(y_{i\alpha}^l - b_0 - b_1 x_{i\alpha}^u)^2 \\ &\qquad + (y_{i\alpha}^u - b_0 - b_1 x_{i\alpha}^l)^2] \quad b_1 < 0. \end{aligned}$$

In this step, we can follow the procedure in two ways:
1) We may, first, pre-determine the sign of b_1, for example, by fitting a classical regression model to the centers of the fuzzy observations, and then follow one of the above expressions with respect to the sign of the slope of the classical linear regression model.
2) We can also employ both expressions and estimate the related coefficients. In such a case, we consider the amounts b_0 or b_1 for which the related objective function is smaller than the other one. To do this, we have to solve the following equations

$$\tfrac{\partial}{\partial b_0}\mathcal{D}^+(b_0, b_1) = 0, \quad \tfrac{\partial}{\partial b_1}\mathcal{D}^+(b_0, b_1) = 0, \qquad \text{for } b_1 \geq 0,$$

and

$$\tfrac{\partial}{\partial b_0}\mathcal{D}^-(b_0, b_1) = 0, \quad \tfrac{\partial}{\partial b_1}\mathcal{D}^-(b_0, b_1) = 0, \qquad \text{for } b_1 < 0.$$

For the positive case, we obtain

$$\begin{aligned} b_0^+(\alpha) &= \bar{Y}(\alpha) - b_1^+(\alpha)\bar{X}(\alpha), \\ b_1^+(\alpha) &= \frac{\sum_{i=1}^n [x_{i\alpha}^l y_{i\alpha}^l + x_{i\alpha}^u y_{i\alpha}^u] - 2n\bar{X}(\alpha)\bar{Y}(\alpha)}{\sum_{i=1}^n [(x_{i\alpha}^l)^2 + (x_{i\alpha}^u)^2] - 2n\bar{X}^2(\alpha)}, \end{aligned}$$

where, $\bar{Y}(\alpha) = \frac{1}{n}\sum_{i=1}^n \frac{y_{i\alpha}^l + y_{i\alpha}^u}{2}$ and $\bar{X}(\alpha) = \frac{1}{n}\sum_{i=1}^n \frac{x_{i\alpha}^l + x_{i\alpha}^u}{2}$. For the negative case, we obtain

$$\begin{aligned} b_0^-(\alpha) &= \bar{Y}(\alpha) - b_1^-(\alpha)\bar{X}(\alpha), \\ b_1^-(\alpha) &= \frac{\sum_{i=1}^n [x_{i\alpha}^l y_{i\alpha}^u + x_{i\alpha}^u y_{i\alpha}^l] - 2n\bar{X}(\alpha)\bar{Y}(\alpha)}{\sum_{i=1}^n [(x_{i\alpha}^l)^2 + (x_{i\alpha}^u)^2] - 2n\bar{X}^2(\alpha)}. \end{aligned}$$

Finally, by integration, we aggregate the functions $b_0^+(\alpha)$ ($b_0^-(\alpha)$) and $b_1^+(\alpha)$ ($b_1^-(\alpha)$) to estimate the regression coefficients β_0 and β_1, as follows

$$\widehat{\beta}_0 = \int_0^1 b_0^+(\alpha)d\alpha \qquad (\text{or } \widehat{\beta}_0 = \int_0^1 b_0^-(\alpha)d\alpha),$$
$$\widehat{\beta}_1 = \int_0^1 b_1^+(\alpha)d\alpha \qquad (\text{or } \widehat{\beta}_1 = \int_0^1 b_1^-(\alpha)d\alpha).$$

Therefore, the estimate of the dependent variable, denoted by $\widehat{\tilde{y}}$, can be obtained by the following fuzzy linear regression model

$$\widehat{\tilde{y}}_i = \widehat{\beta}_0 \oplus \widehat{\beta}_1 \otimes \tilde{x}_i, \qquad i = 1, \ldots, n.$$

Goodness of fit criteria: To evaluate the goodness of fit of the fuzzy regression models we employ a well-known criteria due to Kim and Bishu [7] (see also [2], [6]).

8	$(12.5, 0.5)_T$	$(9.5, 0.5)_T$

Definition 3.1 ([7]): The capability index ($\mathcal{CI}$) of the fuzzy regression model (1) is defined by

$$\mathcal{CI} = \frac{1}{n}\sum_{i=1}^{n} \mathcal{CI}(i),$$

where

$$\mathcal{CI}(i) = \frac{\int |\tilde{y}_i(x) - \widehat{\tilde{y}}_i(x)|\, dx}{\int \tilde{y}_i(x)\, dx}.$$

The capacity index $\mathcal{CI}$ represents the average of errors in estimation and, therefore, smaller values of $\mathcal{CI}$ indicates that the fuzzy linear regression model fits better to the data.

Remark 3.1: It should be noted that Bargiela et al. [1] considered a more or less similar approach to regression modelling with fuzzy data. They used the distance $\mathcal{D}$ for the $\alpha-$level sets of fuzzy observations and then aggregated such distances to obtain the distance between fuzzy estimate and fuzzy observed values of the dependent variable. But, in our proposed approach, we first used the distances between the $\alpha-$level sets of fuzzy observations and fuzzy estimations of $\tilde{y}$ to provide an interval-valued regression model. Then, we integrated the coefficients of the interval-valued regression model to provide the coefficients of the fuzzy regression model.

Remark 3.2: While, most common methods in fuzzy regression modeling require all the observations to have the same type of membership functions for the fuzzy observations, in the proposed approach there is no limitation in the types of the membership functions of the fuzzy observations. The proposed model, therefore, is applicable when the observations have different types of membership functions.

Remark 3.3: Note that, when fuzzy observations reduce to crisp values, the proposed method reduces to the conventional least-squares regression method.

IV. COMPETITIVE STUDY

In this section, we provide two numerical examples to explain how the proposed method is applicable to derive the regression model for fuzzy observations. We also compare the proposed model with some other models.

Example 4.1: In this example, we compare the proposed method in this paper with some other models, using the triangular fuzzy input-output data set given by Sakawa and Yano [14] (Table I).

By applying the introduced procedure in Section III, we obtain the following functions for each $\alpha \in [0, 1]$

$$\widehat{b}_0^+(\alpha) = \frac{-7\alpha^2 + 14\alpha + 11164}{112\alpha^2 - 224\alpha + 3239},$$
$$\widehat{b}_1^+(\alpha) = \frac{112\alpha^2 - 224\alpha + 1736}{112\alpha^2 - 224\alpha + 3239}.$$

Therefore, the estimated coefficients are derived as $\widehat{\beta}_0 = 3.53$ and $\widehat{\beta}_1 = 0.525$. So, the fuzzy linear regression model is as follows

$$\widehat{\tilde{y}} = 3.53 \oplus 0.525 \otimes \tilde{x}.$$

To compare the proposed method with some other methods in fuzzy regression modeling, the index $\mathcal{CI}$ is employed to evaluate the goodness of fit of the models. Different models and their $\mathcal{CI}$ indices are given in Table II. The results indicate that the proposed method outperforms all the models.

Example 4.2: One of the classical problem in hydrology studies is the measurement of suspended load ($\frac{\text{Ton}}{Day}$) and discharge ($\frac{m^3}{s}$) in watersheds [9]. Based on a study in a part of Darband, situated in the province of Khorasan (North west of Iran) between the cities Bojnord and Esferayen, some water characteristics were measured using standard procedures. The daily discharge and suspended load of the watershed are measured for 51 days. But, due to some limitations in experimental environments, the observed data were reported as fuzzy numbers shown in Table IV. Since, in practical studies, it is important to estimate the amount of suspended load in term of discharge, we wish to model the relationship between suspended load as the dependent variable and discharge as independent variable.

According to the proposed method, the estimated coefficients are obtained as $\widehat{\beta}_0 = 5.0845$ and $\widehat{\beta}_1 = 0.3040$, and the fuzzy linear regression model is, therefore

$$\widehat{\tilde{y}} = 5.0845 \oplus 0.3040 \otimes \tilde{x}.$$

For a competitive study we employ some well-known methods to model such a fuzzy data set, as well. Different models and their goodness of fit indices are given in Table III. The results show that the proposed method provides a better performance equal to that of Bargiela et al. and better performance with respect to three other models.

V. CONCLUSIONS

A fuzzy regression model was investigated for fuzzy input-output data set. By utilizing the method of least-squares as a fitting criterion and applying it to each interval-valued data obtained from $\alpha-$level sets of imprecise observations, a regression model is provided at each level of α. The estimates of the parameters were obtained as functions of α. Then, by integrating the coefficients of the provided regression models, the coefficients of the fuzzy regression model were derived.

The proposed model is applicable when the observations have different types of membership functions. When all fuzzy observations reduce to crisp values, the proposed method

***Abstract*—When noise exists in data, it is a very meaningful topic to reveal the dependency between the parameter h (i.e. the threshold value used to measure degree of fit) in Fuzzy linear regression (FLR) model and the input noise. In this paper, the FLR model is first extended to its regularized version, i.e. regularized fuzzy linear regression (RFLR) model, so as to enhance its generalization capability; then RFLR model is explained as the corresponding equivalent *maximum a posteriori* MAP problem; finally, the approximately inverse proportional dependency relationships that the parameter h with Laplacian noisy input and Uniform noisy input should follow are derived, respectively. Our experimental results also confirm this theoretical claim. We believe that this conclusion provides an important reference for us to determine h in FLR model with noisy input.**

Keywords—Fuzzy linear regression model; MAP; Optimal parameter choice

I. INTRODUCTION

Fuzzy linear regression model plays a pivotal role in fuzzy modeling. However, how to choose the parameter h for FLR model with noisy input still keeps an open problem. A bad choice for threshold h will heavily deteriorate the performances of these models. In recent years, how to choose the loss function and the corresponding parameters for support vector regression (SVR) machine with noisy input has been studied well. J.B.Gao and S.R.Gunn pointed out that SVR problem could be transformed into the equivalent MAP problem [1]. Based on this idea, J.T.Kwok derived the linear dependency between ε and the input noise in ε-SVR [2], Shitong Wang et al. investigated the theoretically optimal parameter choices for Huber-SVR and r-SVR [3], and Hongwei Ge et al. investigated the optimal parameter choices for FLR model with Gaussian noisy input [4,5]. Although Gaussian noise is typically adopted in most robustness analyses, there are still other types of noise such as Laplacian distribution noise and uniform noise in real datasets. So, in this paper, particular attention is paid on the dependency relationships between free threshold h and the standard deviations of Laplacian and uniform noisy input. We first extend the traditional FLR model to its regularized version, i.e. regularized fuzzy linear regression (RFLR) model, so as to enhance its generalization capability; and then explain this regularized model by using MAP framework [1-3]; and finally, with the help of this MAP framework, study the dependency between h and the standard deviation of input noise.

The rest of this paper is organized as follows. In section 2, we will introduce the FLR model and the corresponding RFLR model and show the equivalent relationship between RFLR model and MAP. The analysis of the inverse linear dependency between h and the standard deviation of Laplacian noisy input and Uniform noisy input are theoretically derived in section 3, respectively, while section 4 gives the experimental results and last section concludes this paper.

II. FUZZY LINER REGRESSION MODEL AND MAP

A. Fuzzy liner regression model

The FLR model can be summarized as follows. Consider the function:

$$Y = f(\mathbf{x}, \mathbf{A}) = A_0 + A_1 x_1 + A_2 x_2 + \cdots + A_n x_n, \qquad (1)$$

where $\mathbf{x} = (1, x_1, x_2, \cdots, x_n)^T$ is a vector of non-fuzzy inputs, and $\mathrm{A} = (A_0, A_1, \cdots, A_n)^T$ is a vector of fuzzy model parameters. Parameters $A_i (0 \le i \le n)$ are symmetric triangular fuzzy coefficients, and they can be described by $\{\xi_i, \eta_i\}$, where ξ_i is the center and η_i is the spread of A_i.

In vector notation, the fuzzy parameters $\mathbf{A}$ can be written as $\mathrm{A} = (\boldsymbol{\xi}, \boldsymbol{\eta})$ where $\boldsymbol{\xi} = (\xi_0, \xi_1, \xi_2, \cdots, \xi_n)^T$ and $\boldsymbol{\eta} = (\eta_0, \eta_1, \eta_2, \cdots, \eta_n)^T$. Following the principle of extension, the fuzzy membership function for the output can be obtained by

$$\mu_Y(y) = \begin{cases} 1 - \dfrac{\left| y - \boldsymbol{\xi}^T \mathbf{x} \right|}{\boldsymbol{\eta}^T |\mathbf{x}|}, & \mathbf{x} \neq 0, \\ 1, & \mathbf{x} = 0, y = 0, \\ 0, & \mathbf{x} = 0, y \neq 0, \end{cases} \qquad (2)$$

where $|\mathbf{x}| = (1, |x_1|, |x_2|, \cdots, |x_n|)^T$, The center of Y is $\boldsymbol{\xi}^T \mathbf{x}$, and the spread of Y is $\boldsymbol{\eta}^T |\mathbf{x}|$ with $\boldsymbol{\eta}^T |\mathbf{x}| \ge 0$.

Assume we have a dataset with n-dimensional non-fuzzy input $\mathbf{x}$ and one-dimensional non-fuzzy output variable y:

$$D = \{(\mathbf{x}_1, y_1), (\mathbf{x}_2, y_2), \cdots, (\mathbf{x}_N, y_N)\}, \quad \mathbf{x}_i \in R^{n+1}, y_i \in R, i = 1,2,\cdots,N. \qquad (3)$$

We can establish the following FLR model $Y_i^* = \mathbf{A}^{*T} \mathbf{x}_i$, where $\mathbf{x}_i = (1, x_{i1}, x_{i2}, \cdots, x_{in})^T$, $\mathbf{A} = (A_0, A_1, A_2, \cdots, A_n)^T$, $\mathbf{A}^* = (A_0^*, A_1^*, A_2^*, \cdots, A_n^*)^T$, $i = 1,2,\cdots,N$, and $Y_i^*, \mathbf{A}^*$ denote the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

estimates of Y_i, $\mathbf{A}$ respectively. The objective is to minimize the fuzziness of the fuzzy linear model and the following linear programming problem can be formulated [4,5]:

$$\min \Phi(\boldsymbol{\eta},\xi,\Delta) = \sum_i \boldsymbol{\eta}^T |\mathbf{x}_i| + C\sum_i (\Delta_i^- + \Delta_i^+), \tag{4}$$

$$s.t. \begin{cases} \dfrac{y_i - \xi^T \mathbf{x}_i}{\boldsymbol{\eta}^T |\mathbf{x}_i|} \le (1-h) + \Delta_i^-, \\ \dfrac{\xi^T \mathbf{x}_i - y_i}{\boldsymbol{\eta}^T |\mathbf{x}_i|} \le (1-h) + \Delta_i^+, \\ \Delta_i^-, \Delta_i^+ \ge 0, \\ i = 1,2,\cdots,N, \end{cases}$$

where C is a predefined constant, Δ_i^- and Δ_i^+ denote the latent variables of the upper/lower bounds of output respectively, h $(h \in [0,1))$ is the threshold of fitness.

In order to enhance the generalization capability of FLR model and to be easy to analyze, just like SVR techniques in [3, 7, 8], a regularized term $\frac{1}{2}\xi^T\xi$ can be introduced into Eq. (4), i.e.

$$\min \Phi(\boldsymbol{\eta},\xi,\Delta) = \sum_i \boldsymbol{\eta}^T |\mathbf{x}_i| + \frac{1}{2}\xi^T\xi + C\sum_i (\Delta_i^- + \Delta_i^+) \cdot \tag{5}$$

Equation (5) formulates the RFLR model. In the rest of this paper, how to choose the parameter h for RFLR model with Laplacian noisy input and Uniform noisy input will be studied. Obviously, the conclusion will also be very helpful for the practical applications of FLR model.

B. The regression model and MAP

In this subsection, in terms of the evidence theory [1,2], we will demonstrate the RFLR model is equivalent to *maximum a posteriori* MAP estimation, based on maximum likelihood estimation.

Now, the focus is on obtaining a weight vector $\tilde{\xi}$ in the generalized linear regression model such as

$$y_i = \tilde{\xi}^T \mathbf{x}_i + n_i, i = 1,2,\cdots,N \ , \tag{6}$$

for all the data in the dataset (3), where all the data $\mathbf{x}_i$ follow distribution $p(\cdot)$ and all n_i are i.i.d noise following some distribution $\phi(\cdot)$. Thus, the corresponding density function on y can be denoted as $p(y|\mathbf{x}) = \phi(y - \tilde{\xi}^T\mathbf{x})$. The degree of such an approximation can be measured by a loss function $L(\xi^T\mathbf{x}, \boldsymbol{\eta}^T\mathbf{x}, y)$, i.e.

$$L(\xi^T\mathbf{x}, \boldsymbol{\eta}^T\mathbf{x}, y) = \begin{cases} 0, & \dfrac{|\xi^T\mathbf{x} - y|}{\boldsymbol{\eta}^T|\mathbf{x}|} \le 1-h, \\ \dfrac{|\xi^T\mathbf{x} - y|}{\boldsymbol{\eta}^T|\mathbf{x}|} - 1 + h, & otherwise, \end{cases} \tag{7}$$

Assume the loss function $L(\xi^T\mathbf{x}, \boldsymbol{\eta}^T\mathbf{x}, y)$ leads to the following Gaussian probability density function on y:

$$p(y_i|\mathbf{x}_i, \xi, \boldsymbol{\eta}, \beta, h) = \frac{1}{C(\beta,h)} \exp[-\beta L(\xi^T\mathbf{x}_i, \boldsymbol{\eta}^T\mathbf{x}_i, y_i)] \tag{8}$$

where $C(\beta,h) = \iint_D \exp[-\beta L(\xi^T\mathbf{x}, \boldsymbol{\eta}^T\mathbf{x}, y)] d\mathbf{x}dy$, and β is a parameter.

Just as the mathematical analysis in [1,2] does, we adopt the Gaussian prior on $\boldsymbol{\eta}$ and ξ, i.e.

$$p(\boldsymbol{\eta}|\alpha, \mathbf{x}_i) = \frac{1}{M(\alpha)} \exp(-\alpha\boldsymbol{\eta}^T|\mathbf{x}_i|), \tag{9}$$

where $M(\alpha) = \int \exp(-\alpha\boldsymbol{\eta}^T|\mathbf{x}_i|) d\boldsymbol{\eta}$,

$$p(\xi|\gamma) = \frac{1}{F(\gamma)} \exp\left(-\frac{\gamma}{2}\xi^T\xi\right), \tag{10}$$

where $F(\gamma) = \int \exp\left(-\frac{\gamma}{2}\xi^T\xi\right) d\xi$,

and by applying the Bayes rule:

$$p(\boldsymbol{\eta},\xi|D,\beta,h) \propto p(D|\boldsymbol{\eta},\xi,\beta,h) p(\xi|\gamma) \prod_{i=1}^N p(\boldsymbol{\eta}|\alpha,\mathbf{x}_i) p(\mathbf{x}_i), \tag{11}$$

we have

$$\ln p(\boldsymbol{\eta},\xi|D,\beta,h) = -\alpha \sum_{i=1}^N \boldsymbol{\eta}^T|\mathbf{x}_i| - \frac{\gamma}{2}\xi^T\xi - \beta \sum_{i=1}^N L(\boldsymbol{\eta}^T\mathbf{x}_i, \xi^T\mathbf{x}_i, y_i) - N\ln C(\beta,h) + const \cdot \tag{12}$$

With setting $\gamma = \alpha$ and $C = \beta/\alpha$, optimizing (5) can be interpreted as finding for the MAP estimate of $\boldsymbol{\eta},\xi$ at given values of β, h. That is to say, the RFLR model in (5) is equivalent to *maximum a posteriori* MAP estimation.

In order to make the analysis easier, $\frac{1}{N}\sum_{i=1}^N L(\boldsymbol{\eta}^T\mathbf{x}_i, \xi^T\mathbf{x}_i, y_i)$ in (12) is replaced by its expectation:

$$\begin{aligned} E(L(\boldsymbol{\eta}^T\mathbf{x}, \xi^T\mathbf{x}, y)) &= \iint_D L(\boldsymbol{\eta}^T\mathbf{x}, \xi^T\mathbf{x}, y) p(y|\mathbf{x}) p(\mathbf{x}) d\mathbf{x}dy \\ &= \int_D \left[\int_{-\infty}^{\xi^T\mathbf{x} - (1-h)\boldsymbol{\eta}^T|\mathbf{x}|} \left(\frac{\xi^T\mathbf{x} - y}{\boldsymbol{\eta}^T|\mathbf{x}|} - 1 + h \right) p(y|\mathbf{x}) dy \right. \\ &\quad \left. + \int_{\xi^T\mathbf{x} + (1-h)\boldsymbol{\eta}^T|\mathbf{x}|}^{+\infty} \left(\frac{y - \xi^T\mathbf{x}}{\boldsymbol{\eta}^T|\mathbf{x}|} - 1 + h \right) p(y|\mathbf{x}) dy \right] p(\mathbf{x}) d\mathbf{x}, \end{aligned} \tag{13}$$

and $\frac{1}{N}\sum_{i=1}^N \boldsymbol{\eta}^T|\mathbf{x}_i|$ in (12) can also be approximated by

$$E(\boldsymbol{\eta}^T|\mathbf{x}|) = \int_D \boldsymbol{\eta}^T|\mathbf{x}| \, p(\mathbf{x}) d\mathbf{x} \tag{14}$$

Thus, Eq.(12) becomes

$$\ln p(\boldsymbol{\eta},\xi|D,\beta,h) = -\alpha N * E(\boldsymbol{\eta}^T|\mathbf{x}|) - \frac{\gamma}{2}\xi^T\xi - \beta N * E(L(\boldsymbol{\eta}^T\mathbf{x}, \xi^T\mathbf{x}, y)) - N\ln C(\beta,h) + const \, . \tag{15}$$

In order to maximize (15), its derivatives with respect to $\boldsymbol{\eta},\xi,\beta,h$ must be zero.Thus, we can obtain

$$E(L(\hat{\boldsymbol{\eta}}^T\mathbf{x}, \hat{\xi}^T\mathbf{x}, y)) = -\frac{\partial C(\beta,h)/\partial\beta}{C(\beta,h)}, \tag{16}$$

$$\int_D \left[\int_{-\infty}^{\hat{\xi}^T\mathbf{x}-(1-h)\hat{\boldsymbol{\eta}}^T|\mathbf{x}|} p(y\mid\mathbf{x})dy + \int_{\hat{\xi}^T\mathbf{x}+(1-h)\hat{\boldsymbol{\eta}}^T|\mathbf{x}|}^{+\infty} p(y\mid\mathbf{x})dy \right] p(\mathbf{x})d\mathbf{x} = \frac{-\partial C(\beta,h)/\partial h}{\beta C(\beta,h)}. \quad (17)$$

When $\boldsymbol{\eta}=\hat{\boldsymbol{\eta}},\boldsymbol{\xi}=\hat{\boldsymbol{\xi}}$, maximizing (15) actually becomes the following optimization problem:

$$\arg\min_{\alpha,\beta,h} \alpha E(\hat{\boldsymbol{\eta}}^T\mid\mathbf{x}\mid) + \beta E(L(\hat{\boldsymbol{\eta}}^T\mathbf{x},\hat{\boldsymbol{\xi}}^T\mathbf{x},y)) + \ln C(\beta,h). \quad (18)$$

Please note $C(\beta,h)$ in (18). According to its corresponding MAP, we have

$$C(\beta,h) = 2\left(\int_0^{1-h}\exp(0)dt + \int_{1-h}^{+\infty}\exp(-\beta(t-1+h))dt\right) = \frac{2(1+(1-h)\beta)}{\beta}. \quad (19)$$

By substituting (19) into (16) and (17), we obtain

$$E(L(\hat{\boldsymbol{\eta}}^T\mathbf{x},\hat{\boldsymbol{\xi}}^T\mathbf{x},y)) = \frac{1}{\beta(1+(1-h)\beta)}, \quad (20)$$

$$\int_D \left[\int_{-\infty}^{\hat{\xi}^T\mathbf{x}-(1-h)\hat{\boldsymbol{\eta}}^T|\mathbf{x}|} p(y\mid\mathbf{x})dy + \int_{\hat{\xi}^T\mathbf{x}+(1-h)\hat{\boldsymbol{\eta}}^T|\mathbf{x}|}^{+\infty} p(y\mid\mathbf{x})dy \right] p(\mathbf{x})d\mathbf{x} = \frac{1}{1+(1-h)\beta}. \quad (21)$$

III. The Dependency Between h and the Input Noise

A. Laplacian Noise

For the Laplacian noise model,

$$p(y\mid\mathbf{x}) = \frac{1}{2\mu}\exp\left[-\frac{\left|y-\tilde{\boldsymbol{\xi}}^T\mathbf{x}\right|}{\mu}\right], \quad (22)$$

Here, we only consider the simpler case when $\mathbf{x}$ is one-dimensional, with uniform density over the range $[-L,L]$ (i.e. $X\sim U([-L,L])$). When $\mathbf{x}$ is multi-dimensional, we can also arrive at the similar conclusion, if we select suitable integral region for each dimension.

Let $\varepsilon=1-h$, $E=\int_D \hat{\eta}|x|p(x)dx$. After tedious computation, it can be shown that (21) reduce to

$$\begin{aligned}\frac{1}{1+\varepsilon\beta} &= \int_D\left[\int_{-\infty}^{\tilde{\xi}x-\varepsilon\hat{\eta}|x|}\frac{1}{2\mu}\exp\left(-\frac{|y-\tilde{\xi}x|}{\mu}\right)dy + \int_{\tilde{\xi}x+\varepsilon\hat{\eta}|x|}^{+\infty}\frac{1}{2\mu}\exp\left(-\frac{|y-\tilde{\xi}x|}{\mu}\right)dy\right]p(x)dx\\ &= 2\int_{-L}^{0}\left(\int_{\hat{\xi}x+\varepsilon\hat{\eta}x}^{+\infty}\frac{1}{2\mu}\exp\left(-\frac{y-\tilde{\xi}x}{\mu}\right)dy\right)\frac{1}{2L}dx\\ &\quad + 2\int_{0}^{L}\left(\int_{\tilde{\xi}x}^{+\infty}\frac{1}{2\mu}\exp\left(-\frac{y-\tilde{\xi}x}{\mu}\right)dy\right)\frac{1}{2L}dx\\ &\quad + 2\int_{-L}^{0}\left(\int_{\tilde{\xi}x}^{\hat{\xi}x-\varepsilon\hat{\eta}x}\frac{1}{2\mu}\exp\left(-\frac{y-\tilde{\xi}x}{\mu}\right)dy\right)\frac{1}{2L}dx\end{aligned}$$

$$\begin{aligned}&= 1+\frac{\mu}{2L(\tilde{\xi}-\hat{\xi}-\varepsilon\hat{\eta})}\left(1-\exp\left(\frac{-(\tilde{\xi}-\hat{\xi}-\varepsilon\hat{\eta})L}{\mu}\right)\right)\\ &\quad + \frac{\mu}{2L(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})}\left(\exp\left(\frac{-(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})L}{\mu}\right)-1\right).\end{aligned} \quad (23)$$

Similarly, from (13), (20) and (21), we obtain

$$\begin{aligned}\frac{1}{\beta} &= \frac{(\tilde{\xi}-\hat{\xi})L}{2E} + \frac{\mu^2}{LE}\cdot\frac{(\tilde{\xi}-\hat{\xi})^3-3(\tilde{\xi}-\hat{\xi})\varepsilon^2\hat{\eta}^2}{\left((\tilde{\xi}-\hat{\xi})^2-\varepsilon^2\hat{\eta}^2\right)^2}\\ &\quad + \frac{\mu}{2E}\exp\left(-\frac{(\tilde{\xi}-\hat{\xi})L}{\mu}\right)\\ &\quad \left(\frac{(\tilde{\xi}-\hat{\xi}-\varepsilon\hat{\eta})\varepsilon\hat{\eta}L-(\tilde{\xi}-\hat{\xi})\mu+2\mu\varepsilon\hat{\eta}}{(\tilde{\xi}-\hat{\xi}-\varepsilon\hat{\eta})^2L}\exp\left(\frac{\varepsilon\hat{\eta}L}{\mu}\right)\right.\\ &\quad \left.-\frac{(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})\varepsilon\hat{\eta}L+(\tilde{\xi}-\hat{\xi})\mu+2\mu\varepsilon\hat{\eta}}{(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})^2L}\exp\left(-\frac{\varepsilon\hat{\eta}L}{\mu}\right)\right).\end{aligned} \quad (24)$$

By using (20), (23) and (24), we have

$$\begin{aligned}E(L(\hat{\eta}x,\hat{\xi}x,y)) &= \frac{(\tilde{\xi}-\hat{\xi})L-2\varepsilon E}{2E}\\ &\quad + \frac{\mu}{LE}\cdot\frac{(\tilde{\xi}-\hat{\xi})^3\mu-(\tilde{\xi}-\hat{\xi})^2\varepsilon^2\hat{\eta}E-3(\tilde{\xi}-\hat{\xi})\varepsilon^2\hat{\eta}^2\mu+\varepsilon^4\hat{\eta}^3E}{\left((\tilde{\xi}-\hat{\xi})^2-\varepsilon^2\hat{\eta}^2\right)^2}\\ &\quad + \frac{\mu}{2E}\exp\left(-\frac{(\tilde{\xi}-\hat{\xi})L}{\mu}\right)\\ &\quad \left(\frac{(\tilde{\xi}-\hat{\xi}-\varepsilon\hat{\eta})\varepsilon\hat{\eta}L-(\tilde{\xi}-\hat{\xi})\mu+2\mu\varepsilon\hat{\eta}+(\tilde{\xi}-\hat{\xi})\varepsilon E-\varepsilon^2\hat{\eta}E}{(\tilde{\xi}-\hat{\xi}-\varepsilon\hat{\eta})^2L}\exp\left(\frac{\varepsilon\hat{\eta}L}{\mu}\right)\right.\\ &\quad \left._-\frac{(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})\varepsilon\hat{\eta}L+(\tilde{\xi}-\hat{\xi})\mu+2\mu\varepsilon\hat{\eta}+(\tilde{\xi}-\hat{\xi})\varepsilon E+\varepsilon^2\hat{\eta}E}{(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})^2L}\exp\left(-\frac{\varepsilon\hat{\eta}L}{\mu}\right)\right).\end{aligned} \quad (25)$$

We have defined $E=\int_D\hat{\eta}|x|p(x)dx$, $C=\beta/\alpha$, so we obtain

$$\alpha E(\hat{\eta}|x|) = \beta E C^{-1} \quad (26)$$

and

$$\varepsilon\hat{\eta}L = 2\varepsilon E \quad (27)$$

Define $y-\tilde{\xi}x\approx\hat{\xi}x-\tilde{\xi}x=\delta(x)$. It can be shown that

$$E_X\left(\delta^2(x)\right)\approx E_X\left((y-\tilde{\xi}x)^2\right)=2\mu^2. \quad (28)$$

With $X\sim U([-L,L])$, we also obtain $\mathrm{var}(X)=L^2/3$. Consequently

$$E_X\left(\delta^2(x)\right)\approx\mathrm{var}\left((\tilde{\xi}-\hat{\xi})X\right)\approx(\tilde{\xi}-\hat{\xi})^2L^2/3, \quad (29)$$

and hence

$$\mu=(\tilde{\xi}-\hat{\xi})L/\sqrt{6}. \quad (30)$$

After substituting(19), (23), (24), (25), (26), (27) and (30) into (18), minimizing (18) becomes minimizing

$$\begin{aligned}g(\frac{\varepsilon}{\mu}) &= \left(\frac{\sqrt{6}}{2E}+f_1(\frac{\varepsilon}{\mu})+\frac{\exp\left(-\sqrt{6}\right)}{4E}f_2(\frac{\varepsilon}{\mu})\right)^{-1}\\ &\quad \left(\frac{\sqrt{6}-2\frac{\varepsilon E}{\mu}}{2E}+\frac{3\sqrt{6}-\left(6+6\sqrt{6}\right)\frac{\varepsilon^2E^2}{\mu^2}+4\frac{\varepsilon^4E^4}{\mu^4}}{18E-24\frac{\varepsilon^2E^3}{\mu^2}+8\frac{\varepsilon^4E^5}{\mu^4}}\right.\\ &\quad \left.+\frac{\exp\left(-\sqrt{6}\right)}{4E}f_3(\frac{\varepsilon}{\mu})+\frac{E}{\mu C}\right)\end{aligned}$$

$$-\ln\left(1+\frac{\frac{\varepsilon E}{\mu}}{3-2\frac{\varepsilon^2E^3}{\mu^2}}+\frac{\exp(-\sqrt{6})}{2}\left(\frac{\exp\left(-2\frac{\varepsilon E}{\mu}\right)}{\sqrt{6}+2\frac{\varepsilon E}{\mu}}-\frac{\exp\left(2\frac{\varepsilon E}{\mu}\right)}{\sqrt{6}-2\frac{\varepsilon E}{\mu}}\right)\right)$$

$$+\ln\left(\frac{\sqrt{6}}{2E}+f_1(\frac{\varepsilon}{\mu})+\frac{\exp\left(-\sqrt{6}\right)}{4E}f_2(\frac{\varepsilon}{\mu})\right)+const, \quad (31)$$

where

$$f_1(\frac{\varepsilon}{\sigma})=\frac{3\sqrt{6}-6\sqrt{6}\frac{\varepsilon^2E^2}{\mu^2}}{18E-24\frac{\varepsilon^2E^3}{\mu^2}+8\frac{\varepsilon^4E^5}{\mu^4}},$$

$$f_2(\frac{\varepsilon}{\sigma})=\frac{-\sqrt{6}+\left(4+2\sqrt{6}\right)\frac{\varepsilon E}{\mu}-4\frac{\varepsilon^2E^2}{\mu^2}}{3-2\sqrt{6}\frac{\varepsilon E}{\mu}+2\frac{\varepsilon^2E^2}{\mu^2}}\exp\left(2\frac{\varepsilon E}{\mu}\right)$$

$$-\frac{\sqrt{6}+\left(4+2\sqrt{6}\right)\frac{\varepsilon E}{\mu}+4\frac{\varepsilon^2E^2}{\mu^2}}{3+2\sqrt{6}\frac{\varepsilon E}{\mu}+2\frac{\varepsilon^2E^2}{\mu^2}}\exp\left(-2\frac{\varepsilon E}{\mu}\right)$$

$$f_3(\frac{\varepsilon}{\sigma})=\frac{-\sqrt{6}+\left(4+3\sqrt{6}\right)\frac{\varepsilon E}{\mu}-6\frac{\varepsilon^2E^2}{\mu^2}}{3-2\sqrt{6}\frac{\varepsilon E}{\mu}+2\frac{\varepsilon^2E^2}{\mu^2}}\exp\left(2\frac{\varepsilon E}{\mu}\right)$$

$$-\frac{\sqrt{6}+\left(4+3\sqrt{6}\right)\frac{\varepsilon E}{\mu}+6\frac{\varepsilon^2E^2}{\mu^2}}{3+2\sqrt{6}\frac{\varepsilon E}{\mu}+2\frac{\varepsilon^2E^2}{\mu^2}}\exp\left(-2\frac{\varepsilon E}{\mu}\right)$$

Obviously, when $(\frac{\varepsilon}{\mu})$ takes some fixed value, $g(\frac{\varepsilon}{\mu})$ will achieve its minimum, which indicates that there is a linear dependency between ε and μ. Thus, there is an inverse linear dependency between the parameter h and the standard variance σ of the Laplacian input noise because of $\varepsilon=1-h$ and $\sigma=\sqrt{2}\mu$.

B. Uniform Noise

Next, we consider the uniform noise model

$$\phi(n)=\frac{1}{2\mu},\quad n\in[-\mu,\mu] \quad (32)$$

Again, we only consider the simpler case when $\mathbf{x}$ is one-dimensional, with uniform density over the range $[-L,L]$. Let $\varepsilon=1-h$, $E=\int_D\hat{\eta}|x|p(x)dx$. Eq. (21) becomes

$$\frac{1}{1+\varepsilon\beta}=\int_D\left[\int_{-\infty}^{\hat{\xi}x-\varepsilon\hat{\eta}|x|}\frac{1}{2\mu}dy+\int_{\hat{\xi}x+\varepsilon\hat{\eta}|x|}^{+\infty}\frac{1}{2\mu}dy\right]p(x)dx$$

$$=2\int_0^L\left(\int_{\hat{\xi}x+\varepsilon\hat{\eta}x}^{\tilde{\xi}x+\mu}\frac{1}{2\mu}dy\right)\frac{1}{2L}dx$$

$$+2\int_0^{\frac{\mu}{\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta}}}\left(\int_{\tilde{\xi}x-\mu}^{\hat{\xi}x-\varepsilon\hat{\eta}x}\frac{1}{2\mu}dy\right)\frac{1}{2L}dx$$

$$=\frac{(\tilde{\xi}-\hat{\xi})^2L^2-\varepsilon^2\hat{\eta}^2L^2+2\mu(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})L+\mu^2}{4\mu(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})L}. \quad (33)$$

Using (13), (20), (21)and(33), after a little tedious computation, it can be shown that

$$\frac{1}{\beta}=\frac{(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})(\tilde{\xi}-\hat{\xi}-\varepsilon\hat{\eta})^2L^3+3((\tilde{\xi}-\hat{\xi})^2-\varepsilon^2\hat{\eta}^2)L^2(\mu+\varepsilon E)}{12\mu(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})LE}$$

$$+\frac{3\mu(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})L(\mu+2\varepsilon E)+3\mu^2\varepsilon E+\mu^3}{12\mu(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})LE}, \quad (34)$$

$$E(L(\hat{\eta}x,\hat{\xi}x,y))=$$

$$\frac{(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})(\tilde{\xi}-\hat{\xi}-\varepsilon\hat{\eta})^2L^3+3\mu(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})(\tilde{\xi}-\hat{\xi}-\varepsilon\hat{\eta})L^2}{12\mu(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})LE}$$

$$+\frac{3\mu^2(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})L+\mu^3}{12\mu(\tilde{\xi}-\hat{\xi}+\varepsilon\hat{\eta})LE}. \quad (35)$$

As in Section 3.A, consider $\delta(x)=(\hat{\xi}-\tilde{\xi})x$ and assume that

$$E_X\left(\delta^2(x)\right)\approx E_X\left((y-\tilde{\xi}x)^2\right)=\mu^2/3 \quad (36)$$

Using (29) again, we obtain

$$\mu=(\tilde{\xi}-\hat{\xi})L \quad (37)$$

Analogous to Section 3.A, by plugging in (19), (33), (34), (35), (26), (27) and (37), it can be shown that the problem reduces to minimizing

$$g(\frac{\varepsilon}{\mu})=\left(\frac{3E+6\frac{\varepsilon E^2}{\mu}}{2+4\frac{\varepsilon E}{\mu}-\frac{\varepsilon^2E^2}{\mu^2}-\frac{\varepsilon^3E^3}{\mu^3}}\right)\left(\frac{2+\frac{\varepsilon E}{\mu}-4\frac{\varepsilon^2E^2}{\mu^2}+2\frac{\varepsilon^3E^3}{\mu^3}}{3E+6\frac{\varepsilon E^2}{\mu}}+\frac{E}{\mu C}\right)$$

$$-\ln\left(\frac{1+\frac{\varepsilon E}{\mu}-\frac{\varepsilon^2E^2}{\mu^2}}{1+2\frac{\varepsilon E}{\mu}}\right)+\ln\left(\frac{2+4\frac{\varepsilon E}{\mu}-\frac{\varepsilon^2E^2}{\mu^2}-\frac{\varepsilon^3E^3}{\mu^3}}{3E+6\frac{\varepsilon E^2}{\mu}}\right)+const. \quad (38)$$

Again, we can see from (38) that there is a linear dependency between ε and μ. Obviously, because the standard variance σ of the uniform input noise equals to $\mu/\sqrt{3}$ and $\varepsilon=1-h$, there is an the inverse linear dependency relationship between the parameter h and σ.

C. Dependency Between h and the Input Noise

From Section 3.A and 3.B, we come to the conclusion that there are approximately inverse proportional dependency relationships between the parameter h and the standard variance σ of Laplacian input noise and uniform input noise. At the same time, in [4,5], we have derived the analogical conclusion with Gaussian noisy input. Following the same spirit in [2], we can draw the more generic conclusion that the dependency between h and input noise is approximately inverse proportion.

It should be mentioned here that although we investigate the dependency relationship between the parameter h in RFLR model and the input noise, the conclusion is very helpful for the practical applications of both FLR and RFLR model, for FLR model is just a special case of RFLR model.

IV. EXPERIMENTAL STUDIES

In this experiment, we apply RFLR model to a real dataset taken from [6] (see Table1). In [6], fuzzy linear regression was used successfully to analyze the dependence relationship of the atmospheric concentration of carbon monoxide (CO) on a set of meteorological variables, including relative humidity (RH) (%), rain (R) (mm) and wind speed (WS) (m/s).

By using the same method from [6], we also take CO as the output data, RH, R and WS as the input data. Let h=0.5. Now the corresponding regression values $(\xi_i,\eta_i), i=1,2,\cdots,21$ can be obtained, where ξ_i denotes the center and η_i denotes the spread. Next, in order to investigate the dependency relationship between h and the noisy input, let $y_i' = y_i + k\cdot n$, $i=1,2,\cdots,21$, where k is a noise-signal ratio and n represents the Laplacian noise. Then the corresponding sampling dataset $(x_i, y_i'), i=1,2,\cdots,21$ can be generated. Similarly, its corresponding regression values $(\xi_i',\eta_i'), i=1,2,\cdots,21$ can be obtained by using the same RFLR model. In order to make the experimental results fair, σ is taken from [0.1,2.0] with the step length 0.1, and the Laplacian noise distribution is used to generate 20 groups of the corresponding sampling datasets for each given σ. For each given σ, h is taken as the average result of all 20 h values which can minimize $\sum_{i=1}^{21}\sqrt{(\xi_i-\xi_i')^2+(\eta_i-\eta_i')^2}$ respectively for each group of the sampling datasets.

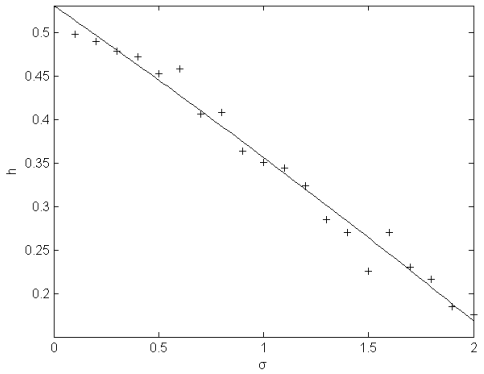

Fig. 1. With Laplacian noisy input，the relationship between h and σ when $k=0.05$

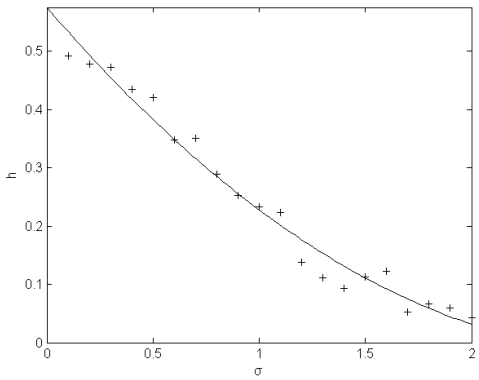

Fig. 2. With Laplacian noisy input，the relationship between h and σ when $k=0.1$

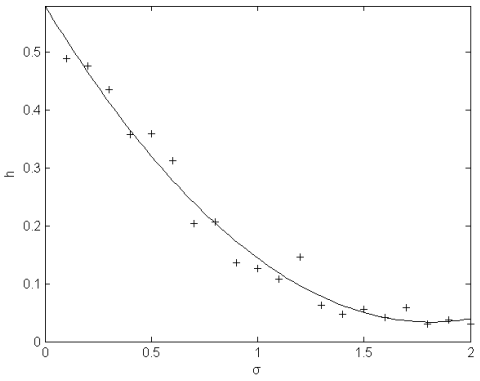

Fig. 3. With Laplacian noisy input，the relationship between h and σ when $k=0.2$

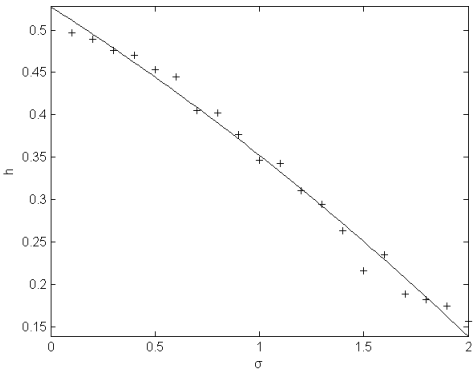

Fig. 4. With uniform noisy input，the relationship between h and σ when $k=0.05$

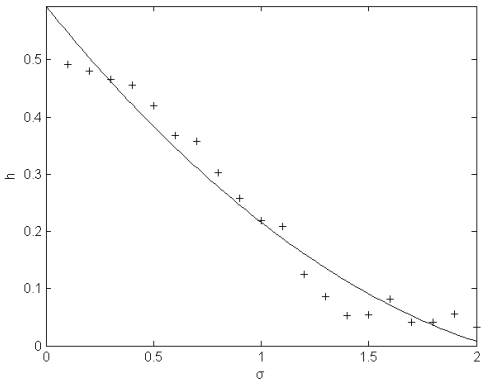

Fig. 5. With uniform noisy input，the relationship between h and σ when $k=0.1$

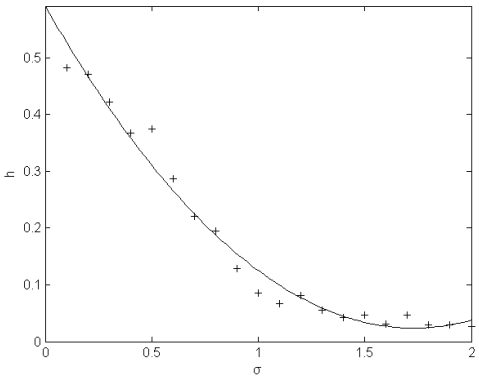

Fig. 6. With uniform noisy input，the relationship between h and σ when $k=0.2$

Fig.1, 2 and 3 depict the dependency relationships between h and σ for all 20 σ values with different k (see + in the figures), where the curves are used to roughly indicate the change tendencies between h and σ, respectively. With the same experimental method as above and the Uniform noise distribution, Figures 4-6 show the experimental results, which again validate our theoretical conclusion.

It can be easily seen from Fig.1-6 that when noise is small, i.e. k and σ is comparatively small, there is an obvious inverse linear dependency relationship between h and σ. However, when k and/or σ are comparatively large, i.e. the datasets are seriously distorted, the inverse linear relationship between h and σ does not exist anymore. In other words, RFLR model may become ineffective for seriously distorted datasets. Of course, although we have arranged many experiments and all these experimental results validate the above obtained conclusion on RFLR model, we just show several experimental results here so as to save the paper's space.

V. Conclusions and Future Work

In this paper, based on the Bayesian frame, the approximately inversely linear dependency relationships between the parameter h and the standard variance σ of Laplacian input noise and uniform input noise are derived. And the experimental results also validate our theoretical conclusion. In fact, the optimal choices of the parameter h are actually dependent on the variance of the input noise. Because Gaussian noise, Laplacian noise and uniform noise are all typical noise, and with the theoretical and experimental results from [4, 5], we can arrive at the more generic conclusion that there is an approximately inverse proportional dependency between h and input noise. The theoretical result here is very useful for the optimal choices of the parameter h. Of course, in order to apply the inversely linear dependency result in practical applications, one has to first arrive at an estimate of the noise level σ. One way to obtain this is by using Bayesian methods [7]. In the future, we will investigate better methods to solve the problem.

***Abstract*—This paper deals with direct adaptive fuzzy control for a class of uncertain nonaffine nonlinear systems with unknown control direction. Within this scheme, a fuzzy system is used to generate directly the control input signal without dynamic system estimation. The adjustable parameters in the used fuzzy system are updated using a gradient descent adaptation algorithm that incorporates a Nussbaum-type function to deal with the unknown control direction. The stability of the closed-loop system is performed using a Lyapunov approach. Simulation results are provided to verify the effectiveness of the proposed design.**

Keywords- fuzzy control, adaptive control, nonaffine nonlinear systems, Nussbaum function.

I. INTRODUCTION

In the past years, based on the universal approximation property of fuzzy systems, adaptive fuzzy control of uncertain nonlinear systems has been intensively conducted and some developments have been achieved in the literature [1, 2]. The stability study in such adaptive methods is performed by using the Lyapunov design approach. Most of the proposed adaptive fuzzy control methods can be roughly classified into two types: the direct adaptive fuzzy control approach where fuzzy systems are used to approximate unknown ideal controllers [1-4], and the indirect adaptive fuzzy control approach where fuzzy systems are used to identify the plant dynamics [1-3, 5]. In [1-5], adaptive fuzzy control design for the affine-in-control nonlinear systems is presented. Adaptive fuzzy control design for nonaffine systems is discussed in [6-9].

In the direct schemes [1-4, 6, 8, 9], the parameter adaptation laws used are designed based on a Lyapunov approach, where an error signal between the desired output and the actual output is used to update the adjustable parameters. However, since in the direct adaptive control approach, the purpose is to approximate an unknown ideal controller by using a fuzzy controller, so it is more convenient to try to adjust the free parameters of the fuzzy controller by using directly the error between the ideal controller and the fuzzy controller [4, 7]. In [7], a direct adaptive fuzzy controller was designed for a class of nonaffine systems where the gradient descent method was used to design the parameter adaptation law in order to minimize the error between an ideal controller and the fuzzy controller.

However, in [7], the control direction is assumed known a priori, i.e., the sign of the control gain (the control gain is the partial derivative over control variable for nonaffine systems) is assumed known for the designer. Without this assumption, the adaptive control design becomes much more difficult, because in this case, one cannot decide the direction along which the control operates and/or the direction of the search of controller parameters. In the adaptive control literature, the unknown control direction problem is mainly solved by using the Nussbaum-type function [10, 11], and it has been successfully applied for robust control design [12, 13] adaptive control design for nonlinear systems [14-17], and adaptive fuzzy control for nonaffine systems [18, 19]. In the literature, other approaches solved the unknown control direction problem by using: the correction vector method for first order nonlinear systems [20]; a switching scheme based on a monitoring function [21]; a hysteresis-type function for indirect adaptive fuzzy control [22, 23]; or by estimating unknown parameters involved in the control gain [24].

In this work we present a direct adaptive fuzzy control scheme for a class of uncertain nonaffine nonlinear systems with unknown control direction. In the design; instead of using fuzzy systems to approximate the unknown nonlinearities in the system, a fuzzy system is used to approximate an unknown desired controller that can achieve control objectives, and a Nussbaum function is introduced in the parameter adaptation law to solve the problem of unknown control direction. The parameter adaptation law is designed to minimize the error between the ideal controller and the fuzzy controller by using the gradient descent method. Using the Lyapunov approach, it is proved that the proposed adaptive fuzzy controller can guarantee the boundedness of all the signals of the closed-loop system and the asymptotic convergence of the tracking error. In fact, this paper presents an extension of our previous work [7] to the case of unknown control direction.

The remainder of the paper is organized as follows. The problem formulation and preliminaries are given in section II. The proposed direct adaptive control scheme is presented in section III with its adaptive law and stability analysis. In section IV, the proposed adaptive control algorithm is used to control a simple nonaffine nonlinear system.

II. PROBLEM FORMULATION AND PRELIMINARIES

A. Problem Formulation

Consider the class of single-input single-output (SISO) nonlinear systems modeled by

$$\begin{cases} \dot{x}_i = x_{i+1}, i = 1,\ldots,n-1 \\ \dot{x}_n = f(\boldsymbol{x},u) \\ y = x_1 \end{cases} \tag{1}$$

or, equivalently

$$y^{(n)} = f(\boldsymbol{x},u) \tag{2}$$

where $\boldsymbol{x} = [x_1,\ldots,x_n]^T \in \mathbb{R}^n$, is the state vector of the system which is assumed available for measurement, $u \in \mathbb{R}$ is the scalar control input, $y \in \mathbb{R}$ is the scalar system output, and $f(\boldsymbol{x},u)$ is an unknown smooth nonlinear function.

In respect of the dynamic system (1), the following assumption will be made:

Assumption 1: The function $g(\boldsymbol{x},u) = \dfrac{\partial f(\boldsymbol{x},u)}{\partial u}$ is nonzero and bounded. Moreover, its sign, i.e. control direction, is unknown.

The objective is to design an adaptive fuzzy controller for system (1) such that the system output $y(t)$ follows a desired trajectory $y_d(t)$ while all signals in the closed-loop system remain bounded.

Regarding the development of the control law, the following assumption should also be made:

Assumption 2: The desired trajectory $y_d(t)$ and its first n derivatives are smooth and bounded.

Now, let us define the tracking error as

$$e = y_d - y \tag{3}$$

and let s be a sliding surface defined as

$$s = \left(\frac{d}{dt} + \lambda\right)^{n-1} e, \quad \lambda > 0 \tag{4}$$

From (4), $s(t) = 0$ represents a linear differential equation whose solution implies that the tracking error $e(t)$ converges to zero with a time constant $(n-1)/\lambda$ [22]. Thus, the control objective becomes the design of a controller to keep $s(t)$ at zero.

The time derivative of s is given by

$$\dot{s} = \upsilon_0 - f(\boldsymbol{x},u) \tag{5}$$

where

$$\upsilon_0 = y_d^{(n)} + \beta_{n-1} e^{(n-1)} + \cdots + \beta_1 \dot{e} \tag{6}$$

with $\beta_j = \dfrac{(n-1)!}{(n-j)!(j-1)!}\lambda^{n-j}$, $j = 1,\ldots,n-1$.

By adding and subtracting $k_1 s + k_2 \tanh(s/\varepsilon)$ to the right-hand side of (6), one obtains

$$\dot{s} = -k_1 s - k_2 \tanh(s/\varepsilon) - \left(f(\boldsymbol{x},u) - \upsilon\right) \tag{7}$$

where k_1 and k_2 are positive design parameters, and $\upsilon = \upsilon_0 + k_1 s + k_2 \tanh(s/\varepsilon)$.

From Assumption 1 and the fact that the signal υ, does not explicitly depend upon the control input u, the partial derivative of $f(\boldsymbol{x},u) - \upsilon$ with respect to the input u satisfies

$$\frac{\partial\left(f(\boldsymbol{x},u) - \upsilon\right)}{\partial u} = \frac{\partial f(\boldsymbol{x},u)}{\partial u} \neq 0 \tag{8}$$

Based on the implicit function theorem [5, 13], we know that the nonlinear algebraic equation $f(\boldsymbol{x},u) - \upsilon = 0$ is locally solvable for the input u for each $\boldsymbol{x}$ and υ. Therefore, there exists some ideal controller $u^*(\boldsymbol{x},\upsilon)$ satisfying the following equality for all $\boldsymbol{x}$ and υ

$$f\left(\boldsymbol{x},u^*(\boldsymbol{x},\upsilon)\right) - \upsilon = 0 \tag{9}$$

If the control input u is chosen as the ideal control law u^*, i.e., $u = u^*(\boldsymbol{x},\upsilon)$, the closed-loop error dynamic (7) becomes

$$\dot{s} = -k_1 s - k_2 \tanh(s/\varepsilon) \tag{10}$$

From which one can conclude that $s(t) \to 0$ as $t \to \infty$ and, therefore, $e(t)$ and all its time derivatives up to $n-1$ converge to zero [25].

However, the implicit function theory only guarantees the existence of the ideal controller u^* for system (1), and does not prescribe a technique for constructing it even if the dynamics of the system are well-known. In the next section, a fuzzy system will be used to construct adaptively this unknown ideal implicit controller and Nussbaum technique will be used to cope with the unknown control direction.

B. Fuzzy Systems

We use in this work the zero-order Takagi-Sugeno fuzzy system that performs a mapping from an input vector $\boldsymbol{z} = [z_1,\ldots,z_m]^T \in \Omega_z \subset \mathbb{R}^m$ to a scalar output variable $y_f \in \mathbb{R}$, where $\Omega_z = \Omega_{z_1} \times \cdots \times \Omega_{z_m}$ and $\Omega_{z_i} \subset \mathbb{R}$. If we define M_i fuzzy sets F_i^j, $j = 1,\ldots,M_i$, for each input z_i, then the fuzzy

system will be characterized by a set of if-then rules of the form [1, 2]

$$\begin{aligned} \mathrm{R}^{k}: &\text{ If } z_1 \text{ is } G_1^k \text{ and} \ldots \text{and } z_m \text{ is } G_m^k \\ &\text{Then } y_f \text{ is } y_f^k \quad (k=1,\ldots,N) \end{aligned} \tag{11}$$

where $G_i^k \in \left\{F_i^1,\ldots,F_i^{M_i}\right\}$, $i=1,\ldots,n$, y_f^k is the crisp output of the k-th rule, and N is the total number of rules.

By using the singleton fuzzifier and the product inference engine, the final output of the fuzzy system is given by [1, 2]

$$y_f(z)=\frac{\sum_{k=1}^{N}\mu_k(z)\,y_f^k}{\sum_{k=1}^{N}\mu_k(z)} \tag{12}$$

where

$\mu_k(z)=\prod_{i=1}^{m}\mu_{G_i^k}(z_i)$, with $\mu_{G_i^k}\in\left\{\mu_{F_i^1},\ldots,\mu_{F_i^{M_i}}\right\}$,

with $\mu_{F_i^j}(x_i)$ is the membership function of the fuzzy set F_i^j.

By introducing the concept of fuzzy basis functions [1], the output given by (10) can be rewritten in the following compact form

$$y_f(z)=\boldsymbol{w}^T(z)\theta \tag{13}$$

where $\theta=\left[y_f^1,\ldots,y_f^N\right]^T$ is a vector grouping all consequent parameters, and $\boldsymbol{w}(z)=\left[w_1(z),\ldots,w_N(z)\right]^T$ is a set of fuzzy basis functions defined as

$$w_k(z)=\frac{\mu_k(z)}{\sum_{j=1}^{N}\mu_j(z)},\ k=1,\ \ldots,N. \tag{14}$$

The fuzzy system (11) is assumed to be well-defined so that $\sum_{j=1}^{N}\mu_j(z)\neq 0$ for all $z\in\Omega_z$.

It has been proved in [1] that fuzzy systems in the form of (12) with Gaussian membership functions can approximate continuous functions over a compact set to an arbitrary degree of accuracy provided that enough number of rules are considered.

C. Nussbaum Functions

In order to deal with the unknown control direction (sign of $g(\boldsymbol{x},u)$), the Nussbaum gain technique is used in this paper. The Nussbaum function technique was originally proposed in [10] and has been effectively used in controller design in solving the difficulty of unknown control directions [11-17]. A function $N(\tau)$ is called a Nussbaum-type function if it has the following properties [10]

$$\limsup_{\nu\to+\infty}\left(\frac{1}{\nu}\int_0^{\nu}N(\tau)\,d\tau\right)=+\infty \tag{15}$$

$$\liminf_{\nu\to+\infty}\left(\frac{1}{\nu}\int_0^{\nu}N(\tau)\,d\tau\right)=-\infty \tag{16}$$

For example, the continuous functions $e^{\tau^2}\cos(\tau)$ and $\tau^2\cos(\tau)$ are Nussbaum-type functions. In this paper, the even Nussbaum function $\tau^2\cos\left(\frac{\pi}{2}\tau\right)$ is used.

The following Lemma regarding the property of Nussbaum functions is used in the controller design and theorem proof of next section.

Lemma 1: Le $V(\cdot)$ and $\tau(\cdot)$ be smooth functions defined on $\left[0,t_f\right)$ with $V(t)\geq 0$, $\forall t\in\left[0,t_f\right)$, $N(\cdot)$ be an even smooth Nussbaum-type function. If the following inequality holds: $V(t)\leq c_0+\int_0^t\left(g(\zeta)N(\tau(\zeta))+c_1\right)\dot{\tau}(\zeta)\,d\zeta$ for $\forall t\in\left[0,t_f\right)$, where $g(\cdot)$ is a piecewise continuous time function which takes values in the unknown closed interval $I=\left[\underline{g},\overline{g}\right]$ with $0\notin I$, c_1 any positive number and c_0 is a constant, then $V(t)$, $\tau(t)$ and $\int_0^t\left(g(\zeta)N(\tau(\zeta))+c_1\right)\dot{\tau}(\zeta)\,d\zeta$ are bounded on $\left[0,t_f\right)$.

Proof: For the proof, please refer to [12].

III. Adaptive Fuzzy Controller Design

In the previous section, based on the implicit function theory, it has been shown that there exists an ideal control law $u^*(\boldsymbol{x},\upsilon)$ that can achieve control objectives. Since the implicit function theory only ensures the existence of this ideal controller and does not provide a way or a procedure for building it. In this section, we propose to use a fuzzy system to adaptively build this unknown ideal implicit controller.

To develop the control law, we assume that the ideal controller $u^*(\boldsymbol{x},\upsilon)$ can be approximated by a fuzzy system in the form of (11) as follows

$$u^*(z)=\boldsymbol{w}^T(z)\theta^* \tag{17}$$

where z is the input vector of the fuzzy system, $\boldsymbol{w}(z)$ is a fuzzy basis function vector fixed by the designer, and θ^* is a unknown bounded time-varying parameter vector with bounded time derivative.

Since the ideal parameter vector θ^* is unknown, let us use its estimate θ instead to form the adaptive control

$$u(z)=\boldsymbol{w}^T(z)\theta \tag{18}$$

To design an adaptation law for the free parameters θ, if the control direction (sign of $g(\boldsymbol{x},u)$) is known, one can consider the minimization problem of the cost function [7]

$$J(\theta)=\frac{1}{2}\left(u^*-u\right)^2=\frac{1}{2}\left(u^*-\boldsymbol{w}^T(z)\theta\right)^2$$

By using the gradient descent method, the following parameters update law can be obtained [7]

$$\dot{\theta}=\gamma\,\mathrm{sgn}\left(g(\boldsymbol{x},u)\right)\boldsymbol{w}(z)\left(\dot{s}+k_1 s+k_2\tanh(s/\varepsilon)\right)$$

with $\gamma>0$. However, since the control direction (sign of $g(\boldsymbol{x},u)$) is unknown, we have to use a Nussbaum-type function instead for designing the parameter adaptation law as the following

$$\dot{\theta}=\gamma N(\tau)\boldsymbol{w}(z)\left(\dot{s}+k_1 s+k_2\tanh(s/\varepsilon)\right) \tag{19}$$

$$\dot{\tau}=\eta\left(\dot{s}+k_1 s+k_2\tanh(s/\varepsilon)\right)^2 \tag{20}$$

$$N(\tau)=\tau^2\cos\left(\frac{\pi}{2}\tau\right) \tag{21}$$

where γ and η are strictly positive constants.

Theorem 1: For nonlinear system (1), under Assumptions 1 and 2 and Lemma 1, the control law (18) with adaptation laws (19)–(21) guarantee the boundedness of all the signals in the closed-loop system and the asymptotic convergence of the tracking error.

Proof: By invoking the mean value theorem, there exists a constant $\bar{\lambda}$ with $0<\bar{\lambda}<1$, such that the nonlinear function $f(\boldsymbol{x},u)$ can be expressed around u^* as follows

$$f(\boldsymbol{x},u)=f\left(\boldsymbol{x},u^*\right)+g(\boldsymbol{x},\bar{u})\left(u-u^*\right) \tag{22}$$

where $\bar{u}=\bar{\lambda}u+\left(1-\bar{\lambda}\right)u^*$.

By substituting (22) into (7), we get

$$\dot{s}=-k_1 s-k_2\tanh(s/\varepsilon)+g(\boldsymbol{x},\bar{u})\left(u^*-u\right) \tag{23}$$

With (17) and (18), one can rewrite (23) as

$$\dot{s}=-k_1 s-k_2\tanh(s/\varepsilon)+g(\boldsymbol{x},\bar{u})\boldsymbol{w}^T(z)\tilde{\theta} \tag{24}$$

where $\tilde{\theta}=\theta^*-\theta$ is the parameter error vector.

Now, consider the following positive definite function

$$V=\frac{1}{2}s^2+\frac{1}{2\gamma}\tilde{\theta}^T\tilde{\theta} \tag{25}$$

The time derivative of V is

$$\dot{V}=s\dot{s}-\frac{1}{\gamma}\tilde{\theta}^T\dot{\theta}+\frac{1}{\gamma}\tilde{\theta}^T\dot{\theta}^* \tag{26}$$

Substituting (19) and (24) into (26), and using the equality $\boldsymbol{w}^T(z)\tilde{\theta}=\tilde{\theta}^T\boldsymbol{w}(z)$, it follows that

$$\begin{aligned}\dot{V}=&-k_1 s^2-k_2 s\tanh(s/\varepsilon)+sg(\boldsymbol{x},\bar{u})\boldsymbol{w}^T(z)\tilde{\theta}+\frac{1}{\gamma}\tilde{\theta}^T\dot{\theta}^*\\&-g(\boldsymbol{x},\bar{u})N(\tau)\boldsymbol{w}^T(z)\tilde{\theta}\left(\dot{s}+k_1 s+k_2\tanh(s/\varepsilon)\right)\end{aligned} \tag{27}$$

From (24) one can obtain

$$\dot{s}+k_1 s+k_2\tanh(s/\varepsilon)=g(\boldsymbol{x},\bar{u})\boldsymbol{w}^T(z)\tilde{\theta} \tag{28}$$

Thus, (26) can be rewritten as

$$\begin{aligned}\dot{V}=&-k_1 s^2-k_2 s\tanh\left(\frac{s}{\varepsilon}\right)-\frac{N(\tau)}{g(\boldsymbol{x},\bar{u})}\left(\dot{s}+k_1 s+k_2\tanh\left(\frac{s}{\varepsilon}\right)\right)^2\\&+sg(\boldsymbol{x},\bar{u})\boldsymbol{w}^T(z)\tilde{\theta}+\frac{1}{\gamma}\tilde{\theta}^T\dot{\theta}^*\end{aligned} \tag{29}$$

Using (20) and the inequality

$$\begin{aligned}sg(\boldsymbol{x},\bar{u})\boldsymbol{w}^T(z)\tilde{\theta}&\le\frac{1}{4\eta}s^2+\eta\left(g(\boldsymbol{x},\bar{u})\boldsymbol{w}^T(z)\tilde{\theta}\right)^2\\&\le\frac{1}{4\eta}s^2+\eta\left(\dot{s}+k_1 s+k_2\tanh(s/\varepsilon)\right)^2\end{aligned} \tag{30}$$

Equation (29) can be bounded as

$$\dot{V}\le-\left(k_1-\frac{1}{4\eta}\right)s^2-k_2 s\tanh\left(\frac{s}{\varepsilon}\right)+\dot{\tau}-\frac{N(\tau)}{g(\boldsymbol{x},\bar{u})}\dot{\tau}+\frac{1}{\gamma}\tilde{\theta}^T\dot{\theta}^* \tag{31}$$

Now, we suppose that the following inequality holds

$$\begin{aligned}\left\|\tilde{\theta}^T\dot{\theta}^*\right\|&\le\kappa_1 s^2+\kappa_2\left(g(\boldsymbol{x},\bar{u})\boldsymbol{w}^T(z)\tilde{\theta}\right)^2+\delta^2\\&\le\kappa_1 s^2+\kappa_2\left(\dot{s}+k_1 s+k_2\tanh(s/\varepsilon)\right)^2+\delta^2\\&\le\kappa_1 s^2+\frac{\kappa_2}{\eta}\dot{\tau}+\delta^2\end{aligned} \tag{32}$$

where κ_1 and κ_2 are positive constants, and δ is a bounded square integrable function.

With (32), (33) can be upper bounded by

$$\begin{aligned}\dot{V}\le&-\left(k_1-\frac{1}{4\eta}-\frac{\kappa_1}{\gamma}\right)s^2-k_2 s\tanh\left(\frac{s}{\varepsilon}\right)\\&+\left(h(\boldsymbol{x})N(\tau)+c_1\right)\dot{\tau}+\frac{1}{\gamma}\delta^2\end{aligned} \tag{33}$$

with $c_1=1+\frac{\kappa_2}{\gamma\eta}$ and $h(\boldsymbol{x},\bar{u})=-1/\left(\eta g(\boldsymbol{x},\bar{u})\right)$.

Assuming that $k_1 > 1 \Big/ \left(\frac{1}{4\eta} + \frac{\kappa_1}{\gamma} \right)$, then by integrating (33) over $[0,t]$, one can obtain the following inequality

$$V(t) \le c_0 + \int_0^t \left(h(\zeta) N(\tau(\zeta)) + c_1 \right) \tau(\zeta) d\zeta \qquad (34)$$

where $c_0 = V(0) + \frac{1}{\gamma} \int_0^\infty \delta^2(t) dt$.

According to Assumption 1, we can consider $h(\cdot)$ as a time-varying parameter which takes values in the interval $I_h = \left[-(\eta \underline{g})^{-1}, -(\eta \overline{g})^{-1} \right]$ with $0 \notin I_h$. Thus, Using Lemma 1, we can conclude from (33) the boundedness of the signals $V(t)$, $N(t)$ and $\int_0^t \left(h(\zeta) N(\zeta) + c_1 \right) \dot{\tau}(\zeta) d\zeta$ for $t \in [0, t_f)$. According to [13], since no finite-time escape phenomenon may happen, then $t_f = \infty$. Therefore, $s(t)$, $\tilde{\theta}(t)$, $\boldsymbol{x}(t)$, and $u(t)$ are bounded. As an intermediate result, $s(t)$ is square integrable and $\dot{s}(t)$ is bounded. Moreover, by invoking Barbalat's lemma, we can conclude the asymptotic convergence of $s(t)$, which further implies the asymptotic convergence of the tracking error $e(t)$ and its first $(n-1)$ derivatives.

Remark 1: In this paper, since the signal $\dot{s}(t)$ in the adaptive laws (19) and (20) is not available for measurement, the following approximation is used $\dot{s}(t) \approx \left(s(t) - s(t - \Delta t) \right) \Big/ \Delta t$ where Δt is a small positive constant. Notice that because of the integral structure of adaptive laws (19) and (20), the noise effect will be considerably reduced.

IV. Simulation Results

To demonstrate the effectiveness of the above proposed adaptive controller, the following second-order nonlinear nonaffine system is used for simulation [7]

$$\begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = x_1^2 + 0.15u + 0.1\left(1 + x_2^2\right)u + \sin(0.1u) \end{cases} \qquad (35)$$

The control objective is to force the system output $y(t) = x_1(t)$ to track the desired trajectory $y_d(t) = \sin(t) + \cos(0.5t)$.

Within this simulation, the unknown ideal controller is approximated by a fuzzy system in the form of (15). The input variables of the fuzzy system are chosen as $\boldsymbol{z} = [x_1, x_2]^T$. For each variable z_i, $i = 1, 2$, five Gaussian membership functions are used with centers -1, -0.5, 0, 0.5 and 1, and a variance equal to 4.

In this simulation, the system initial conditions are $\boldsymbol{x}(0) = [0.1, 0]^T$, the adjustable parameters θ are initialized with zero values, and the design parameters are $\lambda = 1$, $k_1 = 0.5$, $k_2 = 0.5$, $\gamma = 0.1$, $\eta = 0.01$ and $\varepsilon_0 = 0.01$.

Simulation results for the case of an unknown control direction (where $\mathrm{sgn}\left(g(\boldsymbol{x}, u)\right) = 1$) are shown through Figs. 1 to 4. We can see that actual trajectories converge to the desired ones and that the control input signal is bounded.

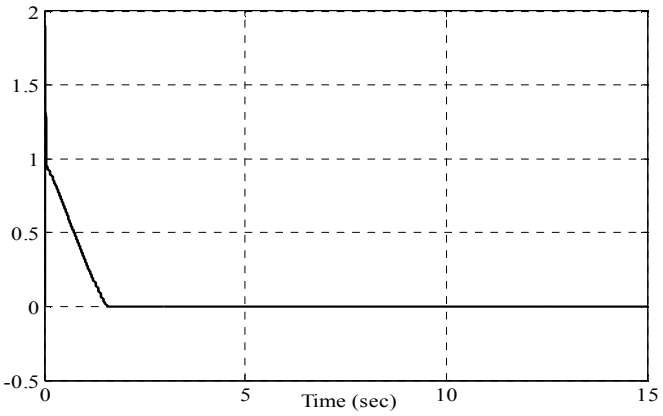

Fig. 4. Sliding surface $s(t)$

V. CONCLUSION

This paper proposed a stable direct adaptive fuzzy control scheme for a class of uncertain SISO nonaffine nonlinear systems with unknown control direction. The scheme consists of an adaptive fuzzy controller with its adaptive law. Within this scheme, a fuzzy system is used to construct adaptively an unknown ideal implicit controller, and its adjustable parameters are updated, by using the gradient descent method, in order to minimize the error between the unknown controller and the fuzzy controller. The parameters adaptation law incorporates a Nussbaum function in order to cope with the unknown control direction problem. Using the Lyapunov synthesis method, all signals in the closed-loop control system have been theoretically shown to be bounded and the tracking error has been shown to be asymptotically stable. Simulation results have verified the effectiveness of the proposed adaptive control approach.

***Abstract*—In this paper, an observer based adaptive iterative learning control is proposed for robotic systems. Due to the joint velocities are assumed to be not measurable, a state observer is introduced to design the iterative learning controller. We first derive an observation error model based on an tracking error observer. Then we apply an averaging filter to design the ILC algorithm. A fuzzy neural learning component using a filtered fuzzy neural network is presented to solve the problem of unknown nonlinearities. A robust learning component using sliding-mode like design is used to overcome the uncertainties, including fuzzy neural approximation error and the error induced by using state estimation errors. We show that all the adjustable parameters as well as internal signals remain bounded for all iterations. Finally, the norm of output tracking error will asymptotically converge to a tunable residual set as iteration goes to infinity.**

***Index Terms*—adaptive iterative learning control; observer; robotic systems; filtered fuzzy neural network; averaging filter approach**

I. Introduction

Due to the repeatability of operation for robotic systems, it is suitable to perform the control task by using the technique of iterative learning control (ILC). The ILC is a non-model based learning approach which is very effective in dealing with repetitive control tasks. Based on the contraction mapping theory and a certain priori knowledge, the ILC algorithms for robotic systems were initially developed in [1]. In general, the most popular designs of the ILC algorithms for robotic system can be roughly classified into D-type ILC [1], [2] and P-type ILC [3], [4]. In D-type ILC, the acceleration error of joint variable is used to construct the learning controller. In order to guarantee the convergence of the learning systems, it is necessary to assume that the nonlinearity of the plant is Lipschitz in states. Although the condition is mild, the acceleration measurement is unfortunately not realizable in practice and becomes the major disadvantage of D-type ILC. On the other hand, P-type ILC uses only the velocity error for the design of updated learning function. Although the requirement of acceleration measurement is removed, more strict conditions on the plant are needed for technical analysis. Recently, adaptive iterative learning control (AILC) have been widely studied [5], [6] for robotic systems. In order to relax the restrict Lipschitz condition on the plant's nonlinearity, the Lyapunov-like approach is applied to analyze the stability and convergence instead of contraction mapping theory. However, both PID-type ILCs and AILCs require at least the joint velocities to develop the ILC algorithms. If only the measurement of joint positions is available, an observer is one of the possible choice to design the ILC.

Actually, observer based ILCs were developed in [7], [8] for a class of nonlinear systems. Same as the case of the most ILC works, the plant nonlinearities must be known or satisfy Lipschitz continuous condition in [7], [8]. In this paper, to solve the relative degree problem caused by the condition that joint velocities are not measurable, an s-domain transfer function technique is adopted to derive an output error model based on a tracking error observer. An averaging filter is then proposed for the controller design. Under the derived error model, a filtered FNN using state estimation vector as the network input is used to design a fuzzy neural learning component for approximation of the unknown nonlinearities. A robust learning component is also constructed to compensate for the uncertainties from approximation error and state estimation error. Based on a Lyapunov like analysis, we show that all the adjustable parameters and internal signals remain bounded during the learning process. Furthermore, the norm of output tracking error will asymptotically converge to a tunable residual set if iteration number is large enough.

In the subsequent discussions, the following notations will be used.

(1) $|\cdot|$ denotes the absolute value of a scalar or the Euclidean or any other consistent norm of a vector or matrix.
(2) $\|(\cdot)_t\|_\infty = \sup_{\tau \le t} |(\cdot)(\tau)|$ denotes the truncated L_∞ norm of the argument function or vector [10].
(3) $\|P(s)\|_\infty$ denotes the H_∞ norm of the transfer function $P(s)$.
(4) $G(s)[u]$ denotes the filtered version of u with any proper or strictly proper transfer function $G(s)$.

II. Problem Formulation

In this paper, we consider an uncertain robotic system with n rigid bodies which can perform a given task repeatedly over a finite time interval $[0, T]$ as follows:

$$D(q^j(t))\ddot{q}^j(t) + B(q^j(t), \dot{q}^j(t))\dot{q}^j(t) + F(q^j(t), \dot{q}^j(t)) = u^j(t) \quad (1)$$

where $j \in Z_+$ denotes the index of iteration number and $t \in [0,T]$ denotes the time index[1]. The signals $q^j, \dot{q}^j, \ddot{q}^j \in R^n$ are respectively the generalized joint position, joint velocity and joint acceleration vectors. $D(q^j) \in R^{n\times n}$ is the inertia matrix, $B(q^j,\dot{q}^j) \in R^{n\times n}$ is the centripetal plus Coriolis force vector, $F(q^j,\dot{q}^j) \in R^n$ is the gravitational plus frictional forces and $u^j \in R^n$ is the joint torque vector. It is noted the inertia matrix $D(q^j)$ is assumed to be positive definite and bounded for all $t \in [0,T]$ and iteration $j \geq 1$ as

$$0 < m_1 I \leq D(q^j) \leq m_2 I$$

where $m_1, m_2 > 0$ and I is an $n \times n$ identity matrix. Since the inverse of inertia matrix exists for all joint variables, the dynamic formulation of the robotic system can be written as follows,

$$\ddot{q}^j = -D^{-1}(q^j)\left[B(q^j,\dot{q}^j)\dot{q}^j + F(q^j,\dot{q}^j)\right] + D^{-1}(q^j)u^j \quad (2)$$

Let $f(q^j,\dot{q}^j) = D^{-1}(q^j)[B(q^j,\dot{q}^j)\dot{q}^j + F(q^j,\dot{q}^j)] \in R^n$ and $b(q^j) = D^{-1}(q^j) \in R^{n\times n}$ and choose the output variable as $y^j = q^j \in R^n$, state variable as $X^j = [x_1^{j\top}, x_2^{j\top}]^\top = [y^{j\top}, \dot{y}^{j\top}]^\top = [q^{j\top}, \dot{q}^{j\top}]^\top \in R^{2n}$, then we have

$$\begin{aligned} \dot{x}_1^j &= x_2^j \\ \dot{x}_2^j &= -f(X^j) + b(X^j)u^j \\ y^j &= x_1^j \end{aligned} \quad (3)$$

or equivalently in the following state-space form :

$$\begin{aligned} \dot{X}^j &= AX^j + B\left[-f(X^j) + b(X^j)u^j\right] \\ y^j &= C^\top X^j \end{aligned} \quad (4)$$

where

$$A = \begin{bmatrix} 0 & I \\ 0 & 0 \end{bmatrix},\ B = \begin{bmatrix} 0 \\ I \end{bmatrix},\ C = \begin{bmatrix} I \\ 0 \end{bmatrix},$$

Here $0 < b(X^j) \leq m_1^{-1} I$. In this paper, we assume that only joint position y^j is measurable for controller design. Let the desired state trajectory be defined as $X_d = [y_d^\top, \dot{y}_d^\top]^\top$. Now, given a specified desired output trajectory y_d, $t \in [0,T]$ and a possible initial resetting error $y_d(0) \neq y^j(0)$ for all $j \geq 1$, the control objective for the robotic systems doing a repeatable task is to force the system output y^j to follow y_d as close as possible.

III. Derivations of Error Model and Controller

A. Derive the Error Model

Define the output error as $e^j = y_d - y^j$ and the state tracking error vector as $E^j = X_d - X^j = \left[e^{j\top}, \dot{e}^{j\top}\right]^\top \in R^{2n}$, then we can derive $\ddot{e}^j$ as follows,

$$\begin{aligned} \ddot{e}^j &= \ddot{y}_d + f(X^j) - b(X^j)u^j \\ &= -K_c^\top E^j + f(X^j) + \ddot{y}_d + K_c^\top E^j - b(X^j)u^j \end{aligned} \quad (5)$$

[1]the time index t will be omitted unless otherwise specified.

where $K_c = [k_2^c I, k_1^c I]^\top \in R^{2n\times n}$ is the feedback gain matrix such that the characteristic polynominal of $A_c = A - BK_c^\top$ is Hurwitz. Therefore, the tracking error dynamics will satisfy

$$\begin{aligned} \dot{E}^j &= A_c E^j + B\Big(f(X^j) + \ddot{y}_d + K_c^\top E^j - b(X^j)u^j\Big) \\ &= A_c E^j + B\Big(f(X^j) + \ddot{y}_d + K_c^\top X_d - K_c^\top X^j \\ &\quad - u^j + (1 - b(X^j))u^j\Big) \\ &= A_c E^j + B\Big(h(X^j) + \alpha - u^j + (1 - b(X^j))u^j\Big) \\ e^j &= C^\top E^j \end{aligned} \quad (6)$$

where $h(X^j) \equiv f(X^j) - K_c^\top X^j$, $\alpha \equiv \ddot{y}_d + K_c^\top X_d$. Note that the state tracking error vector E^j in the tracking error dynamics (6) is not assumed to be available for measurement. Hence, it is necessary to construct a state estimation vector $\widehat{X}^j = [\widehat{x}^{j\top}, \dot{\widehat{x}}^{j\top}]^\top \in R^{2n} \times [0,T]$ for estimation of the state vector. In order to construct a state estimation vector, we define a state tracking error estimation vector $\widehat{E}^j$ as

$$\widehat{E}^j = X_d - \widehat{X}^j = [\widehat{e}^{j\top}, \dot{\widehat{e}}^{j\top}]^\top \in R^{2n} \times [0,T]$$

The tracking error observer is designed as

$$\begin{aligned} \dot{\widehat{E}}^j &= A_c \widehat{E}^j + K_o(e^j - \widehat{e}^j) \\ \widehat{e}^j &= C^\top \widehat{E}^j \end{aligned} \quad (7)$$

where $K_o = [k_1^o I, k_2^o I]^\top \in R^{2n\times n}$ is the observer gain vector such that the characteristic polynomial of $A_o = A_c - K_o C^\top$ is Hurwitz. If we further define the observation error vector as $\widetilde{E}^j = E^j - \widehat{E}^j$, the observation error dynamics can be derived by using (6) and (7) as follows

$$\begin{aligned} \dot{\widetilde{E}}^j &= A_o \widetilde{E}^j + B\Big(h(X^j) + \alpha - u^j + (1 - b(X^j))u^j\Big) \\ \widetilde{e}^j &= C^\top \widetilde{E}^j \end{aligned} \quad (8)$$

Based on the universal approximation theorem, we know that the nonlinear function $h(X^j)$ can be approximated by an FNN [9] $O^{(4)}(X^j, W^j) = W^{j\top} O^{(3)}(X^j)$. Here $O^{(3)}(X^j) \in \mathcal{R}^M$ is the basis function vector with M being the number of rule nodes and W is the weight matrix of the output layer. According to the universal approximation theorem, there will exist an optimal weight matrix W^* such that $h(X^j) = O^{(4)}(X^j, W^*) + \epsilon^j = W^{*\top} O^{(3)}(X^j) + \epsilon^j$, where ϵ^j is the approximation error satisfying $|\epsilon^j| \leq \epsilon^*$ in a certain compact set. This implies that (8) can be rewritten as

$$\begin{aligned} \dot{\widetilde{E}}^j &= A_o \widetilde{E}^j + +B\Big(W^{*\top} O^{(3)}(X^j) + \epsilon^j + \alpha - u^j \\ &\quad + (1 - b(X^j))u^j\Big) \\ &= A_o \widetilde{E}^j + +B\Big(W^{*\top} O^{(3)}(\widehat{X}^j) - u^j + \delta^j \\ &\quad + (1 - b(X^j))u^j\Big) \\ \widetilde{e}^j &= C^\top \widetilde{E}^j \end{aligned} \quad (9)$$

where $\delta^j = W^{*\top}\Big(O^{(3)}(X^j) - O^{(3)}(\widehat{X}^j)\Big) + \epsilon^j + \alpha$ is the lumped uncertainty term which includes the difference between

FNN network with input using state and estimated state, the network approximation error and the desired state trajectory. It is easily proven that the lumped uncertainty term satisfying $|\delta^j| \leq \delta^*$. However, it is noted that the value of the unknown constant δ^* might be large.

To see how to design the iterative learning controller u^j to achieve the control objective, we now adopt the mixed use of a time signal and a Laplace transfer function to obtain the explicit expression of $\widetilde{e}^j$ in (9) in time domain with a filtered version as follows,

$$\widetilde{e}^j = H(s)\Big[W^{*\top}O^{(3)}(\widehat{X}^j) - u^j + \delta^j + (1 - b(X^j))u^j\Big] \quad (10)$$

where $H(s) = C^\top(sI - A_o)^{-1}B = \frac{1}{s^2+(k_1^c+k_1^o)s+(k_1^ck_1^o+k_2^ck_2^o)}$. The observer gain vector $K_o = [k_1^oI, k_2^oI]^\top$ is chosen such that $H(s) = \frac{1}{\ell(s)L(s)}$ with $\ell(s) = s + \lambda$ and $L(s)$ being any Hurwitze polynomial of order 1. Then (10) can be rewritten as

$$\begin{aligned}\widetilde{e}^j &= H(s)L(s)\Big[W^{*\top}\frac{1}{L(s)}\big[O^{(3)}(\widehat{X}^j)\big] - \frac{1}{L(s)}\big[u^j\big] \\ &\quad + \frac{1}{L(s)}\big[(1 - b(X^j))u^j + \delta^j\big]\Big] \\ &= \frac{1}{\ell(s)}\Big[W^{*\top}\xi^j - \frac{1}{L(s)}\big[u^j\big] + \delta_L^j\Big] \end{aligned} \quad (11)$$

where $\xi^j = \frac{1}{L(s)}[O^{(3)}(\widehat{X}^j)]$ and $\delta_L^j = \frac{1}{L(s)}[(1 - b(X^j))u^j + \delta^j]$.

B. Construct Some Useful Signals

According to the filtered version of output tracking error model (11), we define an augmented signal with filtered version as

$$y_a^j = \frac{1}{\ell(s)}\left[v^j - \frac{1}{L(s)}\Big[u^j\Big]\right],\ y_a^j(0) = 0 \quad (12)$$

where v^j is an auxiliary input to be designed later. Then, design an auxiliary error signal as

$$e_a^j = \widetilde{e}^j - y_a^j \quad (13)$$

The initial condition $e_a^j(0)$ will satisfy $|e_a^j(0)| = |\widetilde{e}^j(0) - y_a^j(0)| = |\widetilde{e}^j(0)| \equiv \varepsilon^j$. Substituting (11) and (12) into (13), we can find that

$$e_a^j = \widetilde{e}^j - y_a^j = \frac{1}{\ell(s)}\Big[W^{*\top}\xi^j - v^j + \delta_L^j\Big] \quad (14)$$

It is noted that we apply the Laplace operation to derive the tracking error model (14) for technical analysis later as that used in the traditional model reference adaptive control [10]. The equivalent time-domain state space representation of (14) is

$$\dot{e}_a^j = -\lambda e_a^j + W^{*\top}\xi^j - v^j + \delta_L^j \quad (15)$$

In order to overcome the uncertainty from initial output tracking error, a new signal e_ϕ^j is introduced as follows,

$$e_\phi^j = e_a^j - \phi^j\mathbf{sat}\left(\frac{e_a^j}{\phi^j}\right),\ \phi^j = \varepsilon^j e^{-\lambda t} \quad (16)$$

where $\mathbf{sat}(\frac{e_a^j}{\phi^j}) = [\mathbf{sat}(\frac{e_{a,1}^j}{\phi^j}), \cdots, (\frac{e_{a,n}^j}{\phi^j})]^\top \in R^n$ and

$$\mathbf{sat}\left(\frac{e_{a,i}^j}{\phi^j}\right) = \begin{cases} 1 & \text{if } e_{a,i}^j > \phi^j \\ \frac{e_{a,i}^j}{\phi^j} & \text{if } |e_{a,i}^j| \leq \phi^j,\ i = 1, \cdots, n \\ -1 & \text{if } e_{a,i}^j < -\phi^j \end{cases}$$

and ϕ^j is the width of boundary layer. Note that ϕ^j is designed to decrease along time axis with the initial condition chosen as $\phi^j(0) = \varepsilon^j$ for jth iteration and $0 < \varepsilon^j e^{-\lambda T} \leq \phi^j \leq \varepsilon^j, \forall t \in [0, T], j \geq 1$. According to (16), it is easy to show that $e_\phi^j(0) = 0, \forall j \geq 1$. Now let us differentiate $\frac{1}{2}e_\phi^{j\top}e_\phi^j$ as follows,

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}e_\phi^{j\top}e_\phi^j &= e_\phi^{j\top}\dot{e}_\phi^j \\ &= e_\phi^{j\top}\Big(\dot{e}_a^j - \mathbf{sgn}\Big(e_\phi^j\Big)\dot{\phi}^j\Big) \\ &= e_\phi^{j\top}\Big\{-\lambda e_a^j - \mathbf{sgn}\Big(e_\phi^j\Big)\dot{\phi}^j\Big\} \\ &\quad + e_\phi^{j\top}\Big\{W^{*\top}\xi^j - v^j + \delta_L^j\Big\} \\ &= -\lambda e_\phi^{j\top}e_\phi^j + e_\phi^{j\top}\Big\{W^{*\top}\xi^j - v^j + \delta_L^j\Big\} \end{aligned} \quad (17)$$

where $\mathbf{sgn}(e_\phi^j) = [\mathbf{sgn}(e_{\phi,1}^j), \cdots, \mathbf{sgn}(e_{\phi,n}^j)]^\top$ is the typical signum function vector. In the following, we will show that the uncertainty term δ_L^j in (11) can be bounded in a linearly parameterized form if the following normalization signal m^j [11] is utilized

$$m^j = \frac{\delta_2}{s + \delta_1}\Big[1 + \big|u^j\big|\Big],\quad m^j(0) > \frac{\delta_2}{\delta_1} \quad (18)$$

where $\delta_1, \delta_2 > 0$ and $\delta_1 < \delta^*$. Here δ^* is the least positive constant such that $\frac{1}{L(s-\delta^*)}$ is a stable system. In practical, δ_1 can be chosen as small as possible. Note that $1 - b(X^j)$, α and δ^j are bounded and $\frac{1}{L(s)}$ is a strictly proper stable transfer function. This implies that

$$\Big|\delta_L^j\Big| \leq \theta_1^* m^j + \theta_2^* = [\theta_1^*, \theta_2^*]\begin{bmatrix} m^j \\ 1 \end{bmatrix} \equiv \theta^{*\top}Y^j \quad (19)$$

for some positive constants θ_1^*, θ_2^*.

C. Design the Iterative Learning Controller Using Filtered FNN

Based on the derived error model and the useful signals, we design u^j and v^j as follows

$$u^j = \frac{L(s)}{F^{n-1}(\tau s)}[v^j] \quad (20)$$

$$v^j = W^{j\top}\xi^j + \mathbf{sat}\left(\frac{e_a^j}{\phi^j}\right)\theta^{j\top}Y^j + e_\phi^jY^{j\top}Y^j \quad (21)$$

where W^j is the weight matrix of the network and θ^j is control parameter vector which are used to compensate for the unknown W^* and θ^* respectively. Furthermore, $F(\tau s) = (\tau s + 1)^2$ with $\tau > 0$ being a small constant. In the literature, $\frac{1}{F(\tau s)}$ is referred to as an *averaging filter*, which is obviously a low-pass filter whose bandwidth can be arbitrarily enlarged

as τ approaches 0. If we define the parameter error as $\widetilde{W} = W^j - W^*$ and $\widetilde{\theta}^j = \theta^j - \theta^*$ and substitute (21) into (17), we have the following error dynamics for technical analysis later,

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}e_\phi^{j\top}e_\phi^j \\
&= -\lambda(e_\phi^j)^2 + e_\phi^j\Big\{-\widetilde{W}^{j\top}\xi^j - \mathbf{sat}\left(\frac{e_a^j}{\phi^j}\right)\theta^{j\top}Y^j \\
&\quad - e_\phi^j Y^{j\top}Y^j + \delta_L^j\Big\} \\
&\leq -\lambda(e_\phi^j)^2 - e_\phi^j\widetilde{W}^{j\top}\xi^j - \Big|e_\phi^j\Big|\widetilde{\theta}^{j\top}Y^j - (e_\phi^j)^2 Y^{j\top}Y^j
\end{aligned} \tag{22}$$

A set of stable adaptive laws is necessary to tune the control parameters. The adaptive laws combining time domain and iteration domain adaptation without knowledge of known bounds on optimal parameters or deadzone mechanism are proposed as follows,

$$(1-\gamma_1)\dot{W}^j = -\gamma_1 W^j + \gamma_1 W^{j-1} + \beta_1 e_\phi^j \xi^j \tag{23}$$

$$(1-\gamma_2)\dot{\theta}^j = -\gamma_2\theta^j + \gamma_2\theta^{j-1} + \beta_2|e_\phi^j|Y^j \tag{24}$$

with $W^j(0) = W^{j-1}(T), \theta^j(0) = \theta^{j-1}(T)$ for $j \geq 1$, and $0 < \gamma_1, \gamma_2 < 1$, $\beta_1, \beta_2 > 0$. In these adaptive laws, γ_1, γ_2 and β_1, β_2 are defined as the weighting gains and adaptation gains, respectively. The setting of initial network parameter vector W^0 and θ^0 are specified in [12].

IV. Analysis of Stability and Convergence

To prove the stability and convergence of the proposed learning system, we first give the following two facts.

• **Fact 1** : Choose a Lyapunov-like positive function as

$$V_a^j = \frac{1}{2}e_\phi^{j\top}e_\phi^j + \frac{(1-\gamma_1)}{2\beta_1}tr\Big\{\widetilde{W}^{j\top}\widetilde{W}^j\Big\} + \frac{(1-\gamma_2)}{2\beta_2}\widetilde{\theta}^{j\top}\widetilde{\theta}^j$$

and compute its derivative with respective to time t, we have the following result by using similar technique in [12] as

$$\dot{V}_a^j \leq -kV_a^j + \bar{k}^{j-1} \tag{25}$$

where $k = \min\{2\bar{\lambda}, \frac{\gamma_1}{1-\gamma_1}, \frac{\gamma_2}{1-\gamma_2}\}$, and $\bar{k}^{j-1} = \frac{\gamma_1}{2\beta_1}tr\Big\{\widetilde{W}^{j-1\top}\widetilde{W}^{j-1}\Big\} + \frac{\gamma_2}{2\beta_2}\widetilde{\theta}^{j-1\top}\widetilde{\theta}^{j-1}$. It is noted that $\bar{W}^0 = W^0 - W^* = W^{ini} - W^* \equiv \bar{W}^0$ and $\widetilde{\theta}^0 = \theta^0 - \theta^* = \theta^{ini} - \theta^* \equiv \bar{\theta}^0$ are bounded for all $t \in [0, T]$ so that if $j = 1$, (25) can be rewritten as

$$\begin{aligned}
\dot{V}_a^1 &\leq -kV_a^1 + \bar{k}^0 \\
&= -kV_a^1 + \frac{\gamma_1}{2\beta_1}tr\Big\{\bar{W}^{0\top}\bar{W}^0\Big\} + \frac{\gamma_2}{2\beta_2}\bar{\theta}^{0\top}\bar{\theta}^0
\end{aligned} \tag{26}$$

Note that the initial value $V_a^1(0)$ is bounded since $e_\phi^1(0) = 0$, $\widetilde{W}^1(0) = W^1(0) - W^* = W^0(T) - W^* = \bar{W}^0$, and $\widetilde{\theta}^1(0) = \theta^1(0) - \theta^* = \theta^0(T) - \theta^* = \bar{\theta}^0$. Together with the result of (26), it readily implies $V_a^1, e_\phi^1, \widetilde{W}^1, \widetilde{\theta}^1, W^1, \theta^1 \in L_{\infty e}[0, T]$. Since the basis function vector $O^{(3)^j}$ is bounded for all $j \geq 1$, we conclude that e_a^1 (by (16)) and $\dot{W}^1$ (by 23) $\in L_{\infty e}[0, T]$.

• **Fact 2** : Define a positive function $V^j(T)$ as

$$\begin{aligned}
V^j(T) &= \int_0^T \left[\frac{\gamma_1}{2\beta_1}\widetilde{W}^{j\top}\widetilde{W}^j + \frac{\gamma_2}{2\beta_2}\widetilde{\theta}^{j\top}\widetilde{\theta}^j\right]dt \\
&\quad + \frac{(1-\gamma_1)}{2\beta_1}tr\Big\{\widetilde{W}^j(T)^\top\widetilde{W}^j(T)\Big\} \\
&\quad + \frac{(1-\gamma_2)}{2\beta_2}\widetilde{\theta}^j(T)^\top\widetilde{\theta}^j(T)
\end{aligned} \tag{27}$$

Using the technique of integration by parts, we can show that

$$\begin{aligned}
&V^j(T) - V^{j-1}(T) \\
&\leq \int_0^T \left(e_\phi^{j\top}\widetilde{W}^{j\top}\xi^j + |e_\phi^j|\widetilde{\theta}^{j\top}Y^j\right)dt
\end{aligned} \tag{28}$$

Integrating both side of (22) from 0 to T gives

$$\begin{aligned}
&\int_0^T \left(e_\phi^{j\top}\widetilde{W}^{j\top}\xi^j + |e_\phi^j|\widetilde{\theta}^{j\top}Y^j\right)dt \\
&\leq -\int_0^T \left(\lambda e_\phi^{j\top}e_\phi^j + e_\phi^{j\top}e_\phi^j Y^{j\top}Y^j\right)dt \\
&\quad - \frac{1}{2}e_\phi^{j\top}(T)e_\phi^j(T)
\end{aligned} \tag{29}$$

where we use the property of $\frac{1}{2}e_\phi^{j\top}(0)e_\phi^j(0) = 0$. Substituting (29) into (28), it yields

$$\begin{aligned}
&V^j(T) - V^{j-1}(T) \\
&\leq -\frac{1}{2}e_\phi^{j\top}(T)e_\phi^j(T) - \int_0^T \left(\lambda e_\phi^{j\top}e_\phi^j + e_\phi^{j\top}e_\phi^j Y^{j\top}Y^j\right)dt
\end{aligned} \tag{30}$$

Since $V^1(T)$ is bounded by **Fact 1** and $V^j(T)$ is positive and monotonically decreasing, we conclude by the result of (30) that $V^j(T)$ is bounded for all $j \geq 1$ and will converge as j approaches infinity to some limit value V_T which is independent of j. Furthermore, (30) also implies

$$\int_0^T e_\phi^{j\top}e_\phi^j Y^{j\top}Y^j dt \leq V^{j-1}(T) - V^j(T) \leq V^1(T) \tag{31}$$

$$\int_0^T \lambda e_\phi^{j\top}e_\phi^j dt \leq V^{j-1}(T) - V^j(T) \leq V^1(T) \tag{32}$$

$$\frac{1}{2}e_\phi^{j\top}(T)e_\phi^j(T) \leq V^{j-1}(T) - V^j(T) \leq V^1(T) \tag{33}$$

It follows that $\widetilde{W}^j(T)$, $\widetilde{\theta}^j(T)$ and $e_\phi^{j\top}(T)e_\phi^j(T)$ are bounded for all $j \geq 1$. Furthermore, $\lim_{j\to\infty}\int_0^T e_\phi^{j\top}e_\phi^j dt = 0$, and $\lim_{j\to\infty} e_\phi^{j\top}(T)e_\phi^j(T) = 0$.

Lemma 1 : Consider the robotic system (1) performing a repetitive control task. If we apply the output based fuzzy neural adaptive iterative learning controller (12), (13), (16), (18), (20), and (21) with adaptation laws (23) and (24), then we ensure that all the internal signals are bounded, i.e., e_ϕ^j, e_a^j, $\widetilde{e}^j$, y_a^j, $\widehat{e}^j$, e^j, $\widetilde{E}^j$, $\widehat{E}^j$, E^j, W^j, θ^j, u^j, $\dot{W}^j$, $\dot{\theta}^j \in L_{\infty e}[0, T]$.

Proof : Integrating (25) from 0 to t, we have

$$\begin{aligned}
V_a^j &\leq V_a^j(0) + \int_0^t \bar{k}^{j-1}(z)dz \\
&\leq V_a^j(0) + \int_0^T \bar{k}^{j-1}(t)dt
\end{aligned} \tag{34}$$

Then we can conclude that $V_a^j, e_\phi^j, W^j, \theta^j, e_a^j, \dot{W}^j \in L_{\infty e}[0,T]$ by using Fact 2.

However, the boundedness of $V_a^j, e_\phi^j, \widetilde{W}^j, \widetilde{\theta}^j, e_a^j, \dot{W}^j$ can not guarantee the boundedness of Y^j (or equivalently m^j) and input u^j. In order to show the boundedness of Y^j for all $t \in [0,T]$, we first note that the boundedness of $\int_0^T \gamma \widetilde{e}_\phi^{j\top} \widetilde{e}_\phi^j Y^{1\top} Y^1 dt$ are then established from (31). Furthermore, since $\int_0^t e_\phi^{j\top} e_\phi^j Y^{j\top} Y^j dz \leq \int_0^T e_\phi^{j\top} e_\phi^j Y^{j\top} Y^j dt$, it implies that $\int_0^t e_\phi^{j\top} e_\phi^j Y^{j\top} Y^j dz \in L_{\infty e}[0,T]$. But the boundedness of e_ϕ^j and $\int_0^t e_\phi^{j\top} e_\phi^j Y^{j\top} Y^j dz$ only ensure that Y^j is bounded everywhere except on a set of measure zero. Now we adopt some techniques given in chapter 2 of [10]. Consider u^j in (20),

$$\begin{aligned} u^j &= \frac{L(s)}{F^{n-1}(\tau s)}[v^j] \\ &= \frac{L(s)}{F^{n-1}(\tau s)}\left[W^{j\top}\xi^j + \mathbf{sat}\left(\frac{e_a^j}{\phi^j}\right)\theta^{j\top} Y^j\right] \\ &\quad + \frac{sL(s)}{F^{n-1}(\tau s)}\left[\int_0^t e_\phi^j Y^{j\top} Y^j dz\right] \end{aligned} \tag{35}$$

Since W^j, ξ^j, θ^j and $\int_0^t e_\phi^j Y^{j\top} Y^j dz$ are bounded for $t \in [0,T]$, and $\frac{L(s)}{F^{n-1}(\tau s)}$, $\frac{sL(s)}{F^{n-1}(\tau s)}$ are strictly proper stable transfer functions, (35) implies that u^j will satisfy

$$|u^j| \leq k_1 \|(Y^j)_t\|_\infty + k_1 \leq k_2 |(m^j)_t|_\infty + k_2 \tag{36}$$

for some $k_1, k_2 > 0$ by lemma 2.6 (output is bounded by truncated L_∞ norm of input for a stable linear system) in [10]. Now we construct an extended dynamic equation by using (**??**), (8) and (18) as follows :

$$\begin{aligned} &\begin{bmatrix} \dot{E}^j \\ \dot{m}^j \end{bmatrix} \\ &= \begin{bmatrix} A_c & 0 \\ 0 & -\delta_1 \end{bmatrix}\begin{bmatrix} E^j \\ m^j \end{bmatrix} \\ &\quad + \begin{bmatrix} B \\ 0 \end{bmatrix}\Big(-b(X^j)u^j + W^{*\top} O^{(3)}(\widehat{X}^j) + \delta^j \Big) \\ &\quad + \begin{bmatrix} 0 \\ \delta_2\left(1 + |u^j|\right) \end{bmatrix} \end{aligned} \tag{37}$$

Let X_a^j be the state vector of the extended dynamic equation (37). Taking norms on (37) will yield

$$\|\dot{X}_a^j\| \leq k_3 \|X_a^j\| + k_3 |u^j| + k_3 \leq k_4 \|(X_a^j)_t\|_\infty + k_4 \tag{38}$$

for some $k_3, k_4 > 0$. This implies that X_a^j is regular [10] so that X_a^j and hence, E^j, m^j can grow at most exponentially fast and no finite time escape during a finite time interval $[0,T]$. This condition guarantees a certain degree of smoothness of signal m^j. Therefore, we show that Y^j is a certain degree of smooth signal. Together with the result of $\int_0^t e_\phi^j Y^{j\top} Y^j dz \in L_{\infty e}[0,T]$, we can conclude that $Y^j \in L_{\infty e}[0,T]$. Due to $W^j, \xi^j, \theta^j, Y^j, e_\phi^j \in L_{\infty e}[0,T]$, this also implies that $v^j \in L_{\infty e}[0,T]$ (by (21)). Because $e_\phi^j, W^j, \theta^j, \xi^j, Y^j \in L_{\infty e}[0,T]$, we conclude that $\dot{W}^j(t)$ (by 23)), $\dot{\theta}^j(t)$ (by 24) $\in L_{\infty e}[0,T]$. Since $v^j \in L_{\infty e}[0,T]$ and $\frac{L(s)}{F^{n-1}(s)}$ is a proper stable transfer function, this implies that $u^j \in L_{\infty e}[0,T]$ (by (20)). Since $v^j, u^j \in L_{\infty e}[0,T]$, $\frac{1}{L(s)}$ and $\frac{1}{\ell(s)}$ are strictly proper stable transfer functions, this implies that $y_a^j \in L_{\infty e}[0,T]$ (by (12)). As noted above, $e_a^j, y_a^j \in L_{\infty e}[0,T]$, we have $\widetilde{e}^j \in L_{\infty e}[0,T]$ (by (13)). Moreover, because A_c is a Hurwitz matrix and $\widetilde{e}^j \in L_{\infty e}[0,T]$, this implies that $\widehat{e}^j, \widehat{E}^j \in L_{\infty e}[0,T]$ (by (7)). Finally, since A_c and A_o are Hurwitz matrices and $-b(X^j)u^j + W^{*\top} O^{(3)}(\widehat{X}^j) + \delta^j \in L_{\infty e}[0,T]$, we have $\widetilde{e}^j, \widetilde{E}^j \in L_{\infty e}[0,T]$ (by (8)) and $e^j, E^j \in L_{\infty e}[0,T]$ (by (6)). This completes the proof. Q.E.D.

Based on **Fact 1, Fact 2** and **Lemma 1**, we now get the main result of this learning system.

Theorem 1 : Consider the system set-up in Lemma 1. The proposed adaptive iterative learning controller guarantees the tracking performance and system stability as follows :

(T1) $\lim_{j\to\infty} e_\phi^j(t)^\top e_\phi^j(t) = 0$, for all $t \in [0,T]$.

(T2) $\lim_{j\to\infty} |e_a^j(t)| \leq e^{-\lambda t}\varepsilon^\infty$, for all $t \in [0,T]$.

(T3) $\lim_{j\to\infty} |e^j(t)| \leq e^{-\lambda t}\varepsilon^\infty + \tau k_6$, for all $t \in [0,T]$.

(T4) Let δ be the positive constant such that $\Delta(D-\delta)$ is still a Hurwitz polynomial, then $\lim_{j\to\infty} |\widehat{e}^j(t)| = |\widehat{e}^\infty(t)| \leq m_2\left(\varepsilon^\infty \frac{e^{-\lambda t} - e^{-\delta t}}{\delta - \lambda} + \tau k_6 \frac{1 - e^{-\delta t}}{\delta}\right)$, for all $t \in [0,T]$.

(T5) $\lim_{j\to\infty} |e^j(t)| = |e^\infty(t)| \leq e^{-\lambda t}\varepsilon^\infty + \tau k_6 + m_2\left(\varepsilon^\infty \frac{e^{-\lambda t} - e^{-\delta t}}{\delta - \lambda} + \tau k_6 \frac{1 - e^{-\delta t}}{\delta}\right)$, for all $t \in [0,T]$.

Proof : Based on Fact 1, Fact 2 and Lemma 1, then we can conclude the result of (T1) and (T2). For (T3), Substituting (20) into (12), we can find that e_a^j actually satisfies

$$\begin{aligned} e_a^j &= \widetilde{e}^j - y_a^j \\ &= \widetilde{e}^j - \frac{1}{\ell(s)}\left(1 - \frac{1}{F^{n-1}(\tau s)}\right)\left[v^j\right] \\ &\triangleq \widetilde{e}^j - R^j \end{aligned} \tag{39}$$

Since v^j is bounded and the H_∞ norm of $\|\frac{1}{s}(1 - \frac{1}{F^{n-1}(\tau s)})\|_\infty = 2(n-1)\tau$ and $\|\frac{s}{\ell(s)}\|_\infty = k_5$ for some $k_5 > 0$, we can conclude that

$$|R^j| \leq \left\|\frac{1}{s}\Big(1 - \frac{1}{F^{n-1}(\tau s)}\Big)\right\|_\infty \left\|\frac{s}{\ell(s)}\right\|_\infty \|(v^j)_t\|_\infty \leq \tau k_6$$

for some $k_6 > 0$. Taking norms on (39), we find that

$$|\widetilde{e}^j| \leq |e_a^j| + |R^j| \leq |e_a^j| + \tau k_6$$

As iteration goes to infinity,

$$\lim_{j\to\infty} |\widetilde{e}^j| \leq e^{-\lambda t}\varepsilon^\infty + \tau k_6 \leq \phi^\infty + \tau k_6$$

Finally, we apply a similar technique in [13], (T4) and (T5) are achieved.

V. Simulation Example

In this example, we apply the observer based adaptive iterative learning controller to robotic system [14]

$$\begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix}\begin{bmatrix} \ddot{q}_1^j \\ \ddot{q}_2^j \end{bmatrix} + \begin{bmatrix} -h\dot{q}_2^j & -h(\dot{q}_1^j + \dot{q}_2^j) \\ h\dot{q}_1^j & 0 \end{bmatrix}\begin{bmatrix} \dot{q}_1^j \\ \dot{q}_2^j \end{bmatrix} = \begin{bmatrix} u_1^j \\ u_2^j \end{bmatrix}$$

where $D_{11} = m_1 l_{c1}^2 + m_2(l_1^2 + l_{c2}^2 + 2l_1 l_{c2}\cos(q_2^j)) + I_1 + I_2$, $D_{12} = D_{21} = m_2 l_1 l_{c2}\cos(q_2^j) + m_2 l_{c2}^2 + I_2$, $H_{22} = m_2 l_{c2}^2 + I_2$, $h = m_2 l_1 l_{c2}\sin(q_2^j)$. Here m_i, I_i, l_i and l_{c_i} represent mass, inertia, length of link i, and the distance from the previous joint to the center of mass of link i, respectively. In this simulation, $m_1 = 10$kg, $m_2 = 5$kg, $l_1 = 1$m, $l_2 = 0.5$m, $l_{c1} = 0.5$m, $l_{c2} = 0.25$m, $I_1 = 0.83$kg-m^2 and $I_2 = 0.3$kg-m^2. The control objective is to let $q^j = [q_1^j, q_2^j]^\top$ track the desired trajectory $q_d = [q_{d1}, q_{d2}]^\top = [\sin(t), \cos(t)]^\top$ as close as possible over a finite time interval $[0, 15]$ when only the angular position q^j is measurable. In this simulation, we set $\lambda = 10$, $\gamma_1 = \gamma_2 = 0.5$ and $\beta_1 = \beta_2 = 10$. In this simulation, we assume that the initial output for the first five iterations : $q^j(0) = [0.05, 0.3]^\top, [0.25, 0.8]^\top, [0.14, 0.6]^\top, [0.09, 0.4]^\top, [-0.1, 0.5]^\top$. Finally, we show the learning performance even there exist initial output error in Fig. 1. It is clear that the effectiveness of the proposed controller can be obtained by the simulation results.

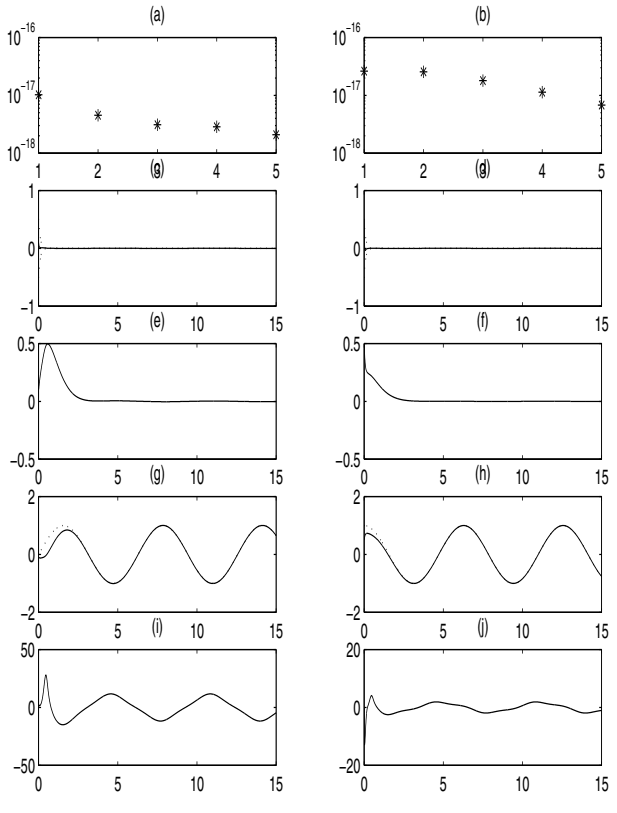

Fig. 1. (a) $\sup_{t\in[0,15]} |e_{\phi_1}^j(t)|$ versus iteration j; (b) $\sup_{t\in[0,15]} |e_{\phi_2}^j(t)|$ versus iteration j; (c) $e_{a_1}^5(t)$ (solid line) and $\pm\phi^5(t)$ (dotted lines) versus time t; (d) $e_{a_2}^5(t)$ (solid line) and $\pm\phi^5(t)$ (dotted lines) versus time t; (e) $e_1^5(t)$ (solid line) versus time t; (f) $e_2^5(t)$ (solid line) versus time t; (g) $q_1^5(t)$ (solid line) and $q_{d_1}(t)$ (dotted line) versus time t; (h) $q_2^5(t)$ (solid line) and $q_{d_2}((t)$ (dotted line) versus time t; (i) $u_1^5(t)$ versus time t; (j) $u_2^5(t)$ versus time t.

VI. Conclusion

An observer based AILC for repeated tracking control of uncertain robotic systems is proposed in this paper. Only joint positions are assumed to be measurable so that a tracking error observer is designed to estimate the unknown joint variables. An error observation dynamic based on the tracking error observer is derived for the design of the AILC. Using a technique of averaging filter, a fuzzy neural learning component based on a filtered FNN is used to approximate the unknown nonlinear function and a robust learning component is designed to compensate for the other uncertainties. Based on a Lyapunov like analysis, we show that all adjustable parameters and the internal signals inside the closed-loop system remain bounded and the output tracking error asymptotically converge to a tunable residual set as iteration goes to infinity.

***Abstract*—In this paper, a novel adaptive interval type-2 fuzzy sliding mode control (AITFSMC) is proposed to handle high level uncertainties facing the fuzzy logic controller (FLC) in dynamic fractional order chaotic systems such as uncertainties in inputs to the FLC, uncertainties in control outputs, linguistic uncertainties and uncertainties associated with the noisy training data. Based on the learning algorithm combining Lyapunov approach and sliding mode control, free parameters of the AITSMC can be tuned on line by output feedback control law and adaptive law to synchronize two different uncertain fractional order chaotic systems. Meanwhile, the chattering phenomena in the control efforts can be reduced. During the design procedure, not only the stability and robustness can be guaranteed but also the external disturbance on the synchronization error can be attenuated. The numerical simulation is performed to illustrate the effectiveness of the proposed control strategy.**

Keywords- Adaptive fuzzy, sliding mode control, fractional order, chaotic synchronization, Lyapuinov synthesis

I. INTRODUCTION

In recent years, dynamics described by fractional differential equations are becoming more and more popular as the underlying facts about the differentiation and integration is significantly different from the integer counterparts and beyond this, many real life systems are described better by fractional order differential equations. For instance, electrochemical processes and flexible structures are modeled by fractional order models [1]-[4], the behavior of some biological systems is explored using fractional calculus [5] and dielectric polarization, electromagnetic waves and viscoelastic systems are involved with fractional order operators. It is observed that the description of some systems is more accurate when the fractional derivative is used [6]-[7]. Nowadays, many fractional-order differential systems behave chaotically, such as the fractional-order Chua's system [8-9], the fractional-order Duffing system [10-11], the fractional-order Lu system [12], the fractional-order Chen's system [13-14], the fractional-order cellular neural network [15-16], and the fractional-order neural network [17].

Recently, synchronization of chaotic system is attractive in many applications such as power converters, biological systems, chemical reactions, information processing and secure communication. Over the past few years, fractional operators have been applied with satisfactory results in modeling and control of complex systems and synchronization of chaos has been investigated in many papers [18-20,40-42]. The algorithms based on active sliding mode controller employed to synchronize two different chaotic systems are proposed in [21]-[23]. However, there exists a chattering phenomenon implementing a sliding mode control (SMC), and this may excite high-frequency dynamics [24]-[26]. In order to eliminate chattering, Palm [27] noted the similarity between fuzzy controller and sliding mode controller with a boundary layer, and provided a fuzzy sliding mode design approach.

Although, type-1 fuzzy logic controllers (FLCs) have been successfully applied in many different applications, for dynamic unstructured environments and many real world applications, there is a need to cope with large amount of uncertainties such as uncertainties in inputs to the FLC, uncertainties in control outputs, linguistic uncertainties and uncertainties associated with the noisy training data. Type-2 FLCs have potential to overcome the limitations of type-1 FLCs and provide improved performance for many applications [32]-[36]. In this paper, a novel adaptive interval type-2 fuzzy sliding mode controller is developed to synchronize two different uncertain fractional order chaotic systems with high level uncertainties.

This paper is organized as follows: In section II, an introduction to fractional derivative and its relation to the approximation solution will be addressed. A brief of the interval type-2 fuzzy neural network (FNN) is presented in section III. Section IV generally proposes the employment of

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the AITFSMC for synchronizing the fractional order chaotic system in presence of uncertainty and its stability analysis. In Section V, application of the proposed method on fractional order expression of Duffing–Holmes chaotic system is investigated. Finally, the simulation results and conclusion will be presented in Section VI.

II. BASIC DEFINITION AND PRELIMINARIES FOR FRACTIONAL ORDER SYSTEMS

Fractional calculus is a mathematical topic more than 300 years. It is a generalization of integration and differentiation to non-integer order fundamental operator, denoted by ${}_aD_t^q$, where a and t are the limits of the operator. This operator is a notation for taking both the fractional integral and functional derivative in a single expression defined as

$$ {}_aD_t^q = \begin{cases} \dfrac{d^q}{dt^q}, & q > 0 \\ 1 & q = 0 \\ \displaystyle\int_a^t (d\tau)^{-q}, & q < 0 \end{cases} \tag{1} $$

There are some basic definitions of the general fractional integration and differentiation. The commonly used definitions are Grunwald-Letnikov and Riemann-Liouville. The Grunwald-Letnikov definition is expressed as

$$ {}_aD_t^q f(t) = \lim_{h\to 0} \sum_{j=0}^{\left[\frac{t-a}{h}\right]} (-1)^j \binom{q}{j} f(t-jh) \tag{2} $$

where $[\cdot]$ is the integer part. The simplest and easiest definition is Riemann-Liouville definition given as

$$ {}_aD_t^q f(t) = \frac{1}{\Gamma(n-q)} \frac{d^n}{dt^n} \int_0^t \frac{f(\tau)}{(t-\tau)^{q-n+1}} d\tau \tag{3} $$

where n is the first integer which is not less q, i.e., $n-1 < q < n$, and Γ is the Gamma function.

The numerical simulation of a fractional differential equation is not simple as that of an ordinary differential equation. In this paper, the algorithm which is an improved version of Adams–Bashforth–Moulton algorithm [28-30] to find an approximation for fractional order systems based on predictor-correctors [30-31] is given. Consider the following differential equation

$$ \begin{aligned} &{}_0D_t^q y(t) = r(y(t), t), \quad 0 \le t \le T \\ &\text{and } y^{(k)}(0) = y_0^{(k)}, k = 0, 1, 2, \cdots, m-1 \end{aligned} \tag{4} $$

where

$$ {}_0D_t^q y(t) = \begin{cases} \dfrac{1}{\Gamma(m-q)} \displaystyle\int_0^t \frac{f^{(m)}(\tau)}{(t-\tau)^{q-m+1}} d\tau, & m-1 < q < m \\ \dfrac{d^m}{dt^m} y(t) & q = m \end{cases} \tag{5} $$

and m is the first integer larger the q. The solution of the equation (4) is equivalent to Volterra integral equation [32] described as

$$ y(t) = \sum_{k=0}^{[q]-1} y_0^{(k)} \frac{t^k}{k!} + \frac{1}{\Gamma(q)} \int_0^t (t-\lambda)^{q-1} r(y(\lambda), \lambda) d\lambda \tag{6} $$

Let $h = T/N$, $t_n = nh$, $n = 0, 1, 2, \cdots N$. Then (6) can be discretized as follows.

$$ \begin{aligned} y_h(t_{n+1}) = &\sum_{k=0}^{[q]-1} y_0^{(k)} \frac{t_{n+1}^k}{k!} + \frac{h^q}{\Gamma(q+2)} r(y_h^p(t_{n+1}), t_{n+1}) \\ &+ \frac{h^q}{\Gamma(q+2)} \sum_{j=0}^{n} a_{j,n+1} r(y_h(t_j), t_j) \end{aligned} \tag{7} $$

where predicted value $y_h^p(t_{n+1})$ is determined by

$$ y_h^p(t_{n+1}) = \sum_{k=0}^{[q]-1} y_0^{(k)} \frac{t_{n+1}^k}{k!} + \frac{h^q}{\Gamma(q)} \sum_{j=0}^{n} b_{j,n+1} r(y_h(t_j), t_j) \tag{8} $$

and

$$ a_{j,n+1} = \begin{cases} n^{q+1} - (n-q)(n+1)^q, & j = 0 \\ (n-j+2)^{q+1} + (n-j)^{q+1} - 2(n-j+1)^{q+1} & 1 \le j \le n \\ 1 & j = n+1 \end{cases} \tag{9} $$

$$ b_{j,n+1} = \frac{h^q}{q} ((n+1-j)^q - (n-j)^q) \tag{10} $$

The approximation error is given as

$$ \max_{j=0,1,2,\cdots N} \left| y(t_j) - y_h(t_j) \right| = \mathrm{O}(h^p) \tag{11} $$

where $p = \min(2, 1+q)$. Therefore, the numerical solution of a fraction order system can be obtained by applying the above mentioned algorithm.

III. BRIEF DESCRIPTION OF INTERVAL TYPE-2 FNN [32]-[36]

In this section, we will describe the interval type-2 fuzzy set and the inference of type-2 fuzzy logic system which leads to interval type-2 fuzzy neural network (T2FNN). Due to the complexity of the type reduction, the general type-2 FLS becomes computationally intensive. In order to make things simpler and easier to compute meet and join operations, the secondary MFs of an interval type-2 FLS are all unity which leads finally to simplify type reduction. The 2-D interval type-2 Gaussian membership function (MF) with uncertain mean $m \in [m_1, m_2]$ and a fixed deviation σ is shown in Fig. 1.

$$ \mu_{\tilde{A}}(x) = \exp\left[-\frac{1}{2} \left(\frac{x-m}{\sigma} \right)^2 \right], \quad m \in [m_1, m_2] \tag{12} $$

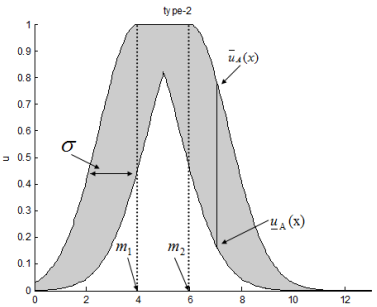

Figure 1. Interval type-2 fuzzy set with uncertain mean

It is obvious that the type-2 fuzzy set is in a region bounded by an upper MF and a lower MF denoted as $\overline{\mu}_{\tilde{A}}(x)$ and $\underline{\mu}_{\tilde{A}}(x)$, respectively, and is called a foot of uncertainty (FOU). In the meantime, the firing strength F^i for the ith rule can be an interval type-1 set [9] expressed as

$$F^i = \begin{bmatrix} \underline{f}^i \\ \overline{f}^i \end{bmatrix} \tag{13}$$

Where

$$\underline{f}^i = \underline{\mu}_{\tilde{F}_1^i}(x_1) * \cdots * \underline{\mu}_{\tilde{F}_n^i}(x_n) = \Pi_{j=1}^n \underline{\mu}_{\tilde{F}_j^i}(x_j) \tag{14}$$

$$\overline{f}^i = \overline{\mu}_{\tilde{F}_1^i}(x_1) * \cdots * \overline{\mu}_{\tilde{F}_n^i}(x_n) = \Pi_{j=1}^n \overline{\mu}_{\tilde{F}_j^i}(x_j) \tag{15}$$

Based on the center of sets type reduction, the defuzzified crisp output from an interval type-2 FLS is the average of y_l and y_r, i.e.,

$$y(\underline{x}) = \frac{y_l + y_r}{2} = \frac{1}{2}(\underline{\xi}_r^T \underline{\Theta}_r + \underline{\xi}_l^T \underline{\Theta}_l) = \frac{1}{2}\begin{bmatrix} \underline{\xi}_r^T & \underline{\xi}_l^T \end{bmatrix}\begin{bmatrix} \underline{\Theta}_r \\ \underline{\Theta}_l \end{bmatrix} = \underline{\xi}^T \underline{\Theta} \tag{16}$$

where $(1/2)[\underline{\xi}_r^T \ \underline{\xi}_l^T] = \underline{\xi}^T$ and $[\underline{\Theta}_r^T \ \underline{\Theta}_l^T] = \underline{\Theta}^T$.

where y_l and y_r are the left most and right most points of the interval type-1 set which can be obtained as

$$y_l = \frac{\sum_i^M f_l^i w_l^i}{\sum_i^M f_l^i} = \frac{\sum_{i=1}^L \overline{f}^i w_l^i + \sum_{i=L+1}^M \underline{f}^i w_l^i}{\sum_{i=1}^L \overline{f}^i + \sum_{i=L+1}^M \underline{f}^i} = \sum_{i=1}^L \underline{q}_l^i y_l^i + \sum_{i=L+1}^M \overline{q}_l^i y_l^i = [\underline{Q}_l \ \overline{Q}^l]\begin{bmatrix} \underline{y}_l \\ \overline{y}^l \end{bmatrix} = \underline{\xi}_l^T \underline{\Theta}_l \tag{17}$$

where $\underline{q}_l^i = \underline{f}^i / D_l$, $\overline{q}_l^i = \overline{f}^i / D_l$ and $D_l = (\sum_{i=1}^L \underline{f}^i + \sum_{i=L+1}^M \overline{f}^i)$. In the meantime, we have $\underline{Q}_l = [\underline{q}_l^1, \underline{q}_l^2, \cdots, \underline{q}_l^R]$, $\overline{Q}^l = [\overline{q}_l^1, \overline{q}_l^2, \cdots, \overline{q}_l^R]$, $\underline{\xi}_l^T = [\underline{Q}_l \ \overline{Q}^l]$ and $\underline{\Theta}_l^T = [\underline{y}_l \ \overline{y}^l]$.

and

$$y_r = \frac{\sum_i^M f_r^i w_r^i}{\sum_i^M f_r^i} = \frac{\sum_{i=1}^R \underline{f}^i w_r^i + \sum_{i=R+1}^M \overline{f}^i w_r^i}{\sum_{i=1}^R \underline{f}^i + \sum_{i=R+1}^M \overline{f}^i} = \sum_{i=1}^R \underline{q}_r^i y_r^i + \sum_{i=R+1}^M \overline{q}_r^i y_r^i = [\underline{Q}_r \ \overline{Q}^r]\begin{bmatrix} \underline{y}_r \\ \overline{y}^r \end{bmatrix} = \underline{\xi}_r^T \underline{\Theta}_r \tag{18}$$

where $\underline{q}_r^i = \underline{f}^i / D_r$, $\overline{q}_r^i = \overline{f}^i / D_r$ and $D_r = (\sum_{i=1}^R \underline{f}^i + \sum_{i=R+1}^M \overline{f}^i)$. In the meantime, we have $\underline{Q}_r = [\underline{q}_r^1, \underline{q}_r^2, \cdots, \underline{q}_r^R]$, $\overline{Q}^r = [\overline{q}_r^1, \overline{q}_r^2, \cdots, \overline{q}_r^R]$, $\underline{\xi}_r^T = [\underline{Q}_r \ \overline{Q}^r]$ and $\underline{\Theta}_r^T = [\underline{y}_r \ \overline{y}^r]$, and M is the total number of rules in the rule base of the RIT2FNN. The weighting factors w_l^i and w_r^j of the consequent part represent the centroid interval set of the consequent type-2 fuzzy set of the $i$the rule. In the meantime, R and L can be determined by using the iterative Karnik-Mendel procedure [32]-[36].

An interval T2FNN system which is an implementation of interval type-2 fuzzy logic system, and some of their parameters and components are presented by fuzzy logic terms, is shown in Fig. 2 [34]. The interval T2FNN is a four layers structure [34]. Layer I and layer II represent input nodes and type-2 fuzzification nodes, respectively, which form the antecedent part of this T2FNN. A classical 2-layer NN with fuzzy rule nodes and output nodes is used to construct layer III and layer IV, respectively, which compose the consequent part of this T2FNN. d_i , $i = 1 \sim z$ are reference signals.

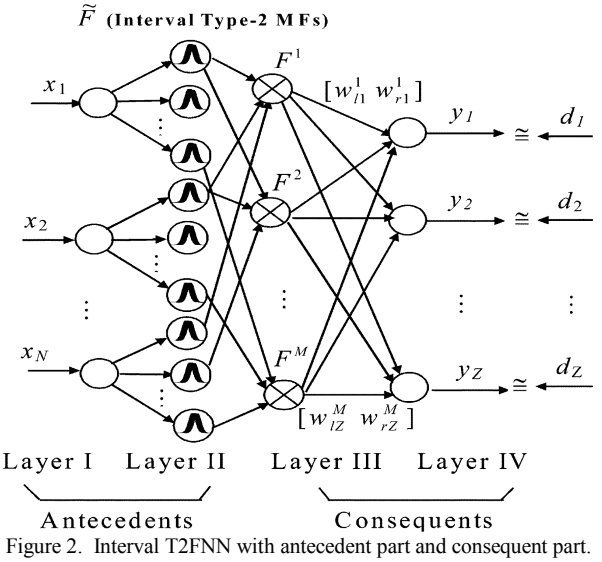

Figure 2. Interval T2FNN with antecedent part and consequent part.

IV. ADAPTIVE INTERVAL TYPE-2 FUZZY SLIDING MODEL SYNCHRONIZATION OF FRACTIONAL ORDER CHAOTIC SYSTEMS

Let's consider two chaotic systems with fractional order derivative, driven system and response system, as follows:

Driven system:

$$D^{(q)} x_1 = x_2$$
$$D^{(q)} x_2 = f(x,t) \tag{19}$$

Response system:

$$D^{(q)} y_1 = y_2$$
$$D^{(q)} y_2 = g(y,t) + u(t) + d(t) \tag{20}$$

where x_1, x_2, y_1 and y_2 are the state variables, $f(x,t)$ and $g(y,t)$ are unknown but bounded nonlinear functions which express system dynamics, $d(t)$ is the external bounded disturbance and $u(t)$ is the control input of the response system. The control objective to synchronize both driven and response systems by designing a nonlinear controller which obtains signals from driven system to tune behavior of the response system.

The synchronization error vector is defined as

$$e = [e_1, e_2] \tag{21}$$

where $e_i = y_i - x_i$. Then, in the space of the synchronization error, sliding surface is given by

$$S(t) = k_1 e_1 + k_2 e_2 \tag{22}$$

where k_1, k_2 are arbitrary constants which are chosen such that dynamic of the sliding surface vanished quickly. The process can be classified into two phases, approaching phase with $S(t) \neq 0$ and sliding phase with $S(t) = 0$. In order to guarantee the trajectory of the synchronization error vector *e* will move from approaching phase to sliding phase, a sufficient condition to is to design the control effort such that sliding condition

$$S(t)\dot{S}(t) \leq -\eta |S(t)|, \quad \eta > 0 \tag{23}$$

is satisfied. We have $S(t) = 0$ and $\dot{S}(t) = 0$ in the sliding phase, if $f(x,t)$ and $g(x,t)$ are known and free of external disturbance, $d(t) = 0$, the corresponding equivalent control effort u_{eq} to force the system dynamics to stay on the sliding surface can be derived from $\dot{S}(t) = 0$.

$$\dot{S}(t) = D^{(1-q)}(D^{(q)}(S(t))) = 0 \rightarrow D^{(q)}(S(t)) = 0 \tag{24}$$

Substituting (22) into (24), we have

$$\begin{aligned} D^{(q)}(S(t)) &= D^{(q)}(k_1 e_1 + k_2 e_2) = k_1 D^{(q)} e_1 + k_2 D^{(q)} e_2 \\ &= k_1 D^{(q)}(y_1 - x_1) + k_2 D^{(q)}(y_2 - x_2) \\ &= k_1 (y_2 - x_2) + k_2 [g(y,t) - f(x,t) + u_{eq}(t)] \\ &= k_1 e_2 + k_2 [g(y,t) - f(x,t) + u_{eq}(t)] = 0 \end{aligned}$$

Then the equivalent control effort can be obtained as

$$u_{eq}(t) = -\frac{k_1}{k_2} e_2 + f(x,t) - g(y,t) \tag{25}$$

During the approaching phase, in order to satisfy the sliding condition (23), a switching control action $u_{sw} = \eta_{sw} \operatorname{sgn}(S(t))$ must be included in the complete sliding control which can be expressed as

$$\begin{aligned} u(t) &= u_{eq}(t) - \eta_{sw} \operatorname{sgn}(S(t)) \\ &= -\frac{k_1}{k_2} e_2 + f(x,t) - g(y,t) - \eta_{sw} \operatorname{sgn}(S(t)) \end{aligned} \tag{26}$$

where η_{sw} i is a positive constant such the approaching condition can be guaranteed for,

$$\eta_{sw} > \left| D^{1-q} d(t) \right| + \left| D^{1-q} \omega \right| \tag{27}$$

where ω is the minimum approximation error, $|d(t)|$ and $|\omega|$ are assumed to be bounded.

However, $f(x,t)$ and $g(x,t)$ are unknown and external disturbance, $d(t) \neq 0$, the ideal control effort (23) cannot be implemented. We replace $f(x,t)$ and $g(x,t)$ by the interval type-2 fuzzy logic system $f(x|\underline{\theta}_f)$ and $g(y|\underline{\theta}_g)$, respectively, in specified form as (16), i.e.,

$$\begin{aligned} f(x|\underline{\theta}_f) &= \frac{1}{2}\left(\underline{\theta}_{fr}^T \underline{\xi}_r(x) + \underline{\theta}_{fl}^T \underline{\xi}_l(x)\right) = \underline{\theta}_f^T \underline{\xi}(x), \\ g(x|\underline{\theta}_g) &= \frac{1}{2}\left(\underline{\theta}_{gr}^T \underline{\xi}_r(y) + \underline{\theta}_{gl}^T \underline{\xi}_l(y)\right) = \underline{\theta}_g^T \underline{\xi}(y) \end{aligned} \tag{28}$$

where $\underline{\theta}_f^T = [\underline{\theta}_{fr}\ \underline{\theta}_{fl}]^T$ and $\underline{\theta}_g^T = [\underline{\theta}_{gr}\ \underline{\theta}_{gl}]^T$. Here the parameters $\underline{\xi}_r(x)$, $\underline{\xi}_l(x)$, $\underline{\xi}_r(y)$ and $\underline{\xi}_l(y)$ depend on the fuzzy membership functions and are supposed to be fixed, while $\underline{\theta}_{fr}^T$, $\underline{\theta}_{fl}^T$, $\underline{\theta}_{gr}^T$ and $\underline{\theta}_{gl}^T$ are adjusted by adaptive laws based on Lyapunov stability criterion. Therefore, the resulting control effort can be obtained as

$$u(t) = -\frac{k_1}{k_2} e_2 + f(x|\underline{\theta}_f) - g(y|\underline{\theta}_g) - \eta_{sw} \operatorname{sgn}(S(t)) \tag{29}$$

Following the proceeding consideration, the following theorem can be obtained.

Theorem: Consider the two fractional order chaotic systems, driven system (16) and response system (17), the control effort of the response system is given in (26) and the fuzzy-based adaptive laws are chosen as

$$D^{(q)} \underline{\theta}_{fr} = -\frac{1}{2} r_1 S(t) \underline{\xi}_r(x) \tag{30}$$

$$D^{(q)} \underline{\theta}_{fl} = -\frac{1}{2} r_2 S(t) \underline{\xi}_l(x) \tag{31}$$

$$D^{(q)} \underline{\theta}_{gr} = \frac{1}{2} r_3 S(t) \underline{\xi}_r(y) \tag{32}$$

$$D^{(q)} \underline{\theta}_{gl} = \frac{1}{2} r_4 S(t) \underline{\xi}_l(y) \tag{33}$$

Then, the overall adaptive scheme guarantees the global stability of the resulting closed-loop system in the sense that all signals involved are uniformly bounded and the synchronization error will converge to zero asymptotically.

Proof: The optimal parameter estimations $\underline{\theta}_f^*$ and $\underline{\theta}_g^*$ are defined as

$$\underline{\theta}_f^* = \arg\min_{\underline{\theta}_f \in \Omega_f} \left[\sup_{x \in \Omega_x} |f(x|\underline{\theta}_f) - f(x,t)| \right] \tag{34}$$

$$\underline{\theta}_g^* = \arg\min_{\underline{\theta}_g \in \Omega g} \left[\sup_{y \in \Omega_y} |g(y|\underline{\theta}_g) - g(y,t)| \right] \tag{35}$$

where Ω_f, Ω_g, Ω_y and Ω_x are constraint sets of suitable bounds on $\underline{\theta}_f$, $\underline{\theta}_g$, y and x respectively and they are defined as $\Omega_f = \{\underline{\theta}_f \,|\, |\underline{\theta}_f| \leq M_f\}$, $\Omega_g = \{\underline{\theta}_g \,|\, |\underline{\theta}_g| \leq M_g\}$, $\Omega_y = \{y \,|\, |y| \leq M_y\}$ and $\Omega_x = \{x \,|\, |x| \leq M_x\}$, where M_f, M_g, M_y and M_x are positive constants. Then, we have

$$\begin{aligned} D^{(q)}(S(t)) &= D^{(q)}(k_1 e_1 + k_2 e_2) = k_1 D^{(q)} e_1 + k_2 D^{(q)} e_2 \\ &= k_1 e_2 + k_2 [g(y,t) - f(x,t) + u(t) + d(t)] \\ &= k_1 e_2 + k_2 \{[g(y,t) - f(x,t)] + [-\frac{k_1}{k_2} e_2 + f(x|\underline{\theta}_f) \\ &\quad - g(y|\underline{\theta}_g) - \eta_{sw} \operatorname{sgn}(S(t))] + d(t)\} \\ &= k_2 \{\frac{1}{2}[(\underline{\theta}_{gr}^* - \underline{\theta}_{gr})^T \underline{\xi}_r(y) + (\underline{\theta}_{gl}^* - \underline{\theta}_{gl})^T \underline{\xi}_l(y) - (\underline{\theta}_{fr}^* - \underline{\theta}_{fr})^T \underline{\xi}_r(x) \\ &\quad - (\underline{\theta}_{fl}^* - \underline{\theta}_{fl})^T] \underline{\xi}_l(x)\} - k_2 [\eta_{sw}(\operatorname{sgn}(S(t)) - d(t) - \omega] \end{aligned}$$

$$= k_2 \frac{1}{2}[\tilde{\underline{\theta}}_{gr}^T \xi_r(y) + \tilde{\underline{\theta}}_{gl}^T \xi_l(y) - \tilde{\underline{\theta}}_{fr}^T \xi_r(x) - \tilde{\underline{\theta}}_{fr}^T \xi_r(x)] - k_2[\eta_{sw}\,\mathrm{sgn}(S(t)) - d(t) - \omega] \quad (36)$$

where $\tilde{\underline{\theta}}_{fr} = \underline{\theta}_{fr}^* - \underline{\theta}_{fr}$, $\tilde{\underline{\theta}}_{fl} = \underline{\theta}_{fl}^* - \underline{\theta}_{fl}$, $\tilde{\underline{\theta}}_{gr} = \underline{\theta}_{gr}^* - \underline{\theta}_{gr}$, $\tilde{\underline{\theta}}_{gl} = \underline{\theta}_{gl}^* - \underline{\theta}_{gl}$ and the minimum approximation error is

$$\omega = [g(y,t) - g(y|\underline{\theta}^*{}_g)] - [f(x,t) - f(x|\underline{\theta}^*{}_f)] \quad (37)$$

Now consider the Lyapunov function candidate

$$V = \frac{1}{2}S^2(t) + \frac{k_2}{2r_1}\tilde{\underline{\theta}}_{fr}^T\tilde{\underline{\theta}}_{fr} + \frac{k_2}{2r_2}\tilde{\underline{\theta}}_{fl}^T\tilde{\underline{\theta}}_{fl} + \frac{k_2}{2r_3}\tilde{\underline{\theta}}_{gr}^T\tilde{\underline{\theta}}_{gr} + \frac{k_2}{2r_4}\tilde{\underline{\theta}}_{gl}^T\tilde{\underline{\theta}}_{gl} \quad (38)$$

where r_1, r_2, r_3 and r_4 are positive constants. Taking the derivative of the (38) with respect to time, we get

$$\begin{aligned} V^{(q)} &= S(t)S^{(q)}(t) + \frac{k_2}{r_1}(D^{(q)}\tilde{\underline{\theta}}_{fr}^T)(\tilde{\underline{\theta}}_{fr}) + \frac{k_2}{r_2}(D^{(q)}\tilde{\underline{\theta}}_{fl}^T)(\tilde{\underline{\theta}}_{fl}) \\ &\quad + \frac{k_2}{r_3}(D^{(q)}\tilde{\underline{\theta}}_{gr}^T)(\tilde{\underline{\theta}}_{gr}) + \frac{k_2}{r_4}(D^{(q)}\tilde{\underline{\theta}}_{gl}^T)(\tilde{\underline{\theta}}_{gl}) \\ &= S(t)k_2\frac{1}{2}[\tilde{\underline{\theta}}_{gr}^T\xi_r(y) + \tilde{\underline{\theta}}_{gl}^T\xi_l(y) - \tilde{\underline{\theta}}_{fr}^T\xi_r(x) - \tilde{\underline{\theta}}_{fr}^T\xi_r(x)] \\ &\quad - k_2[\eta_{sw}\,\mathrm{sgn}(S(t)) - d(t) - \omega] + \frac{k_2}{r_1}(D^{(q)}\tilde{\underline{\theta}}_{fr}^T)(\tilde{\underline{\theta}}_{fr}) \\ &\quad + \frac{k_2}{r_2}(D^{(q)}\tilde{\underline{\theta}}_{fl}^T)(\tilde{\underline{\theta}}_{fl}) + \frac{k_2}{r_3}(D^{(q)}\tilde{\underline{\theta}}_{gr}^T)(\tilde{\underline{\theta}}_{gr}) + \frac{k_2}{r_4}(D^{(q)}\tilde{\underline{\theta}}_{gl}^T)(\tilde{\underline{\theta}}_{gl}) \\ &= k_2\tilde{\underline{\theta}}_{gr}^T[\frac{1}{2}S(t)\xi_r(y) + \frac{1}{r_3}(D^{(q)}\tilde{\underline{\theta}}_{gr})] + k_2(\tilde{\underline{\theta}}_{gl}^T)[\frac{1}{2}S(t)\xi_l(y) \\ &\quad + \frac{1}{r_4}(D^{(q)}\tilde{\underline{\theta}}_{gl})] - k_2\tilde{\underline{\theta}}_{fr}^T[\frac{1}{2}S(t)\xi_r(x) - \frac{1}{r_1}(D^{(q)}\tilde{\underline{\theta}}_{fr})] \\ &\quad - k_2(\tilde{\underline{\theta}}_{fl}^T)[\frac{1}{2}S(t)\xi_l(x) - \frac{1}{r_2}(D^{(q)}\tilde{\underline{\theta}}_{fl})] \\ &\quad - k_2\eta_{sw}|S(t)| + k_2S(t)d(t) + k_2S(t)\omega \end{aligned} \quad (39)$$

Substituting (30)-(33) into (39) and using (27), we have

$$\begin{aligned} V^{(q)} &\le -k_2\{\eta_{sw}|S(t)| - |S(t)||d(t)| - |S(t)||\omega|\} \\ &= -k_2|S(t)|\{\eta_{sw} - |d(t)| - |\omega|\} < 0 \end{aligned} \quad (40)$$

The existence of adaptive fuzzy sliding mode dynamics is confirmed by (40) and the closed-loop system is globally asymptotically stable. The proof is completed.

V. Simulation Example

In this section, we will apply our adaptive interval type-2 fuzzy sliding model controller to synchronize two different uncertain fractional order Duffing-Holmes chaotic systems, the drive system and the response system.

Example: Let us consider two different uncertain fractional order Duffing-Holmes chaotic systems, the drive system and the response system, as follows [37]:

Drive system:

$$\begin{cases} D^{(q)}x_1 = 2.2x_2 \\ D^{(q)}x_2 = -0.40x_1^3 - 0.40x_1 - 0.10x_2 + 22\cos(1.29t) \end{cases} \quad (41)$$

Response system

$$\begin{cases} D^{(q)}y_1 = 2.2y_2 \\ D^{(q)}y_2 = -0.55y_1^3 - 0.30y_1 - 0.20y_2 + 18\cos(1.29t) + u(t) + d(t) \end{cases} \quad (42)$$

The external disturbance is $d(t) = 0.5\sin(t)$. The initial conditions of drive and response systems are chosen as: $\begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$ and $\begin{bmatrix} y_1(0) \\ y_2(0) \end{bmatrix} = \begin{bmatrix} -1 \\ -2 \end{bmatrix}$, respectively. All design constants are selected as, k_1=0.2, k_2=1, r_1=60, r_2=2, r_3=60, $r4$=4, $\eta_{sw} = 1$ and step size h=0.002. The values of $q = 0.98$ is considered.

For free of control input, the 3-D phase portrait of the drive and response systems is given in Figure. 3. It is obvious that both systems are not synchronized without control effort added in response system.

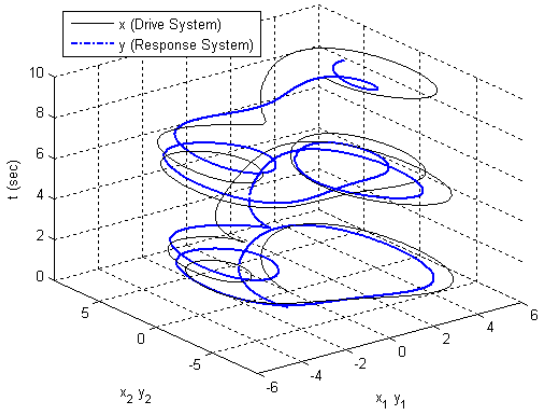

Figure 3. 3-D Phase portrait of chaotic drive and response systems.

From the adaptive laws (30)-(33), the control effort of the response system is given by

$$u(t) = -\frac{k_1}{k_2}e_2 + f(x|\underline{\theta}_f) - g(y|\underline{\theta}_g) - \eta_{sw}\,\mathrm{sgn}(S(t)) \quad (43)$$

The simulation results of both adaptive type-1 FNN SMC and adaptive interval type-2 FNN SMC are listed as follows: Figure 4 and Figure 5 show the trajectories of the states x_1, y_1 and x_2, y_2, respectively. Control effort trajectory is given in Figure 6 and 3-D phase portrait, synchronization performance, of the drive and response systems is shown in Figure 7. Sliding surface trajectory, *S*(t), is given in Figure 8. Figure 9 shows the graph of $V^{(q)}(t)$ which is always negative defined and consequently is stable.

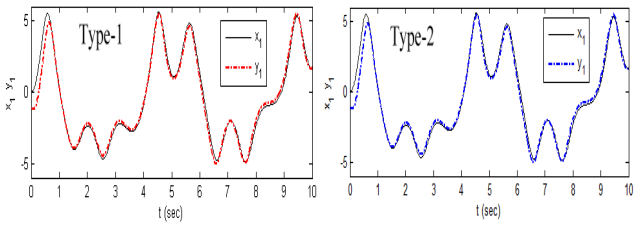

Figure 4. The trajectories of the states x_1 and y_1 .

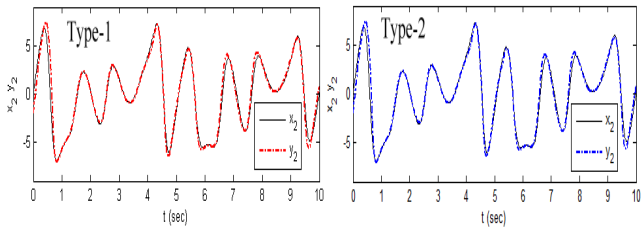

Figure 5. The trajectories of the states x_2 and y_2.

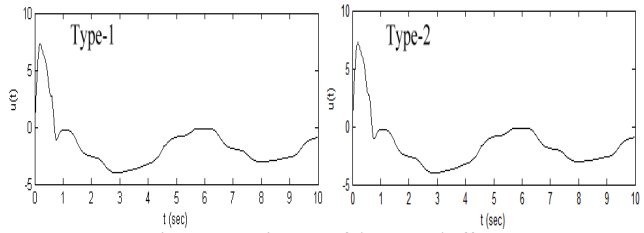

Figure 6. Trajectory of the control effort.

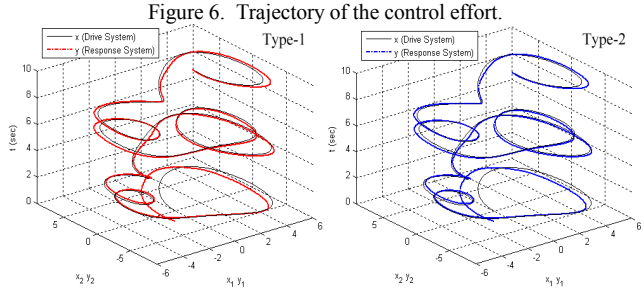

Figure 7. 3-D Phase portrait, synchronization performance, of the drive and response systems.

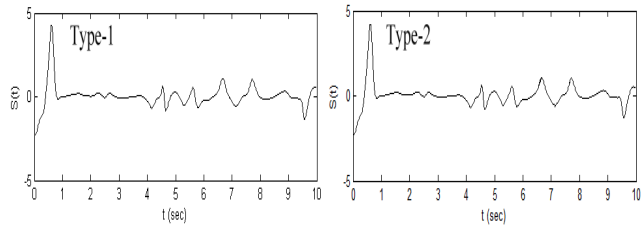

Figure 8. Sliding surface trajectory , S(t).

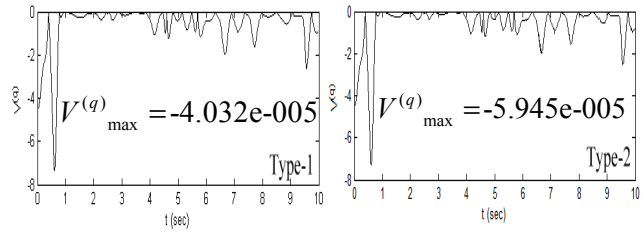

Figure 9. The graph of $V^{(q)}(t)$.

In order to show that the interval type-2 FLS can handle the measurement uncertainties, training data are corrupted by white Gaussian noise with signal-to-noise ratio (SNR) 20 dB. The trajectories of the states x_1, y_1 and x_2, y_2, respectively, are given in Figure 10 and Figure 11. Figure 12 show the control effort trajectory and 3-D phase portrait, synchronization performance, of the drive and response systems is shown in Figure 13. Sliding surface trajectory, S(t), is given in Figure 14. Figure 15 shows the graph of $V^{(q)}(t)$ which is always negative defined and consequently is stable.

VI. CONCLUSIONS

In this paper adaptive interval type-2 FNN SMC is proposed to deal with chaos synchronization between two different uncertain fractional order chaotic systems with linguistic uncertainties and internal noise. During the process of design, the free parameters of the adaptive fuzzy controller can be tuned on line by output feedback control law and adaptive law by using Lyapunov synthesis approach, and the chattering phenomena in the control efforts can be reduced. The simulation example, chaos synchronization of two different fractional order Duffing-Holmes chaotic systems, is given to demonstrate that interval type-2 FLC can overcome the limitations of type-1 FLC in high uncertain environments. The significance of the adaptive fuzzy sliding model control in the simulations for different values of q is manifest. Simulation results show that a fast synchronization of drive and response systems can be achieved and q is reduced the chaos is seen reduced, i.e., the synchronization error is reduced, accordingly.

***Abstract*—In this paper, an adaptive hybrid fuzzy neural network (FNN) controller is proposed to achieve prescribed tracking performance of fractional order chaotic systems. Based on the trade-off between plant knowledge and control knowledge, a weighting factor can be adjusted by combining the indirect adaptive FNN control effort and the direct FNN adaptive control effort. Nonlinear fractional order chaotic response system is fully illustrated to track the trajectory generated from fractional order chaotic drive system. The numerical results show that tracking error and control effort can be made smaller and the proposed hybrid intelligent control scheme is more flexible during the design process.**

Keywords- Fractional order chaotic systems; fuzzy neural network (FNN), adaptive hybrid control.

I. INTRODUCTION

In recent years, fractional calculus deals with derivatives and integrations of arbitrary order [30]-[32] and numerous applications of fractional order systems in many areas of science and engineering have been proposed such as control theory, electromagnetic waves, viscoelastic systems, diffusion signal processing and bio-engineering [33]-[36]. It is observed that the description of some systems is more accurate when the fractional derivative is used. Nowadays, many fractional-order differential systems behave chaotically, such as the fractional-order Chua's system [37], [38], the fractional-order Duffing system [39], [40], the fractional-order Lu system [41], the fractional-order Chen's system [42], [43], the fractional-order cellular neural network [15]-[16], the fractional-order neural network [17].

Owing to its potential applications in secure communication and control processing [18], study of chaos tracking, synchronization, in fractional order dynamical systems and related phenomena is receiving growing attention [19], [20]. The tracking problem of fractional order chaotic systems is first investigated by Deng and Li [21] who carried out tracking in case of the two fractional Lü systems. Afterwards, they studied chaos tracking of the Chen system with a fractional order in a different manner [22]-[24].

Furthermore, the advent of fuzzy set techniques provides us with a powerful tool to solve demanding real word problem with uncertain and unpredictable environments. Based on the universal approximation theorem, [1]-[5] (fuzzy logic controllers are general enough to perform any nonlinear control actions) there is rapidly growing interest in systematic design methodologies for a class of nonlinear systems using fuzzy adaptive control schemes. By equipping with a training algorithm an adaptive fuzzy controller is synthesized from a collection of fuzzy IF-THEN rules and the parameters of the membership functions characterizing the linguistic terms in the IF-THEN rules changed according to some adaptive law for the purpose of controlling a plant to track a reference trajectory.

Like the conventional adaptive control, the adaptive FNN control is classified into direct and indirect FNN adaptive control categories [27]-[29]. A direct adaptive FNN controller uses fuzzy logic systems as controller in which linguistic fuzzy control rules can be directly incorporated into the controller. On the other hand, an indirect adaptive FNN controller uses fuzzy descriptions to model the plant in which fuzzy IF-THEN rules describing the plant can be directly incorporated into the indirect FNN controller. Moreover, a hybrid adaptive FNN controller can be constructed using a weighting factor to sum together the control efforts from indirect adaptive FNN controller and direct adaptive FNN controller [44],[45].

In this paper, by combining the approximate mathematical model, linguistic model description and linguistic control rules into a single adaptive FNN controller, an adaptive hybrid fuzzy neural network (FNN) controller is proposed to achieve prescribed tracking performance of fractional order chaotic systems. A new adaptive H^{∞} fuzzy control algorithm

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

incorporated Lyapunov stability criterion is proposed so that not only the stability of adaptive fuzzy control system is guaranteed but also the influence of the approximation error and external disturbance on the tracking error can be attenuated to an arbitrarily prescribed level.

This paper is organized as follows: In section II, an introduction to fractional derivative and its relation to the approximation solution will be addressed. A brief description of the fuzzy neural networks is presented in section III. Section IV generally proposes adaptive hybrid FNN control of uncertain fractional order systems in presence of uncertainty and its stability analysis. In Section V, application of the proposed method on fractional order expression chaotic system is investigated. Finally, the simulation results and conclusion will be presented in Section VI.

II. BASIC DEFINITION AND PRELIMINARIES FOR FRACTIONAL ORDER SYSTEMS

The fractional calculus has been known more than 300 years, since the development of regular calculus. It is a generalization of integration and differentiation to non-integer order fundamental operator, denoted by ${}_aD_t^q$, where a and t are the limits of the operator. This operator is a notation for taking both the fractional integral and functional derivative in a single expression defined as

$$ {}_aD_t^q = \begin{cases} \dfrac{d^q}{dt^q}, & q > 0 \\ 1 & q = 0 \\ \int_a^t (d\tau)^{-q}, & q < 0 \end{cases} \tag{1} $$

There are some basic definitions for the general fractional and the commonly used definitions are Grunwald-Letnikov and Riemann-Liouville. The Grunwald-Letnikov definition is expressed as

$$ {}_aD_t^q f(t) = \lim_{h\to 0} \sum_{j=0}^{\left[\frac{t-a}{h}\right]} (-1)^j \binom{q}{j} f(t-jh) \tag{2} $$

where $[\cdot]$ is the integer part. The simplest and easiest definition is Riemann-Liouville definition given as

$$ {}_aD_t^q f(t) = \frac{1}{\Gamma(n-q)} \frac{d^n}{dt^n} \int_0^t \frac{f(\tau)}{(t-\tau)^{q-n+1}} d\tau \tag{3} $$

where n is the first integer which is not less q, i.e., $n-1 < q < n$, and Γ is the Gamma function.

The numerical simulation of a fractional differential equation is not simple as that of an ordinary differential equation. In this paper, the algorithm which is an improved version of Adams–Bashforth–Moulton algorithm [12]-[13] to find an approximation for fractional order systems based on predictor-correctors [12], [14] is given. Consider the following differential equation

$$ {}_0D_t^q y(t) = r(y(t),t), \quad 0 \le t \le T \quad \text{and } y^{(k)}(0) = y_0^{(k)}, k = 0,1,2,\cdots,m-1 \tag{4} $$

where

$$ {}_0D_t^q y(t) = \begin{cases} \dfrac{1}{\Gamma(m-q)} \int_0^t \dfrac{f^{(m)}(\tau)}{(t-\tau)^{q-m+1}} d\tau, & m-1 < q < m \\ \dfrac{d^m}{dt^m} y(t) & q = m \end{cases} \tag{5} $$

and is the first integer larger the q. The solution of the equation (4) is equivalent to Volterra integral equation [34] described as

$$ y(t) = \sum_{k=0}^{[q]-1} y_0^{(k)} \frac{t^k}{k!} + \frac{1}{\Gamma(q)} \int_0^t (t-\lambda)^{q-1} r(y(\lambda),\lambda) d\lambda \tag{6} $$

Let $h = T/N$, $t_n = nh$, $n = 0,1,2,\cdots N$. Then (6) can be discretized as follows.

$$ y_h(t_{n+1}) = \sum_{k=0}^{[q]-1} y_0^{(k)} \frac{t_{n+1}^k}{k!} + \frac{h^q}{\Gamma(q+2)} r(y_h^p(t_{n+1}),t_{n+1}) + \frac{h^q}{\Gamma(q+2)} \sum_{j=0}^{n} a_{j,n+1} r(y_h(t_j),t_j) \tag{7} $$

where predict value $y_h^p(t_{n+1})$ is determined by

$$ y_h^p(t_{n+1}) = \sum_{k=0}^{[q]-1} y_0^{(k)} \frac{t_{n+1}^k}{k!} + \frac{h^q}{\Gamma(q)} \sum_{j=0}^{n} b_{j,n+1} r(y_h(t_j),t_j) \tag{8} $$

and

$$ a_{j,n+1} = \begin{cases} n^{q+1} - (n-q)(n+1)^q, & j = 0 \\ (n-j+2)^{q+1} + (n-j)^{q+1} - 2(n-j+1)^{q+1} & 1 \le j \le n \\ 1 & j = n+1 \end{cases} \tag{9} $$

$$ b_{j,n+1} = \frac{h^q}{q} ((n+1-j)^q - (n-j)^q) \tag{10} $$

The approximation error is given as

$$ \max_{j=0,1,2,\cdots N} \left| y(t_j) - y_h(t_j) \right| = \mathrm{O}(h^p) \tag{11} $$

where $p = \min(2, 1+q)$. Therefore, the numerical solution of a fraction order system can be obtained by applying the above mentioned algorithm.

III. A BRIEF DESCRIPTION OF THE FUZZY NEURAL NETWORKS [6]-[9], [25]

Fuzzy logic systems are knowledge-based or rule-based systems which consist of so called fuzzy IF-THEN rules. The basic configuration the T-S FNN system includes a fuzzy rule base, which comprises of a collection of fuzzy IF-THEN rules in the following form:

$$ R^{(l)}: \text{ IF } x_1 \text{ is } F_1^l, \text{ and } \cdots, \text{ and } x_n \text{ is } F_n^l, \text{THEN } y_l = q_0^l + q_1^l x_1 + \cdots + q_n^l x_n = \underline{\theta}_l^T [1\ \underline{x}^T]^T \tag{12} $$

where F_i^l are fuzzy sets and $\underline{\theta}_l^T = [q_0^l, q_1^l, \cdots, q_n^l]$ is a vector of the adjustable weight factors of the consequence part of the fuzzy rule. Also y_l is a fuzzy inference engine to combine the fuzzy IF-THEN rules in the fuzzy rule base into a mapping from an input linguistic vector $\underline{x}^T = [x_1, x_2, \cdots, x_n] \in R^n$ to an output variable $y \in R$. Let M be the number of the fuzzy IF-THEN rules. The output of the fuzzy logic systems with central average defuzzifier, product inference and singleton fuzzifier can be expressed as

$$ y(\underline{x}) = \frac{\sum_{l=1}^{M} \phi^l \cdot y_l}{\sum_{l=1}^{M} \phi^l} = \frac{\sum_{l=1}^{M} \phi^l \cdot \underline{\theta}_l^T [1\ \underline{x}^T]}{\sum_{l=1}^{M} \phi^l} \tag{13} $$

where $\mu_{F_i^l(x_i)}$ is the membership function value of the fuzzy variable x_i and $\phi^l = \prod_{i=1}^{n} \mu_{F_i^l(x_i)}$ is the true value of the l^{th} implication. Equation (13) can be rewritten as

$$y(\underline{x}) = \underline{\theta}^T \underline{\psi}(\underline{x}) \quad (14)$$

where $\underline{\theta}^T = \left[\underline{\theta}_1^T \ \underline{\theta}_2^T \ \cdots \ \underline{\theta}_M^T\right]$ is an adjustable parameter vector and $\underline{\psi}^T(\underline{x}) = [\psi^1(\underline{x}), \psi^2(\underline{x}), \cdots, \psi^M(\underline{x})]$ is a fuzzy basis function vector defined as

$$\psi^l(\underline{x}) = \frac{\phi^l[1 \ \underline{x}^T]}{\sum_{l=1}^{M} \phi^l} \quad (15)$$

When the inputs are fed into the T-S FNN, the true value υ^l of the lth implication is computed. Applying the common defuzzification strategy, the output of the neural networks expressed as (13) is pumped out. The overall configuration of the T-S FNN is shown in Fig.1 [27]-[29].

Based on the universal approximation theorem [26], the above fuzzy logic system is capable of uniformly approximating any well-defined nonlinear function over a compact set U_c to any degree of accuracy. Also it is straightforward to show that a multi-output system can always be approximated by a group of single-output approximation systems.

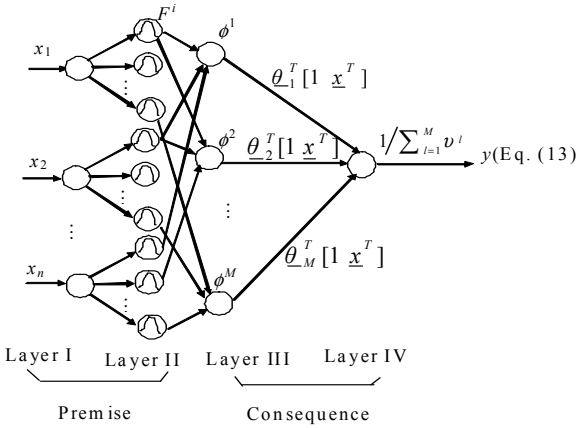

Figure1 The configuration of the T-S fuzzy-neural networks.

IV. Adaptive Hybrid Fuzzy H^∞ Tracking Control of Uncertain Fractional Order Chaotic Systems

In this section, we study adaptive H^∞ tracking control of uncertain fractional order chaotic systems, i.e., to force output trajectory of the response system to track output trajectory of the drive system.

Consider a fractional order chaotic dynamic system

$$\begin{aligned} x^{(nq)} &= f(\underline{x},t) + g(\underline{x},t)u + d(t) \\ y &= x_1 \end{aligned} \quad (16)$$

where $\underline{x} = [x_1, x_2, \cdots, x_n]^T = [x, x^{(q)}, x^{(2q)}, \cdots, x^{((n-1)q)}]^T$ is the state vector, $f(\underline{x},t)$ and $g(\underline{x},t)$ are unknown but bounded nonlinear functions which express system dynamics, $d(t)$ is the external bounded disturbance and $u(t)$ is the control input. The control objective is to force the system output y to follow a bounded reference signal y_d which is the output trajectory of a drive system, under the constraint that all signals involved must be bounded. To begin with, the reference signal vector $\underline{y}_d$ and the tracking error vector $\underline{e}$ will be defined as

$$\underline{y}_d = \left[y_d, y_d^{(q)}, \cdots, y_d^{((n-1)q)}\right]^T \in R^n,$$
$$\underline{e} = \underline{y}_d - \underline{x} = [e, e^{(q)}, e^{(2q)}, \cdots, e^{((n-1)q)}]^T \in R^n, e^{(iq)} = y_d^{(iq)} - x^{(iq)} = y_d^{(iq)} - y^{(iq)}$$

Let $\underline{k} = \left[k_1, k_2, \cdots, k_n\right]^T \in R^n$ to be chosen such that $p(s) = s^{(nq)} + k_n s^{(n-1)q} + \cdots + k_1$ is a Hurwitz polynomial. If the functions $f(\underline{x},t)$ and $g(\underline{x},t)$ are known and the system is free of external disturbance d, then control law of the certainty equivalent controller is obtained as [38]

$$\bar{u} = \frac{1}{g(\underline{x},t)}\left(-f(\underline{x},t) + y_d^{(nq)} + \underline{k}^T \underline{e}\right) \quad (17)$$

Substituting (17) into (16), we have [30]

$$e^{(nq)} + k_n e^{(n-1)q} + \cdots + k_1 e = 0$$

which is the main objective of control, $\lim_{t\to\infty} e(t) = 0$.

However, $f(\underline{x},t)$ and $g(\underline{x},t)$ are unknown and external disturbance, $d(t) \neq 0$, the ideal control effort (17) cannot be implemented. We replace $f(\underline{x},t)$ and $g(\underline{x},t)$ by the fuzzy logic system $f(\underline{x}|\underline{\theta}_f)$ and $g(\underline{y}|\underline{\theta}_g)$ in specified form as (14), i.e.,

$$f(\underline{x}|\underline{\theta}_f) = \xi^T(\underline{x})\underline{\theta}_f, \quad g(\underline{x}|\underline{\theta}_g) = \xi^T(\underline{x})\underline{\theta}_g \quad (18)$$

Here the fuzzy basis function $\xi(\underline{x})$ depends on the fuzzy membership functions and is supposed to be fixed, while $\underline{\theta}_f$ and $\underline{\theta}_g$ are adjusted by adaptive laws based on Lyapunov stability criterion.

However, depending on plant knowledge and control knowledge, a hybrid adaptive FNN controller can be constructed by incorporating both fuzzy description and fuzzy control rules using a weighting factor α to combine the indirect adaptive FNN controller and the direct adaptive FNN controller. Based on the trade-off between plant knowledge and control knowledge, the weighting factor $\alpha \in [1, 1]$ can be adjusted. Therefore, the total control effort can be expressed as

$$u = \alpha u_i + (1-\alpha)u_d \quad (19)$$

where the direct adaptive FNN controller u_d and the indirect adaptive FNN controller u_i are given as follows:

$$u_d = u_D(\underline{x}|\underline{\theta}) - \frac{u_a}{g(\underline{x}|\underline{\theta})} \quad (20)$$

$$u_i = \frac{1}{g(x|\theta_g)}[-f(x|\theta_f) + y_d^{(nq)} + \underline{k}^T \underline{e} + u_a] \quad (21)$$

where the robust compensator u_a is employed to attenuate the external disturbance and the fuzzy approximation errors and $u_D(\underline{x}|\underline{\theta})$ is obtained by fuzzy logic system specified as

$$u_D(\underline{x}|\underline{\theta}_D) = \xi^T(\underline{x})\underline{\theta}_D \quad (22)$$

By substituting (19) into (16), the error dynamic equation can be obtained in state space representation as

$$\begin{aligned} \underline{e}^{(q)} = A\underline{e} + B\{&\alpha\left(\left[f(\underline{x}|\theta_f) - f(\underline{x},t)\right] + \left[g(\underline{x}|\theta_g) - g(\underline{x},t)\right]u_i\right) \\ &-(1-\alpha)\left(g(\underline{x},t)\left[u_D(\underline{x}|\theta) - \bar{u}\right]\right) + u_a - d(t)\} \end{aligned} \quad (23)$$

where $A=\begin{bmatrix} 0 & 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 0 & 1 \\ -k_1 & -k_2 & -k_3 & -k_4 & \cdots & -k_{(n-1)} & -k_n \end{bmatrix}$ and $B=\begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}$

The optimal parameter estimations $\underline{\theta}_f^*$, $\underline{\theta}_g^*$ and $\underline{\theta}_D^*$ are defined as

$$\underline{\theta}_f^* = \arg\min_{\underline{\theta}_f \in \Omega_f}[\sup_{x \in \Omega_x} | f(\underline{x}|\underline{\theta}_f) - f(\underline{x},t) |] \quad (24)$$

$$\underline{\theta}_g^* = \arg\min_{\underline{\theta}_g \in \Omega g}[\sup_{x \in \Omega_x} | g(\underline{x}|\underline{\theta}_g) - g(\underline{x},t) |] \quad (25)$$

and

$$\underline{\theta}_D^* = \arg\min_{\underline{\theta}_D \in \Omega_D}[\sup_{x \in \Omega_x} | u_D(\underline{x}|\underline{\theta}_g) - \overline{u} |] \quad (26)$$

where Ω_f, Ω_g, Ω_D and $\Omega_{\underline{x}}$ are constraint sets of suitable bounds on $\underline{\theta}_f$, $\underline{\theta}_g$, $\underline{\theta}_D$ and $\underline{x}$ respectively and they are defined as $\Omega_f = \{\underline{\theta}_f \,|\, |\underline{\theta}_f| \le M_f\}$, $\Omega_g = \{\underline{\theta}_g \,|\, |\underline{\theta}_g| \le M_g\}$, $\Omega_D = \{\underline{\theta}_D \,|\, |\underline{\theta}_D| \le M_D\}$ and $\Omega_x = \{x \,|\, |x| \le M_x\}$, where M_f, M_g, M_D and M_x are positive constants.

By using (24)-(26), error dynamic equation (23) can be rewritten as

$$\begin{aligned} \underline{e}^{(q)} = \mathrm{A}\underline{e} + \mathrm{B}\{ & \alpha\left(\left[f(\underline{x}|\theta_f) - f(\underline{x}|\theta_f^*)\right] + \left[g(\underline{x}|\theta_g) - g(\underline{x}|\theta_g^*)\right]u_i\right) \\ & -(1-\alpha)\, g(\underline{x},t)\left[u(\underline{x}|\theta) - u(\underline{x}|\theta^*)\right] + u_a + \omega\} \end{aligned} \quad (27)$$

where the minimum approximation errors is defined as

$$\begin{aligned} \omega = & \alpha\left(f(\underline{x}|\theta_f^*) - f(\underline{x},t) + \left[g(\underline{x}|\theta_g^*) - g(\underline{x},t)\right]u_i\right) \\ & -(1-\alpha)\, g(\underline{x},t)\left[u_D(\underline{x}|\theta^*) - \overline{u}\right] - d(t) \end{aligned} \quad (28)$$

If $\tilde{\underline{\theta}}_f = \underline{\theta}_f - \underline{\theta}_f^*$, $\tilde{\underline{\theta}}_g = \underline{\theta}_g - \underline{\theta}_g^*$ and, $\tilde{\underline{\theta}}_D = \underline{\theta}_D - \underline{\theta}_D^*$, we have

$$\underline{e}^{(q)} = A\underline{e} + B[\underline{\xi}(\underline{x})^T \tilde{\underline{\theta}}_f + \underline{\xi}(\underline{x})^T \tilde{\underline{\theta}}_g u_i + \underline{\xi}(\underline{x})^T \tilde{\underline{\theta}}_D + u_a + \omega] \quad (29)$$

Following the proceeding consideration, the following theorem can be obtained.

Theorem: Consider the fractional order SISO nonlinear chaotic system (16) with control input (19), if the robust compensator u_a and the fuzzy-based adaptive laws are chosen as

$$u_a = -\frac{1}{r} B^T P \underline{e} \quad (30)$$

$$\underline{\theta}_f^{(q)} = -r_1 \underline{\xi}(\underline{x}) B^T P \underline{e} \quad (31)$$

$$\underline{\theta}_g^{(q)} = -r_2 \underline{\xi}(\underline{x}) B^T P \underline{e} u_i \quad (32)$$

$$\underline{\theta}_D^{(q)} = r_3 \underline{\xi}(\underline{x}) g(x,t) B^T P \underline{e} \quad (33)$$

where $r > 0, r_i > 0, i = 1 \sim 3$, and $P = P^T > 0$ is the solution of the following Ricatti-like equation

$$PA + A^T P + Q - PB\left(\frac{2}{r} - \frac{1}{\rho^2}\right) B^T P = 0 \quad (34)$$

where $Q = Q^T > 0$ is a prescribed weighting matrix. Therefore, the H^∞ tracking performance can be achieved for a prescribed attenuation level ρ and all the variables of the closed-loop system are bounded.

Proof: In order to analyze the closed-loop stability, the Lyapunov function candidate is chosen as

$$V = \frac{1}{2}\underline{e}^T P \underline{e} + \frac{\alpha}{2r_1}\tilde{\underline{\theta}}_f^T \tilde{\underline{\theta}}_f + \frac{\alpha}{2r_2}\tilde{\underline{\theta}}_g^T \tilde{\underline{\theta}}_g + \frac{(1-\alpha)}{2r_3}\tilde{\underline{\theta}}_D^T \tilde{\underline{\theta}}_D \quad (35)$$

Taking the derivative of the (35) with respect to time, we get

$$\begin{aligned} V^{(q)}(t) = & \frac{1}{2}(\underline{e}^{(q)}(t))^T P \underline{e}(t) + \frac{1}{2}\underline{e}^T(t) P \underline{e}^{(q)}(t) \\ & + \frac{\alpha}{r_1}(\tilde{\underline{\theta}}_f^T)(\tilde{\underline{\theta}}_f^{(q)}) + \frac{\alpha}{r_2}(\tilde{\underline{\theta}}_g^T)(\tilde{\underline{\theta}}_g^{(q)}) + \frac{1-\alpha}{r_3}(\tilde{\underline{\theta}}_D^T)(\tilde{\underline{\theta}}_D^{(q)}) \end{aligned} \quad (36)$$

$$\begin{aligned} V^{(q)} = & \frac{1}{2}\underline{e}^T \mathrm{A}^T P \underline{e} + \left[\alpha\left(\underline{\xi}^T \tilde{\underline{\theta}}_f + \underline{\xi}^T \tilde{\underline{\theta}}_g u_i\right) - (1-\alpha)\, g(x,t)\underline{\xi}^T \tilde{\underline{\theta}}_D + \omega\right]^T \mathrm{B}^T P \underline{e} \\ & + \frac{1}{2}\underline{e}^T P \mathrm{A}\underline{e} + \underline{e}^T P \mathrm{B}\left[\alpha\left(\underline{\xi}^T \tilde{\underline{\theta}}_f + \underline{\xi}^T \tilde{\underline{\theta}}_g u_i\right) - (1-\alpha)\, g(x,t)\underline{\xi}^T \tilde{\underline{\theta}}_D + u_a + \omega\right] \\ & + \frac{\alpha}{r_1}\tilde{\underline{\theta}}_f^T \tilde{\underline{\theta}}_f^{(q)} + \frac{\alpha}{r_2}\tilde{\underline{\theta}}_g^T \tilde{\underline{\theta}}_g^{(q)} + \frac{(1-\alpha)}{r_3}\tilde{\underline{\theta}}_D^T \tilde{\underline{\theta}}_D^{(q)} \\ & = \frac{1}{2}\underline{e}^T (PA + A^T P - \frac{2}{r} PBB^T P)\underline{e} + (\alpha \underline{e}^T PB\underline{\xi}^T(\underline{x}) + \frac{\alpha}{\gamma_1}\tilde{\underline{\theta}}_f^{(q)T})\tilde{\underline{\theta}}_f \\ & + (\alpha \underline{e}^T PB\underline{\xi}^T(\underline{x})u_i + \frac{\alpha}{\gamma_2}\tilde{\underline{\theta}}_g^{(q)T})\tilde{\underline{\theta}}_g - \left((1-\alpha)\,\underline{e}^T PBg(\underline{x},t)\underline{\xi}(\underline{x})^T - \frac{(1-\alpha)}{\gamma_3}\tilde{\underline{\theta}}_D^{(q)T}\right)\tilde{\underline{\theta}}_D \\ & + \frac{1}{2}(\omega^T B^T P\underline{e} + \underline{e}^T PB\omega) \end{aligned} \quad (37)$$

From the robust compensator u_a and the fuzzy-based adaptive laws are given (30)-(33), after simple manipulation, we have

$$\begin{aligned} V^{(q)}(t) = & -\frac{1}{2}\underline{e}^T Q\underline{e} - \frac{1}{2\rho^2}\underline{e}^T PBB^T \underline{e} + \underline{e}^T PB\omega \\ = & -\frac{1}{2}\underline{e}^T Q\underline{e} - \frac{1}{2}(\frac{1}{\rho}B^T P\underline{e} - \rho\omega)^T(\frac{1}{\rho}B^T P\underline{e} - \rho\omega) + \frac{1}{2}\rho^2\omega^T\omega \\ \le & -\frac{1}{2}\underline{e}^T Q\underline{e} + \frac{1}{2}\rho^2\omega^T\omega \end{aligned} \quad (38)$$

Integrating (38) from $t = 0$ to $t = T$, we have

$$V(T) - V(0) \le -\frac{1}{2}\int_0^T (\underline{e}^T Q\underline{e} + \frac{1}{2}\rho^2\omega^T\omega)\, dt \quad (39)$$

Since $V(T) \ge 0$, (39) can be rewritten as follows:

$$\int_0^T \underline{e}^T Q\underline{e}\ dt \le \underline{e}^T(0)P\underline{e}(0) + \underline{\theta}^T(0)\underline{\theta}(0) + \rho^2\int_0^T \omega^T\omega\ dt \quad (40)$$

Therefore, the H^∞ tracking performance can be achieved. The proof is completed.

V. SIMULATION EXAMPLE

In this section, we will apply our adaptive hybrid H^∞ FNN controller to force the fractional order chaotic response system to track the trajectory of the fractional order chaotic drive system.

Example: The fractional order chaotic drive and response systems are given as follows:

Drive System:

$$\begin{cases} D^{(q)}y_1 = y_2 \\ D^{(q)}y_2 = 1.2y_1 - y_2 - y_1^2 + 0.5\cos(t) \end{cases}$$

Response System:

$$\begin{cases} D^{(q)}x_1 = x_2 \\ D^{(q)}x_2 = x_1 - 1.8x_2 - x_1^2 + 0.9\cos(t) + u(t) + d(t) \end{cases}$$

where external disturbance $d(t) = 0.1\sin(t)$. The main objective is to control the trajectories of the response system to track the reference trajectories obtained from the drive system. The initial conditions of drive and response systems are chosen as $\begin{bmatrix} y_1(0) \\ y_2(0) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$ and $\begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix} = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$, respectively. values of $q = 0.95$ are considered. All design constants are specified as k_1=k_2=1, $r_1 = 200$, $r_2 = 40$, $r_3 = 100$, $r_4 = 10$, $r = 0.005$, $\rho = 0.05$ and step size h=0.01.

Case 1. q=0.95, α=0.7 : For $q = 0.95$ and free of control input, the phase portrait of the drive and response systems is given in Fig. 2.

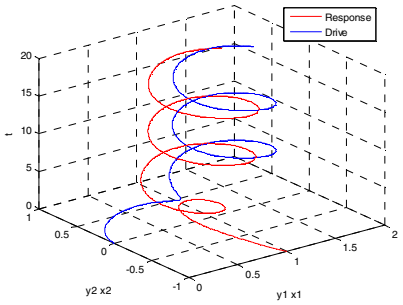

Figure 2. Phase portrait of chaotic drive and response systems.

The membership functions for x_i $i = 1, 2$ are shown in Fig. 3 and are selected as follows:

$$\mu_{F_1^i}(x_i) = \exp\left[-0.5\left(\frac{x_i - 2}{0.8}\right)^2\right],\ \mu_{F_2^i}(x_i) = \exp\left[-0.5\left(\frac{x_i - 1.5}{0.8}\right)^2\right],$$

$$\mu_{F_3^i}(x_i) = \exp\left[-0.5\left(\frac{x_i - 1}{0.8}\right)^2\right],\ \mu_{F_4^i}(x_i) = \exp\left[-0.5\left(\frac{x_i - 0.5}{0.8}\right)^2\right],$$

$$\mu_{F_5^i}(x_i) = \exp\left[-0.5\left(\frac{x_i}{0.8}\right)^2\right],\ \mu_{F_6^i}(x_i) = \exp\left[-0.5\left(\frac{x_i + 0.5}{0.8}\right)^2\right],$$

$$\mu_{F_7^i}(x_i) = \exp\left[-0.5\left(\frac{x_i + 1}{0.8}\right)^2\right]$$

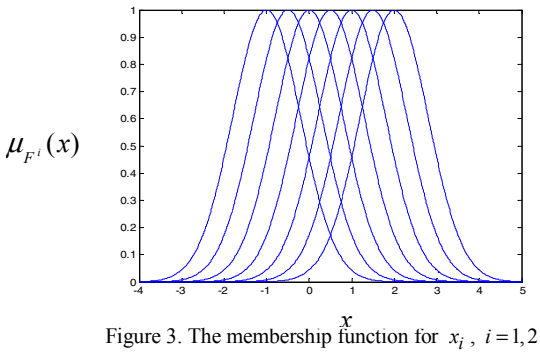

Figure 3. The membership function for x_i, $i = 1, 2$.

From the adaptive laws (33)-(36) and the robust compensator (32), the control effort of the response system can be obtained as

$$u = \alpha u_i + (1 - \alpha)u_d \tag{41}$$

Fig. 4 and 5 show the trajectories of the states x_1, y_1 and x_2, y_2, respectively. Control effort trajectory is given in Fig 6 and phase portrait, tracking performance, of the drive and response systems is shown in Fig. 7. Fig. 8 shows the graph of $V^{(q)}(t)$ which is always negative defined and consequently is stable.

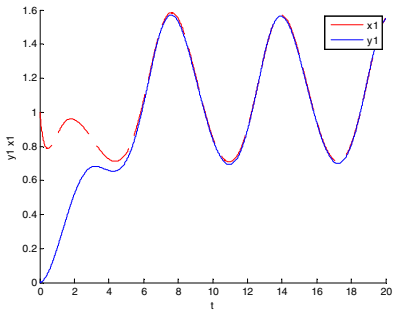

Figure 4. The trajectories of the states x_1 and y_1.

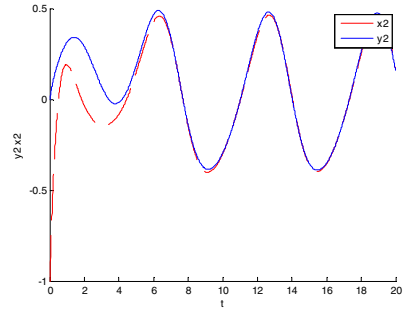

Figure 5. The trajectories of the states x_2 and y_2.

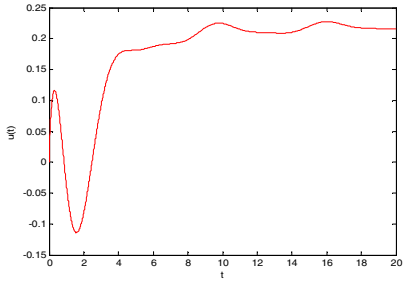

Figure 6. Trajectory of the control effort.

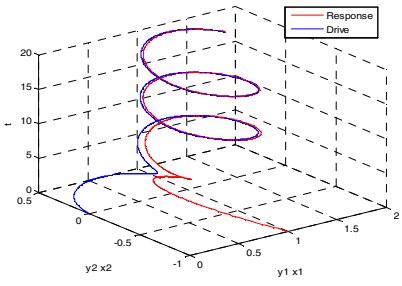

Figure 7. Phase portrait, tracking performance, of the drive and response systems.

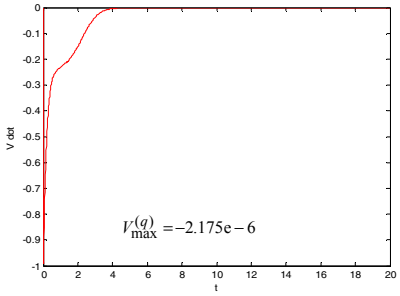

Figure 8. The graph of $V^{(q)}(t)$.

In order to show the robustness of the proposed adaptive fuzzy H^{∞} control, the control effort is activated at 5 second. The phase portrait, tracking performance, of the drive and response systems is given in Fig. 9. Fig. 10 and 11 show the trajectories of the states x_1, y_1 and x_2, y_2, respectively. We can see that a fast synchronization of drive and response is achieved as the control effort is activated. Control effort trajectory is given in Fig 12.

VI. Conclusions

A novel adaptive hybrid FNN controller is proposed to achieve prescribed tracking performance of fractional order chaotic systems in this paper. It is a flexible design methodology by the trade-off between plant knowledge and control knowledge using a weighting factor α adopted to sum together the control effort from indirect adaptive FNN controller and direct adaptive FNN controller. Based on the Lyapunov synthesis approach, free parameters of the adaptive fuzzy controller can be tuned on line by output feedback control law and adaptive laws. The simulation example, the output trajectory of the fractional order chaotic response system to tracking the trajectory of the fractional order chaotic drive system, is given to demonstrate the effectiveness of the proposed methodology. The significance of the adaptive fuzzy H^{∞} control in the simulations for different values of q is manifest. Simulation results show that a fast synchronization of the drive and response systems can be achieved and q is reduced the chaos is seen reduced, i.e., the synchronization error is reduced, accordingly.

***Abstract*—Imperfect information inevitably appears in real situations for a variety of reasons. Although efforts have been made to incorporate imperfect data into classification techniques, there are still many limitations as to the type of data, uncertainty and imprecision that can be handled. In this paper, we will present a Fuzzy Random Forest ensemble for classification and show its ability to handle imperfect data into the learning and the classification phases. Then, we will describe the types of imperfect data it supports. We will devise an augmented ensemble that can operate with others type of imperfect data: crisp, missing, probabilistic uncertainty and imprecise (fuzzy and crisp) values. Additionally, we will perform experiments with datasets used in other papers to show the advantage of being able to express the true nature of imperfect information.**

***Index Terms*—Fuzzy Random Forest; Imperfect Data**

I. Introduction

Classification has always been a challenging problem [1], [2]. Many techniques and algorithms have been developed to address this issue. There is a wide range of classification techniques based on different theoretical proposals [3]–[6]. Unfortunately, most of the conventional techniques did not consider the sources of uncertainty. As a result, incomplete and imprecise data have usually been discarded or ignored in the classifier's learning and in its subsequent classification process. However, this data is inevitable when dealing with real-world applications.

Imperfect information inevitably appears in realistic domains and situations. Instrument errors or corruption from noise during experiments may give rise to information with incomplete data when measuring a specific attribute. In other cases, the extraction of exact information may be excessively costly or unfeasible. Moreover, it might be useful to complement the available data with additional information from an expert, which is usually elicited by imperfect data (interval data, fuzzy concepts, etc). In most real-world problems, data have a certain degree of imprecision. Sometimes, this imprecision is small enough for it to be safely ignored. On other occasions, the imprecision of the data can be modeled by a probability distribution. However, there is a third kind of problem, where the imprecision is significant, and a probability distribution is not the most natural way to model it. This is the case of certain practical problems where the data are inherently fuzzy [7]–[10]. For these cases, it is necessary to incorporate the handling of information with attributes which may present missing and imprecise values in the classifier's learning and classification phases.

In general, we can say that there are many restrictions to the type of imperfection allowed in the input examples or in the data. For this reason, we propose to extend the treatment of imperfect information with a classification technique based on multiple classifier systems. This technique is a Fuzzy Random Forest (FRF) ensemble. Beside its ability to handle imperfect information, FRF also proved to be effective when dealing with regular data, e.g., without imperfect information [11].

FRF uses a fuzzy decision tree as base classifier. Therefore, FRF leverages the robustness of fuzzy decision trees and tree ensembles, the power of randomness to increase the diversity of the trees in the forest, and the flexibility of fuzzy logic to manage imperfect data. In Section II we review the major elements that constitute the FRF ensemble. In Section III, we describe the types of imperfect data supported by the FRF ensemble and we devise an augmented ensemble that can operate with others type of imperfect data. In Section IV, we perform experiments with imperfect datasets used in other papers to show the advantage of being able to express the true nature of imperfect information. Finally, we present our conclusions in Section V.

II. An ensemble based on Fuzzy Decision Trees

FRF was originally presented in [11]. In this section we describe the basic elements that compose a FRF ensemble and the types of data that are supported by this ensemble in both learning and classification phases.

A. Fuzzy Random Forest Learning

FRF learning phase uses Algorithm 1 to generate the FRF ensemble whose trees are fuzzy decision trees. Each tree in the FRF ensemble is a fuzzy tree. Algorithm 2 shows the fuzzy decision tree learning algorithm.

Although the user chooses the size of the FRF, computational studies have shown that good accuracy is obtained on sizes between [100,150] trees, [11]. Algorithm 2 has been designed so that the trees can be constructed without considering all the attributes to split the nodes. Algorithm 2 is an algorithm to construct trees based on ID3, where the numeric attributes have been discretized by a fuzzy partition. The domain of each numeric attribute is represented by trapezoidal fuzzy sets,

Algorithm 1 - FRF ensemble Learning

FRFlearning(*in:E, Fuzzy Partition; out:Fuzzy Random Forest*)
begin

1. Take a random sample of $|E|$ examples with replacement from the dataset E.
2. Apply Algorithm 2 to the subset of examples obtained in the previous step to construct a fuzzy tree, using the fuzzy partition.
3. Repeat steps 1 and 2 until T fuzzy trees are built to constitute the FRF ensemble.

end

Algorithm 2 - Fuzzy Decision Tree Learning

FuzzyDecisionTree(*in: E, Fuzzy Partition; out: Fuzzy Tree*)
begin

1. Start with the examples in E with values $\chi_{Fuzzy_Tree,root}(e) = 1$.
2. Let M be the set of attributes where all numeric attributes are partitioned according to the Fuzzy Partition.
3. Choose an attribute to do the split at the node N.

3.1. Make a random selection of attributes from the set of attributes M.

3.2. Compute the information gain for each selected attribute using the values $\chi_{Fuzzy_Tree,N}(e)$ of each e in node N.

3.3. Choose the attribute such that information gain is maximal.

4. Divide N in children nodes according to possible outputs of the attribute selected in the previous step and remove it from the set M. Let E_n be the dataset of each child node.
5. Repeat steps 3, 4 with each (E_n,M) until the stopping criteria is satisfied.

end

$A_1, \ldots, A_f$ so each internal node of the tree, whose division is based on a numerical attribute, generates a child node for each fuzzy set of the partition. Moreover, Algorithm 2 uses a function, denoted by $\chi_{t,N}(e)$, that indicates the degree with which the example e satisfies the conditions that lead to node N of tree t. Each example e is composed of attributes which can take crisp, missing or fuzzy values belonging to the fuzzy partition of the corresponding attribute. Each of these examples (according of the attribute value) has the following treatment:

- Each example e used in the training of the tree t has been assigned an initial value 1 ($\chi_{t,root}(e) = 1$).
- According to the membership degree of the example e to different fuzzy sets of partition of a split based on a numerical attribute:
  - If the value of e for that attribute is crisp, the example e may belong to one or two children nodes ($\mu_{fuzzy_set_partition}(e) > 0$). In this case $\chi_{t,childnode}(e) = \chi_{t,node}(e) \times \mu_{fuzzy_set_partition}(e)$.
  - If the value of e for that attribute is a fuzzy value, it must match one of the sets of the fuzzy partition of the attribute (e will descend to the child node associated with that set). In this case, $\chi_{t,childnode}(e) = \chi_{t,node}(e)$.
  - When the example e has a missing value on the attribute used as split in a node, the example e descends to each child node with value $\chi_{t,childnode}(e) = \chi_{t,node}(e) \times \frac{1}{number_outputs_{split}}$.

The construction process of this fuzzy tree is a modification of fuzzy ID3 algorithm [12] to allow treatment of the attributes with crisp, fuzzy and missing values [11].

B. Fuzzy Random Forest Classification

In this section we describe how the classification is carried out using the FRF ensemble. We present two alternative strategies to obtain the decision of the FRF ensemble for a target example.

When the example e runs through each tree t, we obtain the matrix L_FRF of size $(T \times MAX_{N_t})$ with $MAX_{N_t} = max\{N_1, N_2, \ldots, N_T\}$ and N_i the number of reached leaves in tree i. Each element of the matrix is a vector of size I containing the support for every class provided by every activated leaf n on each tree t. Therefore, the matrix L_FRF contains all the information generated by the FRF ensemble when it is used to classify an example e and from which it makes its decision or class with certain methods of combination[1]. In the Appendix, we present concrete instances of these methods of combination used in the experiments.

The fuzzy classifier module operates on fuzzy trees of the FRF ensemble using one of these two possible strategies:

Strategy 1: Combining the information from the different leaves reached in each tree to obtain the decision of each individual tree and then applying the same or another combination method to generate the global decision of the FRF ensemble. In order to combine the information of the leaves reached in each tree, the $Faggre1_1$ function is used and the $Faggre1_2$ function is used to combine the outputs obtained with $Faggre1_1$ (functions that define the combination method), and so, we obtain vector D_FRF (vector with size I that indicates the confidence assigned by the FRF ensemble to each class i).

Strategy 2: Combining the information from all reached leaves from all trees to generate the global decision of the FRF ensemble. We use function $Faggre2$ (function that define the combination method) to combine the information generated by all the leaves obtaining vector D_FRF (vector with size I that indicates the confidence assigned by the FRF ensemble to each class i).

From vector D_FRF, obtained with Strategy 1 or 2, FRF ensemble assigns class c to example e such that

$$c = \arg \max_{i,\ i=1,\ldots,I} \{D_FRF_i\}$$

[1]In [11] a set of combination methods are defined.

As we can see, the output of FRF ensemble (regardless of the strategy) is obtained from vector D_FRF, which contains the membership degree of the target example to each class. Finally, the FRF ensemble assigns the class c with maximum value to example e.

III. Extending FRF ensemble

FRF ensemble is a versatile technique, which is able to adapt itself to new elements. Having introduced the FRF ensemble, we now describe an extension of this technique to allow the incorporation of new imprecise data. This extension involves changes in the learning and classification phases of the technique. In this section, we will describe the new types of imprecise data that we will incorporate and the new elements and changes needed to carry out the FRF ensemble's extension.

A. New types of imprecise data

In Section II-A we described the types of data supported by the FRF ensemble, in both the learning and classification phases, as originally proposed in [11]. Now, we want to extend the information processing in the FRF ensemble to incorporate data containing attributes measured by fuzzy values (which may be different from the fuzzy values which constitute the fuzzy partition of the attribute), and attributes with interval values. Furthermore, we want to allow the class attribute to be set-valued. Figure 1 illustrates the proposed extension.

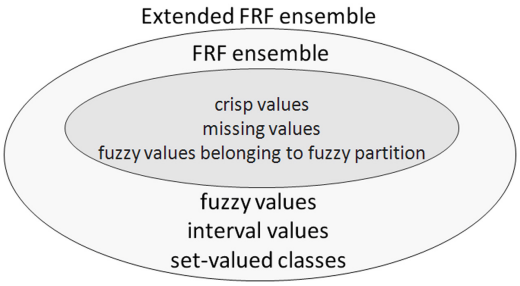

Fig. 1. Extending information processing in FRF

To incorporate these new types of data, we need to modify the following elements of FRF ensemble:

- Define an extended function to measure the membership degree of these new types of data in the fuzzy partitions of the numerical attributes used by the ensemble.
- The definition of this function requires a modification of the *information gain* function in both learning and classification phases of FRF ensemble.
- To incorporate set-valued classes, we need to modify and to define the learning and classification phases.

Let's further analyze these new elements and their required modifications.

B. Fuzzy and Interval values

To incorporate attribute values measured by a fuzzy value (fuzzy set) different from the sets of the partition of the attribute, or attributes measured by interval values, we must extend the function that measures the membership degree of these types of values to the different fuzzy sets forming the partition of the numeric attributes. In [13] we can find a review of similarity measures. We define the measure $\mu_{simil}(\cdot)$ which captures change in the value $\chi_{t,node}(e)$ of the example e when it descends in the fuzzy tree. e has attributes whose values are expressed by intervals or fuzzy values that do not match any of the fuzzy values of the partition used by the fuzzy tree and therefore by the ensemble. This function μ_{simil} will be used in both learning and classification phases of extended FRF ensemble.

In these cases, we use a membership function ($\mu_{simil}(\cdot)$) that, given the attribute "$Attr$" to be used to split a node, measures the similarity between the values of the fuzzy partition of the attribute and fuzzy values or intervals of the example in that attribute. When the example e must descend to different child nodes, the function $\chi(\cdot)$ is calculated as $\chi_{t,childnode^i}(e) = \chi_{t,node} \times \mu^i_{simil}(e)$.

Function $\mu^i_{simil}(e)$ is defined as:

$$\mu^i_{simil}(e) = \frac{\int_{\mathbb{R}}(\min\{\mu_e(x), \mu_{A_i}(x)\})dx}{\sum_{i=1}^{f}\int_{\mathbb{R}}(\min\{\mu_e(x), \mu_{A_i}(x)\})dx}, \quad i = 1, \ldots, f$$

where:

- $\mu_e(x)$ is the membership function that represents the fuzzy or interval value in the example e
- $\mu_{A_i(x)}$ is the membership function that represents the i-th fuzzy value of the partition of the attribute $Attr$
- f is the cardinality of the partition of the attribute $Attr$

C. Set-valued classes

We assume that if an example is labeled with a set-valued we are not stating that it belongs to all categories at time (which is not an imprecise assert). We are expressing that we are not sure about the class of the example, [14].

As described in Section II, the examples in the dataset are weighted examples (initially with weight 1). When we incorporate in FRF ensemble examples whose class can be expressed by a set of values, it is necessary to modify the way we treat this weight in the learning phase of FRF ensemble. Thus, step 3.2 of Algorithm 2 should calculate the information gain considering the example as belonging to *each* potential class. For this, the example in step 1 of the algorithm, must be replicated for each class of its class attribute, using an associated weight of $1/(n\ values\ classes\ of\ example)$. Therefore, the initial weight of the replicated examples will be $1/(n\ values\ classes\ of\ example)$.

When the ensemble is learned, we need to extend the classification phase in which the function $\mu_{simil}(e)$ is used.

As an example descends through various branches of the tree (using function $\mu_{simil}(e)$), different leaf nodes are activated. Each of these activated leaf nodes assigns a weight to each possible classes. According to the combination method used, we obtain from the FRF ensemble a weight for each class. The resulting weight vector of classes is denoted by D_FRF.

At this point, when we perform a test of the FRF ensemble results to classify a dataset we can follow the decision process:

If class(e)==class$_{FRF}$(e) and size(class(e)==1) then successes++
else
If class(e)$\cap$ class$_{FRF}$(e)$\neq \emptyset$ then success_or_error++
else errors++

As result of this test, we obtain the interval $[min_error, max_error]$ where min_error is calculated considering only errors indicated in the variable $errors$ from the previous process and max_error is calculated considering as errors $errors + success_or_error$.

D. Changes of learning and classification algorithms

Learning and classification phases should now be modified to allow the FRF ensemble to learn, infer, and classify from an example expressed with the types of values presented in Section III-A. This subsection shows these modification.

Algorithm 2 is modified in steps 1 and 3.2. The new step 1 is "Start with the examples in E with values $\chi_{Fuzzy_Tree,root}(e) = 1/(n\ values\ classes\ of\ example)$" and the new step 3.2 is "Compute the information gain for each selected attribute using the values $\chi_{Fuzzy_Tree,N}(e)$ of each e in node N taking into account the function $\mu_{simil(e)}$ for the cases required."

FRF Classification with Strategy 1 is modified. The decisions of trees are modified because obtaining of matrix L_FRF takes into account the function μ_{simil} for the cases required. On the other hand, the decision of FRF ensemble is modified due to FRF ensemble assigns the set of classes c to example e such that $c = \arg \max_{i,\ i=1,\ldots,I} \{D_FRF_i\}$.

Finally, FRF Classification with Strategy 2 is modified. The decisions of tree are modified because obtaining of matrix L_FRF takes into account the function $\mu_{simil(e)}$ for the cases required. Again, FRF ensemble assigns the set of classes c to example e such that $c = \arg \max_{i,\ i=1,\ldots,I} \{D_FRF_i\}$.

IV. Experiments and Results

In this section we describe several experiments. These experiments are designed to measure the behavior of FRF ensemble using datasets and results proposed in [14], [15]. We define the experimental settings quite similar to those proposed in [14], [15] to compare with their results.

A. Datasets and parameters for FRF ensemble

To obtain these results we have used real-world datasets about medical diagnosis and high performance athletics [14], [15], whose characteristics are shown in Table I.

TABLE I
Datasets

Dataset	Abbr	$\|E\|$	$\|M\|$	I
Long-4	Long-4	25	4	2
100ml-4-I	ml-4-I	52	4	2
100ml-4-P	ml-4-P	52	4	2
Dyslexia	Dyslexic	65	12	4

The table shows the number of examples ($|E|$), the number of attributes ($|M|$) and the number of classes (I) for each dataset. "Abbr" indicates the abbreviation of the dataset used in the experiments.

All FRF ensembles use a forest size of 100 trees. The number of attributes chosen at random at a given node is $\log_2(|\cdot| + 1)$, where $|\cdot|$ is the number of available attributes at that node, and each tree of the FRF ensemble is constructed to the maximum size (node pure or set of available attributes is empty) and without pruning.

In experiments described in [14], [15], fuzzy partitions used are uniform. We will use both uniform and non-uniform fuzzy partitions. These last ones are obtained by the NIP1.5 tool available in "http://heurimind.inf.um.es/".

B. Experimentation with low quality data

These experiments were conducted to test the accuracy of FRF ensemble applied to real-world datasets with imperfect values and compare the results with the ones obtained by the GFS classifier proposed in [14].

In these experiments we used the available datasets in "http://sci2s.ugr.es/keel/" and the available results in [14], [15]. These are datasets from two different real-world problems. The first one is related to the composition of teams in high performance athletics and the second one is a medical diagnosis problem.

1) High performance athletics: The score of an athletics team is the sum of the individual scores of the athletes in the different events. It is the coach's responsibility to balance the capabilities of the different athletes in order to maximize the score of a team according to the regulations. The variables that define each problem are as follows:

- There are four indicators for the long jump that are used to predict whether an athlete will pass a given threshold: the ratio between the weight and the height, the maximum speed in the 40 meters race, and the tests of central (abdominal) muscles and lower extremities;
- There are also four indicators for the 100 meters race: the ratio between weight and height, the reaction time, the starting or 20 m speed, and the maximum or 40 m speed.

A more detailed description of this problem may be found in [14]. The datasets used in this experiment are the following:

- Dataset "Long-4": Dataset used to predict whether an athlete will improve certain threshold in the long jump, given the indicators mentioned before. The set has 25 examples (25 athletes), 4 attributes, 2 classes, and no missing values. All attributes, including the output attribute, are interval-valued.
- Dataset "100ml-4-I": Used for predicting whether a mark in the 100 meters sprint race is being achieved. Actual measurements are taken by three observers, and are combined into the smallest interval that contains them. The set has 52 examples, 4 attributes, 2 classes, and no missing values. All attributes, including the output attribute, are interval-valued.
- Dataset "100ml-4-P": Same dataset as "100ml-4-I" but the measurements have been replaced by the subjective grade

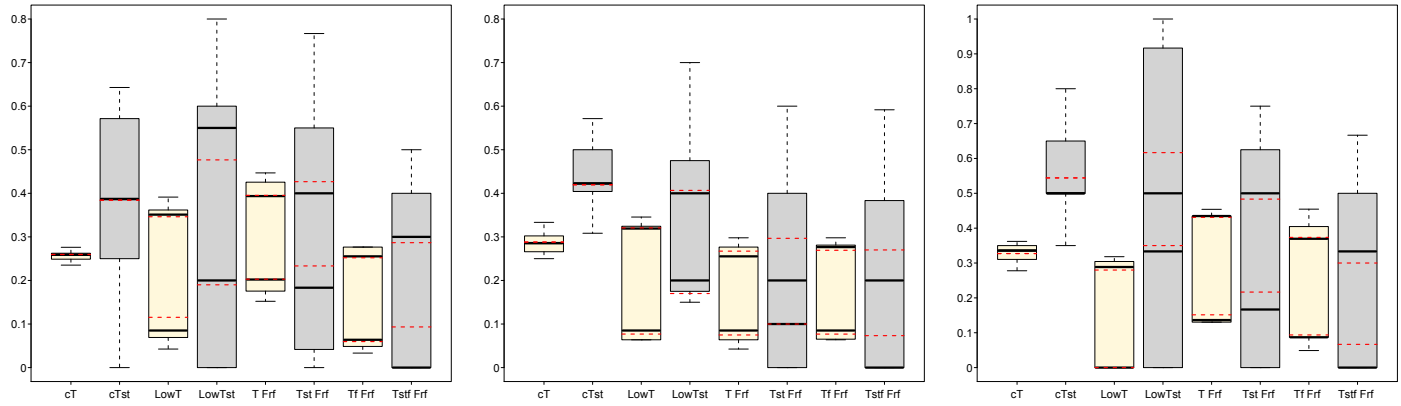

Fig. 2. Boxplots ml-4-I, ml-4-P and Long-4 with five labels/attribute. cT and cTst are the results for train and test respectively of the crisp algorithm proposed in [14]. LowT and LowTst are the results for train and test of the extended algorithm proposed in [14]. T-Frf, Tst-Frf, Tf-Frf adn Tstf-Frf are the results for train and test of FRF with uniform and non-uniform fuzzy partitions (results marked in bold).

the trainer has assigned to each indicator (i.e. "reaction time is low" instead of "reaction time is 0.1 sec").

As in [14], we have used a 10 fold cross-validation design for all datasets. Table II shows the results obtained in [14] and the ones obtained by the FRF ensemble with the six combination methods proposed in Appendix. Except for the crisp algorithm proposed in [14], in this table, the interval $[mean_min_error, mean_max_error]$ obtained for each dataset according to the decision process described in Section III-C, is shown.

In these experiments we used different types of fuzzy partitions of the attributes. We used uniform fuzzy partitions with size of five labels/attribute, as commented in [14]. In addition, we used non-uniform fuzzy partitions. These last ones are obtained by the NIP1.5 tool and they have (3,0,3,3), (0,2,3,6) and (3,3,2,0) labels/attribute for "100ml-4-I", "100ml-4-P" and "100ml-4-P", respectively. To obtain these fuzzy partitions for each dataset, attributes with interval values have been changed by its average value.

In Figure 2 is shown the boxplots with the best results of FRF ensemble. Observe that the boxplots of the imprecise experiments are not standard. We have used the extended boxplot proposed in [14]. They propose to use a box showing the 75% percentile of the maximum and the 25% percentile of the minimum error (thus the box displays at least the 50% of data). In addition, they represent the interval-valued median of the maximum and minimum result. For this reason, they draw two marks inside the box.

In Figure 2, we show the results of FRF with uniform and non-uniform fuzzy partitions marked in bold and the results of Crisp [14] and GGFS [14].

The results obtained by the extended GPS proposed in [14] and FRF ensemble, are very promising because we are representing the information in a more natural and appropriate way, and in this problem, we are allowing the collection of knowledge of the coach by ranges of values and linguistic terms. The results of FRF ensemble are very competitive.

2) Diagnosis of dyslexic: Dyslexia is a learning disability in people with normal intellectual coefficient, and without further physical or psychological problems explaining such disability. A more detailed description of this problem can found in [14], [15].

In these experiments, we have used three different datasets. Their names are "Dyslexic-12', "Dyslexic-12-01" and "Dyslexic-12-12". Each dataset has 65 examples, 4 classes and 12 attributes. The output variable for each of these datasets is a subset of the labels that follow: • No dyslexic; • Control and revision; • Dyslexic; and • Inattention, hyperactivity or other problems.

Both input and the output exhibit imprecision and missing values. These three datasets differ only in their outputs:

- "Dyslexic-12" comprises the four mentioned classes.
- "Dyslexic-12-01" does not make use of the class "control and revision", whose members are included in class "no dyslexic".
- "Dyslexic-12-12" does not make use of the class "control and revision", whose members are included in class "dyslexic".

All experiments are repeated 100 times for bootstrap resamples with replacement of the training set. The test set comprises the "out of the bag" elements. As mentioned above, the boxplots of the imprecise experiments are not standard. We have used the extended boxplot proposed in [14].

In these experiments we used different types of fuzzy partitions of the attributes. We used uniform fuzzy partitions with size of four and five labels/attribute, as commented in [14], [15]. In addition, we used non-uniform fuzzy partitions. These last ones are obtained by the NIP1.5 tool and they have (0,0,2,0,0,7,4,0,0,0,3,3), (0,2,2,2,3,3,4,0,0,2,0,2) and (0,0,3,2,2,3,0,0,2,2,2,2) labels/attribute for "Dyslexic-12", "Dyslexic-12-01" and "Dyslexic-12-12P", respectively. To obtain these fuzzy partitions for each dataset, attributes with interval values have been changed by its average value.

In Table III, we show the results obtained when we run FRF ensemble with these type of partitions for datasets "Dyslexic-12", "Dyslexic-12-01" and"Dyslexic-12-12'. Also, in Table III, we compare the results obtained by FRF ensemble with the best ones obtained in [15]. Again, in this table, the interval $[mean_min_error, mean_max_error]$ obtained for each dataset according to the decision process described in Section III-C, is shown. The statistical significance of the differences is displayed in Figure 3. In Figure 3, we show the results with FRF with uniform and non-uniform fuzzy partitions marked in bold and the results of Crisp CF^0 [15], GGFS [14] and GGFS CF^0 [15] with four labels.

As we can see, FRF with non-uniform fuzzy partitions obtains better results in test that FRF with uniform fuzzy partitions. FRF ensemble is a significant improvement over the crisp GFS. As also discussed in [15] is preferable to use an algorithm which is capable of learning with low quality data than removing the imperfect information and using a

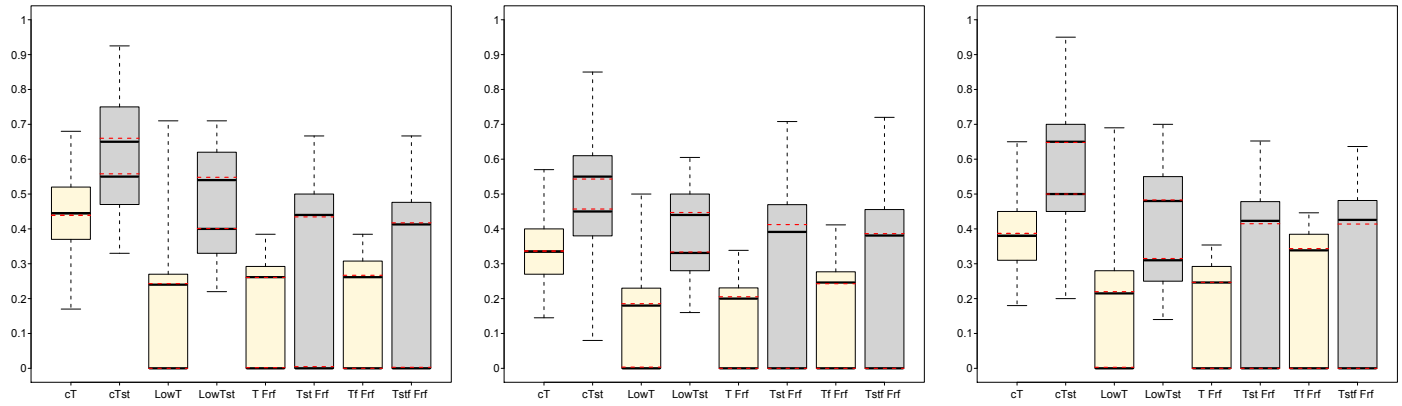

Fig. 3. Boxplots Dyslexic-12, Dyslexic-12-01 and Dyslexic-12-12 with four labels/attributes. cT and cTst are the results for train and test, respectively, of crisp algorithm CF_0 proposed in [15]. LowT and LowTst are the results of the extended algorithm CF_0 proposed in [15]. T-Frf, Tst-Frf, Tf-Frf and Tstf-Frf are the results for train and test of FRF with uniform and non-uniform fuzzy partitions (results marked in bold).

conventional algorithm.

The results of the dataset "Dyslexic-12-01" are better than "Dyselxic-12" and "Dyslexic-12-12". Moreover, if the class "control and revision" is not used, the individuals in this class tend to be assigned to the group "no dyslexic" rather than to the group "dyslexic".

V. Conclusions

We have presented FRF ensemble, which is an ensemble based on fuzzy decision trees. The FRF ensemble can manage imperfect data directly and has a good classification performance with relatively small ensembles sizes. The FRF ensemble has been extended to include the treatment of new types of imperfect data in both input and output attributes. This technique is very versatile due to the ease with which we can extend it to new situations.

We have presented experimental results obtained by applying the FRF ensemble to various datasets. FRF ensemble has been applied to real-problems datasets, such as the composition of teams in high performance athletics and a medical diagnosis problem. The results obtained by FRF ensemble are promising, concluding, as in [14], [15], that by using ranges of values and linguistic terms instead of crisp, imputed numbers, we better capture the nature of the underlying information.

Our conclusion, as many papers in the literature are indicating, is that it is necessary to design and/or adapt classification techniques so they can manipulate real data that can be imperfect in some cases. The transformation of these imperfect values to (imputed) crisp values may cause undesirable effects with respect to accuracy of the technique.

Appendix

In this appendix, we use the notation above defined in Section II-B. For each strategy for fuzzy classifier module in the FRF ensemble that is described in Section II we can define several functions $Faggre1_1$, $Faggre1_2$ and $Faggre2$. The overall set of functions is described in [11]. In this appendix, the utilized methods in this paper are described in detail:

Non-trainable methods - In these combination methods, a transformation is applied to the matrix L_FRF so that each leaf reached assigns a simple vote to the majority class.

For $t = 1, \ldots, T$

For $n = 1, \ldots, N$

For $i = 1, \ldots, I$

$$L_FRF_{mod_{t,n,i}} = \begin{cases} 1 & if\ i = \arg \max_{j,\ j=1,\ldots,I} \{L_FRF_{t,n,j}\} \\ 0 & otherwise \end{cases}$$

Within this group we define the following methods. We get two versions depending on the strategy used:

- *Simple Majority vote:*

Strategy 1→ method SM1

The function $Faggre1_1$ is defined as:

$Faggre1_1(t, i, L_FRF) =$

$$= \begin{cases} 1 & if\ i = \arg \max_{j,\ j=1,\ldots,I} \left\{ \sum_{n=1}^{N_t} L_FRF_{mod_{t,n,j}} \right\} \\ 0 & otherwise \end{cases}$$

In this method, each tree t assigns a simple vote to the most voted class among the N_t reached leaves by example e in the tree. We will denote by T_FRF to the out matrix of $Faggre1_1$.

The function $Faggre1_2$ is defined as:

$Faggre1_2(i, T_FRF) = \sum_{t=1}^{T} T_FRF_{t,i}$

Strategy 2 → method SM2

For Strategy 2 it is necessary to define the function $Faggre2$ combining information from all leaves reached in the ensemble by example e. Thus, the function $Faggre2$ is defined as:
$Faggre2(i, L_FRF) = \sum_{t=1}^{T} \sum_{n=1}^{N_t} L_FRF_{modt,n,i}$

Trainable explicitly dependent methods-

• *Majority vote Weighted by Leaf:*

In this combination method, a transformation is applied to the matrix L_FRF so that each leaf reached assigns a weighted vote to the majority class. The vote is weighted by the degree of satisfaction with which example e reaches the leaf.

For $t = 1, \ldots, T$
For $n = 1, \ldots, N$
For $i = 1, \ldots, I$

$L_FRF_{mod_{t,n,i}} =$

$$= \begin{cases} \chi_{t,n}(e) & if\ i = \arg \max_{j,\ j=1,\ldots,I} \{L_FRF_{t,n,j}\} \\ 0 & otherwise \end{cases}$$

Again, we have two versions according to the strategy used.

Strategy 1 → method MWL1

The functions $Faggre1_1$ and $Faggre1_2$ are defined as:
$Faggre1_1(t, i, L_FRF) =$

$$= \begin{cases} 1 & if\ i = \arg \max_{j,\ j=1,\ldots,I} \left\{ \sum_{n=1}^{N_t} L_FRF_{mod_{t,n,j}} \right\} \\ 0 & otherwise \end{cases}$$

$Faggre1_2(i, T_FRF) = \sum_{t=1}^{T} T_FRF_{t,i}$

Strategy 2 → method MWL2

The function $Faggre2$ is defined as:
$Faggre2(i, L_FRF) = \sum_{t=1}^{T} \sum_{n=1}^{N_t} L_FRF_{t,n,i}$

• *Majority vote Weighted by Leaf and by Tree:*

Again, in this combination method, a transformation is applied to the matrix L_FRF so that each leaf reached assigns a weighted vote to the majority class. The vote is weighted by the degree of satisfaction with which example e reaches the leaf.

For $t = 1, \ldots, T$
For $n = 1, \ldots, N$
For $i = 1, \ldots, I$

$L_FRF_{mod_{t,n,i}} =$

$$= \begin{cases} \chi_{t,n}(e) & if\ i = \arg \max_{j,\ j=1,\ldots,I} \{L_FRF_{t,n,j}\} \\ 0 & otherwise \end{cases}$$

In addition, in this method a weight for each tree obtained is introduced by testing each individual tree with the OOB dataset. Let $\overline{p} = (p_1, p_2, \ldots, p_T)$ be the vector with the weights assigned to each tree. Each p_t is obtained as $\frac{N_success_OOB_t}{size_OOB_t}$ where $N_success_OOB_t$ is the number of examples classified correctly from the OOB dataset used for testing the t-th tree and $size_OOB_t$ is the total number of examples in this dataset.

Strategy 1 → method MWLT1

The function $Faggre1_1$ is defined as:

$Faggre1_1(t, i, L_FRF) =$

$$= \begin{cases} 1 & if\ i = \arg \max_{j,\ j=1,\ldots,I} \left\{ \sum_{n=1}^{N_t} L_FRF_{mod_{t,n,j}} \right\} \\ 0 & otherwise \end{cases}$$

Vector $\overline{p}$ is used in the definition of function $Faggre1_2$:
$Faggr1_2(i, T_FRF) = \sum_{t=1}^{T} p_t \cdot T_FRF_{t,i}$

Strategy 2 → method MWLT2

The vector of weights $\overline{p}$ is applied to Strategy 2.
$Faggre2(i, L_FRF) = \sum_{t=1}^{T} p_t \sum_{n=1}^{N_t} L_FRF_{t,n,i}$

***Abstract*—We advance the theory of aggregation operators and introduce non-monotone aggregation methods based on minimization of a penalty for inputs disagreements. The application in mind is processing data sets which may contain noisy values. Our aim is to filter out noise while at the same time preserve signs of unusual values. We review various methods of robust estimators of location, and then introduce a new estimator based on penalty minimisation.**

***Index Terms*—Aggregation operator, penalty function, estimators of location, outliers.**

I. Introduction

The need to aggregate several inputs into a single representative output frequently arises in fuzzy systems. Aggregation of membership values is typically performed in fuzzy rule-based systems by using triangular norms and conorms (t-norms and t-conorms). Averaging aggregation functions, including weighted arithmetic means, ordered weighted averaging (OWA) functions and fuzzy integrals (Choquet and Sugeno integrals in particular) are also frequently used in multicriteria decision making, image analysis and machine learning, see [1]–[3].

By their definition, aggregation functions are monotone in all variables. The role of averaging functions is to provide a representative value of the inputs. Some of the existing averaging functions, however, are not monotone. A particular example is the mode, illustrated in Section II. One can argue that the mode does provide a representative value, as it returns the most frequently observed input. But when the inputs are not repeated, the mode is not defined uniquely: any input is the mode in that case. In this article we investigate other non-monotone averaging functions which play the same role as the mode, but can be used when all inputs are different. This is important when the number of inputs is small, but they can take many values, and specifically any real value from $[0, 1]$, as it happens in fuzzy logic.

Our motivation is the following. Suppose we have a flow of noisy inputs, such as computer network traffic, or digital images. We want to combine the inputs into representative values, for example to reduce the size of the data in image reduction. On the other hand, we want to preserve some interesting aspects of the data, such as narrow spikes in pixel intensity or network traffic. When we aggregate the data using standard averaging functions, these interesting features may be lost. For example a small detail in an image will disappear in the background. However, we wish to reduce the noise in the data at the same time.

We think of a datum as noise when its value is distinct from some group of similar values of the neighboring data. In the image processing context, too large or too small a value of an individual pixel compared to the neighboring pixels is considered noise. But if two or more neighboring pixels take similar values distinct form the background, they possibly represent a fine detail of an object. Such values should be preserved when averaging across the neighboring pixels. A similar reasoning applies to a flow of network packets in network traffic analysis. A narrow spike in the intensity may be an early indication of a cyberattack.

Our objective is to study averaging operators which have the capability to filter out noise, yet preserve interesting but not dominant features of the inputs.

The structure of the paper is as follows. In Section II we provide preliminary definitions. In Section III we review various definitions of existing non-monotone means. In Section IV we introduce a new type of mode-like aggregation. Conclusions are presented in Section V.

II. Preliminaries

A. Aggregation functions

The research effort concerning aggregation functions, their behavior and properties, has been disseminated throughout various fields including decision making, knowledge based systems, artificial intelligence and image processing. Recent books providing a comprehensive overview include [1]–[3].

Definition 1: A function $f : [a, b]^n \to [a, b]$ is called an aggregation function if it is monotone non-decreasing in each variable and satisfies $f(\mathbf{a}) = a$, $f(\mathbf{b}) = b$, with $\mathbf{a} = (a, a, \ldots, a), \mathbf{b} = (b, b, \ldots, b)$.

Definition 2: An aggregation function f is called *averaging* if it is bounded by the minimum and maximum of its arguments

$$\begin{aligned} \min(\mathbf{x}) := \min(x_1, \ldots, x_n) &\leq f(x_1, \ldots, x_n) \\ \leq \max(x_1, \ldots, x_n) &:= \max(\mathbf{x}). \end{aligned}$$

It is immediate that averaging aggregation functions are idempotent (i.e., $\forall t \in [a, b] : f(t, t, \ldots, t) = t$) and (because of monotonicity) vice versa. Then clearly the boundary conditions $f(\mathbf{a}) = a$, $f(\mathbf{b}) = b$ are satisfied.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

A function is called *internal* if its output coincides with one of the inputs. A function f is called *shift-invariant*, if $f(\mathbf{x}+\mathbf{a}) = f(\mathbf{x}) + a$, where $\mathbf{a} = (a, a, \ldots, a)$. A function f is *homogeneous* (of degree one) if $f(\lambda \mathbf{x}) = \lambda f(\mathbf{x})$.

Well known examples of averaging functions are the arithmetic mean and the median. It is known that the arithmetic means and the median are solutions to simple optimization problems, in which a measure of disagreement between the inputs is minimized (see [2], [4]–[6]). The reasoning is as follows. Let $\mathbf{x}$ be the inputs and y the output. If all the inputs coincide $x = x_1 = \ldots = x_n$, then the output is $y = x$, and we have a unanimous vote. If some input $x_i \neq y$, then we impose a "penalty" for this disagreement. The larger the disagreement, and the more inputs disagree with the output, the larger (in general) is the penalty. We look for an aggregated value which minimizes the penalty.

Let us define a suitable measure of disagreement, or dissimilarity.

Definition 3: Let $P : [a, b]^{n+1} \to \Re$ be a penalty function with the properties

i) $P(\mathbf{x}, y) \geq 0$ for all $\mathbf{x}, y$;
ii) $P(\mathbf{x}, y) = 0$ if all $x_i = \mathbf{y}$;
iii) $P(\mathbf{x}, y)$ is quasiconvex in y for any $\mathbf{x}$.

The penalty based function is

$$f(\mathbf{x}) = \arg\min_y P(\mathbf{x}, y),$$

if y is the unique minimizer. If the set of minimizers is the interval $[a, b]$ then $y = \frac{a+b}{2}$.

Remark 1: $f(y)$ is quasiconvex if $f(ay_1 + (1-a)y_2) \leq \max\{f(y_1), f(y_2)\}$ for all $a \in [0, 1]$ and all y_1, y_2 within its domain.

In [4] it was shown that any averaging aggregation function can be represented as a penalty based function. Further, the classical means, such as the arithmetic mean and the median are represented via the following penalty functions. The arithmetic mean is the solution to

$$minimize_y \sum_{i=1}^{n} (x_i - y)^2$$

whereas the median is a solution to

$$minimize_y \sum_{i=1}^{n} |x_i - y|.$$

Not all penalty-based functions are monotone. Let $P(\mathbf{x}, y) = \sum_{i=1}^{n} p(x_i, y)$, with $p(t, s) = 1, t \neq s$ and $p(t, t) = 0$. Then the minimizer of P is the mode. Note that the mode is not monotone non-decreasing, for example

$$Mode(5, 5, 5, 3, 3, 2, 2) = 5 > 3 = Mode(5, 5, 5, 3, 3, 3, 3).$$

Hence mode is not an aggregation function.

III. Non-monotone averaging functions

As we mentioned, the mode has a disadvantage in that it is not well defined when the inputs are distinct. The usual practice to discretize the inputs by assigning frequency values to intervals of equal distance is too sensitive to the choice of the intervals. Here we look at other alternatives which provide a mode-type average.

Our motivation is the following. We think of y as a representative value of the inputs x_i if at least some of the inputs are grouped together around y, i.e. form a compact cluster around y. Other inputs could be far from y, in which case we do not take them into account to avoid any bias toward them. Consider the following inputs $\mathbf{x} = (1, 2, 3, 6, 6.1)$. It appears that the two largest values form a cluster, whereas the first three inputs are dispersed. Hence we may want to choose y near 6 as a representative of the inputs. If x_5 were 6, then the mode would have given us $y = 6$.

The median is one aggregation function robust with respect to outliers in the data. In our example the median is 3, and it does not represent a cluster around 6. Let us now recall other robust estimators of location, which appeared in statistical literature, see e.g., [7].

Definition 4: The *shorth* of a sample is the arithmetic mean of the shortest contiguous subsample with the half of the observations.

To calculate the shorth, we sort the inputs in ascending order and then find the smallest of the differences $x_{(h)} - x_{(1)}, x_{(h+1)} - x_{(2)}, \ldots, x_{(n)} - x_{(n-h+1)}$, with $h = [\frac{n}{2}] + 1$. Let the smallest difference be $x_{(h+j-1)} - x_{(j)}$. Here and in the rest of this paper $x_{(i)}$ denotes the i-th smallest input. Then the inputs falling into the interval $[x_{(h+j-1)}, x_{(j)}]$ are averaged.

A related quantity is the least median of squares estimator [7], [8], defined by

$$LMS(\mathbf{x}) = \arg\min_y Med(x_i - y)^2.$$

Here we also take the shortest contiguous half of the sample, but instead of taking the mean, we take the midpoint of the shortest half. If several shortest halves exist, one could take the average of their midpoints. LMS is based on minimizing a special penalty function, cf. Definition 3, which is not quasiconvex in y (and hence several optima may exist).

Another interesting example is the least trimmed squares estimator, see [7], [8],

$$LTS(\mathbf{x}) = \arg\min_y \sum_{i=1}^{h} r_{(i)}^2.$$

with the residuals $r_i = x_i - y$ and $r_{(i)}$ denoting the i-th smallest (by absolute value) residual. Here, in difference to the LMS estimator, the mean of each contiguous half of $\mathbf{x}$ is computed,

$$\bar{x}^{(i)} = \frac{1}{h} \sum_{j=i}^{i+h-1} x_{(j)},$$

and then the corresponding sum of squares is computed

$$SQ^{(i)} = \sum_{j=i}^{i+h-1} (x_{(j)} - \bar{x}^{(j)})^2.$$

The LTS solution is the mean $LTS(\mathbf{x}) = \bar{x}^{(i)}$ which corresponds to the smallest $SQ^{(i)}$. However, it may be different from the shorth.

The least Winsorized squares estimator is

$$LWS(\mathbf{x}) = \arg\min_y \sum_{i=1}^{h} r_{(i)}^2 + (n-h) r_{(h)}^2.$$

Explicitly, the LWS is the midpoint of the contiguous half which leads to the lowest value of the objective function above.

The averaging functions in this section are symmetric, homogeneous and shift-invariant, but not necessarily monotone or continuous in x_i. Take, for instance, the shorth. We have $Shorth(0, 0.6, 1) = 0.8 > Shorth(0.4, 0.6, 1) = 0.5$.

We note that the functions considered in this section are robust to outliers, the components of $\mathbf{x}$ with aberrantly large or small values. The median is also robust to outliers. The resulting value y remains the same even if half of the components of $\mathbf{x}$ are replaced with arbitrary (possibly infinite) values. However, none of the mentioned functions provides the output close to the desired value 6 in our example.

IV. Non-monotone averages minimizing a penalty

Let us return to Definition 3 and consider other types of penalties.

We are interested in identifying clusters of similar values in the inputs, and taking as the output representative values of such clusters. An input vector may have more than one cluster, and in this case we choose the most compact and large cluster, in some way balancing these two contradictory selection criteria. This can be achieved, in principle, by a clustering algorithm, such as k-means. However, the input vector can also contain only one cluster, which makes clustering methods struggle.

We define an averaging function as follows

$$f(\mathbf{x}) = \arg\min_y P(\mathbf{x}, y) = \arg\min_y \sum_{i=1}^{n} w_i p(|r_{(i)}|), \qquad (1)$$

where p is a penalty term for disagreement with the output. We observe that as in the LTS estimator, the residuals $r_i = x_i - y$ are ordered according to their magnitude. As opposed to LTS, all residuals are taken into account. The function p is chosen as

$$p(t) = \begin{cases} t & \text{if } t \le C, \\ Cs & \text{otherwise.} \end{cases}$$

C is a threshold which reflects scale, and s is a parameter which reflects the relative weighting of the inputs far from the output y.

The reasoning is as follows. On one hand we want y to represent compact clusters of the inputs, and not be affected by inputs far away from y, which can be seen as noise. On the other hand, we want to account for the number of inputs far from y: the smaller is such number, i.e., the larger is the cluster around y, the smaller is the penalty. Finally, we want to have a robust estimate of scale, i.e., C should be related to the inputs values rather than fixed a priori.

For a fixed y, we define C as a multiple of the smallest residual which is not zero. If all the inputs are different, and y coincides with one of the inputs, we take $C = M \times |r_{(2)}|$, and we fix M at 3. Then p will account for all the residuals within C units from y. The inputs outside this range will also contribute to the total penalty P, but only in terms of their number, not their distances from y. This way C is determined automatically.

By construction, the penalty P is aimed to: a) penalize non-compact clusters (through the choice of p and C), b) penalize small clusters (controlled by s), c) penalize y away from the centers of clusters. Among two clusters of inputs of the same size C, P will be smaller for the cluster which contains more data. Among two clusters of the same number of inputs, P will be smaller for the more compact cluster with smaller C. The parameter s controls the relative weighting of two criteria: the size and compactness of clusters. The larger s, the more emphasis is on the size of the cluster. The value s is the only user-defined parameter in our approach.

The weights w_i are associated with the individual inputs, not their distances from y. That is, they can be seen as weights of relative importance of the inputs, and can be omitted if all the inputs have the same importance.

Let us now examine some properties of the function f. First, f is shift-invariant, and symmetric when all the weights are equal. Second, f is also homogeneous. This can be seen from the fact that $p(\lambda x) = \lambda p(x)$, and that the residuals r_i are shift-invariant and homogeneous. The function f is also idempotent, but it is not monotone. The latter can be seen by aggregating the values in the following example: $\mathbf{x}_1 = (0, 1, 2, 3, 3)$ and $\mathbf{x}_2 = (2, 2, 2, 3, 3)$, which results in $f(\mathbf{x}_1) = 3 > 2 = f(\mathbf{x}_2)$.

Minimization of (1) has to be performed numerically, and it requires a global optimization method. For univariate minimization as in (1) we suggest Pijavski-Shubert method [9], see also [10]–[12], which is deterministic and numerically efficient. A significant simplification comes when the function f can be internal. Then the values of $P(\mathbf{x}, y)$ are calculated for all the inputs, and the input with the smallest value of P is returned. The computational complexity in this case is $O(n^2)$, n is the length of the input vector, because a selection algorithm to determine C runs in $O(n)$ time. This is the same complexity as that of a clustering method, when all x_i are tested as cluster centers (we remind that k-means clustering also leads to a global optimization problem, whose objective has complexity $O(n)$, same as in the proposed method).

For the example input vector we considered earlier $\mathbf{x} = (1, 2, 3, 6, 6.1)$, our approach gives $f(\mathbf{x}) = 6$ or 6.1, as desired. In contrast, $med(\mathbf{x}) = 3$, $Shorth(\mathbf{x}) = LMS(\mathbf{x}) = LTS(\mathbf{x}) = 2$, and mode can be any of the inputs.

Let us now look at the following illustrative example. Consider calculation of the moving average, which is often

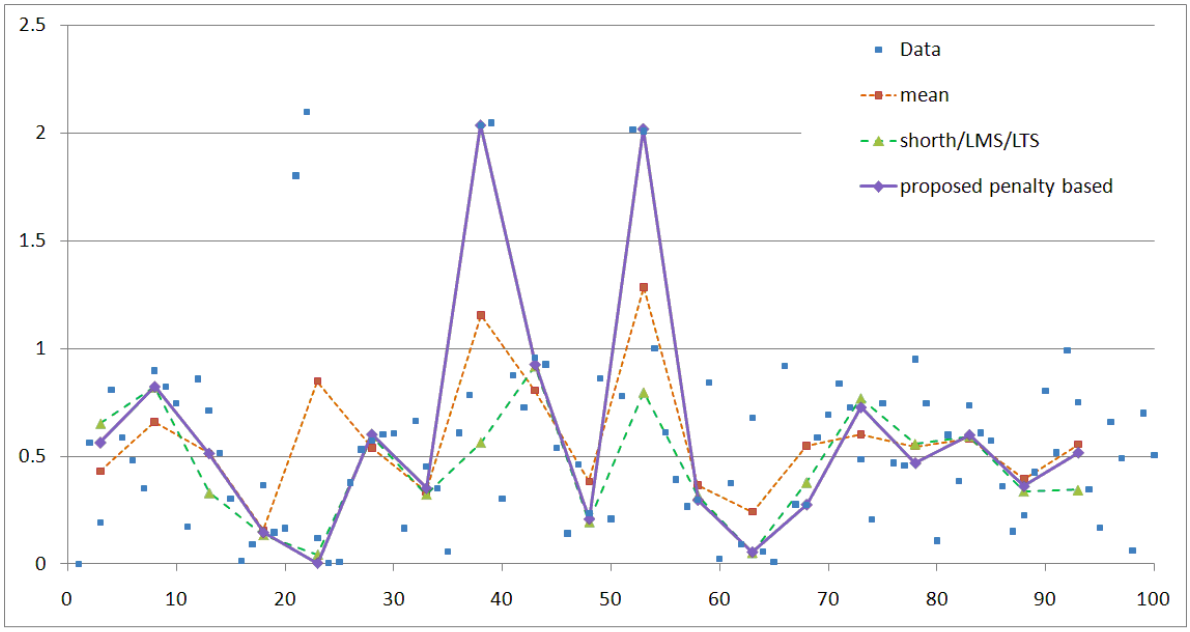

Fig. 1. Illustration of various averages in the moving average example with $m = 5$. The shorth, LMS and LTS estimators give almost the same values in this example and are represented with the dashed line. The arithmetic mean is illustrated with the dotted line. The proposed penalty based average is the solid line. It is the only method which picks two events of interest near 2, and discards abnormal data at positions 21 and 22, because they do not form a compact cluster. Hence these values are considered noise. At other places this method gives the averages similar to shorth/LMS/LTS methods.

used to reduce the size of a time series. We calculate an average of each m consecutive values in the data set, and reduce the length of the data set by the same factor m. Here we randomly generated 100 points with the uniform distribution $U(0, 1)$, and we replaced the data at positions 21,22,38,39, 52 and 53 with (unequal) random values near 2. These spikes in data represent events of interest (e.g., in anomaly detection). The data and various means we considered, along with the simple moving average (for $m = 5$), are illustrated in Figure 1.

We observe that the existing methods filter out the events of interest at the above mentioned positions. The arithmetic mean is affected by the outliers, and results in the values not representative of the corresponding subsamples. The proposed method gives averages close to those of shorth/LMS/LTS methods, but pinpoints the outliers, if they form clusters.

V. Conclusions

We discussed aggregation operators which are not monotone with respect to the inputs. Our motivation was to calculate the outputs representative of inputs that form clusters. Several robust location estimators have been recalled. We introduced a penalty-based averaging function, which favors the values representative of compact clusters.

Compared with the median, and several existing robust estimators of location, the proposed method delivers the outputs similar to those of the mode function, which are representatives of compact clusters of the input values. Unlike the mode, it works when all the inputs are distinct. In the subsequent research we aim at applying such averaging to image processing and analysis of network traffic.

***Abstract*—In this paper a methodology is proposed for providing a linguistic summary of the comparison of time series. This series are obtained as a result of queries which the user defines over a data cube with time dimension. Our objective is that the final summary describe the similarity between series by using local changes. Definitions of the degree and sign of local changes are proposed. The understandability of the linguistic summary is achieved by means of linguistically quantified sentences. So are the coverage and brevity by using a hierarchical partition of time dimension inherited from the data warehouse. Our linguistic summaries are well suited to be included in an interface layer of a data warehouse system, improving the quality of human-machine interaction and the understandability of the results.**

***Index Terms*—Linguistic Summarization, Time series, OLAP, Business Intelligence, Multidimensional Data Model, Fuzzy Logic.**

I. Introduction

Summarization is widely accepted as a data mining task, since summaries of data are extracted non-trivially, they are very useful since they contribute to a better understanding, and they provide a novel, previously unseen view of data.

In the setting of data mining, summaries are expected to be an understandable description of knowledge present in the data. The simpler form of such knowledge are plain facts, as in the case of using statistics (i.e., the average value of a certain variable in a database, etc.). However, much complex summaries may be obtained using more sophisticated knowledge representation languages with richer semantics. Due to its good understandability to the user, one very interesting possibility is to obtain linguistic summaries of data, i.e., summaries expressed in (usually a subset of) natural language.

One of the areas where linguistic summaries can be very useful is that of Business Intelligence solutions, intended to help managers in order to obtain a better understanding of its commercial procedure and operations and, this way, supporting decision-making. Data warehousing systems use to incorporate an interface layer responsible of providing such information (see for example the case of scorecards [1]). One of the tools that undoubtedly can help in building this kind of interfaces is to use natural language as a vehicle to describe data, as a human assistant in charge of this task would do [2].

Part of the research was supported by the Andalusian Government (Junta de Andalucía, Consejería de Innovación, Ciencia y Empresa) under project P07-TIC-03175 *Representación y Manipulación de Objetos Imperfectos en Problemas de Integración de Datos: Una Aplicación a los Almacenes de Objetos de Aprendizaje*. Part of the research was supported by the Spanish Government (Science and Innovation Department) under project TIN2009-08296.

Many queries to data warehousing systems involve the evolution of data along time. Data cubes usually have a time dimension because time plays a crucial role in any commercial activity. Hence, many OLAP queries in data cubes with time dimension produce as result time series data. In particular, many queries are intended to provide a comparison between datasets, like for example the total amount of sales in different shops of a supermarket chain or, involving time, about the evolution of those sales in the same shops. As a consequence, there is a necessity for tools able to provide understandable, accurate, and relevant information about the similarities and differences between time series.

In this work we propose a methodology for providing a linguistic summary of the comparison of time series obtained as a result to a user's query. The summary comes in the form of a collection of *accurate* linguistic quantified sentences describing the similarity between local changes in the whole time domain considered. On the basis of a hierarchical partition of the time dimension, available through the datacube structures, we not only achieve a complete *coverage* of the time domain, but we also avoid obtaining two sentences for the same time period and, in this sense, our summary is also *brief*. The *relevance* of the information is assumed since it is the user who asks for the comparison of the series by means of a specific query , and since we choose the most representative among all the possible sentences for a given time period, also on the basis of the user's preferences. Finally, as we indicated before, *understandability* is taken into account in that the information is provided in the form of a linguistic description in natural language.

As related work, many approaches to data summarization with the use of Soft Computing concepts can be found in the literature. Among these proposals, linguistic summarization is of special interest because of the above mentioned need for sentences close to natural language to describe data. An important seminal part of this research can be found in Ronald R. Yager's works, where he first proposes the use of quantified sentences in the sense of L. Zadeh [3] and later introduces his own way of quantification with OWA (Ordered Weighted Averaging) operators in [4], [5]. Also following Zadeh's footsteps, we can find J. Kacprzyk et al. ([6], [7], [8], [9]) introducing new quality measures and using the protoform concept in order to reach different summary profiles. The same author

The query language employed is not relevant for the purpose of our work.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

has provided methods for linguistic comparison of time series [10], though of a different kind and with different objectives than we intend here. Raschia et al. have created a model named SaintEtiQ [11], working with hierarchies composed by summaries with different abstraction levels. From a different point of view, Bosc and Dubois propose the use of association rules to obtain knowledge from data and even for case based prediction [12]. Our work here is based on an approach to the linguistic summarization of a single time series on the basis of a hierarchical partition of time dimension [13]. The basis for a better understanding of this work can be found in [14], [15] and a detailed study is available at [16].

The document is organized as follows: Section II is devoted to present the source our data come from, introducing OLAP queries on fuzzy data cubes as a mean to obtain the time series to compare. The use of fuzzy data cubes with time dimension provides us with a hierarchical organization of the time domain that plays a determining role in our approach. Section III introduces our proposal to compare two query results in the form of two time series that share the same time line. In this section, we first analyze the characteristics of the series where the comparison focus on and then we set the linguistic framework used to build the summaries. Two greedy algorithms to compute the linguistic summaries are also presented in this section. Section IV contains a descriptive example of the use of the proposed approach and, finally, section V concludes the paper.

II. Describing time series coming from OLAP cubes

Time plays a main role in data warehouses that store *historical* information regarding the daily operation of the organization. This way, decision-makers can analyze the evolution of several aspects of the business along the time. One of the most extended models for building data warehouses is the use of datacubes (also known as OLAP cubes).

We can briefly describe a data cube as a n-dimensional set of cells. Each dimension consists of a set of members that can be arranged along a hierarchy or many hierarchies. Thanks to the hierarchical organization of dimensions, granularity in the data cube can vary according to the selected level chosen in each dimension. OLAP operations permit the user to take advantage of this fact and query the data cube in order to get the desired data in each moment. According to the previous paragraph, among the dimensions of a data cube, we usually find the time dimension.

OLAP cubes have been extended in order to add the capability of dealing with fuzzy data. In our approach, we use as basis the model proposed in [17], [18]. One of the main characteristics of this model is that the hierarchical organization of dimensions can be made by means of linguistic partitions. The use of this model provides a suitable framework for the linguistic description of time series.

Figure 1 describes a (generic) data cube with a time dimension. Each cell contains the value of the variable *V* according to the context defined by the members of each dimension. As we can see, using conventional OLAP operations, we can query the data cube focusing on a given member of each of the non-time dimensions: the result of this query is a time series of data.

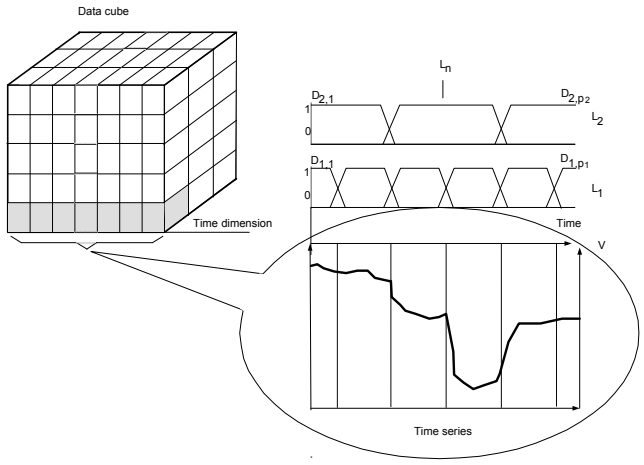

Fig. 1. Time series from OLAP cubes

Suppose that the time dimension is described in its finest grained level of granularity by members $T = \{t_1, ..., t_m\}$. Then, the above mentioned query result will have the following form: $\{< t_1, v_1 >, ..., < t_m, v_m >\}$, where every v_i is a value of the basic domain of the variable V. We will use $TS(t_i)$ to refer to v_i when necessary.

In order to linguistically describe the time information in our approach, the time dimension is hierarchically organized in n levels, namely, L=$L_1, ..., L_n$. Each level L_i has a partition $\{D_{i,1}, ..., D_{i,p_i}\}$ of the basic time domain associated. There is no restriction concerning the form of the membership function of a label apart from that it must be normalized. In our approach, we will use trapezoidal functions. When necessary, labels $D_{i,j}$ in time dimension can be the union of a set of trapezoidal functions.

In this work, a set of labels $\{X_1, ..., X_r\}$ is a partition on X iff:

1) $\forall x \in X, \exists X_i, i \in \{1..r\} | \mu_{X_i}(x) > 0$.
2) $\forall i, j \in \{1..r\}, i \neq j, core(X_i) \cap core(X_j) = \emptyset$.

Additionally, considering the hierarchy of the time dimension, we add the following constraints:

1) $\forall i, j \in \{1..n\}, i < j, p_i > p_j$ (i.e, as we move upward in the hierarchy, the number of labels of the partition decreases).
2) $\forall i \in \{2..n\}, \forall j \in \{1..p_i\}, \forall k \in \{1..p_{i-1}\} | (D_{i,j} \subseteq D_{i-1,k}) \rightarrow (D_{i,j} = D_{i-1,k})$ (i.e., labels cannot generalize another label of an upper level).

As an example, consider a data warehouse with data related to medical centers in a given country. A data cube of this data warehouse can be built with information regarding the patient inflow according to the dimensions *medical center*, *service*, and *time*. If we focus (slice and dice) on a given medical center C and aggregate (roll up) across the service dimension, we obtain the time series "Total patient inflow in center C

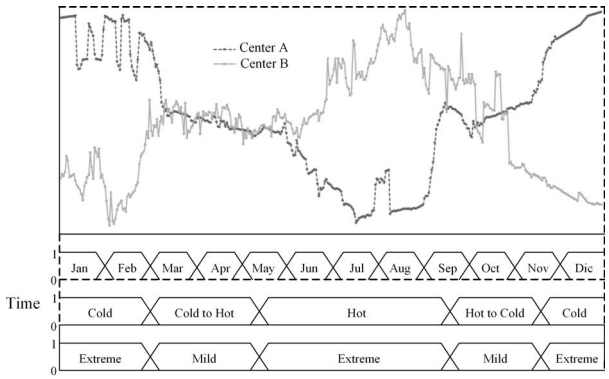

Fig. 2. Patient inflow data series

along the time". In this example, the time dimension is fuzzy hierarchically organized using a meteorological criteria.

Figure 2 contains two time series that shows the patient inflow along a given year to two medical centers. As we can see, the time dimension is hierarchically organized thanks to three fuzzy partitions of the time domain, namely: one based on approximate months (in order to avoid a strong dependence of the obtained summaries with respect to the crisp boundaries of conventional months) and two others based on a meteorological criteria with two levels of granularity. Fuzziness is specially useful in these two last partitions because transitions between periods are clearly fuzzy.

In previous works, we have focused on the linguistic summarization of a single time series [13]. In this work, we extend our approach to the case of the linguistic comparison of the trends of two time series like the ones depicted in Figure 2.

III. Local change based comparison of time series

Once we have described the framework where the time series are defined, the next step is to introduce the new approach to linguistically compare the information related to two time series. There are several ways to compare series. Among them, special attention has been paid to value-based comparison and trend-based comparison. In a previous work [13] we introduced an approach to value-based comparison of two time series. With respect to trend-based comparison, Kacprzyk et al.'s work is of interest [10]. This approach compares the trends trough the analysis of significant segments in the series with respect to duration, dynamics (slope), and variability.

In this work, our interest is centered on the comparison of trends but with a different perspective: we study the dynamics of change through the local variations in the points of the series and we take advantage of the hierarchical partition of the time domain when building the summaries. Our summaries are comprised of several linguistically quantified sentences.

A. Comparing the dynamics of change

The current subsection is devoted to describe the process we follow in order to compare de dynamics of change. The bases will be set by means of the introduction of some important definitions.

We use consecutive points in order to analyze the dynamics of change in the series. To do that, we measure the local change for every time point with respect to the next one in each individual series. This local change can be formalized with the next definitions.

Definition 1 (Local change): Let $TS = \{< t_1, v_1 >, ..., < t_m, v_m >\}$ be a time series and t_i with $i \in [1, m-1]$ be a given time point. The local change $\Delta_{TS}(t_i)$ of t_i in TS is defined as follows: $\Delta_{TS}(t_i) =$

$$= \arctan\left(\frac{TS(t_{i+1}) - TS(t_i)}{t_{i+1} - t_i}\right) = \arctan\left(\frac{v_{i+1} - v_i}{t_{i+1} - t_i}\right)$$

Hence, we are defining local change as the slope of the line joining two consecutive points in the time series. We assume that this slope comes in the form of a value in $[-\pi/2, \pi/2]$.

In Figure 3 the reader can graphically see the intuitive semantics behind our definitions concerning the local change at a given point t_i.

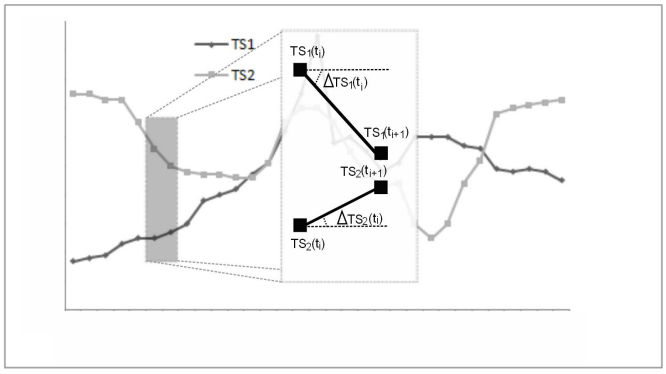

Fig. 3. Local change

Our approach tries to linguistically compare the local change of two time series. To do that, we need a linguistic framework in order to express this comparison by means of natural language. The following definitions are devoted to this aim.

Definition 2 (Same sign function): Let TS_1 and TS_2 be two time series defined on $t_1..t_m$. The same sign function SS_{TS_1,TS_2} is defined, for every $t_i \in \{t_i, ..., t_m - 1\}$ as follows:

$$SS_{TS_1,TS_2}(t_i) = \begin{cases} 1, & \text{if } (\Delta_{TS_1}(t_i) * \Delta_{TS_2}(t_i) \geq 0) \\ 0, & \text{otherwise} \end{cases}$$

Similarly, we can define the different sign function.

Definition 3 (Different sign function): Let TS_1 and TS_2 be two time series defined on $t_1..t_m$. The different sign function DS_{TS_1,TS_2} is defined, for every $t_i \in \{t_i, ..., t_m - 1\}$ as follows:

$$DS_{TS_1,TS_2}(t_i) = \begin{cases} 0, & \text{if } (\Delta_{TS_1}(t_i) * \Delta_{TS_2}(t_i) \geq 0) \\ 1, & \text{otherwise} \end{cases}$$

It is obvious that $SS_{TS_1,TS_2}(t_i) = 1 - DS_{TS_1,TS_2}(t_i)$. If we only focus on the magnitude of the change, we can define two additional functions.

Definition 4 (Degree of similar variation): Let TS_1 and TS_2 be two time series defined on $t_1..t_m$ and t_i with $i \in [1, m-1]$ be a given time point. The degree of similar variation $SV_{TS_1,TS_2}(t_i)$ in point t_i between series TS_1 and TS_2 is defined as follows:

$$SV_{TS_1,TS_2}(t_i) = 1 - \frac{||\Delta_{TS_1}(t_i)| - |\Delta_{TS_2}(t_i)||}{\pi/2}$$

By means of the computation of the degree of similar variation we obtain the similarity observed between the two angles responsible of the local change at a given t_i in both series, without taking into account the sign.

Similarly, we can define the degree of different variation:

Definition 5 (Degree of different variation): Let TS_1 and TS_2 be two time series defined on $t_1..t_m$ and t_i with $i \in [1, m-1]$ be a given time point. The degree of different variation $DV_{TS_1,TS_2}(t_i)$ in point t_i between series TS_1 and TS_2 is defined as follows:

$$DV_{TS_1,TS_2}(t_i) = \frac{||\Delta_{TS_1}(t_i)| - |\Delta_{TS_2}(t_i)||}{\pi/2}$$

Again, it is obvious that $SV_{TS_1,TS_2}(t_i) = 1 - DV_{TS_1,TS_2}(t_i)$.

B. Linguistically quantified sentences

Fuzzy quantification extends classical quantification by considering (fuzzy) linguistic quantifiers, a generalization of the ordinary quantifiers $\exists$ and $\forall$ of first order logic [19]. A large number of applications can be found in the literature in areas like quantifier-guided aggregation, linguistic summarization, computing with words, and quantification in fuzzy description logics, among many others.

The most usual quantified sentences considered in the literature are of the form "Q of X are A" or "Q of D are A", where Q is a linguistic quantifier, X is a (finite) crisp set, and A, D are fuzzy subsets of X. These sentences are called type I and type II sentences, respectively. Linguistic quantifiers are normal, convex fuzzy subsets of integers $\mathbb{Z}$ (absolute quantifiers) or $[0, 1]$ (relative quantifiers). Particularly, in this paper, linguistic quantifiers are represented by trapezoidal functions.

There are many different approaches for evaluating quantified sentences; we shall use the method called GD introduced in [20] as follows: the evaluation of "Q of D are A" by means of GD is

$$GD_Q(A/D) = \sum_{\alpha_i \in \triangle(A/D)} (\alpha_i - \alpha_{i+1}) Q\left(\frac{|(A \cap D)_{\alpha_i}|}{|D_{\alpha_i}|}\right) \quad (1)$$

where $(A \cap D)(x) = \text{Min}(A(x), D(x))$, $\triangle(A/D) = \Lambda(A \cap D) \cup \Lambda(D)$, $\Lambda(D)$ being the level set of D, and $\triangle(A/D) = \{\alpha_1, ..., \alpha_p\}$ with $\alpha_i > \alpha_{i+1}$ for every $i \in \{1, ..., p\}$, we consider $\alpha_1 = 1$ and $\alpha_{p+1} = 0$ (although α_{p+1} is not in the level set we consider it in the formula). The set D is assumed to be normalized. If not, D is normalized and the same normalization factor is applied to $A \cap D$ (D and $A \cap D$ will be divided by the greater value in D) .

The GD method has been used due to its efficiency and non-strict character. The method also fulfills some interesting properties related to relative quantifiers (defined in [20]). Another point is that it is easy to implement. Anyway, let us remark that the strategies presented in this paper are not dependent on the evaluation method.

As we have mentioned, we consider that the user is interested in linguistic comparisons that take the form of a collection of quantified sentences. In this sense, our approach will deliver a collection of sentences of the form "Q of $D^S_{i,j}$ are A^S" where:

- Q is a linguistic quantifier.
- $D_{i,j}$ is a label member of a certain level i of the hierarchy associated to the time dimension and

$$D^S_{i,j}(< t, v >) = D_{i,j}(t). \quad (2)$$

- A is a label or the union of a subset of labels of the partition of the variable V under study. In this case V represents the local change, and

$$A^S(< t, v >) = A(v). \quad (3)$$

With this kind of sentences, the approach will be able to produce results like "Most (Q) days of the cold season ($D^S_{i,j}$), both series exhibit a local change with the same sign and similar variation (A^S)".

With respect to the quantifier Q, the user must provide a collection of quantifiers defining the kind of fuzzy quantities and percentages she/he is interested in. This can be defined by choosing among a collection of predefined quantifiers. In this work, we consider that the user provides a *totally ordered* subset $\{Q_1, ..., Q_{qmax}\}$ of a coherent family of quantifiers $\mathcal{Q}$ [21] to be used in the summarization process.

Definition 6 (Coherent family of quantifiers): Let $\mathcal{Q}$=$\{Q_1$, ..., $Q_l\}$ be a linguistic quantifier set, we shall say it is coherent if it verifies that:

- The membership functions of elements in $\mathcal{Q}$ are non-decreasing functions.
- A partial order relation $\succeq$ is defined in $\mathcal{Q}$. It has as its maximal element $Q_1 = \exists$ and as its minimal one $Q_l = \forall$. Furthermore $\forall Q_i, Q_j \in \mathcal{Q}$, $Q_i \subseteq Q_j \Rightarrow Q_j \succeq Q_i$.
- The membership function of the quantifier $\exists$ is given by $Q_1(x) = 1$ if $x \neq 0$ and $Q_1(0) = 0$, whereas the membership functions of $\forall$ will be $Q_l(x) = 0$ if $x \neq 1$ and $Q_l(1) = 1$.

To play the role of D, we can take any of the labels $D_{i,j}$ defined in the hierarchy associated to the time domain in our fuzzy OLAP cube.

Finally, we can consider the definition of A according to the previous definitions:

As the data set X is assume to be finite, D is considered to be finite, and hence the number of relevant α-cuts is also finite.

- Points where local change has the same sign (whatever the variation). In this case:

$$A(t_i) = SS_{TS_1,TS_2}(t_i)$$

- Points where local change has different sign (whatever the variation). In this case:

$$A(t_i) = DS_{TS_1,TS_2}(t_i)$$

- Points where local change has similar variation (whatever the sign). In this case:

$$A(t_i) = SV_{TS_1,TS_2}(t_i)$$

- Points where local change has different variation (whatever the sign). In this case:

$$A(t_i) = DV_{TS_1,TS_2}(t_i)$$

C. Obtention of the summaries

According the above defined linguistic framework, our approach will deliver a summary composed by a collection of sentences of the form "Q of D^S are A^S" with the above described semantics. To obtain this collection, apart from the linguistic framework analyzed in the previous subsection, the user will provide a threshold τ for the minimum accomplishment degree she/he wishes for the quantified sentences comprising the summaries. It is also necessary that the user specify wether she/he is interested in summarizing the local changes according to the sign or the variation.

Once we have defined all the parameters we need, it is time to launch a process able to compute the desired summary. Algorithm 1 explores all the possible A labels of C before exploring solutions with a less strict quantifier, beginning with the *strictest* quantifier provided by the user.

In order to look for *brevity*, we start from the time periods at the top level of the hierarchy. Each level has its own quantifier bound ($Qbound_i$) that indicates the least strict quantifier to be considered. The set $ToSummarize$ is the collection of time periods for which a quantified sentence is missing. The set $Summarized$ is the collection of time periods for which a quantified sentence is found. If it is possible to obtain an accomplishment degree greater than or equal to τ for a certain period using a quantifier Q and an A label of C, the procedure obtains a summary for that period.

If all A labels are tried without success, the algorithm repeats the process again, but with a less strict quantifier, until $Qbound_i$ is reached. When a summary is found in a certain time period we say that the period is $covered$.

If there is no result for a given period $D_{i,j}$, we try to obtain such sentences with the *corresponding children* $ch(D_{i,j})$ in the next level of the time domain (line 21).

For every $D_{i,j}$, $ch(D_{i,j})$ is defined as follows:

- $ch(D_{1,j}) = \emptyset$ for all j.
- Otherwise, $ch(D_{i,j}) = \{D_{i-1,k}, k \in \{1..p_{i-1}\} | D_{i-1,k} \cap D_{i,j} \neq \emptyset$ and $\neg\exists D \in ToSummarize \cup Summarized$, $(D_{i-1,k} \cap D_{i,j}) \subseteq D\}$.

Algorithm 1 to obtain linguistic summaries.

Input

Two time series TS_1 and TS_2
A hierarchical fuzzy partition of the time dimension D
A totally ordered subset $\{Q_1..Q_{qmax}\}$ of a coherent family of quantifiers Q.
A threshold τ as minimum accomplishment for quantified sentences.
For each L_i, maximum number of quantifiers to use ($Qbound_i$).
Two collections of alternatives for A, $C \subseteq \{SS_{TS_1,TS_2}, DS_{TS_1,TS_2}\}$ or $C \subseteq \{SV_{TS_1,TS_2}, DV_{TS_1,TS_2}\}$.

Output

A Summary of the comparison of time series TS_1 and TS_2

Algorithm

1: $ToSummarize \leftarrow L_n$;
2: $Summary \leftarrow \emptyset$; $Summarized \leftarrow \emptyset$;
3: **while** $ToSummarize \neq \emptyset$ **do**
4: Take $D_{i,j} \in ToSummarize$
5: $ToSummarize \leftarrow ToSummarize \backslash \{D_{i,j}\}$;
6: $p \leftarrow qmax$; $covered \leftarrow false$;
7: **while** $p \geq Qbound_i$ and $not\ covered$ **do**
8: Let $A \leftarrow argmax_{B \in C_k} GD_{Q_p}(B^S / D^S_{i,j})$;
9: **if** $GD_{Q_p}(B^S / D^S_{i,j}) \geq \tau$ **then**
10: $Summary \leftarrow Summary \cup \{Q_p$ of $D^S_{i,j}$ are $A^S\}$;
11: $Summarized \leftarrow Summarized \cup (D_{i,j})$;
12: $covered \leftarrow true$;
13: **end if**
14: $p \leftarrow p - 1$;
15: **end while**
16: **if** $not\ covered$ and $i > 1$ **then**
17: $ToSummarize \leftarrow ToSummarize \cup ch(D_{i,j})$;
18: **end if**
19: **end while**

With regards to the computational complexity of the algorithms, as can be seen, it exponentially depends on $|A|$ (the number of labels defined in A) and linearly depends on $\sum_i p_i$ (the number of labels in the time partitions) and $qmax$ (the number of quantifiers). In any case, $|E|$ is usually low and it is not necessary to explore its entire powerset due to the user-defined bounds.

IV. Experimentation

This section is devoted to show the performance of the proposed approach. With that purpose we use two series representing the gasoline price in New York and Texas during the same period of time.

As it was mentioned before, once the user has the corresponding time series data, he/she is in charge of defining the linguistic background and setting the parameters following his/her specific needs. The different partitions on the variable and time domains will define the type of sentences he/she will be able to obtain at the end of the summarization process. Moreover, he/she has to set the parameters values to inform the algorithm of his/her exploration preferences (sign/variation, threshold and boundaries).

The series used in this example represent the weekly all grades all formulation retail gasoline prices (in cents per gallon) in New York and Texas during the decade 2000-2010. In this example we do not have all the measures on year 2000 but only those corresponding to the second half of the year. The same thing occurs when dealing with 2010 where we only have

values for the first quarter of the year. In total, we count on 513 measures representing the 513 weeks. Series are depicted in Figure 4.

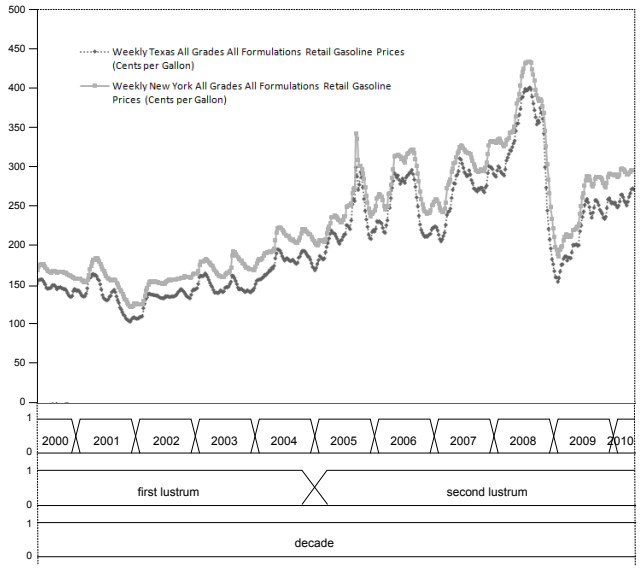

Fig. 4. Weekly all grades all formulation retail gasoline prices (in cents per gallon)

As we can see in Figure 4, the time dimension is hierarchically organized in three levels. The more general level represents the whole decade, while the second is made up of partitions representing two approximate periods of five years (lustrums). Finally, the finest grained level partition represents approximate years. In this context, fuzziness is used in order to avoid sharp transitions between time periods. The hierarchical partition of the time domain is defined in Table I.

Level	Label	Definition
1	Second half of year 2000	(0, 0, 28, 32)
	Year 2001	(28, 34, 80, 84)
	Year 2002	(80, 84, 132, 136)
	Year 2003	(132, 136, 184, 188)
	Year 2004	(184, 188, 236, 240)
	Year 2005	(236, 240, 288, 292)
	Year 2006	(288, 292, 341, 345)
	Year 2007	(341, 345, 393, 397)
	Year 2008	(393, 397, 445, 449)
	Year 2009	(445, 449, 497, 501)
	First quarter of year 2010	(497, 501, 513, 513)
2	First lustrum	(0, 0, 230, 249)
	Second lustrum	(230, 249, 513, 513)
3	Whole decade	(0, 0, 513, 513)

TABLE I
PARTITION OF THE TIME DIMENSION

The example has been carried out using the set of linguistic quantifiers shown at Table II. The threshold value has been set as $\tau = 0.7$. Regarding $Qbound_i$, this parameter has value 1 in levels 3 and 2, and value 2 in level 1 ($Qbound_3 = Qbound_2 = 1$ and $Qbound_1 = 2$). This is due to the fact that the user wants to use stricter quantifiers in levels holding bigger periods of time, and less strict quantifiers in the finest grained partition in order to obtain representative summaries.

Quantifier	Definition
Most	(0, 0.7, 0.9, 1)
At least 70%	(0, 0.6, 0.8, 1)
At least 60%	(0, 0.5, 0.7, 1)
At least 50%	(0, 0.4, 0.6, 1)

TABLE II
QUANTIFIERS

In the first case, we are going to consider that the user is interested or she/he considers useful only those labels representing the local changes in terms of sign as C. As a result, we obtain this set of quantified sentences.
- Most days of second lustrum, both series exhibit a local change with the same sign (0.716765).
- At least 70% of the days of a half of year 2000, both series exhibit a local change with the same sign (0.770035).
- Most days of year 2001, both series exhibit a local change with the same sign (0.714104).
- At least 70% of the days of year 2003, both series exhibit a local change with the same sign (0.821261).
- Most days of year 2004, both series exhibit a local change with the same sign (0.812402).

In the second case, the user focusses the attention on those labels representing the local changes in terms of variation as C. The obtained set of quantified sentences is:
- At least 70% of the days of a half of year 2000, both series exhibit a local change with similar variation (0.727618).
- At least 70% of the days of year 2002, both series exhibit a local change with similar variation (0.707482).
- At least 70% of the days of year 2003, both series exhibit a local change with similar variation (0.763968).
- At least 70% of the days of year 2004, both series exhibit a local change with similar variation (0.784934).
- Most days of year 2005, both series exhibit a local change with similar variation (0.761454).
- Most days of year 2006, both series exhibit a local change with similar variation (0.736421).
- At least 70% of the days of year 2007, both series exhibit a local change with similar variation (0.75718).
- Most days of year 2008, both series exhibit a local change with similar variation (0.736357).
- At least 70% of the days of year 2009, both series exhibit a local change with similar variation (0.754698).
- It has not been possible to find any kind of information referring to the rest of time periods.

The reader can see that the algorithm has obtained a short summary using sign local changes while the summary is a little bit longer using variation local changes. In the first execution the algorithm has come up with a suitable sentence describing the whole second lustrum. In the second execution

the accuracy of the sentence produce for the same period of time using variation is not enough and smaller periods have to be analyzed. We can conclude that the series are more similar according to local changes in sign that according to local changes related to variation.

We have to keep in mind that the presented method analyzes local trends by doing the calculation with pairs of consecutive time points. It could be possible that the obtained results surprised the user if he/she was expecting a summary comprising a global trend description. In some occasions the local trends can coincide with the global one, but this is not necessarily true.

V. Conclusion and future work

Linguistic summarization of data is a very interesting data mining task providing highly understandable knowledge. In this work we have proposed a methodology for providing linguistic summaries to answer a usual kind of queries in data warehouses, i.e., the comparison of time series. These queries are frequent as data cubes use to have a time dimension.

The comparison is focused on the analysis of the degree and sign of the local change observed in every time point. The summary is a collection of *accurate* linguistic quantified sentences describing the similarity between local changes in the whole time domain considered. A hierarchical partition of the time dimension permits us not only to achieve a complete *coverage* of the time domain, but also to obtain *brief* summaries. The *relevance* of the information is assumed since it is the user who asks for the comparison of the series by means of a specific query, and since we choose the most representative among all the possible sentences for a given time period, also on the basis of the user's preferences. Our linguistic summaries are well suited to be included in an interface layer of a data warehouse system, improving the quality of human-machine interaction and the understandability of the results.

We are currently extending the approach so that the user can interleave both the analysis in term of sign and in term of variation at the same time. This way, different levels of granularity can be managed by the algorithm in its look for a *brief* and *accurate* summary of the comparison of the dynamic of local changes in the series.

***Abstract*—This paper presents a novel pheromone update strategy for improving the clustering results of ant colony optimization (ACO). The proposed algorithm is motivated by the observation that most of the ACOs only keep track of the *promising* foraging information, which has the potential to lead to better solutions than all the other search directions in the pheromone table. This eventually makes the search converge to particular search directions in later iterations because the pheromone values on good routing paths will be reinforced. As such, the breadth of search (diversity) will be reduced, thus limiting the clustering results of ACO. The proposed algorithm adds a second pheromone table to ACO for recording the *unpromising* foraging information that is worse than all the other search directions and using a novel construction method to explore the new search directions. In other words, by leveraging the strengths of diversification and intensification, the proposed algorithm can find better solutions than traditional ACO. To evaluate the performance of the proposed algorithm, we use it to solve the data clustering problem. Our experimental results indicate that the proposed algorithm can significantly improve the quality of ant colony optimization.**

keyword: ant colony optimization; pheromone table, and clustering.

I. Introduction

Partitional clustering is a traditional clustering approach [1], [2], [3] that partitions n patterns in d-dimensional space into k groups according to some predefined criteria. The ultimate goal of clustering is to find a partitioning that minimizes the distance between all patterns and their centroids while at the same time maximizing the distance between clusters. In practice, the most popular metric used to measure the clustering results is the sum of squared errors (SSE) defined as

$$\text{SSE} = \sum_{i=1}^{k} \sum_{j=1}^{n_i} \|x_{ij} - c_i\|^2, \tag{1}$$

where k denotes the number of clusters; n_i the number of patterns in the ith cluster; x_{ij} the jth pattern in the ith cluster; $c_i = (1/n_i) \sum_{j=1}^{n_i} x_{ij}$ the mean (centroid) of the ith cluster; and $n = \sum_{i=1}^{k} n_i$ the number of patterns. On the other hand, metrics other than SSE such as f-measure or entropy can be used when the same clustering algorithm is applied to solve other clustering problems.

Clustering technologies are important because many applications such as search engine [4], [5], [6], document analysis [7], [8], bio-information [9], [10], financial analysis [11], and human face recognition [12], [13] rely on the clustering technologies. More recently, how to find an approximate solution to a clustering problem, which is NP-hard [14], in a reasonable time has become a very important research topic partially because the dataset size has become larger and larger and partially because finding the optimum solution to a clustering problem takes an extraordinary amount of time.

Since 1950's, many methods have been proposed to solve the clustering problem. Some of them are deterministic, some stochastic, and some statistic. The k-means [15], [16] algorithm is undoubtedly one of the most well known clustering algorithms because it is very easy to implement and it will converge to a local optimum very quickly. However, the clustering results of k-means are not satisfied for many applications because the k-means algorithm has several drawbacks. Of them are: the final result is very sensitive to the initial solutions; it is incapable of separating clusters that are non-linearly separable; and it may fall into local minima at early iterations. In addition to k-means, metaheuristics provide another way for clustering the data to mitigate the problems of k-means. Over the past, many metaheuristics have been employed to solve the clustering problem such as genetic algorithm (GA) [17], [18], tabu search (TS) [19], particle swarm optimization (PSO) [20], [21], and ant colony optimization (ACO) [22], [23]. Of them, ACO is among one of the most efficient metaheuristic algorithms because it uses social behavior to search for the clustering solution.

Although ACO can provide better results than other metaheuristic algorithm algorithms, it is still facing the local minima problem on its convergence process because by reinforcing the pheromone values on some routing paths that provide better solutions, the breadth of the search directions is limited. However, solutions on worse routing paths may provide partial solutions of the optimum soltuion or better search directions

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

even though the chance is very small. For this reason, ACO-based algorithms may lose partial optimum solutions at the future search process by only reinforecing the promising paths. As such, how to improve the end results has recently become a promising research topic. In this paper, we present a novel ACO-based algorithm based on ant colony system (ACS), called ant colony optimization with dual pheromone tables (ACODPT), that adds a second pheromone table to it for keeping track of a different kind of information for improving the end results. A new recombination method for solution construction is also presented to explore the new search directions that may find better solution of clustering. To evaluate the performance of the proposed algorithm, we compare it to three state-of-the-art clustering algorithms: standard k-means [16], ant colony system [24], and genetic k-means algorithm [17].

The remainder of the paper is organized as follows. Section II gives a brief introduction to the genetic algorithm and approaches taken to enhance its performance. Section III describes in detail the proposed algorithm. Also given in Section III is a simple example to demonstrate how the proposed algorithm works. Performance evaluation of the proposed algorithm is presented in Section IV. Conclusion is drawn in Section V.

II. Related Work

Generally speaking, the clustering algorithms [25] that are inspired by the behavior of ants can be divided into two categories: ant-based clustering algorithm (ACA) [26], [27], [28], [29] and ant colony optimization (ACO) [30], [24], [31], [32]. In this section, we will give a brief introduction to these clustering algorithms.

A. Ant-based clustering algorithms

The ant-based clustering algorithm is inspired by the behavior of ant colonies in clustering their corpses and sorting their larvae [33]. The initial study was done by Deneubourg et al. [26] in which they proposed a model to make the ants move randomly and used the behavior of ants in "picking up" and "dropping" patterns to cluster the patterns. In [27], Lumer and Faieta extended the study in [26] to improve the quality of the clustering results. Generally, the clustering algorithms in this class are called the ant-based clustering algorithm (or ACA for short). Fig. 1 shows the basic concept and the major operators used by ACA [27].

```
1 Initialize()
2 while the termination criterion is not met
3     randomly select an ant to move
4     s = DropItem()
5     s = PickupItem()
6 end
7 OutputResult()
```

Fig. 1. Outline of the ACA.

As shown in Fig. 1, the very first step ACA takes is to initialize all the parameters, randomly scatter data items on the toroidal grid, and randomly place ants on the toroidal grid. The *DropItem* operator checks to see if ant j carries a pattern and is placed at a free grid position. It decides probabilistically whether to drop the pattern at the current position by Eqs. (2) and (4). The *PickupItem* operator checks to see if ant j does not carry any pattern and has arrived at a grid position occupied by a data pattern. It decides probabilistically whether to pick up this pattern by Eqs. (3) and (4).

$$p_{\text{drop}}(i) = \begin{cases} 2f(i) & \text{if} f(i) < k^-, \\ 1 & \text{otherwise}, \end{cases} \tag{2}$$

$$p_{\text{pick}}(i) = \frac{k^+}{k^+ + f(i)}, \tag{3}$$

$$f(i) = \max\left\{0, \frac{1}{\sigma^2}\sum_{j\in L}\left(1 - \frac{d(i,j)}{\alpha}\right)\right\}. \tag{4}$$

where k^+ and k^- are constants, $f(i)$ is a neighborhood function, $d(i,j)$ is the similarity measurement between patterns i and j, α is a data-dependent scaling parameter, and σ^2 is the size of the local neighborhood L.

In [33], Yang and Kamel presented a parallel model by using the multi-ant colonies model that contains independent ant colonies and a queen ant. The proposed three information exchange methods between the queen ant and ant colonies. They are: keeping predecessor, circular exchange, and lowest outliers. The experimental results show that the multi-ant colonies algorithm [33] outperforms single-ant-based algorithm and k-means in terms of several different criteria. In [34], Boryczka presented an extended version of ACA, by modifying the density function $f(i)$ to solve the problem in which the stable value of neighborhood scaling parameter may sometimes cause inappropriate behavior. Another modification is the new α-adaptation scheme that uses simulated annealing to determine its value. In summary, the advantages of ACA are in that it can automatically determine the number of clusters and the clustering results outperforms the statistical methods [25].

B. ACO-based algorithms for clustering

Ant Colony Optimization (ACO) [30], [24], [31], [32] is an efficient method proposed in the early 1990s for attacking the combinatorial optimization problems. It is inspired by the foraging behavior of real ant colonies. Fig. 2 shows the basic concept and the major operators used by ACO to find good solutions.

```
1 Initialize()
2 while the termination criterion is not met
3     s = SolutionConstruction()
4     τ = PheromoneUpdate()
5     LocalSearch(s) // optional
6 end
7 OutputResult()
```

Fig. 2. Outline of the ACO.

As shown in Fig. 2, the very first step ACO takes is to initialize all the parameters such as the best-so-far solution, the iteration-best solution, and the pheromone values τ. After that, the main procedure on lines 2 through 6 will be repeated until the stop condition is met. In general, the main procedure is composed of two required operators *SolutionConstruction*() and *PheromoneUpdate*() and one optional operator *LocalSearch*().

The *SolutionConstruction*() operator on line 3 that calculates the probability p_{ij}^k for choosing the next sub-solution is defined as follows:

$$p_{ij}^k = \begin{cases} \frac{[\tau_{ij}]^\alpha [\eta_{ij}]^\beta}{\sum_{j \in \mathcal{N}_i^k} [\tau_{ij}]^\alpha [\eta_{ij}]^\beta} & \text{if } j \in \mathcal{N}_i^k, \\ 0 & \text{otherwise,} \end{cases} \tag{5}$$

where $\mathcal{N}_i^k$ denotes the set of feasible (or candidate) sub-solutions that can be the next sub-solution of i; τ_{ij} the pheromone value between the sub-solutions i and j; η_{ij} a heuristic value, which is also referred to as the *heuristic information*, used to denote the quality of sub-solution s_{ij}^k that will affect each ant's determination to move to j when at i; and α and β the weight of exploration and exploitation.

The *PheromoneUpdate*() operator on line 4 that is employed in updating the pheromone value τ_{ij} on each edge e_{ij} is defined as follows:

$$\tau_{ij} = (1-\rho)\tau_{ij} + \rho \sum_{k=1}^{m} \triangle \tau_{ij}^k, \tag{6}$$

$$\triangle \tau_{ij}^k = \frac{1}{L^k} \tag{7}$$

where m denotes the number of ants; L^k either the length of the tour created by ant k, the length of the iteration-best solution, or the length of the best-so-far solution. Normally, local search, such as problem-specific permutation method, is used as an option for improving the quality of the solution of ACO if ACO cannot find an applicable solution.

Recently, several studies [35], [36], [37], [38], [39], [40], [41], [42] have used ACO to solve the clustering problem because it can provide better result than the other traditional clustering algorithms such as k-means. Šilc et al. [35] used the generalized Lloyd algorithm to create a partition, which is then used as the initial solution for ACO to solve the mesh-partitioning problem. Kuo et al. [36], [37] presented another combination to solve the clustering problem that integrates ACO and k-means, called ant k-means algorithm (AK). This algorithm adds four operators to ACO, that is, *divide*, *agglomerate_obj*, *agglomerate*, and *remove*. Initially, all the patterns are grouped into a root cluster. The divide operator plays the role of dividing the root cluster into several new clusters by the predefined criteria. The agglomerate_obj operator is then used to agglomerate the patterns into the suitable clusters while the agglomerate operator is used to merge clusters that are simliar to each other. The remove operator is employed to remove patterns that are dissimilar in the cluster to which they belong. The simulation results show that AK [37] outperforms self organizing maps with k-means and self organizing maps with genetic algorithm. Tsai et al. [38] presented another modified version of ACO to solve the clustering problem by adding several efficient strategies, called ant colony optimization with different favor (ACODF). One of the efficient strategies is that ACODF does not require ant to visit all the patterns (nodes) to be clustered. Another efficient strategy is that ACODF splits patterns the pheromone value between them is less than a predefined threshold into different groups. Li et al. [39] parallelized the ACO for the codebook generation problem (CGP) by using MPI. The simulation results show that the parallel strategy can improve the quality of ACO for CGP by about 0.1 up to 0.2 dB of peak signal-to-noise ratio (PSNR). Han and Shi [40] presented an efficient ant-based algorithm for fuzzy clustering the image segmentation problem. First, k centers are selected based on the image histogram. Then, the gradients of the k centers are used to determine the neighboring features to reduce the computation time.

Ramos et al. [41] combined hyperboxes and ACO to solve the clustering problem, called hyperbox clustering with ACO (HACO). More precisely, the hyperboxes are placed in the search space to reduce the number of patterns that ACO needs to compute. The hyperboxes are then grouped by using the nearest-neighbor (NN) method. The computation time of HACO can then be reduced so that it is faster than ACO. Korürek and Nizam [42] used ACODF [38] to cluster unknown patterns to train the arrhythmia detection system. The nearest neighborhood classifier is used to test the system. The results show that ACO can be used to improve the analysis results of the medical signals such as electrocardiography (ECG).

III. The Proposed Algorithm

In this section, we present an efficient ACO-based algorithm based on two pheromone tables, called ant colony optimization with dual pheromone tables (ACODPT). We will begin with a brief introduction to the proposed algorithm and an example of ACODPT before we move on to the details of the proposed algorithm.

A. The concept

In general, most of the ACO-based algorithms use pheromone to record and propagate the *positive information* between ants in the population. Consequently, when one or more ants find a good path (search direction or solution), the other ants in the population will follow this path by a positive feedback to the pheromone table. That is, the ACO-based algorithms only keep the positive information to the pheromone table. As such, the breadth of the search directions will be reduced as the number of iterations increases. In this paper, we add a second pheromone table to lay down the negative information. As shown in Fig. 3, the proposed algorithm, ACODPT, has two different kinds of pheromone tables: the positive pheromone table and the negative pheromone table. After the transition and mean update operator, the pheromone values of some paths in the positive pheromone table will be strengthened when ants routing on these paths find better results than the other ants. At the same time, the pheromone

values of some paths in the negative pheromone table will be increased when ants routing on these paths find worse results than the other ants.

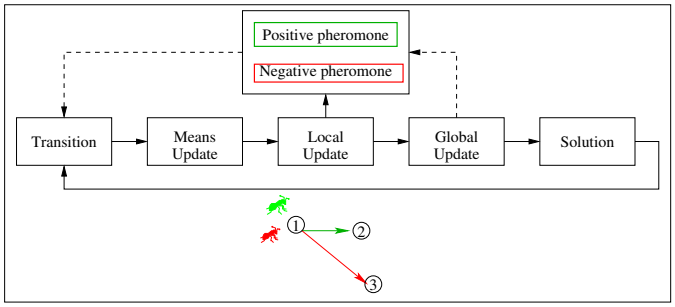

Fig. 3. An illustration of the proposed algorithm.

For example, as depicted at the bottom of Fig. 3, the green ant finds a better route path (starting with node 1 to node 2) than the red ant (node 1 to node 3). The green ant then updates the positive pheromone table to keep its route path whereas the red ant updates the negative pheromone table to keep its route path. Simply speaking, the underlying idea is to prevent the ant from routing the some paths they have already traveled that are worse than paths (solutions) created by the other ants. From this perspective, it is used to avoid only searching the similar directions that can find better result.

B. The ant colony optimization with dual pheromone tables

In order to integrate two pheromone tables into the proposed algorithm, the way the probability is calculated has to be modified, which in turn changes the solution construction operators, as given below.

$$s = \begin{cases} \arg\max_{u \in \mathcal{N}_r^k} \{[\tau_{ru}] \cdot [\eta_{ru}]^\beta\} & \text{if } q \le q_0, \\ v & \text{if } q_0 < q \le q_1, \\ w & \text{otherwise,} \end{cases} \quad (8)$$

$$q_{rz}^k = \begin{cases} \frac{[\tau_{rz}] \cdot [\eta_{rz}]^\beta}{\sum_{u \in J(r)} [\tau_{ru}] \cdot [\eta_{ru}]^\beta} & \text{if } z \in \mathcal{N}_r^k \setminus B_r^k, \\ 0 & \text{otherwise,} \end{cases} \quad (9)$$

$$B_r^k = B_r^k \cup \{\overline{rz}\} \quad \forall z \in \mathcal{N}_r^k \text{ and } \tau_{rz}^b < q_b, \quad (10)$$

where q is a random value to determine which strategy will be used to construct the next sub-solution, q_0 and q_1 are used to predefine the intervals of the three strategies used in ACODPT. Similar to ACS, as defined in Eq. (8), the first two selection strategies are: select the best next sub-solution (when $q \le q_0$) and select the next solution with the probability calculated by Eq. (5) (when $q_0 < q \le q_1$).

When $q > q_1$, the proposed algorithm will, of course, use Eqs. (9) and (10) to determine the next sub-solution. As defined in Eq. (10), B_r^k represents the path that will not be selected, $q_b \in (0, 1)$ is a random value, and $\tau^b \in (0, 1)$ represents the second kind of pheromone on the path. In other words, the path will be included to the set B_r^k if the pheromone value τ^b is less than q_b. As a consequence, the paths (solutions) that are worse than the other existing paths found by ants will not be selected when the ACODPT uses q_{rz}^k to determine the next sub-solutions.

```

3     for each ant k
4        1. assign all patterns to the clusters to which they belong by
5           Eqs. (8), (9) and (10).
6        2. update centroids
7        3. local update each path rs ant k moved
8     end
9     global update each path rs by Eqs. (11) and (12)
10 end
11 Output the best result
```

Fig. 4. Outline of ACODPT

Fig. 4 gives an outline of the proposed algorithm. ACODPT will first initialize the positive pheromone table and the negative pheromone table by setting all the paths to the initial value, followed by setting the parameters, such as α, β, ρ, and SSE to their initial values. Next, ACODPT will enter the main loop, which will be performed until the stop criterion is met. At the solution construction step (lines 3–7), each ant in the population will take care of assigning the input patterns to the clusters by using the equations Eqs. (8), (10) and (9).

In this paper, the proposed algorithm uses the group ID of all patterns to represent the clustering result. As shown in Fig. 5, suppose that we have four input patterns to be partitioned into three groups (clusters). The solution of each ant k of the proposed algorithm can be denoted by $s^k = \{s_1^k, s_2^k, s_3^k, s_4^k\}$, with s_i^k indicating to which cluster pattern i belongs, determined by Eqs. (8), (10) and (9) (see also lines 4 and 5).

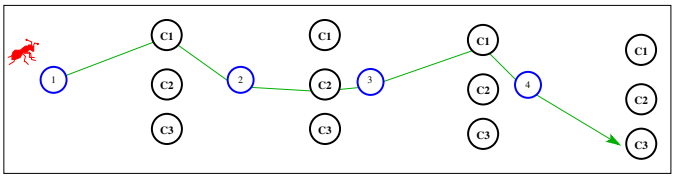

Fig. 5. Example illustrating how ACODPT assigns a pattern to the cluster to which it belongs.

This procedure will be repeated for all the input patterns. The centroids of the solution created by the ant k will then be updated when that ant completed the tour. In addition to local update the pheromone values in the positive pheromone table, ACODPT will also global update the pheromone values in the positive pheromone table defined as

$$\tau_{rs} = (1 - \rho)\tau_{rs} + \rho\Delta\tau_{rs}^{\text{bs}}, \quad \forall \overline{rs} \in T^{\text{bs}}, \quad (11)$$

where T^{bs} denotes the best-so-far tour and τ^{bs} the pheromone value that will be increased by the global update of this path, and the pheromone values in the negative pheromone table defined as

$$\tau_{rs}^b = \gamma\tau_{rs}^b, \quad \forall \overline{rs} \in T^{\text{iw}}, \quad (12)$$

where T^{iw} denotes the iteration-worst tour. Moreover, γ is set to 0.999 as far as this paper is concerned. When the termination criterion is met, ACODPT will output the best-so-far solution as the final solution.

IV. Simulation Results

In this section, the performance of the proposed algorithm is evaluated by comparing it with several state-of-the-art clustering algorithms. But before that, we will first give the parameter settings and datasets used.

A. Parameter settings and datasets

To evaluate the performance of ACODPT, we compare it with three state-of-the-art clustering algorithms: standard k-means [16], genetic k-means algorithm [17], and ant colony system [24]. The empirical analysis is conducted on an Intel i7 CPU 920 with 2.67 GHz CPU and 4GB of memory running on Fedora 12 with Linux 2.6.31.5-127. Also, the programs are written in C and compiled by gcc version 4.4.2 20091027 (Red Hat 4.4.2-7). Moreover, for GKA, the population size is fixed at 25, so is the population size of ACS (i.e., the number of ants). Same as the GKA, the crossover operator is replaced by a 2-iteration k-means operator, the mutation probability is 0.01, and the number of generations is 1,000. For the ACS and ACODPT, α is set to 0.1, β to 11.0, ρ to 0.1, and τ to 0.01. q_0 and q_1 are set to 1 and 75, respectively. To avoid premature convergence, the proposed method is started at iteration 2. For comparison, the datasets used in this paper to evaluate the performance of these clustering algorithms are iris, wine, yeast, and abalone, all from [43].

B. Results

Table I compares the performance of ACODPT with the following clustering algorithms: k-means, GKA, and ACS. It shows that GKA provides a better result than k-means while ACS providing a better result than GKA for the benchmarks yeast and abalone. In contrast, our observation shows that the proposed algorithm, ACODPT, provides a better result than ACS because these two benchmarks (yeast and abalone) are more difficult than the others (iris and wine). For this reason, the proposed algorithm can further improve the quality of ACS by about 1.43% and 29.24% for the benchmarks ecoli, yeast, and abalone. Moreover, although the clustering results of ACODPT of benchmarks wine, ecoli, and yeast are worse than GKA, we believe that it is because the ACS and the proposed algorithm do not use the local search to fine tune the clustering results but GKA does.

TABLE I
Simulation results

Data set	$x \times y \times z$	k-means	GKA
iris	$3 \times 4 \times 150$	85.34	78.94
wine	$3 \times 13 \times 178$	2,370,690.00	2,370,689.69
glass	$9 \times 6 \times 214$	394.58	340.82
ecoli	$8 \times 7 \times 336$	2,284.85	1,815.70
yeast	$10 \times 8 \times 1484$	49.06	45.83
abalone	$29 \times 8 \times 4177$	1,144.10	572.99
Data set	$x \times y \times z$	**ACS**	**ACODPT**
iris	$3 \times 4 \times 150$	78.94	78.94
wine	$3 \times 13 \times 178$	2,370,690.00	2,370,690.00
glass	$9 \times 6 \times 214$	336.06	336.06
ecoli	$8 \times 7 \times 336$	2,579.26	1,995.67
yeast	$10 \times 8 \times 1484$	47.44	46.30
abalone	$29 \times 8 \times 4177$	484.93	482.57

x, y, z denote, respectively, the number of clusters, attributes, and patterns.

V. Conclusion

In this paper, we proposed an efficient method, called ACODPT, to improve the quality of ACS-based clustering algorithms. The major concept is to add a negative pheromone table to record the route paths which may lead the ants to create worse solutions. It is inspired by how to prevent the ants from falling into the local minima region again and again. For this reason, the solution construction operator is modified to take into account the way the strategies are selected. In addition to a simple example given to show the design concept, we also describe in detail the proposed algorithm. Our simulation results showed that the proposed algorithm outperforms all the other clustering algorithms compared in this paper in terms of the quality of the end result, especially for large scale datasets. Our future goal is to reduce the computation time of the proposed algorithm while at the same time improving the quality of the end result such as local search methods..

***Abstract*—This paper presents a novel ant colony optimization (ACO) based on an efficient solution construction strategy (transition operator) for improving the quality of the end results of job shop scheduling problem (JSSP). Inspired by the observation that the quality of the end results of ACO is largely affected by their operators—especially the transition operator, a novel solution construction strategy is presented in this paper. The proposed algorithm uses two different strategies to compute the probability of solution construction to improve the end results. Our experimental results show that the proposed algorithm outperforms all state-of-the-art job shop scheduling algorithms evaluated in this paper and can significantly improve the quality of ant colony optimization for JSSP.**

Keyword: ant colony optimization; job shop scheduling problem; transition operator.

I. Introduction

As one of the most well known combinatorial optimization problems, the job shop scheduling problem (JSSP) [1], [2], [3], [4], [5] is to assign a finite set of jobs, each of which consists of a sequence of operations, to a finite set of machines in such a way that the maximum completion time or makespan is minimized while assuming that each operation of a job is assigned to a different machine in the order given and is processed to completion without being preempted. Formally, the JSSP is usually defined as follows: Given a set of m machines and a set of n jobs—each of which consists of a sequence of operations $\langle O_{1j}, O_{2j}, \ldots, O_{mj} \rangle$, with O_{ij} to be processed on a given machine μ_{ij} for p_{ij} time where $\mu_{ij} \neq \mu_{i+1,j}$ for $i = 1, 2, \ldots, m-1$—the problem is to find an assignment of the n jobs to the m machines that minimizes the maximum completion time or makespan. In symbols,

$$C_{\max} = \min \max_{1 \leq j \leq n} C_j$$

where C_j denotes the completion time of the jth job.

Recently, the JSSP has become an important research topic for several reasons. The first is that it has become extremely important to minimize the computation time, or maximize the throughput, in this era because it is important to conserve the energy so as to protect the environments or reduce the cost. For example, the cost can be reduced by fabricating the same products with less energy. The second is that an efficient solution to the JSSP can be used to solve many other problems. As such, several variants of JSSP have been introduced in recent years to solve the nurse scheduling problem, the flexible job shop scheduling problem, the fuzzy job shop scheduling problem, and the flow shop scheduling problem. However, even after all these efforts, the NP-hard job shop scheduling problem [6] is still very hard to be solved to optimality even if the size of benchmark is small. For this reason, it has always been a popular research topic of combinatorial optimization problems because a better solution can be used to enhance the work efficiency or reduce the energy cost of a factory.

One of the most well known examples to explain the difficulty of JSSP was introduced by Fisher and Thompson [1] in 1960s, which is a 10×10 instance (i.e., $n = 10$ and $m = 10$), and its optimal solution was not found until 20 years after this problem was introduced. The good news is that the optimum solution has been found by Carlier and Pinson [7]. They used a branch and bound algorithm to solve the JSSP in 1989. However, although the exhaustive search algorithm can find the optimum solution of this benchmark (i.e., the 10×10 instance), it is still very hard to find the optimum solution when the size of benchmark becomes 20×20 [8]. For this reason, since 1990's, approximation algorithms (some of which are called metaheuristics) such as priority dispatch, shifting bottleneck procedure [9], tabu search (TS) [10], [11], simulated annealing (SA) [12], genetic algorithm (GA) [13], [14], and ant colony

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

optimization (ACO) [15], [16], [17], [18], [19] have been used to solve the JSSP in a reasonable time. In addition to using the original version of the above metaheuristic algorithms, many studies have tried to integrate these algorithms to find a better result. A good example is the TSSA by Zhang et al. [8], which combines TS with SA.

Among these researches, ACO is apparently one of the most promising metaheuristic algorithms to solve the JSSP because its search abilities are very efficient for the combinatorial optimization problems. More important, ACO is not sensitive to the initial solutions. In this paper, we present an efficient algorithm, called hybrid selection strategy for ant colony optimization (HSSACO), to solve the JSSP that provides a better result than traditional metaheuristics can. The new transition operator of the proposed algorithm is designed to modify the solution construction strategy which integrates more than one objective compared to the traditional ACO for JSSP, which considers only one objective at a time (e.g., earliest starting time; or EST for short) so as to improve the quality of the end results. To evaluate the performance of the proposed algorithm, we compare it with four ACO-based algorithms for several well known benchmarks for the JSSP. Experimental results show that the proposed algorithm, HSSACO, outperforms all state-of-the-art algorithms for the JSSP compared in this paper.

The remainder of the paper is organized as follows. Section II gives a brief introduction to the genetic algorithm and approaches taken to enhance its performance. Section III provides a detailed description of the proposed algorithm. Also given in Section III is a simple example to demonstrate how the proposed algorithm works. Performance evaluation of the proposed algorithm is presented in Section IV. Analysis of the proposed algorithm is given in Section IV. Conclusion is drawn in Section V.

II. Related Work

Proposed by Dorigo et al. in the 90s, the ant colony optimization (ACO) [20], [21], [22] is a promising metaheuristic algorithm inspired by the foraging behavior of real ants. The focus of the early version of ACO has been on solving the combinatorial optimization problems such as the traveling salesman problem and the quadratic assignment problem. Basically, ACO is made up of two required operators *SolutionConstruction*() and *PheromoneUpdate*() as well as one optional operator *LocalSearch*().

The *SolutionConstruction*() operator plays the role of calculating the probability of choosing the next sub-solution of i, which is defined as follows:

$$p_{ij}^k = \begin{cases} \frac{[\tau_{ij}]^\alpha [\eta_{ij}]^\beta}{\sum_{j \in \mathcal{N}_i^k} [\tau_{ij}]^\alpha [\eta_{ij}]^\beta} & \text{if } j \in \mathcal{N}_i^k, \\ 0 & \text{otherwise,} \end{cases} \quad (1)$$

where $\mathcal{N}_i^k$ denotes the set of feasible (or candidate) sub-solutions that can be the next sub-solution of i; τ_{ij} the pheromone value between the sub-solutions i and j; and η_{ij} the quality of the sub-solution j that will affect each ant's determination to move to j when at i. The parameters α and β are used to adjust the weight of exploration and exploitation. The *PheromoneUpdate*() operator is employed in updating the pheromone value τ_{ij} on each edge e_{ij}, which is defined as follows:

$$\tau_{ij} = (1-\rho)\tau_{ij} + \rho \sum_{k=1}^{m} \triangle \tau_{ij}^k, \quad (2)$$

where m denotes the number of ants; $\triangle \tau_{ij}^k = 1/L^k$; L^k the quality of solution created by ant k. Moreover, $\rho \in (0, 1]$ denotes the evaporation rate of pheromone values on the pheromone table. The optional operator *LocalSearch*() is employed in improving the quality of the solution of ACO. A good example is problem-specific permutation method.

Recently, several studies [15], [16], [18], [19] have attempted to use ACO to solve the JSSP because of its potential to find solutions that are closer to the optimum solution than all traditional heuristic algorithms. In 1994, Colorni et al. [15] used the early version of ACO, ant system (AS), to solve the JSSP in which the way the solution is represented is similar to that of the traveling salesman problem, which consists of $n+1$ nodes and $n(n-1)/2+n$ edges. Their simulation results showed that AS can find approximate solution to the JSSP that is about 7% to 10% away from the optimum solution of the benchmark they tested. In 1999, Zwaan and Marques [16] first analyzed the performance of the parameter settings of AS and then used the information so obtained to fine-tune the parameter values of AS. More precisely, the interaction between α and β was first tested, followed by the values of ρ and the numbers of ants. Then, Zwaan and Marques suggested that the number of ants of AS be close to $n \times m$ where n and m are the number of jobs and the number of machines, respectively.

More recently, Heinonen and Pettersson [18] combined ACO with efficient local search method to improve the results of ACO in solving the JSSP. The local search method first identifies the critical path in the schedule constructed by ACO. The critical path can be decomposed into a number of blocks each of which is a maximal sequence of adjacent operations that require to be processed by the same machine. Then, the local search method is used to swap operations to improve the makespan of the schedule. Their simulation results showed that ACO with efficient local search method can find a near-optimum solution to the MT10 problem the relative error of which is about 3.9%. In [19], Huang and Liao presented a hybrid algorithm, called ACO combined with fast TS (ACOFT), that uses ant colony optimization to find the global search directions and tabu search to fine-tune the soltuion. Their simulation results showed that ACOFT can find a near-optimum soltuion the relative error of which is 1.798% on average. In addition to using ACO to solve the JSSP, some studies [23], [24] also apply ACO to solve the variants of JSSP. Examples are the felxible job shop scheduling problem and the fuzzy job shop scheduling problem.

III. The Proposed Algorithm

In this section, we will begin with the concept, followed b is a detailed description of the proposed algorithm.

A. The concept

Generally speaking, most ACO-based algorithms for JSSP use only one kind of strategy to optimze the makespan such as earliest starting time (EST), most remaining operations (MRO), shortest processing time (SPT), and most work remaining (MWR). More precisely, $\eta(o_{ij})$ can be computed as EST, MRO, or the others. However, even though all the heuristic methods are aimed to minimize the makespan, the strategies they use are very different. For example, the EST is aimed to perform the jobs at the earliest possible starting time whereas the SPT is aimed to perform the shortest jobs first.

In this paper, we integrate two different heuristics into the solution construction method of the ACO-based algorithms for solving JSSP. As shown in Eq. (3), the probability, p_{ij}^k, of the proposed algorithm is made up of two different search strategies. One is the earliest starting time (as shown in Eq. (5)) while the other is the most remaining operations (as shown in Eq. (6)).

$$p_{ij}^k = \frac{[\tau_{ij}]^\alpha [\eta_{\text{em}}(o_{ij})]^\beta}{\sum_{o_{ij} \in \mathcal{N}_i} [\tau_{ij}]^\alpha [\eta_{\text{em}}(o_{ij})]^\beta}, \tag{3}$$

$$\eta_{\text{em}}(o_{ij}) = \eta_{\text{est}}^{w_1}(o_{ij}) \times \eta_{\text{mro}}^{w_2}(o_{ij}), \tag{4}$$

$$\eta_{\text{est}}(o_{ij}) = \frac{\frac{1}{s_{ij}+1}}{\sum_{o_{ij} \in \mathcal{N}_i} \frac{1}{s_{ij}+1}}, \tag{5}$$

$$\eta_{\text{mro}}(o_{ij}) = \frac{r_{ij}+1}{\sum_{o_{ij} \in \mathcal{N}_i} r_{ij}+1}, \tag{6}$$

where s_{ij} denotes the possible starting time of o_{ij}; r_{ij} the number of remaining operations of o_{ij}; $\mathcal{N}_i$ the remaining operations that satisfy the processing order restriction but have not started yet; w_1 and w_2 (where $w_1, w_2 \in [0, 1]$ and $w_1 + w_2 = 1$) the weights of the two makespan optimization strategies. As shown in Eq. (4), more than one makespan optimization strategy is considered at a time to avoid the ACO-based algorithms from falling into local minima at early iterations. Moreover, $\eta_{\text{em}}(o_{ij})$ is the weighted geometric mean of these two strategies $\eta_{\text{est}}^{w_1}(o_{ij})$ and $\eta_{\text{mro}}^{w_2}(o_{ij})$. The proposed algorithm not only considers searching the possibility of earliest possible starting time of the job, it also takes into account performing the job thatwhich has a larger number of operations that are not started yet. For instance, suppose $w_1 = w_2 = 0.5$. Then, $\eta_{\text{em}} = \eta_{\text{est}}^{0.5} \times \eta_{\text{mro}}^{0.5} = \sqrt{\eta_{\text{est}}} \times \sqrt{\eta_{\text{mro}}}$. Moreover, to avoid converging to a single direction, we also normalize the values of these two makespan optimize strategies, as shown in Eqs. (5) and (6).

B. The hybrid selection strategy for ant colony optimization

In the previous section, we present a new solution construction strategy (also called the transition operator) for the ACO-based algorithm. As Eqs. (3)–(6) show, the hybrid selection strategy for ant colony optimization is as follows.

1) Input the dataset and its parameters.
2) Initialization:
   a) Set the values of all paths τ_{ij} in the pheromone table to τ_{init}.
   b) Initialize the parameters of ACO.
   c) Put all the ants on the start node.
3) Solution Construction:
   For each ant,
   a) Compute the probability distribution by using Eq. (3).
   b) Construct the solution by using the probability distribution p_{ij}^k.
   c) Update the local pheromone by using Eq. (2).
4) Update the pheromone of the best solution.
5) Perform local search to improve the solution.
6) If the stop condition is not met, go to 2.
7) Otherwise, output the best so far solution as the final solution.

Because our aim is to apply the proposed algorithm to all the ACO-based algorithms, the description of the proposed algorithm herein is for the general design of ACOs. First, the proposed algorithm will read the dataset and its parameters. Next, set all the paths in the pheromone table (an $m \times n$ array) to the initial value τ_{init}. Then, initialize all the other parameters of ACO such as α, β, ρ, w_1, and w_2. In the solution construction stage, HSSACO will first use Eq. (3) to compute the probability distribution of ant k. Then, ant k will use the probability distribution p_{ij}^k to determine which will be the next sub-solution. For the JSSP, it means the next operation. After the next sub-solution is determined, the proposed algorithm will then perform the local pheromone update if required by the ACO we use. In addition to the local pheromone update, the global pheromone update will then be performed. In this paper, the proposed algorithm also performs local search to improve and fine-tune the final results. The above operators will be repeatedly performed until convergence or the stop condition is met.

IV. Simulation Results

To simplify the discussion of the simulation results, the following conventions are employed in this paper.

$$\Delta = \frac{\Delta_{\text{HSS}+\psi} - \Delta_\psi}{\Delta_\psi} \times 100\%, \tag{7}$$

where Δ denotes the enhancement of $\Delta_{\text{HSS}+\psi}$ compared with Δ_ψ in percentage of makespan. That is, ψ denotes either earliest starting time (EST) or most remaining operations (MRO) used by the ant system (AS) [15], elitist ant system (EAS) [25], [20], rank ant system (RAS) [26], and ant colony system (ACS) [21].

A. Parameter settings and datasets

The empirical analysis was conducted on an SUN X4150 machine with 2.5 GHz Xeon CPU and 4GB of memory running CentOS 5.4 with Linux 2.6.18. Moreover, all the programs are written in C++ and compiled using g++ (GNU C++ compiler).

TABLE I
PARAMETER SETTINGS OF THE ACO ALGORITHMS.

Algorithm	α	β	ρ	τ
AS	1	10	0.1	$1/C$
ACS	—	10	0.1	1.0
EAS	1	10	0.1	a_n/C
AS-rank	1	10	0.1	$0.5w(w-1)/C$

Moreover, all the simulations are carried out for 30 runs, and all the ACO-based algorithms tested in this paper use 25 ants and 100 iterations. The parameter κ of EAS is set to 25. C denotes the makespan produced randomly; a_n the number of ants. The number of elitist ants w of AS-rank is set to 6. For the other settings, some of them are repeated below in Table I for easy reference.

The datasets used in this paper are the la series from la01 up to la40. These datasets contain from 10 up to 30 jobs and from 5 up to 15 machines. Moreover, these datasets are available for download from OR-Library at http://people.brunel.ac.uk/~mastjjb/jeb/info.html.

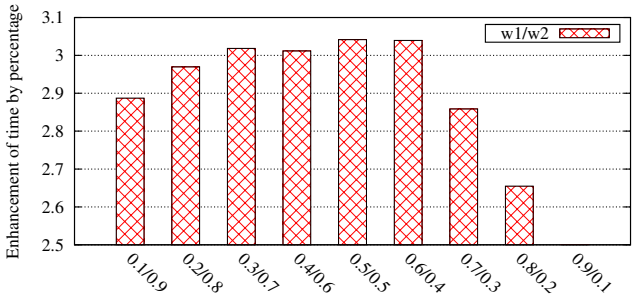

Fig. 1. Impact of w_1 and w_2 on average.

B. Results and Analysis

Table II shows the impact of w_1 and w_2 on the performance of different ACO-based algorithms. Moreover, Table II also shows the results of setting $w_1 = 1.0$ and $w_2 = 0.0$ for the 40 la series datasets from la10 up to la40 on average. As shown in Fig. 1, the settings of $w_1 = w_2 = 0.5$ and $w_1 = 0.6, w_2 = 0.4$ provide better results than the other settings. For this reason, we set $w_1 = w_2 = 0.5$ for all the simulations to be given later in this paper. Tables III and IV show the results of applying the proposed algorithm to four ACO-based algorithms—AS, EAS, RAS, and ACS. For each of these algorithms, two heuristic methods, EST and MRO, are used to compute η. In other words, δ_{est} and δ_{mro} denote, respectively, the enhancement of the proposed algorithm compared with the ACO-based algorithms with EST and MRO. Also, BKS denotes the best known solution of each benchmark.

Table III shows the results of ACO and ACO with the proposed algorithm but no local search. For all the benchmarks tested, the results show that the proposed algorithm can improve the makespan by from 1.53% up to 6.00% on average, by 0.00% in the worst case, and by 10.71% in the best case. Some of the results show that the improvement of HSS is 0.00%. That is because like AS and HSS+AS with MRO for la05 and la10, HSS and MRO get the BKS. In addition, Table III shows that the proposed algorithm can find the better results compared with the original ACO for all the benchmarks tested. Table IV gives the results with local search

proposed by Nowicki and Smutnicki [27]. The results show that the ACO-based algorithms can find solutions closer to the optimum value. However, even in this case, the proposed algorithm can still improve the makespan by from 0.22% up to 5.42% on average, by -1.60% in the worst case, and by 12.18% in the best case. This shows that the proposed algorithm can effectively improve the makespan.

According to our observation, the proposed algorithm, HSSACO, can improve the final results of ACO-based algorithms, especially for the large scale datasets. This characteristic is shown in using the AS to solve la01 with the EST method. The proposed algorithm cannot improve the final results of the original version of AS for some of the benchmarks. It is because the results are very close to the optimum solution. However, the good news is that the proposed algorithm can improve the final results as the size of the dataset increases such as AS for la33. The proposed algorithm can improve the results by about 7.44% compared with AS using the EST method. Moreover, the proposed algorithm can also improve the results of EAS, RAS, and ACS. In summary, even though some of the final results of these simulations are not very close to the BKS, these comparisons have shown that the proposed algorithm has the potential to improve the quality of the end results of the ACO-based algorithms, especially when the solutions are not close to the optimum solution.

V. Conclusion

This paper presents a novel technique for improving the quality of ACO-based algorithms, called hybrid selection strategy for ant colony optimization (HSSACO). The proposed algorithm uses two different heuristic stragegies to compute the probability for the solution construction operator so as to maintain the diversity of the solutions. To evaluate the performance of the proposed algorithm, we apply it to four state-of-the-art ACO-based algorithms—AS, EAS, RAS, and ACS. Moreover, we also use it to solve 10 JSSP datasets, the size of which are from 10 up to 20 jobs and from 5 up to 20 machines. The simulation results show that the proposed algorithm can effectively improve the results of ACO and its variants from 1.23% up to 4.05% on average. Our future focus will be on speeding up the proposed algorithm.

***Abstract* — This paper shows the results of the sensing system which was designed for the autonomous mobile robot Emmy III. The proposed Sensing System has as its mean part the Paraconsistent Neural Network. This artificial neural network is based on the Paraconsistent Evidential Logics – Eτ. The objective of the Sensing System is to inform the other robot components about the obstacle position. The reached results have been satisfactory.**

***Keywords* - Paraconsistent Neural Network; Paraconsistent Logics; Automous Mobile Robot; Sensing System.**

I. INTRODUCTION

This article describes the Emmy III robot architecture emphasizing the sensing system of the robot [1]. The Emmy III robot is designed to achieve a set point in an environment which is divided into coordinates [2]. The Emmy III robot may be considered as a system divided into three other subsystems: the Planning Subsystem, the Sensing Subsystem and the Mechanical Subsystem.

The Planning Subsystem is responsible for generating the sequence of movements the robot must perform to achieve a set point. The Sensing Subsystem has the objective of informing the Planning Subsystem about the position of obstacles; and the Mechanical Subsystem is the robot itself, it means, the mobile mechanical platform which carries all devices away from the other subsystems. This platform must also perform the sequence of movements which are borne by the Planning Subsystem.

The Planning Subsystem and the Sensing Subsystem have already been implemented, but the Mechanical Subsystem has not been implemented yet.

The Sensing Subsystem uses the Paraconsistent Artificial Neural Network [3] and [4]. This artificial neural network is based on the Paraconsistent Evidential Logics – Eτ.

It is described some concepts about the Paraconsistent Evidential Logics – Eτ in the next section.

II. PARACONSISTENT EVIDENTIAL LOGICS

The Paraconsistent Evidential Logics – Eτ [5] is a type of paraconsistent logic in which there may be a Favorable Evidence Degree - μ and a Contrary Evidence Degree - λ in each analyzed sentence.

The Favorable Evidence Degree (μ) is a value between 0 and 1 that represents the favorable evidence in which the sentence is true.

The Contrary Evidence Degree (λ) is a value between 0 and 1 that represents the contrary evidence in which the sentence is true.

Through the Favorable and Contrary Degrees it is possible to represent the four extreme logic states, as shown in the figure 1.

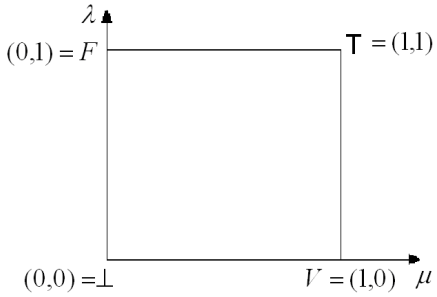

Figure 1. Extreme logic states

The four extreme logic states are:

- True (V)
- False (F)
- Paracomplete (⊥)
- Inconsistent (T)

In [6] it is proposed the Paranalyzer Algorithm. By this algorithm it is also possible to represent the non-extreme logic state. The figure 2 shows this.

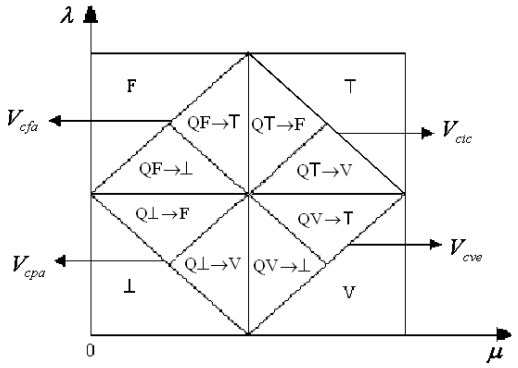

Figure 2. Non extreme logic states

The eight non-extreme logic states are:

- Quasi-true tending to Inconsistent - QV→T
- Quasi-true tending to Paracomplete - QV→⊥
- Quasi-false tending to Inconsistent - QF→T
- Quasi-false tending to Paracomplete - QF→⊥
- Quasi-inconsistent tending to True - QT→V
- Quasi-inconsistent tending to False - QT→F
- Quasi-paracomplete tending to True - Q⊥→V
- Quasi-paracomplete tending to False - Q⊥→F

The Uncertainty Degree: $G_{un}(\mu, \lambda) = \mu + \lambda - 1$ and the Certainty Degree: $G_c(\mu, \lambda) = \mu - \lambda$ $(0 \leq \mu, \lambda \leq 1)$

Some additional control values are:

- V_{cic} = maximum value of uncertainty control
- V_{cve} = maximum value of certainty control
- V_{cpa} = minimum value of uncertainty control
- V_{cfa} = minimum value of certainty control

In the next section we describe the proposed sensing system.

III. SENSING SYSTEM

The sensing system is a set of electronic components and softwares responsible for analyzing the environment around the robot and detecting the obstacle positions. After that, it must inform the other components of the robot the position of the obstacles.

The sensing system may get information from any type of sensor. It is shown in this paper a sensing system able to deal with information from just one ultrasonic sensor. But, if there is more than one sensor in the robot, it is possible to build a sensing system similar to the one shown here for each sensor.

In [7] it is presented a method of robot perception and world's modeling that uses a probabilistic tessellated representation of spatial information called the Occupancy Grid. It is proposed here a similar method, but instead of using probabilistic representation, it is used the Paraconsistent Evidential Logic Eτ.

The proposed sensing system aims to generate a Favorable Evidence Degree in each environment position. The Favorable Evidence Degree is related to the sentence: there is obstacle in the analyzed position.

The sensing system is divided into two parts. The first part is responsible for receiving the data from the sensors and sending information to the second part of the system. And the second part is the Paraconsistent Artificial Neural Network itself. The figure 3 shows this idea.

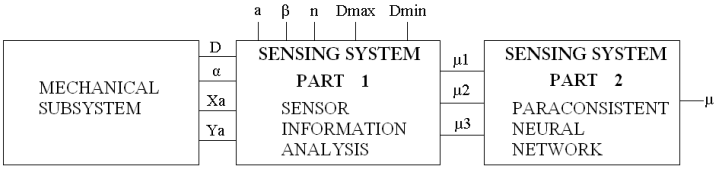

Figure 3. Representation of the sensing system

The proposed sensing system is prepared to receive data from ultrasonic sensors. The robot sensors are on the Mechanical Subsystem. So, this subsystem must treat the data generated by the sensors and send information to the first part of the Sensing Subsystem. The data the Mechanical Subsystem must send to the first part of the Sensing Subsystem are: D, α, Xa and Ya.

a) The distance between the sensor and the obstacle (D).

b) The angle between the horizontal axis of the environment and the direction to the front of the sensor (α). The figure 4 shows the angle α.

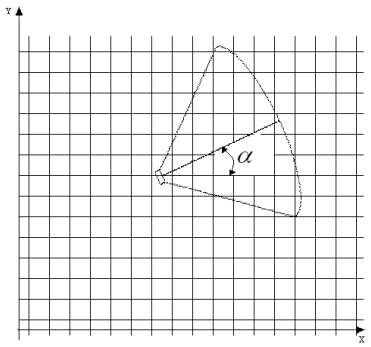

Figure 4. Angle α

c) The coordinate where the robot is (Xa, Ya).

In the first part of the Sensing Subsystem there are also some configuration parameters. They are:

a) The distance between the environment coordinates (a). The figure 5 shows this.

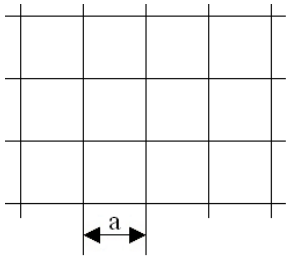

Figure 5. Distance between coordinates

a) The angle of the ultrasonic sensor conical field of view (β). The figure 6 shows this.

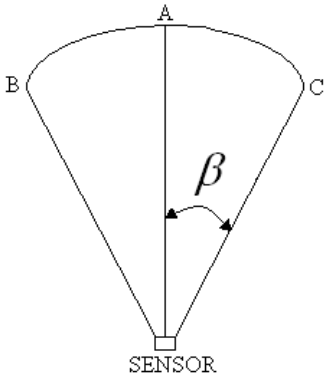

Figure 6. Ultrasonic sensor conical field of view (β)

a) The number of positions on the arch BC, shown in the figure 6, considered by the system (n).

b) The maximum distance measured by the sensor which the system considers (Dmax).

c) The minimum distance measured by the sensor which the system considers (Dmin).

The first part of the Sensing System generates three Favorable Evidence Degree, μ_1, μ_2 and μ_3.

The Favorable Evidence Degree μ_1 is related to the distance between the sensor and the obstacle. The nearer the obstacle is to the sensor the bigger μ_1 value is.

The Favorable Evidence Degree μ_2 is related to the coordinate position on the arch AC shown in the figure 6. As the analyzed coordinate is near to the point A as bigger is μ_2 value. And as the analyzed coordinate is near to the points A and C, as smaller is the μ_2 value. The inspiration of this idea comes from [8] which says that the probability of the obstacle be near to the point A is high. And this probability decreases as we analyze the region near to the points B and C.

Eventually, the Favorable Evidence Degree μ_3 is the previous value of the coordinate Favorable Evidence Degree.

IV. PARACONSISTENT ARTIFICIAL NEURAL NETWORK

The Sensing Subsystem neural network of the robot is composed of two types of cells: Analytic Paraconsistent Artificial Neural Cell – CNAPa and Passage Paraconsistent Artificial Neural Cell - CNAPpa. In the follow it is described the cells.

A. Analytic Paraconsistent Artificial Neural Cell - CNAPa

This cell has two in-puts (μ_{RA} and μ_{RB}) and two out-puts (S1 and S2). Also there are two configuration parameter in-puts (Ftct and Ftc). The figure 7 shows the graphic representation of this cell.

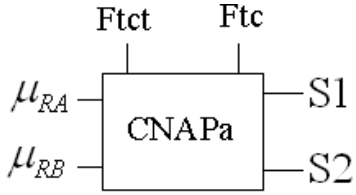

Figure 7. Graphic representation of the Analytic Paraconsistent Artificial Neural Cell

The in-put evidence degrees are:

μ_{RA}, such as: $0 \leq \mu_{RA} \leq 1$

μ_{RB}, such as: $0 \leq \mu_{RB} \leq 1$

There are also two control values:

Contradiction Tolerance Factor – Ft_{ct}, such as: $0 \leq Ft_{ct} \leq 1$

Certainty Tolerance Factor – Ft_c, such as: $0 \leq Ft_c \leq 1$

The Analytic Paraconsistent Artificial Neural Cell – CNAPa has two out-puts. The out-put 1 (S1) is the Resultant Evidence Degree - μ_E.

μ_E, such as: $0 \leq \mu_E \leq 1$

The out-put 2 (S2) is the Resultant Evidence Interval – φ_E.

φ_E, such as: $0 \leq \varphi_E \leq 1$

The Analytic Paraconsistent Artificial Neural Cell calculates the maximum value of certainty - V_{cve}, the minimum value of certainty control - V_{cfa}, the maximum value of uncertainty control - V_{cic} and the minimum value of uncertainty control - V_{cpa} by this way:

$$V_{cve} = \frac{1 + Ft_c}{2} \quad (1)$$

$$V_{cfa} = \frac{1 - Ft_c}{2} \quad (2)$$

$$V_{cic} = \frac{1 + Ft_{ct}}{2} \quad (3)$$

$$V_{cpa} = \frac{1 - Ft_{ct}}{2} \quad (4)$$

The Resultant Evidence Degree – μ_E, is determined in this way:

$$\mu_E = \frac{G_c + 1}{2} \quad (5)$$

As $G_c = \mu - \lambda$:

$$\mu_E = \frac{\mu - \lambda + 1}{2} \quad (6)$$

It is called as Certainty Interval (φ) the Certainty Degree interval that can be modified without changing the Uncertainty Degree value. This value is determined in this way.

$$\varphi = 1 - |G_{ct}| \quad (7)$$

B. Passage Paraconsistent Artificial Neural Cell - CNAPpa

The Passage Paraconsistent Artificial Neural Cell – CNAPpa has one in-put (μ), one out-put (S1) and one parameter control in-put (Ftc). The figure 8 shows the graphic representation of CNAPpa.

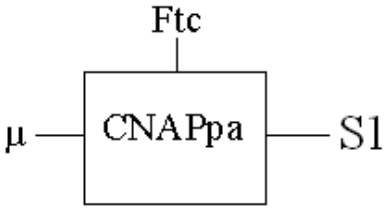

Figure 8. Graphic representation of the Passage Paraconsistent Artificial Neural Cell

The in-put is the Favorable Evidence Degree (μ).

μ, such as: $0 \leq \mu \leq 1$

The value of the out-put S1 is the same as the in-put μ. But, the out-put value may be limited through the parameter control in-put Ftc.

The Passage Paraconsistent Artificial Neural Cell calculates the maximum value of certainty - V_{cve} and the minimum value of certainty control - V_{cfa} by the equations (1) and (2).

It also determines the Resultant Evidence Degree - μ_E by the equation (6). For this, λ is considered as the following.

$$\lambda = 1 - \mu \quad (8)$$

The out-put S1 assumes the same value as in the in-put μ when the follow situation is true:

$$[(V_{cve} \leq \mu_E) \text{ or } (\mu_E \leq V_{cfa})]$$

Otherwise, S1 is 0,5.

C. Paraconsistent Artificial Neural Architecture

It is possible to see in the figure 9 the chosen Paraconsistent Neural Network Architecture for the Sensing Subsystem.

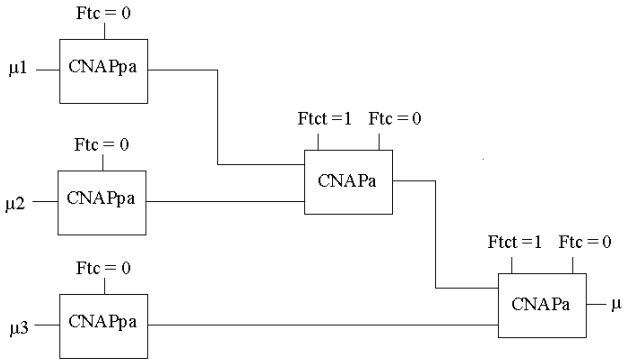

Figure 9. The chosen Paraconsistent Neural Network Architecture for the Sensing System

V. REACHED RESULTS

The Sensing System has been tested by simulating its in-puts and analyzing the database generated. The database stores the Favorable Evidence Degree in each environment position analyzed. It is shown here the result of three tests. The information from one ultrasonic sensor was considered as the Sensing System in-puts.

A. First test

The configuration parameters of this test were the following. The distance between the environment coordinates (a): 10. The angle of the ultrasonic sensor conical field of view (β): 30. The number of positions on the arch of the sensor conical field of view considered by the system (n): 10. The maximum distance measured by the sensor which the system considers (Dmax): 800. The minimum distance measured by the sensor which the system considers (Dmin): 8.

The Mechanical Subsystem treats the data from the sensors and generates the Sensing Subsystem in-puts. It was needed to simulate the Sensing Subsystem in-puts because the Mechanical Subsystem has not been implemented yet.

Thus, the simulated Sensing Subsystem data were the ones described in the follow. The distance between the sensor and the obstacle (D): 200. The angle between the horizontal axis of the environment and the direction to the front of the sensor (α): 30. The coordinate where the robot is (Xa, Ya): (0, 0).

It was simulated the first measuring of the sensor, then, μ_3 initially was 0.

It is shown in the figure 10 the representation of the coordinates in which the Sensing System considered to have obstacles in. Summarizing, the figure 10 is a graphical representation of the database generated by the Sensing Subsystem.

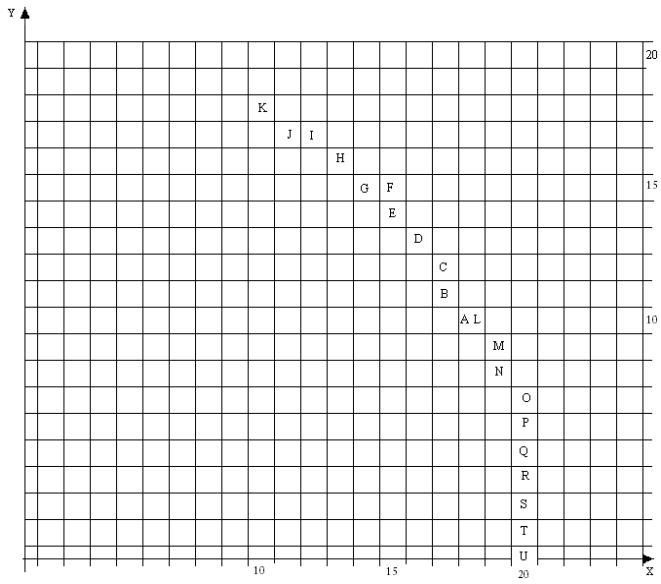

Figure 10. The graphical representation of the database generated by the first test of the Sensing Subsystem.

The analyzed coordinates and their Favorable Evidence Degree are shown in the table 1.

TABLE I. RESULTS OF THE FIRST TEST

B. Second test

The configuration parameters of this test were the same as the ones from the first test.

The simulated Sensing Subsystem data were the ones described in the follow. The distance between the sensor and the obstacle (D): 400. The angle between the horizontal axis of the environment and the direction to the front of the sensor (α): 45. The coordinate where the robot is (Xa, Ya): (0, 0).

It was simulated the first measuring of the sensor, then, μ_3 was initially 0.

It is shown in the figure 11 the graphical representation of the database generated by the Sensing Subsystem.

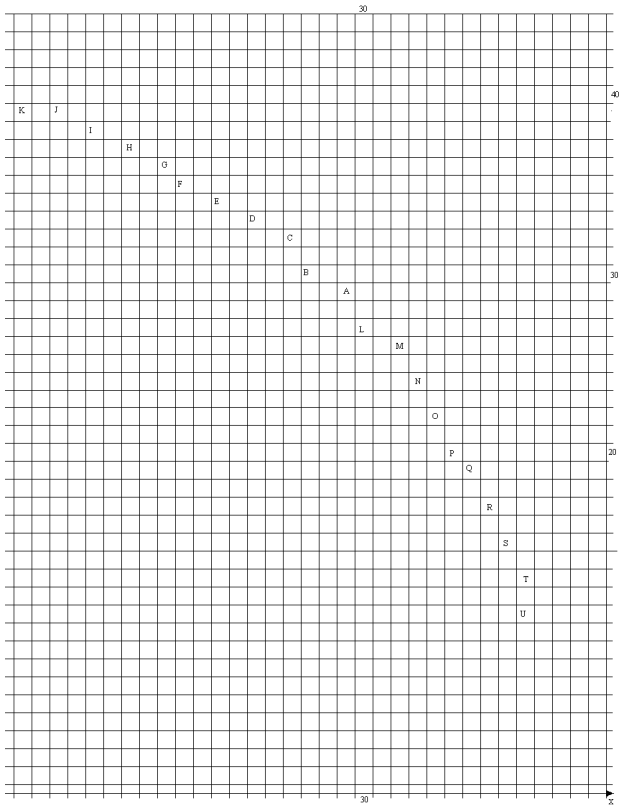

Figure 11. The graphical representation of the database generated by the second test of the Sensing Subsystem

The analyzed coordinates and their Favorable Evidence Degree are shown in the table 2.

TABLE II. RESULTS OF THE SECOND TEST

C. Third Test

The configuration parameters and the Sensing Subsystem data were the same ones of the second test, then; the analyzed coordinates were the same as the second test. The third test has been done just after the second, therefore, their Favorable Evidence Degree were different from the second test because μ_3 was the Favorable Evidence Degree generated by the second test.

The analyzed coordinates and their Favorable Evidence Degree are shown in the table 3.

TABLE III. RESULTS OF THE THIRD TEST

If it is considered the sequence of positions from K to U as an arch in the three tests, it is perceived that the Favorable Evidence Degree (μ) decreases as the coordinate is farther distant from the center of the arch. It means that the system is working as desired.

VI. CONCLUSIONS

This paper presents a proposal for the autonomous mobile robot Emmy III. This robot is composed of three modules: Sensing Subsystem, Planning Subsystem and Mechanical Subsystem. The Mechanical Subsystem has not been implemented yet. It is emphasized here the Sensing Subsystem.

The aim of the Sensing Subsystem is to inform the Planning Subsystem about the positions in which obstacles may happen. It considers the environment divided into coordinates.

The Sensing Subsystem is based on the Paraconsistent Artificial Neural Network. The Sensing Subsystem neural network is composed of two types of cells: Analytic Paraconsistent Artificial Neural Cell – CNAPa and Passage Paraconsistent Artificial Neural Cell - CNAPpa.

The out-put of the Sensing Subsystem is the Favorable Evidence Degree related to the statement: there is an obstacle in the position. In fact, the Sensing Subsystem generates a database with the Favorable Evidence Degree for each analyzed coordinate.

Some tests have been made with the Sensing Subsystem. The reached results are satisfactory.

The next step is the implementation of the Mechanical Subsystem and the connection of the three subsystems.

***Abstract*—We deal with the problem of how to evaluate the performance of an investment (mutual) fund, over a past period. We assume a widely assumed attitude that an investment fund is said to have performed well if its unit price have been rising faster than its benchmark during a period of growth, and has been falling slower than its benchmark during the period of decline. We develop a novel, flexible and human consistent comparison method that operates on the comparison of trends (segments) extracted from the times series representing the behavior of the fund and its benchmark. The result of comparison becomes a new data set that is linguistically summarized using the method proposed in our previous works.**

***Index Terms*—Linguistic summaries, computing with with words, fuzzy logic, mutual (investment) fund comparison.**

I. Introduction

This paper is a continuation of our previous works (cf. Kacprzyk, Wilbik, Zadrożny [1], [2], [3] or Kacprzyk, Wilbik [4]) which deal with the problem of how to effectively and efficiently support a human decision maker in making decisions concerning investments in some financial instruments, notably in investment (mutual) funds. Decision makers are here basically interested in future gains/losses. We follow the decision support paradigm (as in Fig. 1), that is, assume primarily the user autonomy and a need to support, not replace, him/her. We are not concerned with the forecasting of future daily prices.

We deal with investment decisions that are made on a continuous basis over some period of time. Though the revenues resulting from those decisions are certainly very important, an omnipresent uncertainty calls for a different basis on which those decisions are to be based which is more robust under changing conditions. That is, we are less interested in exact values of quotations of the investment fund considered but more on the stability of their behavior, in relation to its benchmark. This stability is basically meant as the growth and/or decline, and variability.

Basically, in our work we advocate a view that the most promising paradigm is that of decision support, that is, that the system should provide the decision maker with results of some additional analyses of data that may give more insight into the situation. Then, the decision maker can make decision by himself/herself.

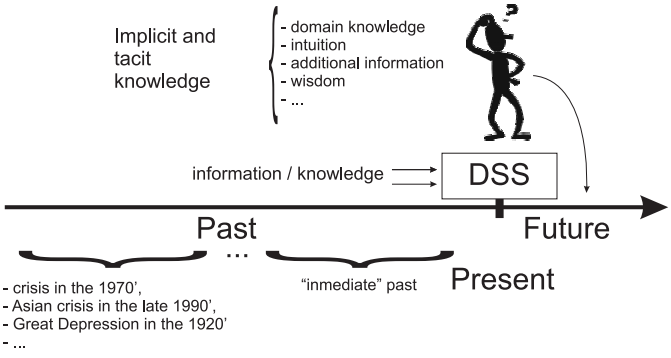

Fig. 1. Decision support paradigm

We deal with analysis of past performance of mutual funds. In our previous papers we have worked in two directions. One topic is the analysis of past performance for which we have proposed and used linguistic summaries of time series. In our works [3], [5], [4] segments (trends) derived from consecutive values have been used. We have used the following (classical) protoforms of linguistic summaries employed: "among all y's Q are P" exemplified by "among all segments (of time series), most are slowly increasing" and "among all Ry's Q are P" exemplified by "among all short segments (of time series), most are slowly increasing". Later we (cf. Kacprzyk and Wilbik [6]) have introduced new, so-called temporal protoforms: "E_T among all y's Q are P" exemplified by "recently among all segments (of time series), most are slowly increasing" and "E_T among all Ry's Q are P" exemplified by "initially, among all short segments (of time series), most are slowly increasing", that explicitly take into account importance of the time of occurrence. We have proposed several quality criteria to evaluate the linguistic summaries derived.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

The second area of our analysis is the comparison of past performance of the fund and past performance of its benchmark. A mutual fund benchmark can provide information on whether the mutual fund is performing up to the expectations. Every type of mutual funds should have a benchmark that can be used for the comparison purposes.

This is obvious and mentioned in every analysis, guideline, advice, etc. For instance [7]: "Evaluate the funds performance. Every fund is benchmarked against an index .... Investors should compare fund performance over varying time frames vis-a-vis both the benchmark index and peers. Carefully evaluate the funds performance across market cycles particularly the downturns" or even stronger "the best way to evaluate the performance of any mutual fund is to compare it to an appropriate benchmark" [8]. Moreover, they say: "Measure your results. How do your funds stack up against the rest? One of the best ways to know is to compare the funds results with those of its benchmarks. The idea behind benchmarks is to see how your mutual fund compares with an index, one that most closely resembles the holdings of your fund. ... Another way to measure your fund results is to see how a funds returns compare with one of the major market indexes" [9], or "Often cited in news reports, market indexes can be especially helpful to mutual fund investors by offering market 'standards' to help them evaluate the risk and the return history of their own investments. ... While indexes are good methods of gauging how a mutual fund performs in relation to the overall market, they shouldn't be the deciding factor in determining if a fund may meet your needs and objectives. ... The benchmark listed in your fund's prospectus will give you a good idea of what to expect from your mutual fund. However, remember that standardized tests are just that standardized" [10]". We could cite here much more similar articles and opinions.

However investors should be careful while choosing the benchmark, as "recent study from the University of Southern California shows that 42% of actively managed domestic stock funds list benchmarks in their prospectuses that do not match their investment style. No wonder investors have a hard time deciding on a relevant benchmark! Fund management is well aware that its results are being compared to benchmark indexes. In many cases, managers can most easily beat their benchmark by simply changing the index to which their fund is compared" [11]. However in this paper we will not deal with the problem if benchmark is proper for the analyzed fund or not.

In our previous works [12], [13] we had evaluated only the similarity between two time series. The degree of similarity of two time series was meant here as the degree to which, for instance, "most" of the long, overlapping segments are similar (for instance, such that "almost all" of their features are similar). Later [14], [15] we evaluated the similarity on linguistic summaries describing each time series. In such case the degree of similarity of two time series was meant as the degree to which, e.g., "most" of the valid summaries of the fund have the truth values similar to a majority of similar summaries of the benchmark.

Here we go one step further and assess if the fund is better then the benchmark. This is often done by calculating only the benchmark returns, i.e. a fund's returns compared to its benchmark. However we may compare those two time series over some defined time span, and check how the fund is performing. We take a widely assumed general principle that an investment fund is said to have performed well if its unit price have been rising faster than its benchmark during a period of growth, and has been falling slower than its benchmark during the period of decline. In other words, the funds is said to outperform its benchmark when these two conditions have been met.

II. Time series segmentation

The first step in many application and also here in the proposed method is segmentation. We have assumed that segments are linear. There are many methods for a piecewise linear segmentation of time series, e.g., on-line (sliding window) methods, top-down or bottom-up strategies or employing hybrid or genetic strategies [16], [17]. Generally, the algorithm has a minor impact on the obtained segments (cf. [18]) and what really matters is the assumed granulation, expressed in the form of maximal accepted (vertical) distance from the point to the segment, ε.

For the purposes of this work we use an on-line algorithm (also called sliding window). In general the algorithms work by checking if it is possible to add the new point to the currently constructed segment, and if so, then the segment is extended. However, if not, for instance because of the exceeding of the threshold value of the accepted error, ε, then the currently constructed segment is terminated and this new point creates a new segment. In the algorithm used here the segment links two points: the first and the last covered by the segment, as proposed by Sklansky and Gonzalez [19].

Each segment is described by three features:

- dynamics of change,
- duration, and
- variability.

By *dynamics of change* we understand the speed of change of the consecutive values of time series. It may be described by the slope of a line representing the trend (segment). Thus, to quantify dynamics of change we may use the interval of possible angles $\eta \in \langle -90; 90 \rangle$.

However it might be impractical, and not human consistent, to use such a scale directly while describing dynamics of change of the trends. We may use a fuzzy granulation in order to meet the users' needs and task specificity. The user may construct a scale of linguistic terms corresponding to various inclinations of a trend line as, e.g.:

- quickly decreasing,
- decreasing,
- slowly decreasing,
- constant,
- slowly increasing,
- increasing,
- quickly increasing

Figure 2 illustrates possible lines corresponding to the particular linguistic terms.

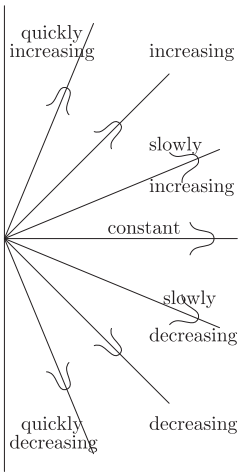

Fig. 2. A visual representation of angle granules defining the dynamics of change

In fact, each term represents a fuzzy granule of directions. In Batyrshin et al. [20], [21] there are presented many methods of constructing such a fuzzy granulation. The user may define a membership functions of particular linguistic terms depending on his or her needs.

We map a single value α characterizing dynamics of change of a trend identified by the algorithm chosen into a fuzzy set (linguistic label) best matching a given angle. We can use, for instance, some measure of a distance or similarity, cf. the book by Cross and Sudkamp [22]. Then we say that a given trend is, e.g., "decreasing to a degree 0.8", if $\mu_{decreasing}(\alpha) = 0.8$, where $\mu_{decreasing}$ is the membership function of a fuzzy set representing "decreasing" that is the best match for angle α.

Duration describes the length of a single trend, meant as a linguistic variable whose linguistic value (label) may be exemplified by a "long trend" defined as a fuzzy set.

The definitions of linguistic terms describing the duration depend clearly on the perspective or purpose assumed by the user.

Variability refers to how "spread out" ("vertically", in the sense of values taken on) a group of data is. We compute it as a weighted average of values taken by some measures used in statistics:

- the range (maximum – minimum),
- the interquartile range (IQR),
- the variance,
- the standard deviation,
- the mean absolute deviation (MAD).

Similarly as in the case of dynamics of change, we find for a given value of variability obtained as above a best matching fuzzy set (linguistic label) using, e.g., some measure of a distance or similarity, cf. the book by Cross and Sudkamp [22]. Again, the measure of variability is treated as a linguistic variable and expressed using linguistic terms (labels) modeled by fuzzy sets defined by the user.

III. Linguistic summaries of trends

A linguistic summary of data (database) is a (usually short) sentence (or a few sentences) that captures the very essence of the data; the date is assumed here numeric, its amount is large and not comprehensible for human users. We use here Yager's [23] basic approach, and a linguistic summary includes:

- a summarizer P,
- a quantity in agreement Q, i.e. a linguistic quantifier,
- truth (validity) $\mathcal{T}$ of the summary and
- optionally, a qualifier R.

An extended, implementable approach was shown in Kacprzyk and Yager [24], and Kacprzyk, Yager and Zadrożny [25].

Thus, the core of a linguistic summary is a linguistically quantified proposition in the sense of Zadeh [26] which may be written, respectively, as

$$Qy's \text{ are } P \tag{1}$$

$$QRy's \text{ are } P \tag{2}$$

which may be exemplified, respectively by: "*Most* of employees earn *low* salary", $\mathcal{T}$=0.7, or "*Most* of *young* employees earn *low* salary", $\mathcal{T}$=0.82.

For clarity and convenience we employ Zadeh's protoforms for dealing with linguistic summaries – cf. Kacprzyk and Zadrożny [27]. A *protoform* is a more or less abstract prototype (template) of a linguistically quantified proposition. The two basic types of protoforms of linguistic summaries of trends are:

- a simple (short) form:

  $$\text{Among all segments, } Q \text{ are } P \tag{3}$$

  e.g., "Among all segments, *almost all* are *slowly increasing*".
- an extended form:

  $$\text{Among all } R \text{ segments, } Q \text{ are } P \tag{4}$$

  e.g., "Among all *very short* segments, *most* are *increasing*".

The basic quality criterion is the truth value (degree) [23]. Using Zadeh's calculus of linguistically quantified propositions [26] it is calculated as:

$$\mathcal{T}(\text{Among all } y\text{'s, } Q \text{ are } P) = \mu_Q\left(\frac{1}{n}\sum_{i=1}^{n}\mu_P(y_i)\right) \tag{5}$$

$$\begin{aligned}\mathcal{T}(\text{Among all } Ry\text{'s, } Q \text{ are } P) &= \\ = \quad \mu_Q&\left(\frac{\sum_{i=1}^{n}\mu_R(y_i)\wedge\mu_P(y_i)}{\sum_{i=1}^{n}\mu_R(y_i)}\right)\end{aligned} \tag{6}$$

where n is the number of extracted segments, Q is a fuzzy set representing the linguistic quantifier in the sense of Zadeh [26], i.e. regular, nondecreasing and monotone and $\wedge$ is the minimum (or a t-norm, cf. Kacprzyk, Wilbik and Zadrożny [28]).

There are also some other quality criteria introduced for the evaluation of linguistic summaries, like degrees of focus,

specificity, covering or appropriateness and measure of informativeness and others. Those quality criteria were discussed in our works (cf. Kacprzyk and Wilbik [29], [30], [31], [32]).

IV. Comparison of the mutual fund and its benchmark

There are several possibilities how to assess if the fund is better than its benchmark. A very simple approach is to compare just the absolute return rate of the fund and benchmark after a certain period. Then we can just compare those two values to assess if the fund is better than benchmark. This is known as a *benchmark return*.

The second option is to compare the return rates of the fund and its benchmark over a certain period. First, we obtain two time series of daily return rates of an investment and its benchmark. Then we subtract the values of the time series of the benchmark from that of the time series of the fund. Next we can analyze the results, e.g., if most of the values of the new time series is above 0 or a certain value, then the fund is better than the benchmark, if most values are close to 0 then the fund is comparable with the benchmark, otherwise it is worse. Such an approach is somewhat similar to the method proposed by Castillo-Ortega, Marín and Sánchez [33].

However that approach can be inappropriate in our context of mutual funds since, usually, the difference between the fund and its benchmark may be very fluctuating. This may be caused because the daily values are compared, not the segments (or trends), and usually there is a small temporal shift between the values of the benchmark and the fund. We will show this later in the section on numerical example.

Therefore we propose to make the assessment on the basis of some trends (or linear segments), in order to avoid those rapid changes in values. We want to globally asses the interplay between the benchmark and the investment fund quotations. This is much more then the analysis of quotations and its related benchmark values but also the analysis of dynamics and behavior. Fund quotations are not directly comparable in financial terms with the values of the benchmark (the WIG index in our case), but they are related.

We assess whether the fund is better than its benchmark using the following widely accepted principle: it is said that a mutual (investment) fund is better than its benchmark when it rises faster than the benchmark and falls slower than the benchmark.

The time series is represented by its segments (trends). Each segment is described by the following four values:
- starting time, called here a partition point,
- duration of the segment (expressed in time units),
- dynamics of change (expressed as the slope of the segment),
- variability occurring in the segment, describing the variability of differences between the trend (segment line) and the particular time series values over the duration of this trend.

Let us assume that we wish to assess which of the two time series A and B is better. As a result of the segmentation procedure time series A is divided into k segments, represented by a_j, $j = 1, \ldots, k$ and time series B is divided into l segments, represented by b_j, $j = 1, \ldots, l$.

A simple approach would be that the segments have the same partition points. This may be attained at the expense of using an artificial fixed point segmentation. In our case we follow a different way and assume that segmentations of the investment fund and benchmark time series are taken as they are, and there may be different partition points between the segments. This clearly complicates the analysis.

Next we create the set of partition points of the two time series considered, i.e. this set contains the time points when at least one segment has started. There are at most $k + l$ such partition points. Those times are sorted, so that the earlier ones come first.

Now between any consecutive partition points (e.g. p_i and p_{i+1}) there is only one segment (or a part of it) of each time series. We may denote those segments as a_{p_i} and b_{p_i}, i.e., a_{p_i} is the segment representing time series A that take place between p_i and p_{i+1}, as in Figure 3.

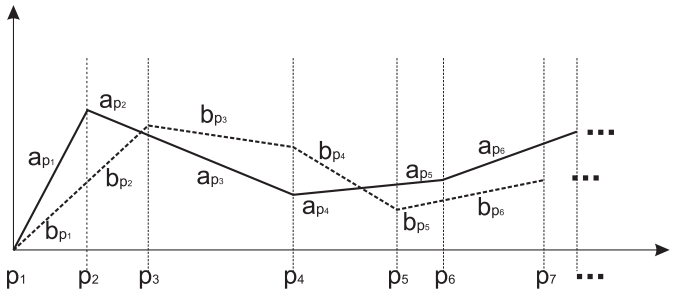

Fig. 3. Partition points for two time series

For the assessment purposes the values of the dynamic and duration are only used. First, we assess if the fund is better than its benchmark between two consecutive partition points, i.e., we compare the segments between those partition points. We subtract the value of the dynamics of change of the segment representing the benchmark's time series, from the value of the dynamics of change of the segment representing the benchmark's time series. This difference is treated as a linguistic variable and expressed using linguistic terms (labels) modeled by fuzzy sets defined by the user. Three linguistic labels should be sufficient, notably "better", "indifferent" and "worse". We could aggregate those partial scores, via a quantifier driven aggregation. However, the definition mentioned above distinguish 2 situations, an increase and a decrease of the values of the benchmark. Therefore it would be interesting to present this relationship in the form of a linguistic summary.

V. Numerical example

In this numerical example we analyze the mutual fund quotations from the last two years, i.e., from January 5, 2009 until January 3, 2011, presented in Fig. 4. The investment fund considered is an equity fund that invests at least 66% assets in shares listed at the Warsaw Stock Exchange. It may also invest at the Zagreb Stock Exchange or Moscow Interbank

Currency Exchange. The fund aims at achieving a long term capital growth (the minimal saving time is recommended to be 5 years) and promises a high profit, however at a high risk, in particular in short term.

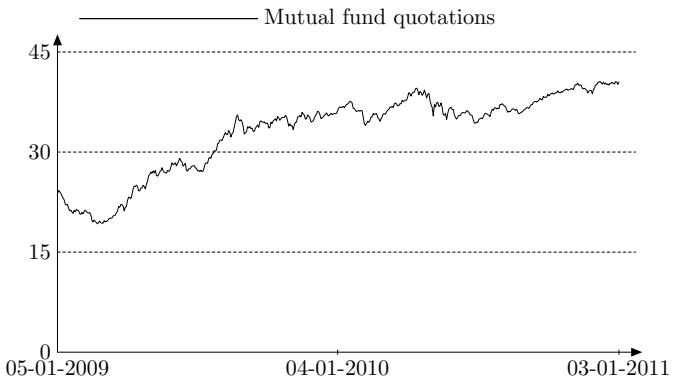

Fig. 4. Daily quotations of the investigated fund

In the analyzed time span, the benchmark of this fund was the WIG index, a total return index, which includes dividends and pre-emptive rights. More information about this index can be found at `www.gpw.pl`. The performance of the WIG index is presented in Fig. 5.

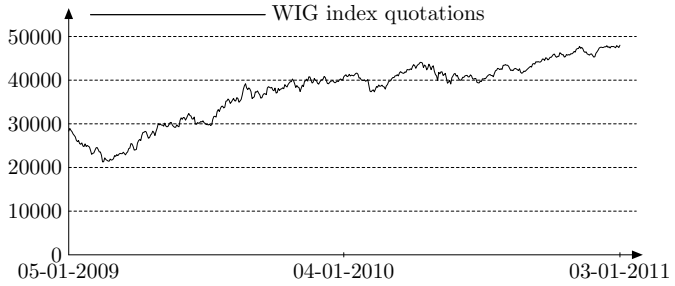

Fig. 5. Daily quotations of the WIG index

Just for information, the return rates for the fund and the WIG index over the given period are equal, respectively, to 1.60% and 1.82%. The benchmark return rate is -0.22%, so it is very small.

We could scale the both time series, i.e. interpreting the scaled values as the value of our investment of the same sum of money at a specific time point. Then we could easily subtract those values. As a result we would obtain the time series as in Fig. 6 and obtain the linguistic summaries "most values are practically the same" meaning that the difference in profit of the two instruments, meant as given above, is irrelevant in most days.

We may notice very big oscillations, and this time series looks similar to a white noise.

Let us now analyze the results of the method proposed. Using a piecewise linear segmentation method with a moderate value of the maximum accepted error we have found 28 segments for the fund quotations time series and 40 segments for the WIG quotations time series. We computed also the degree of similarity of the fund and WIG time series using

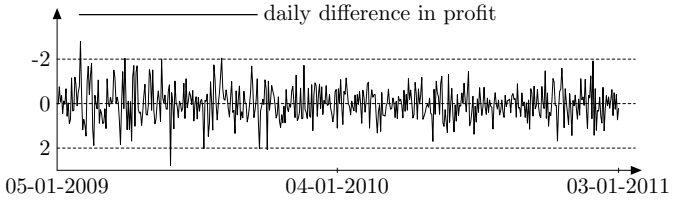

Fig. 6. Daily difference in profit of two investment instruments

a method propsed in our previous paper [12], and it is equal 0.7830, so both time series are quite similar.

Some of the linguistic summaries describing the dynamics of change of two time series and the difference of angles (slopes of the segments) are the following:

- In most cases if the dynamics of change of the investment fund was decreasing, the dynamics of change of WIG index was also decreasing, $\mathcal{T}$ = 1.0000
- In most cases if the dynamics of change of the WIG index was constant, the dynamics of change of investment fund was also constant, $\mathcal{T}$ = 1.0000
- In most cases if the dynamics of change of the investment fund was increasing, the dynamics of change of WIG index was also increasing, $\mathcal{T}$ = 0.9140
- In most cases if the dynamics of change of the WIG index was increasing, dynamics of change of the fund was worse, $\mathcal{T}$ = 1.0000
- In most cases if the dynamics of change of the WIG index was constant, dynamics of change of the fund was indifferent, $\mathcal{T}$ = 0.9107
- In most cases if the dynamics of change of the WIG index was decreasing, dynamics of change of the fund was better, $\mathcal{T}$ = 0.7727

The first 3 summaries describe relationships betweens segments describing the fund and WIG time series. The next 3 summaries compare the fund and WIG stating that, generally, the fund outperforms its benchmark, when it falls, but underperforms the benchmark when it rises. This basically means that the fund is not performing as we have wished it to do. This may be a very important clue for the funds managers. Also this may be a valuable conclusion in the context of bad situation on the economic and financial market that we have observed for a few last years.

This intuitive, human consistent assessment is a "raw estimate" and in investments practices much more sophisticated criteria are used. This is however beyond the scope of this paper.

VI. Concluding remarks

We dealt with the problem of how to evaluate the performance of an investment (mutual) fund, over a past period. We took as a point of departure a widely assumed attitude that an investment fund was said to have performed well if its unit price had been rising faster than its benchmark during a period of growth, and had been falling slower than its benchmark during the period of decline. We developed a

novel, flexible and human consistent comparison method that operated on the comparison of trends (segments) extracted from the times series representing the behavior of the fund and its benchmark. The result of comparison became a new data set that was linguistically summarized using the method proposed in our previous works. The new method proposed was tested on an open investment fund listed on Polish and international financial market whose benchmark was the most important, general index of the Warsaw Stock Exchange. The results obtained provided a valuable insight into the very essence of the behavior of the fund's quotations in relation to its benchmark, and could be useful while making investment decisions.

***Abstract*—An important question is how to determine if a person is exhibiting suicidal tendencies in behavior, speech, or writing. This paper demonstrates a method of analyzing written material to determine whether or not a person is suicidal. The method involves an analysis of word frequencies that are used in a fuzzy cognitive map. The fuzzy cognitive map determines if there are suicidal tendencies. The method could have substantial potential in suicide prevention as well as in other forms of sociological behavior studies that also might exhibit their own identifying patterns.**

Keywords-fuzzy cognitive maps; causality; suicide; language; natural language processing

I. INTRODUCTION

Computationally recognizing causality is a very difficult task. However, discovered causality can be one of the most useful predictive tools. One utilitarian outcome that causality can provide is the prediction of human behavioral patterns, either in a broad domain such as nations or religious groups, or in groups of individuals. One group of individuals that can be analyzed is the people who commit suicide. Describing the causalities involved is difficult to do quantitatively, so it must be represented qualitatively. The purpose of this work is to use fuzzy cognitive maps to discover and isolate root causal relationships based on words in suicide notes.

The long term goal of this work is to discover causal patterns in written material. The focus is on patterns in the frequency of words as opposed to grammatical structure. The objective of this work, which will be the first step toward the long term goal, is to analyze a specific human behavioral pattern, i.e. suicide, in the form of suicide notes in a way as to contrast it with non-suicide notes. The central hypothesis is that suicidal behavioral patterns can be extracted from word frequencies in written material, and that these patterns can be represented using fuzzy cognitive maps.

To test the central hypothesis and accomplish the objective of this research, three specific aims are pursued:

A. Discover and extract patterns in written material in order to produce an initial fuzzy cognitive map to describe causality.

The first step toward this aim is the analysis of suicide notes according to the working hypothesis that using discovered word frequency patterns can discover causal patterns. This will be done for both the original written material and a set of the same data with spelling corrections.

The reason for making the distinction between spelling errors and corrected errors is that misspellings in suicide notes could have patterns that are exclusive to such writings as opposed to other written material. If, on the other hand, it turns out that misspellings are not significantly tied in with either suicide or non-suicide notes then notes that have had their spelling corrected will not be considered in the analysis, then only the original notes will be used in developing the fuzzy cognitive map.

The second step is an analysis of non-suicide notes based on the same working hypothesis. Again this has to be done for both the original and corrected versions of the data. Once this analysis has been done, the frequency patterns of the data will be used to produce an initial fuzzy cognitive map for analysis in the second aim.

B. Perform rigorous testing on the fuzzy cognitive map on the original data and make adjustments where necessary.

Once the first aim has been accomplished and the patterns discovered are converted to a fuzzy cognitive map, then testing must be performed in order to ensure that the map will be able to tell the difference between the suicide notes and the non-suicide notes that were originally tested.

Again, as in the first aim, this must be broken up into testing the original data and the data with spelling corrections. These must be further divided up into testing groups of notes and testing individual notes. This will show how sensitive the fuzzy cognitive map is to the amount of data available. Once the map has been altered to a point where the results are acceptably reliable then aim three will be performed.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

C. *Perform rigorous testing on the fuzzy cognitive map based on different material.*

Once the cognitive map is able to distinguish between the two original data sets used to build it, the map must be able to find the patterns in different written sources to ensure that it can work on a variety of writing. This is also broken up into two steps as in the first two aims.

The first step is using the misspelled words as written, and the second step is using the corrected words. As with the second aim, this must be tested for both individual notes and for groups of notes to determine if the amount of data affects the outcome. If satisfactory results have not been attained, then the new data must be factored into the fuzzy cognitive map until the results are reliably accurate. Then aim three must be performed again using a different source of data.

II. BACKGROUND

A. *Suicide research*

Much of the research on suicide has been in two major areas: clinical studies and analysis of suicide notes. Clinical studies usually involve two types of studies. The first type of study is statistical analysis. This usually involves analyzing suicides based on age and gender as well as other demographics such as social and educational status [5]. This method has been traditionally a primary means of analysis in researching suicide [6]. For example, some studies have shown that nearly one-third of all suicides are found in the elderly over 60 years of age [1]. By using this technique, it is possible to discover what kinds of people are more likely to commit suicide and when. This allows researchers and suicide prevention organizations to identify particular trends in the demographics where they can focus their work in discovering ways to prevent such suicides.

The second type of clinical study involves psychological analysis of individual patients that are displaying suicidal thoughts and actions. This allows for discovering reasons for committing suicide on an emotional and psychological level. This method is done by studying people with suicidal thoughts in order to correlate emotional, mental, or physical state with suicide. An example would be to study the emotional state of people who are losing eyesight, who especially have a fear of losing sight, and how it correlates with suicidal thoughts [7]. If the thought processes of people who are undergoing blindness can be thoroughly understood, than it would be possible to anticipate and treat psychopathological symptoms before they lead to suicide [7].

The analysis of suicide notes has been primarily a study into the content of the notes in an attempt to discover the state of the persons thinking and thereby understand what circumstances and emotional states were driving the individual to commit suicide. These circumstances can be divided up into situations, relationships, emotional state, cognitive state, and demographic variables [3]. These different aspects are then analyzed to determine causes and motivations for suicide similar to the clinical studies approach.

B. *Causality*

Causality is a description of what causes a particular event or group of events in order to happen [10]. Causality is more than a statistical correlation as it contains both a direction, i.e. one event causes another event and not the other way around. Causality also has a particular order in a string of events that, if changed, would alter the result of the events [10]. If causality can be extracted from outside information, it would help intelligent systems in modeling its environment for decision making [11]. Also, causal relationships are more stable in describing the world than probabilistic models [12]. However, constructing causal relationships is difficult as often it is difficult to determine whether a particular event is necessary for the causal relationship or is merely coincidental [13]. Two methods used for modeling causality are text information extraction and graphs.

One of the challenging aspects of analyzing language is that language is highly complicated and often ambiguous; consequently making computer understanding difficult [14]. Extracting causal knowledge from text is of interest because the internet can provide a huge amount of text that is machine-readable. These documents have a great deal of information in them that can be used to establish causal models, e.g. analyzing newspaper articles in order to determine causal economic trends [15]. Another use in computationally extracting causal patterns from text documents is to answer questions by analyzing lexical and semantic constructions within the sentences [16].

Graph structures can be used for both modeling outside events, such as Mideast relations [9], as well as to describe causal relations in textual data [17]. The reason why these networks are powerful is that the graphs are made up of simple elements but create complex models that can be used to describe complex relationships [18]. One type of graph structure that can capture causality is a fuzzy cognitive map.

C. *Fuzzy Cognitive Maps*

Fuzzy cognitive maps are a fairly recent development in the attempt to capture causality in a way that can be useful for studying the real world. These maps are directed weighted graphs that describe relationships between events. The nodes and edges together capture domain information allowing the fuzzy cognitive map to depict uncertain causal reasoning [8]. The individual nodes represent particular events and the directed weighted edges represent what kind of an influence each node has on the other nodes that it connects to. If node one has a positive influence on node two, then if the event of node one increases, the event of node two will also increase; if they are connected with a negative edge, then if node one increases, node two will decrease [9]. Each node in the graph is a fuzzy set that goes from 0% to 100% [9]. Also, each edge can be a set of concepts such as “a little” up to “a lot” or a range of numbers such as 0% to 100% as with the nodes [9] [2].

III. CREATING THE INITIAL FUZZY COGNITIVE MAP

A. *Extracting patterns in general categories from written material*

The first step in accomplishing the first aim, and, developing the initial fuzzy cognitive map was to analyze the written data of both suicide notes and non-suicide notes. The group of suicide notes that were studied consisted of notes written by those that successfully committed suicide. The non-suicide notes consist of three sets that are approximately the same size as the number of words used in the group of suicide notes.

The data sets are taken from informal sources, i.e., each source represents a natural human form of communication as opposed to magazine articles, professional journals, and other such written works. The first set is a collection of various product reviews extracted from Amazon.com. This sample set was taken from a number of different products over a range of different ratings that ranged from the highest rating of five stars to the lowest rating of one star. The second set is a collection of notes from a private blog at archbishopcranmer.blogspot.com. This is different from the Amazon.com data because it represents an individual instead of a group of people. The final set comes from a political website called www.biggovernment.com. This set contains more specific topics than are covered by random product reviews on Amazon.com and random notes from an individual.

All of the words were grouped into investigator defined abstract general categories and sorted in order from most frequently used to least frequently used words. Each grouping was defined by how dense they are by percentage compared to the entire dataset, i.e., how frequently each group is used in a given set of data. The categories used are references to self, others, financial terms, medical terms, religious terms, negative and positive words, and misspelled words. The densities of these categories are shown in Fig. 1.

In addition to these categories, past tense and present tense words were also included along with their corresponding negative and positive references as shown in Fig. 2.

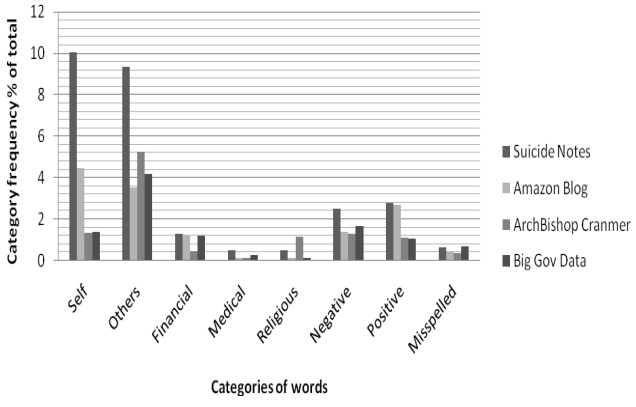

Figure 1. Word densities by percentage part 1

The results show that the greatest differentiation between the suicide notes and the non-suicide notes is found in the references to self and others as shown in Fig. 1, and, present tense as shown in Fig. 2. Also, according to the data, there is not a significant amount of misspellings and even the small amount that there is, does not show significant variation between suicide and non-suicide notes. However, these are chiefly dominated by the set of suicide notes. This means that there would be no nodes in the fuzzy cognitive map that would push the final result toward a non-suicidal classification as if it was analyzing a non-suicidal case. Therefore, the patterns have to be extracted on a word by word basis.

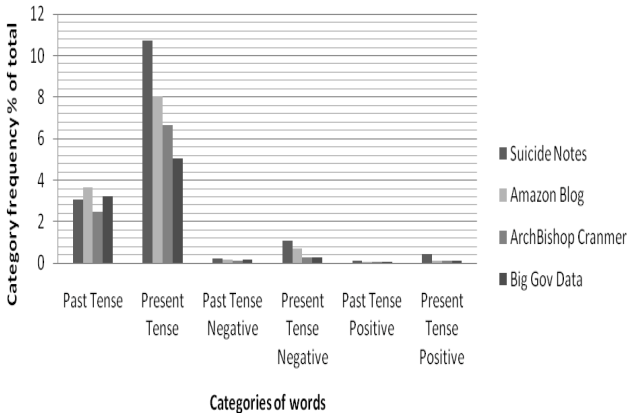

Figure 2. Word densities by percentage part 2

B. *Extracting patterns from specific words in written material*

The three best places to gather words that can provide varying reliable patterns are the groups for self references, references to others, and present tense. These groups contain the most references than any other kind and, therefore, the words in these categories are most likely to be found in a random set of notes to be analyzed and classified as suicidal or non-suicidal. The densities for these words, however, are not based on how many of each word is used in the entire dataset but rather on how many of each word is used in the group it occupies.

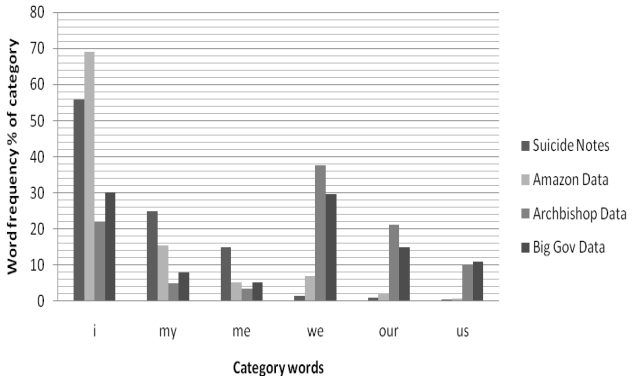

Figure 3. Word densities in self references by percentage

Upon further analysis of the three groups, there were a number of words that proved to have either distinct suicidal influences or distinct non-suicidal influences. All words that had small percentages over all four datasets or did not vary significantly between suicide and non-suicide were removed from consideration. Fig. 3 shows the final results for references to self.

On average each word has a specific affiliation to either the suicide notes or non-suicide notes. However, the Amazon.com data shows definite anomalies in the words "I," "we," "our," and "us" as compared with the other two non-suicide collection of notes. However, the apparent pattern is that suicide notes have more singular self references, i.e. "I," "my," and "me," while non-suicide notes seem to have more group self references, i.e. "we," "our," and "us." Fig. 4 shows the results for references to others.

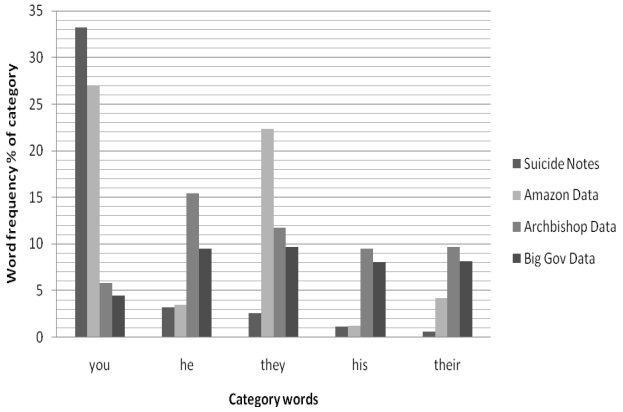

Figure 4. Word densities in others references by percentage

As before, there was a definite pattern with suicide notes having a large amount of references to the word "you" and the non-suicide notes having larger references to "he," "they," "his," and "their." Again, the Amazon.com data shows anomalies being similar to the suicide data in the word "you" but showing a great deal more influence in the word "they." The final results for present tense words are shown in Fig. 5.

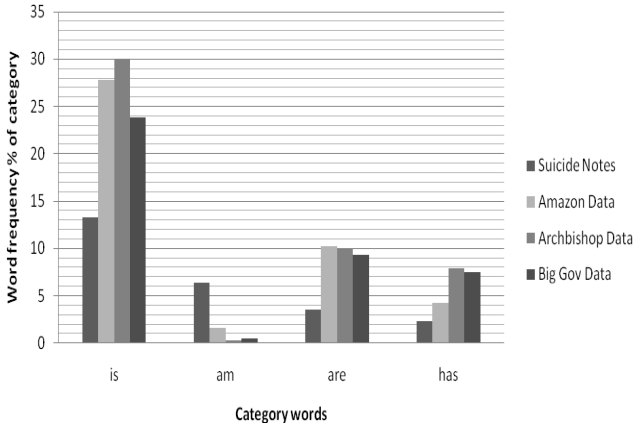

Figure 5. Word densities in present tense by percentage

In this group, the Amazon.com data acts similarly to the other non-suicide data except that the percentage for the word "has" is a little low, although not entirely problematic.

C. Developing the Initial Fuzzy Cognitive map

The fuzzy cognitive maps consist of a series of connected nodes that will represent the words being used from Fig. 3-5. These words will in some way connect to a suicidal node that will determine the classification of the dataset. The simplest graph that can be constructed, is for the suicidal node to be central with all word nodes connected to only that one node as shown in Fig. 6.

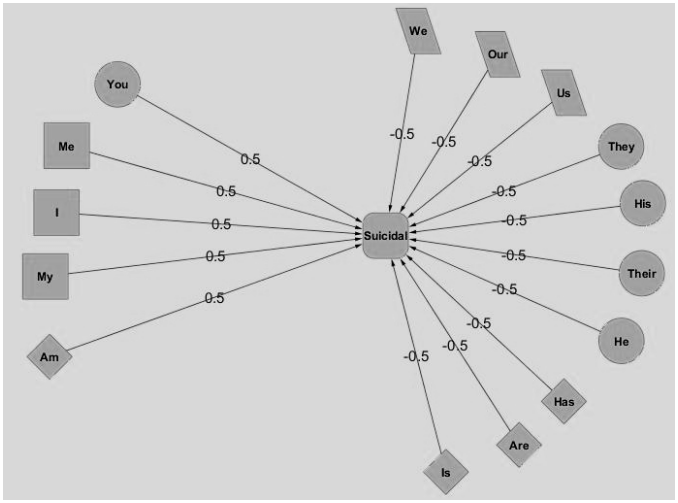

Figure 6. Initial fuzzy cognitive map

Each of the edges has a weight between -1.00 and 1.00 that is attached to it to determine how much influence and what kind of influence a particular node has on the suicidal node. The nodes on the left of Fig. 6 are all the nodes that are associated with suicide notes and thus have a positive influence, while all the nodes on the right represent non-suicide notes and are therefore negative in their influence.

All of the initial weights start at 0.5 or -0.5. This was making the simplifying assumption that all nodes have equal influence on the classification; this simplifying assumption is most likely not correct. However, by starting at this assumption, it can be determined whether or not the general structure of the map is good or bad.

Each of the nodes starts at a particular value between 0.00 and 1.00 and then the graph is allowed to iterate in a computer program until the program either reaches a breaking point or until the graph reaches equilibrium. If the graph has reached equilibrium, then the final value of the suicide node is examined. If the value is over 0.80, i.e. over 80%, then the graph has determined the dataset to be suicidal. If the value is under 30%, then the dataset would be non-suicidal, and if the value is between 30% and 80%, then the classification is uncertain.

The starting values of the nodes were determined by normalizing the data in the particular group, e.g. in Fig. 5, all four datasets would be normalized according to the

archbishop result for the word "is." This means that about 30% is the new 100% which all other values are compared to within that group. Fig. 3 and 4 would have their own number for normalization. The starting number for the suicidal node is 0.00 because it is assumed that there is no initial influence from this node.

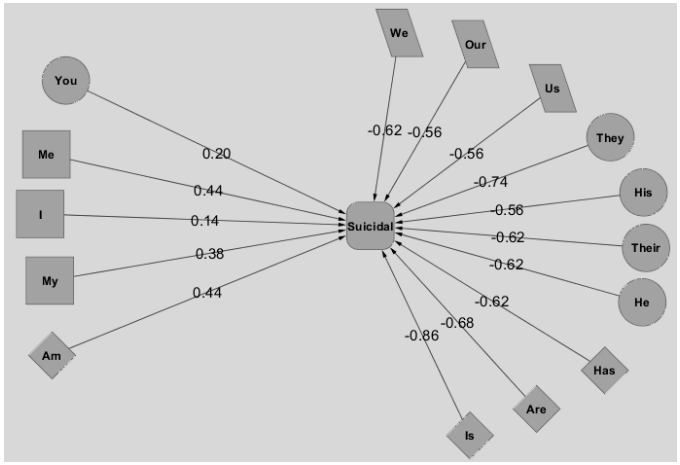

Figure 7. Final fuzzy cognitive map for testing

The final results for the fuzzy cognitive maps for each dataset were not entirely successful. The Amazon.com data was particularly unsuccessful because of its anomalies that made it similar to the suicide notes. Therefore, in order to determine if this map structure can distinguish between the datasets correctly, a set of weights must be found that can find the dividing line. By using machine learning techniques (supervised learning), it was discovered that there is a set of weights which allows the fuzzy cognitive map to correctly classify each dataset. The graph with its final weights is shown in Fig. 7.

IV. TESTING THE FUZZY COGNITIVE MAP

Once a fuzzy cognitive map had been developed that could accurately classify the four datasets, this design was tested against other collections of notes to see if the map could properly classify a random set of data.

A. General Category Testing

Three more datasets were used for testing. These consist of two sets of suicide notes and one non-suicide with each one only a fraction the size of the original four datasets. The first data set was a collection of suicide notes that contains some notes from the original suicide note collection as well as new ones. This was obtained from the website www.well.com/~art/suicidenotes.html and is labeled as suicide notes 2 in the analysis. The second set is a collection of suicide notes from famous actors, poets, and musicians labeled as suicide notes 3 in the analysis that was obtained from the website www.corsinet.com/braincandy/dying3.html. The final dataset is a collection of non-suicide notes from the private blog gregmankiw.blogspot.com. Before going straight into the word analysis, the results for the general categories were compared with the original datasets. This was for the purpose of making sure that all of the datasets are following a predictable pattern. Fig. 8 and 9 show the results for each of the general categories.

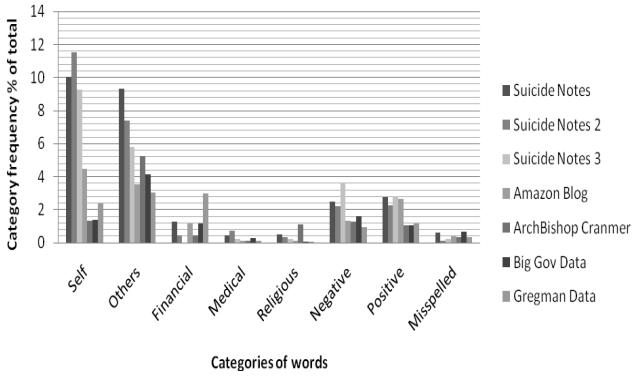

Figure 8. Results of all seven datasets in general categories part 1

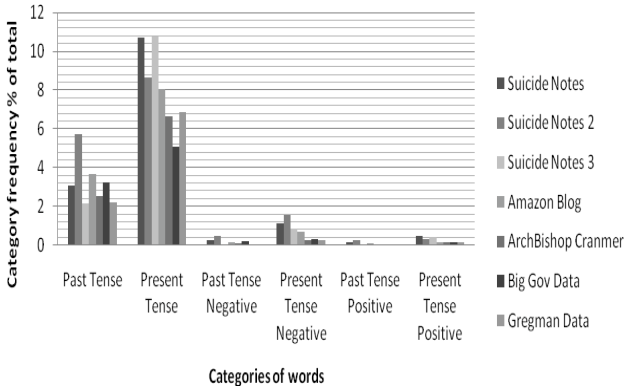

Figure 9. Results of all seven datasets in general categories part 2

As can be seen from Fig. 8 and 9, the three new datasets follow similar patterns in both the suicide and non-suicide cases. Since there were no significant differences, then the specific word analysis could begin.

B. Specific Word Analysis

The final results for the word analysis are shown in Fig. 10, 11, and 12. As can be seen from the graphs, the three new datasets follow the same pattern for their respective classification with the exception of suicide notes 3 which produces some anomalies in the form of very large values in Fig. 12 for the words "is" and "are" which are very close to non-suicide patterns.

Each of the new cases was normalized into the starting values for the nodes of Fig. 7. Each time, the fuzzy cognitive map accurately identified each dataset as either suicidal or non-suicidal. These findings suggest that this fuzzy cognitive map design is somewhat robust in that it was able to handle a random relatively small collection of suicide notes, i.e. suicide notes 3, and correctly identify them as such

even with the non-suicidal like behavior that were found in Fig. 12.

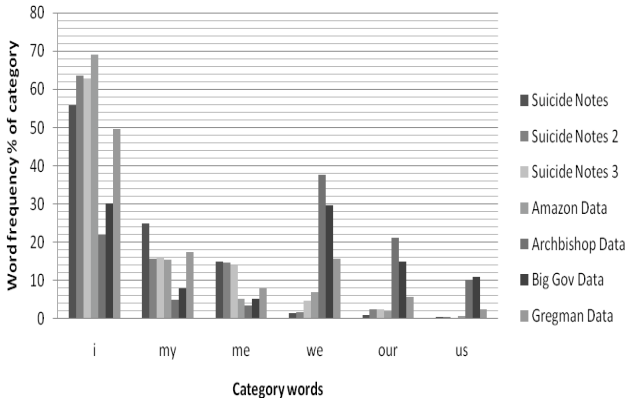

Figure 10. Word densities in self references by percentage

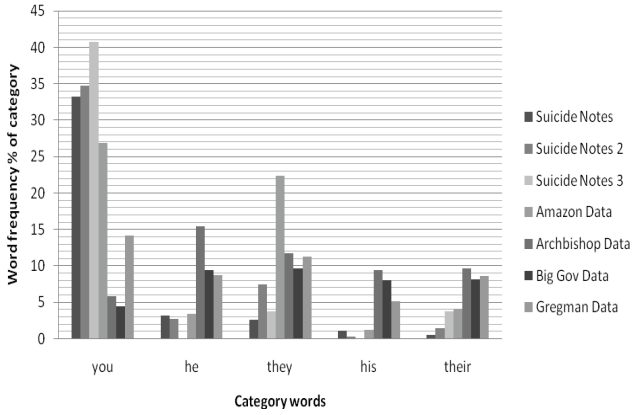

Figure 11. Word densities in others references by percentage

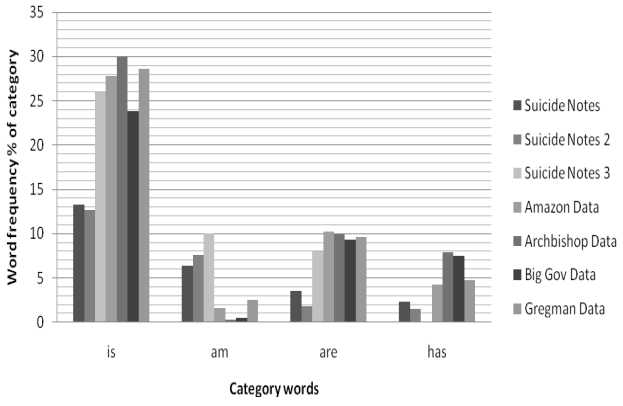

Figure 12. Word densities in present tense by percentage

V. Further Testing

One of the further tests done was an analysis based on gender distinction. A set of male and female notes were taken from the first set of suicide notes and separated to see if gender was a factor in word frequency patterns. In addition, a separate set of male and female suicide notes were taken from [3]. None of these four sets of notes showed any significant difference in word frequency patterns and were correctly identified by the fuzzy cognitive map in Fig. 7. Two non-suicide note collections were then added. The first was from a personal blog colinhughes.blogspot.com that was correctly identified. The second collection was a set of personal letters from the 1820's that were written by patients to Dr. James Carmichael. These were part of a collection from the University of Virginia found at carmichael.lib.virginia.edu. The fuzzy cognitive map was unable to distinguish these notes from the suicide notes. By performing a principle component analysis (PCA), Fig. 13, on the values of the values of the nodes in the map, it is easy to see why the Carmichael notes do not separate.

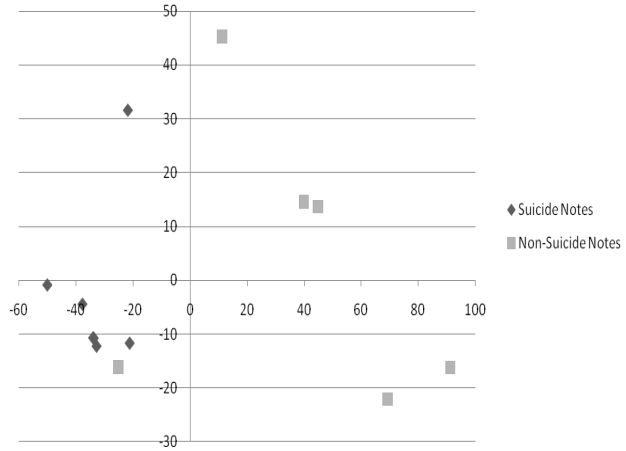

Figure 13. PCA of 13 notes

As can be seen in Fig. 13, the suicide and non-suicide notes are clearly separate from one another with the exception of the Carmichael notes which are found in with the cluster of suicide notes on the bottom left of Fig. 13. One possible explanation for why these particular notes are similar to suicide notes is that suicide notes generally take the form of a personal letter that is directed from one individual to another. This could cause particular word patterns to form that would be similar to other personalized letters. This could be especially true for the words found in the self references and references to others categories.

The problem was solved by adding more words from a new general category. Five more words were chosen from the past tense general category. The five words are "tried," "got," "told," "wanted," and "were." By adding these words, there were enough distinct word patterns that were able to separate the Carmichael notes from the cluster of suicide notes. All that was left to be done was to find a new set of weights that would be able to separate the suicide from the non-suicide notes. After redistributing the weights, the new fuzzy cognitive map, Fig. 14, was able to successfully identify the Carmichael notes as non-suicidal.

Finally, two more sets of personal letters were added to datasets for a total of 15. The first set was a collection of

letters from Alexander Bell to his wife. These were most similar to the Carmichael data. The last dataset was a collection of personal letters from a soldier during the Spanish American War. Both sets came from the digital collection at the Library of Congress. The final results are shown in the PCA of the data, Fig. 15.

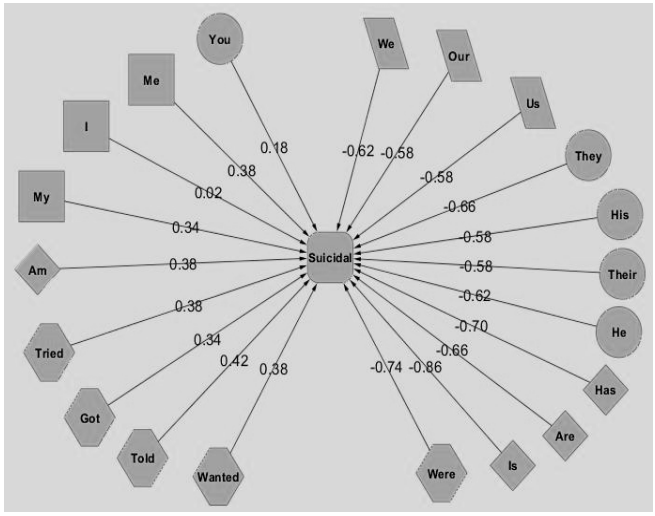

Figure 14. New fuzzy cognitive map

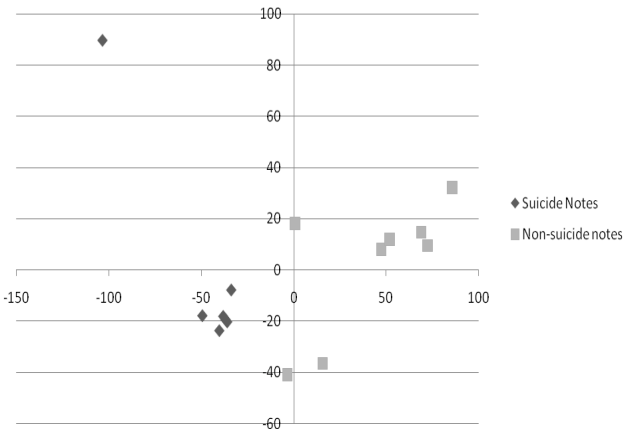

Figure 15. Final results for all 15 datasets

With the addition of the five past tense words, the Carmichael notes have shifted away from the suicide cluster and are almost at the y-axis at y ≈ -40. Immediately to the right is the collection of Alexander Bell's letters. Finally, the Spanish American War letters are found in the cluster on the right hand side of the graph near x ≈ 75.

VI. Conclusion

The results appear to provide strong evidence that it is possible to differentiate between suicidal behavioral patterns and non-suicidal patterns. Further testing must be done in order to ensure that this method can be used in all given situations. Testing needs to be done on age based collections. There is the possibility that notes from adolescents, for example, are different from adults. Another such testing would be an analysis of suicidal ideation or intent to commit suicide [1] which may or may not result in an attempted suicide. Also, further tests can be done from other collections of suicide notes and non-suicide notes that may result in further adjustments to the fuzzy cognitive map.

This work is creative and original because it employed the use of fuzzy cognitive maps based on word frequencies in order to define human behavioral patterns. It is expected that the results of this research can further the understanding of causality discovery in text and the prediction of human behavior. The broad application and positive impact of this work is a further development in the techniques for capturing causal relationships. Identification of causal relationships may allow the ability to predict the consequences of actions from military activities, governmental restructuring or societal rebuilding [2] [4]. In the context of this work, fuzzy cognitive mapping was used to analyze writing and potentially it may be used to predict suicidal acts and allow possible intervention that could save lives.

Constant Penalty Functions to Simplify Optimization of the Choquet Integral under Constraints

Tanja Magoč
Center for Bioinformatics and Computational Biology

Email: t.magoc@gmail.com

***Abstract*—The Choquet integral have been used in many decision making problems as the optimization function that needs to be maximized or minimized. The complexity of these optimization problems is often increased by numerous constraints that are imposed to the solution. Several methods have been developed for optimization under constraints, one of them being penalty functions method. This method transforms a constrained optimization problem in an equivalent unconstrained optimization problem by adding penalties to the solutions that do not satisfy one of more constraints. Penalty functions method is an iterative process, which adjusts penalty functions in each iteration, often yielding a large number of iterations until a satisfying solution is found. To speed the process of the Choquet integral optimization under constraints, we propose to use constant penalty functions. This approach requires only one iteration, and is therefore much faster than the generic penalty function method. In this paper, we derive the constant penalty function that guarantees that the optimal solution found in the first iteration satisfies all constraints.**

Keywords-the Choquet integral; optimization; constant penalty function; decision making

I. Introduction

The Choquet integral has often been used as an optimization function in decision making such as finance [1], geographic information systems [2], evaluation of mental workload [3], and environmental structure evaluation [4]. Many real-life and scientific problems can be formulated in terms of decision making. Some decisions are relatively straightforward. However, other problems may require more strategizing such as in the case of decision under uncertainty and multi-criteria decision making. Multi-criteria decision making seeks an optimal solution among a set of alternatives that are characterized by several attributes, i.e., criteria. For example, if an individual wants to buy a car, this individual would most probably consider the price, miles per gallon, safety rating, color, and other characteristics of cars. The first difficulty faced with different criteria used to make decisions is the domain of values that each criterion could take. Some criteria take qualitative values while others take quantitative values that might be discrete or continuous. The color could be expressed using qualitative values (.e.g., {red, blue, black}); the safety rating could be expressed using discrete integers representing the number of stars rating a car's safety (e.g., {1,2,3,4,5}); and the price could be expressed in terms of a continuous variable taking values within an interval (e.g., [11000,50000]).

Furthermore, a decision maker usually has preferences within each criterion in terms of the values he/she would rather choose compared to other possible values of the criterion. For example, a car buyer would like to buy the car that is the cheapest, has the highest safety rating, travels the most miles per gallon of gas, and is of the decision buyer's favorite color. However, only in miracle situations, an available alternative (e.g., a car) is characterized by the best value for each criterion. In general, the alternative that reaches the maximum value of one attribute does not reach the maximum value of another attribute (e.g., the cheapest car usually does not have five stars safety rating). Thus, a decision maker has to accept some tradeoff between criteria, and maximize the total payoff of choosing a particular alternative. The total payoff could be calculated in various ways. Maximax, maximin, weighted sum, and the Choquet integral are most commonly used methods to combine values of each criterion into a global value. While maximax, maximin, and weighted sum are attractive approaches in decision making situation where criteria are mutually independent, the Choquet integral is well suited for situations where there are dependences between criteria used in decision making. Different approaches have been employed to optimize the Choquet integral including genetic algorithm [5], branch and bound method [6], and particle swarm optimization technique [7].

In many situations, certain constraints are imposed to the possible solution, which results in a more complex optimization problem. Numerous methods have been developed to deal with constraints while optimizing a function including simplex method ([8],[9]), Lagrange multiplier approach ([10],[11]), branch and prune method [12], and penalty functions technique [13]. The method of penalty functions relies on adding the penalty (i.e., decreasing the value of a maximizing function, or increasing the value of a minimizing function) at the points or intervals that do not satisfy constraints. Typically, the penalty function is defined as a polynomial (often the first degree polynomial) function of the inputs representing the values of the criteria considered in the decision making. The coefficients of the penalty function are adjusted in each iteration of the optimization process. However, in some situations, this functions could be replaced by a constant function, which simplifies optimization process while guaranteeing that the points not satisfying the constraint will not be selected as an

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

optimal solution.

In this paper, we first present the basics of the Choquet integral and its use in multi-criteria decision making (section 2). In the section 3, we present a few common constraints to an optimizing function such as the Choquet integral. The common method of penalty functions to deal with constraints is presented in the section 4. Finally, in the section 5, we describe how a constant function could be used as a penalty function in optimizing the Choquet integral. We conclude the paper with future work in extending the proposed method to other optimizing functions.

II. The Choquet Integral as the Optimization Function in Multi-Criteria Decision Making

A multi-criteria decision making (MCDM) problem seeks the optimal choice among a (usually finite) set of alternatives. It can formally be defined as a triple $(X, I, (\succeq_i)_{i\in I})$ where

- $X \subset X_1 \times \cdots \times X_n$ is the set of alternatives with each set X_i representing a set of values of the criterion i.
- I is the (finite) set of criteria (or attributes).
- $\forall i \in I$, $\succeq_i$ is a preference relation (a weak order) over X_i.

The next task is to "combine" the partial preference relations $\succeq_i$ of an alternative into a global value for the alternative such that the final order of the alternatives is in the agreement with the decision maker's partial preferences. The natural way to construct a global preference is by using a utility function for each criterion to reflect partial preferences of a decision-maker, and then combine these monodimensional utilities into a global utility function using an aggregation operator. The utility functions

$$u_i : X_i \to \mathbb{R} \tag{1}$$

such that

$$\forall x_i, y_i \in X_i, u_i(x_i) \geq u_i(y_i) \text{ if and only if } x_i \succeq_i y_i \tag{2}$$

map the values of all attributes onto a common scale (often the interval [0,1]). The existence of monodimensional utility functions is guaranteed under relatively loose hypotheses by the work presented in [14].

Numerous aggregation operators could be used to combine monodimensional utilities into a single number that represents the value of an alternative. Two simple approaches that correspond to optimistic and pessimistic behavior of the decision maker are maximax and maximin strategies, respectively, assuming that the goal of a decision-maker is to maximize the utility. The maximax method compares the utilities of all criteria of an alternative and chooses the highest utility value, $\max_i u_i(x_i)$, to represent the global utility of the alternative $\mathbf{x} = (x_1, ..., x_n)$. This approach reflects an optimistic behavior of the decision-maker since he/she is concerned only with the attribute that has the highest utility for the given alternative. The maximax method tries to maximize the best criterion:

$$\max_{\mathbf{x}\in X}(\max_{i\in\{1,...,n\}} u_i(x_i)). \tag{3}$$

On the contrary, the maximin method reflects a pessimistic behavior of the decision-maker as the decision-maker is concerned only with the criterion that could result in the worst value. This method compares the utilities of all attributes of an alternative and chooses the lowest utility value, $\min_i u_i(x_i)$, to represent the global utility of the alternative $\mathbf{x}$. The decision-maker tries to maximize the value of the worst case scenario:

$$\max_{\mathbf{x}\in X}(\min_{i\in\{1,...,n\}} u_i(x_i)). \tag{4}$$

To allow for a position between these extremes when making a decision, a simple combination of maximax and maximin approaches is achieved by a weighted aggregation operator, named Hurwicz criterion [15],

$$\max_{\mathbf{x}\in X}(\alpha \max_i u_i(x_i) + (1-\alpha)\min_i u_i(x_i)), \tag{5}$$

where $\alpha \in [0, 1]$ is the weight given by the decision maker. This approach simplifies to the optimistic case if $\alpha = 1$ and to the pessimistic case if $\alpha = 0$.

These simple approaches are very tempting to use for quick decisions. However, they focus only on one or two criteria and ignore the impact of other characteristics of alternatives. This approach often does not suit a given situation in which a decision has to be made. Thus, we usually need to consider more complex aggregation operators that take into consideration all attributes. The simplest and most natural of them is a weighted sum approach, in which the decision-maker is asked to provide weights, w_i, that reflect the importance of each criterion. Thus, the global utility of the alternative $\mathbf{x} = (x_1, ..., x_n) \in X$ is given by

$$u(\mathbf{x}) = \sum_{i=1}^{n} w_i u_i(x_i). \tag{6}$$

The best alternative is the one that maximizes this value. Even though this approach is attractive due to its low complexity, it can be shown that using an additive aggregation operator, such as weighted sum, is equivalent to assuming that all the attributes are independent [16]. In practice, this is usually not realistic and therefore, we need to turn to non-additive approaches, that is to aggregation operators that are not linear combinations of partial preferences.

Before approaching non-additive methods, we give the definition of a non-additive measure, a tool for building non-additive aggregation operators such as the Choquet integral. For practical purposes, we restrict ourselves to measures defined on a finite set I.

Definition 1. [Non-additive (fuzzy) measure]: *Let I be the set of attributes and $\mathcal{P}(I)$ the power set of I. A set function $\mu : \mathcal{P}(I) \to [0, 1]$ is called a non-additive measure (or a fuzzy measure) if it satisfies the following three axioms:*

(1) $\mu(\emptyset) = 0$ *: the empty set contains no information.*
(2) $\mu(I) = 1$ *: the maximal set contains all the information.*
(3) $\mu(B) \leq \mu(C)$ *if B, $C \subset \mathcal{P}(I)$ and $B \subset C$: a new criterion added cannot make the importance of a coalition (a set of criteria) diminish.*

A non-additive integral, such as the Choquet integral [17], is a type of a general averaging operator that can model the behavior of a decision maker. The decision-maker provides a set of values of importance, this set being the values of the non-additive measure on which the non-additive integral is computed from. Formally, the Choquet integral in finite case is defined as follows:

Definition 2. [Choquet integral]: *Let μ be a fuzzy measure on $(I, \mathcal{P}(I))$ and an application $f : I \to \mathbb{R}^+$. The Choquet integral of f w.r.t. μ is defined by:*

$$(C)\int_I f d\mu = \sum_{i=1}^{n}(f(\sigma(i)) - f(\sigma(i-1)))\mu(A_{(i)}), \qquad (7)$$

where σ is a permutation of the indices in order to have $f(\sigma(1)) \leq \cdots \leq f(\sigma(n))$, $A_{(i)}$ is $A_{(i)} = \{\sigma(i), \ldots, \sigma(n)\}$, and $f(\sigma(0)) = 0$, by convention.

It can be shown that many aggregation operators can be represented by Choquet integrals with respect to some fuzzy measure. Although the Choquet integral is well suited for quantitative measurements, it has a major drawback. The decision maker needs to input a value of importance of each subset of attributes, that is total of 2^n values, which is intractable due to its exponential complexity. However, we can overcome intractability by using 2-additive measure to limit the complexity to a $O(n^2)$ (as shown in [18]) and still get accurate results.

Before giving the definition of a 2-additive measure, we need to define notion of interaction indices of orders 1 and 2. The importance of a criterion (or the interaction index of degree 1) is best described as the value this attribute brings to each coalition it does not belong to. It is given by the Shapley value [19]:

Definition 3. [Shapley value]: *Let μ be a non-additive measure over I. The Shapley value of index i is defined by:*

$$v(i) = \sum_{B \subset I \setminus \{i\}} \gamma_I(B)[\mu(B \cup \{i\}) - \mu(B)] \qquad (8)$$

with

$$\gamma_I(B) = \frac{(|I| - |B| - 1)! \cdot |B|!}{|I|!} \qquad (9)$$

and $|B|$ denoting the cardinal of B.

While the Shapley value gives the importance of a single attribute to the entire set of attributes, the interaction index of degree 2 represents the interaction between two attributes, and is defined by ([20],[21]):

Definition 4. [Interaction index of degree 2]: *Let μ be a non-additive measure over I. The interaction index between i and j is defined by:*

$$I(i,j) = \sum_{B \subset I \setminus \{i,j\}} (\xi_I(B) \cdot (\mu(B \cup \{i,j\}) - \mu(B \cup \{i\}) - \mu(B \cup \{j\}) + \mu(B))$$

with

$$\xi_I(B) = \frac{(|I| - |B| - 2)! \cdot |B|!}{(|I| - 1)!}. \qquad (10)$$

The interaction indices belong to the interval $[-1, +1]$ and

- $I(i,j) > 0$ if the attributes i and j are complementary;
- $I(i,j) < 0$ if the attributes i and j are redundant;
- $I(i,j) = 0$ if the attributes i and j are independent.

Even though we can define interaction indices of any order, defining the importance of attributes and the interaction indices between two attributes is generally enough in multi-criteria decision making problems. Thus, 2-additive measures constitute a feasible and accurate tool in this setting. The formal definition of a 2-additive measure follows [20]:

Definition 5. [2-additive measure]: *A non-additive measure μ is called 2-additive if all its interaction indices of order equal to or larger than 3 are null and at least one interaction index of degree two is not null.*

It has been shown [22] that the Shapley values and the interaction indices of order two offer us an elegant way to represent a Choquet integral. Therefore, in a decision-making problem, we can ask the decision maker to give the Shapley values, I_i, and the interaction indices, I_{ij}, and then use the Choquet integral with respect to a 2-additive measure, μ, to obtain the aggregation operator:

$$\begin{aligned}(C)\int f d\mu = &\sum_{I_{ij}>0} (f(i) \wedge f(j))I_{ij} \\ &+ \sum_{I_{ij}<0} (f(i) \vee f(j))|I_{ij}| \\ &+ \sum_{i=1}^{n} f(i)(I_i - \frac{1}{2}\sum_{j \neq i} |I_{ij}|).\end{aligned}$$

This form of the Choquet integral is a practical approach to many multi-criteria decision making situations ([1],[2],[3],[4]).

III. Examples of Constraints

Numerous constraints could be imposed on the input variables (i.e., variables representing the values of criteria in multi-criteria decision making). A typical constraint in many optimization problems is that (some) variables could not take negative values, $x_i \geq 0$. As we have seen in the previous section, the values of variables in a multi-criteria decision making are often mapped to the interval [0,1]; thus the non-negativity constraint is imposed to all variables. Moreover, in this particular situation, the maximum value of each variable is

1, thus another constraint should be imposed to each variable, $x_i \leq 1$.

However, not every constraint should be imposed to all variables. For example, when buying a car, we might want to buy a car only if it is relatively safe, so we might decide to consider only cars with a safety rating of at least three stars. Using utility functions, the rating of 3 stars would map to the value of 0.5. Thus, the constraint that we need to consider is $x_{\text{safety}} \geq 0.5$.

All of the above examples of constraints are hard constraints, so they must always be satisfied. On the other hand, there might be soft constraints, which we would like to be satisfied, but it is not necessary that they are satisfied. For example, we might not want to buy a car that costs more than $20,000, thus yielding the constraint $x_{\text{price}} \leq 20,000$. However, if there is a great deal available for a car that is a bit more expensive, we might be willing to somewhat sacrifice this soft constraint and buy a car that doesn't satisfy this constraint.

Finally, a constraint does not have to be imposed to only a single variable. It could be imposed to a combination of variables, such as a sum of two or more variables. Let us consider the problem of selecting an optimal financial investment portfolio where the variables represent the portion of money invested in each financial investment assets. A multi-criteria decision making problem is designed to determine the best distribution of money among n assets so that the largest amount of money will be earned in a year [2]. Certain amount of money needs to be invested in each of n assets in order to reduce risk of losing all money ([23],[24]) (we assume here that the n assets were previously selected from thousands of investment assets that exist in the world, so that n is a realistic number for the size of an investment portfolio). Thus, all the variables should be positive (rather than just non-negative), $x_i > 0$, and strictly smaller than 1, $x_i < 1$, since not all money could be invested in the same asset. Moreover, not more than all money could be invested in the portfolio (we are making simplifying assumptions that an investor can not borrow money from one institution to invest it in another asset), thus the sum of all money should be no more than 1 (i.e., 100% of money), $\sum_{i=1}^{n} x_i \leq 1$. This is a typical example of a hard constraint when the value of one variable depends on the values of other variables.

Soft constraints could also be imposed to the variables that depend on each other. For example, we might require that at least 50% of all money is invested in the financial assets, $\sum_{i=1}^{n} x_i \geq 0.5$. However, in some situations (e.g., in economic recessions, gain of investing money could be very low compared to the risk of investing money), we might accept to invest smaller amount of money if no good investment option is available.

Even though the presented examples are all represented by linear inequalities, a more complex constrains could be imposed to the solution of an optimization problem.

IV. Penalty Functions

Several methods have been developed to deal with constraints imposed to the solution of an optimization problem. The method of penalty functions ([11],[13]) transforms a constrained optimization problem into an unconstrained optimization problem, which is accomplished by adding penalties in a minimization problem (or subtracting penalties in a maximization problem) to the solutions that do not satisfy one or more constraints. A penalty function is assigned to each constraint and is adjusted through iterative process of the algorithm. Each penalty function is designed so that its value is equal to 0 if the constraint is satisfied, and greater than 0 if the constraint is not satisfied. Let $c_i(\mathbf{x})$ be the i^{th} constraint. Then the penalty function is defined as:

$$p_i(\mathbf{x}) = 0 \text{ if } c_i(\mathbf{x}) \text{ is satisfied.}$$
$$p_i(\mathbf{x}) > 0 \text{ if } c_i(\mathbf{x}) \text{ is not satisfied.} \quad (11)$$

Let us consider a constrained optimization problem:

maximize $f(\mathbf{x})$

subject to the following constraints:

$$g_i(\mathbf{x}) \geq 0, i = 1, \ldots, m;$$
$$h_j(\mathbf{x}) = 0, j = 1, \ldots, s.$$

This problem is transformed into maximizing the function $f'(\mathbf{x}) = f(\mathbf{x}) - \sum_{i=1}^{m} r_i(\mathbf{x}) - \sum_{j=1}^{s} q_j(\mathbf{x})$, where r_i and q_j are penalty functions. The goal of penalty functions is to decrease the values of the objective function at the elements of the search space that do not satisfy all the constraints. However, finding the maximum of the function $f'(\mathbf{x})$ does not guarantee that the solution is found since the maximum of this function still might not satisfy all the constraints. In order to find a solution that maximizes the objective function and satisfies all the constraints, the penalty functions are changed and the objective function is evaluated again. The process is iterated until an optimal solution that satisfies all the constraints is reached.

The method could be simply described by the following algorithm:

```
PenaltyFunctions
{
   for each constraint
   {
      initialize penalty function
   }
   while (solution not found)
   {
      evaluate objective function
      for each constraint
      {
       add penalties to objective function
      }
      increase penalty functions
   }
}
```

Note that each minimization problem, $min\ f(\mathbf{x})$, could be transformed in the maximization problem $max\ (-f(\mathbf{x}))$. Thus, in this paper, without loss of generality, we assume that we have a maximization problem.

V. A Constant Penalty Function to Optimize the Choquet Integral with Respect to a 2-additive Measure

Even though the penalty functions method could be very effective in solving constrained optimization problems, it suffers a few drawbacks, one of them being the complexity of selecting a good starting penalty function. It is not clear how to initialize a penalty function. The most common approach used to define a penalty function is to square the subrange of the objective function that does not satisfy the constraint. The next question is how to adjust the penalty functions after each iteration of the optimization process. Usually, the adjusted penalty function is simply a multiply of the original penalty function. However, this method might lead towards numerous iterations until the optimal solution is found, which yields another drawback, namely how to define the end of the iterative optimization process.

While the general form of the penalty function method is designed so that it could be applied in any constrained optimization problem regardless of the type of the optimization function, it sometimes takes a large amount of time to obtain the optimal solution. Instead, the penalty function could be defined by a much simpler form such as a constant function. This form is well suited for optimization functions that are bounded on the entire interval that input variables could take. Note that it is enough that the optimization function be bounded from above in an maximization problem, and from below in a minimization problem. One such an optimization function is the Choquet integral with respect to a 2-additive measure constructed by the utility method, which maps the values of all criteria to the interval [0,1] (as described in the section 2).

In this situation, the penalty applied should be a value that is greater or equal to any value that the Choquet integral with respect to a 2-additive measure could possibly take. The reason for this penalty is that if the constraint is not satisfied at a particular point in the search space, we do not want to consider this point as a possible solution to the problem since the problem becomes impractical if a (hard) constraint is not satisfied. Thus applying the penalty whose value is larger than the maximum value the Choquet integral could theoretically take will ensure that the value of the objective function is a negative value and therefore will certainly not be selected as a maximum value.

To determine the value of the penalty, let us consider the formula of the Choquet integral with respect to a 2-additive measure:

$$(C)\int f d\mu = \sum_{I_{ij}>0} (f(i) \wedge f(j)) I_{ij} + \sum_{I_{ij}<0} (f(i) \vee f(j)) |I_{ij}| + \sum_{i=1}^{n} f(i)(I_i - \frac{1}{2}\sum_{j\neq i} |I_{ij}|).$$

If we consider the first two sums, we conclude that each interaction index of order 2 is covered by at most one of the sums (the interaction indices of 0 are not covered at all). Each element of each summation is a minimum or a maximum of two utility values multiplied by the absolute value of the corresponding interaction index of order 2. Each utility value and the absolute value of each interaction index belong to the interval [0,1]. Using interval computation arithmetics (see e.g., [25]), we conclude that each element of any of the first two summation is at most equal to one. The maximum number of elements in two summations is the number of interaction indices of order 2, which is $\frac{n\cdot(n-1)}{2}$, where n is the number of criteria considered. Further, the third summation is the multiplication of a Shapley value and a utility value decreased by a certain amount. Thus, to find its maximum value, we can disregard the subtracted part, and only find the maximum value of the utility value multiplied by a Shapley value. As both of these values fall into the interval [0,1], the maximum value of each element of the third summation is one, and thus, the value of the summation can not exceed n. The maximum value that the Choquet integral can theoretically take is therefore the sum of the maximum value the first two sums could take, $\frac{n\cdot(n-1)}{2}$, and the maximum value the third sum could take, n:

$$\frac{n\cdot(n-1)}{2} + n = \frac{n^2+n}{2} < \frac{n^2+n^2}{2} = n^2. \quad (12)$$

Thus, the penalty that should be applied for a violation of each hard constraint should be equal to at least n^2 to ensure that even if just one constraint is not satisfied at a particular point, the penalty will decrease the value of the optimization function at this point below zero, and therefore this point will surely not yield the maximum value of the optimization function.

However, when considering soft constraints, we would like that they are satisfied, but would accept a solution that yield an optimal value even if the soft constraint is not satisfied. In this situation, we could consider a lower penalty function for soft constraints than for hard constraints. Moreover, since we would allow an optimal solution to not satisfy soft constraints, we do not want to decrease the value of the optimization function below zero if only one soft constraint is not satisfied. In some situations, we might allow for multiple soft constraints to be unsatisfied. If we allow i soft constraints to be unsatisfied, the constant penalty function should be defined as

$$\frac{n^2}{i-1}. \quad (13)$$

The proposed penalty function will assure that if i soft constraints are unsatisfied, the optimization function still might

yield a positive value; however, if the $(i+1)^{\text{th}}$ soft constraint is not satisfied, the optimization function will yield a non-positive value.

Furthermore, if not all soft constraints have the same importance, we might define penalty functions differently for each soft constraints. For example, if not satisfying a soft constraint $C1$ is less important than not satisfying a soft constraint $C2$, then the penalty function for the constraint $C1$ should be smaller than the penalty function for the constraint $C2$.

Finally, in some situations, we might prefer a solution that barely missed to satisfy a soft constraint over a solution that is far from satisfying a soft constraint. In these situations, we apply a penalty function to the objective function. However, the constant penalty function is increased by the distance from satisfying the constraint. The distance is usually calculated as the Euclidean distance between the proposed solution and the constraints.

VI. Conclusion

Numerous situation is life require decision making of some sort. Some situations are so simple that we do not even realize that we are making a decision. However, many situations require more strategies to be employed when making a decision. Different approaches have been taken to select an optimal alternative among available options, one of them being the Choquet integral with respect to a 2-additive measure, which is especially well suited for situations where criteria considered in making decision are mutually dependent.

Optimization of the Choquet integral is not a trivial process itself. The complexity of this process is increased even more by imposing constraints to possible solutions. The constraints could range from simple linear equalities or inequalities applied to one variable at a time to non-linear equalities or inequalities that combine multiple variables. Moreover, constraints could be hard (i.e., constraints that must be satisfied) or soft (i.e., constraints that we would like to be satisfied, but would accept that some of them not be satisfied if that yields a much better optimal solution than if these constraints were satisfied).

Numerous approaches have been used to deal with constraints, one of them being the penalty functions method, which adds penalty to the value of the optimization function if a constraint is not satisfied by subtracting (adding in minimization problem) the value of the penalty function from the maximizing function. The penalty functions method could result in a large number of iterations due to difficulty in adjusting the penalty from one iteration to another. To simplify this method, a constant penalty function could be applied when maximizing the Choquet integral since the Choquet integral is bounded from above. In the case of hard constraints, the penalty function should take the value n^2, where n is the number of criteria used in the decision making problem to ensure that each point that does not satisfy even one hard constraint will yield a non-positive value, and therefore will not be selected as an optimal value. In the case of soft constraints, the constant penalty function should be defined in proportion to the number of soft constraints allowed, and could also be increased based on the distance from satisfying the constraint to give a better chance of being selected as the optimum to points that are closer to satisfying the constrains than the points that are further away from satisfying the constraints.

In this paper, we presented how constant penalty functions could be used in the optimization of the Choquet integral with respect to a 2-additive measure. However, a similar approach could be applied to any other function that is bounded from above in the maximization problem, or bounded below in a minimization problem.

***Abstract*. A Hub Location Problem (HLP) deals with finding the locations of hub facilities and assignment of demand nodes to established facilities. Hubs play a central role in many networks such as telecommunication networks and their unavailability may lead to network breakdown or poor service levels. An objective in design of a hub-and-spoke network is maximization of reliability to transfer flows. This paper puts forward design of a reliable single-allocation hub-and-spoke network using an interactive fuzzy goal programming. To model and solve the problem, a fuzzy goal programming approach was developed for design of network in an interactive manner between decision maker and the model. To validate the model and the proposed solution approach, a test problem is presented and comparison of results is made using this problem.**

Keywords. Reliable hub location problem, Interactive decision making, Fuzzy goal programming, Network design, Bi-objective programming.

I. INTRODUCTION

Decisions are usually categorized as strategic, tactical and operational. A strategic or long-term decision does not take place on a regular basis and needs major capital investments. An example of a long-term decision is determination of facility location ([1]). Facility Location (FL) has been an important concern for around 100 years. Applications of FL could be found in both public and private sectors, since more and more managers realize the importance of decisions made concerning location of facilities.

Hub location problem (HLP) has been an attractive, yet tricky variant of facility location. It arises in many different contexts such as telecommunications, cross-docking, airline industry, computer networks, etc. For example, nowadays many LTL trucking companies designed their networks based on the hub-and-spoke structure. This has led to better efficiency and improved service levels. In a typical HLP, the following questions are to be answered: a) Where to locate hub facilities b) How to allocate demand nodes to hubs, so the objective of the whole network is optimized. Since these decisions are interconnected, their separation may easily lead to sub-optimal results. Therefore, these questions are to be considered in a single model.

HLPs are often categorized as single-allocation and multiple allocation types. While in a single-allocation HLP, each spoke is allocated to one and only one hub node, in the multiple-allocation case, a spoke may be allocated to more than one hub. In this paper, a single-allocation HLP will be studied. Another interesting issue to be considered in design of hub-and-spoke networks is the discount factor associated with arcs which is a value between zero and one to represent the economies of scale. Generally, a flow in a hub-and-spoke network is in accordance with one of the seven types shown in fig. 1. In each of these types, the reliabilities of hubs and arcs play a pivotal role in a successful, on-time delivery of flow. Since hubs and arcs in a network are liable to disruption, design of a reliable network is of great value to decision makers. Kim and O'Kelly [2] proposed the reliable hub location problem and presented two models. As far as we know, this subject has not been considered much to date.

Perez et al. [3] claimed that real applications of facility location can be full of linguistic vagueness that can be appropriately modeled using fuzzy variables. In a HLP, many parameters could not be determined precisely such as demands, distances or reliabilities. In addition, it is sometimes difficult to describe parameters such as reliability as random variables. In these situations, fuzzy logic has been proven to be useful. However, reviewing the literature of HLP, we came to notice that the fuzzy version of HLP has gained little attention.

The rest of this paper is organized as follows: In the preceding section, a brief literature review of HLP and its recent publications is presented. Then, the mathematical formulation of this paper will be proposed. Section 4 is devoted to a brief introduction of fuzzy goal programming. The proposed interactive fuzzy goal programming (IFGP) will be set out in section 5. Afterwards, computational experiments are given in section 6. Finally, conclusions and areas for future research will be given in section 7.

II. LITERATURE REVIEW

Hub Location Problem (HLP) has a long and wealthy background. From the beginning of the 21st century, an increase in the number of publications regarding HLP has been witnessed. The emergence of HLP dates back to late 60s when Goldman [4] defined the network hub location problem for the first time. Later, O'Kelly [5] presented the first seminal paper of HLP by proposing a mathematical formulation for a hub location problem. He studied the American airline passenger network and proposed the single allocation *p*-hub median problem which has gained the most attention so far among various hub location problems. He also proposed a well-known dataset (CAB) for hub location problems involving the passenger flows between 25 US cities. Since then, contributions to HLP have been presented in a variety of ways. It should be noted that a great deal of publications has been about the HLP models in which cost or time have been considered.

The most recent review of HLP is Alumur and Kara [6] which is an elegant and comprehensive review of network hub location problems. They classified their review into four distinct sections as *p*-hub median problem, the hub location problem with fixed costs, the *p*-hub center problem and hub covering problems. Since Alumur and Kara [6] is a comprehensive and valuable review, in this paper, only some recent publications will be presented. One may refer to [6] or other reviews and references therein to get more knowledge about the HLP literature before 2008.

Recently, some heuristics and metaheristics have been proposed to solve various HLPs. Using tabu search to solve the single-allocation hub covering HLP in incomplete networks (Calik et al. [7]), using ant colony optimization for the single-allocation *p*-hub center problem (Meyer et al. [8]). VNS for the single-allocation *p*-hub median problem (Illic et al. [9]), using Lagrangian relaxation for the single-allocation HLP (Contreras et al. [10]) are some instances, to name a few.

Using fuzzy logic in HLP has been recently considered by Chou [11]. He studied the container transshipment hub locations in southeastern Asia. He proposed a fuzzy multiple criteria decision making model to select the container transshipment hub port. Davari et al. [12] studied the single-allocation *p*-hub maximum reliability model of Kim and O'Kelly[(2] in a fuzzy sense. They considered reliability of each arc to be a fuzzy variable and presented an effective simulation-embedded simulated annealing to solve this problem.

Additionally, the Partitioning-Hub-Location-Routing Problem (PHLRP) by Catanzaro et al. [13], HLP in a competitive environment by Gelareh et al. [14] and Eiselt and Marianov [15], the time-definite *p*-hub median problem by Campbell [16], HLP assuming hub congestion by De Camargo et al. [17], considering the size of hubs as a decision variable by Correia et al. [18], stochastic *p*-hub center problem by Sim et al. [19], hierarchical HLP (Yaman [20]) are some recent extensions to the classical HLP.

Obviously, there has not been much attempt in literature to model fuzzy reliable hub location problems. Considering the publications to date, this paper contributes to the literature of HLP in two distinct aspects. First, a new method is proposed to calculate the reliability of a path in a hub-and-spoke network which seems to represent the real-world applications better. In addition, using fuzzy logic in hub location problems has not gained enough consideration so far and is addressed in this paper. Moreover, this paper will present using IFGP in solving HLP considering fuzzy aspiration levels. To the best of our knowledge, this has not been considered in the literature of HLP before.

III. MODEL FORMULATION

The model in this paper is an extension to Kim and O'Kelly [2]. Before presenting the problem formulation, let's define indices, parameters and variables.

Parameters

W_{ij} The flow between nodes *i* and *j*

R_{ij}^{km} The reliability of the flow between nodes *i* and *j* which is routed via hubs *k* and *m*

P Number of hubs to be located

Variables

X_{ij}^{km} Equals 1 if the flow between *i* and *j* is routed via hubs *k* and *m*

Z_k Equals 1 if a hub is located at hub *k*

Model:

$$Max \sum_i \sum_j \sum_k \sum_m W_{ij} R_{ij}^{km} X_{ij}^{km} \quad (1)$$

$$Max \ \omega \quad (2)$$

$$\omega \le W_{ij} R_{ij}^{km} X_{ij}^{km} + (1 - X_{ij}^{km}) M \quad \forall (i,j,k,m); i \ne j \quad (3)$$

$$\sum_k Z_{kk} = P \quad (4)$$

$$\sum_k Z_{ik} = 1 \quad \forall i \quad (5)$$

$$Z_{ik} \le Z_{kk} \quad \forall i, k (i \ne k) \quad (6)$$

$$\sum_m X_{ij}^{km} = Z_{ik} \quad \forall j > i; k \quad (7)$$

$$\sum_k X_{ij}^{km} = Z_{jm} \quad \forall j > i; m \quad (8)$$

$$Z_{ik} \in \{0,1\} \quad (9)$$

$$0 \le X_{ij}^{km} \le 1 \quad (10)$$

Equation (1) is the objective function, where the weighted reliability of the network is to be maximized. The fitness of a

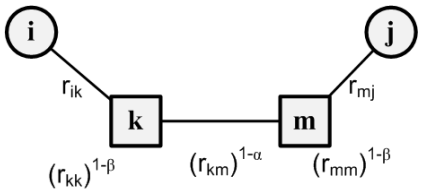
solution is found by adding the weighted reliabilities of each OD pair together. Equations (2) and (3) represent the second objective presenting the center objective which maximizes the minimum reliability in the network. Constraint (4) holds that *P* hubs are to be opened. Constraint (5) states that each node must be assigned to one and only one hub. Constraint (6) states that an assignment could be made to only hub nodes. Constraints (7) and (8) force that a flow from *i* to *j* is routed via hub pair (*k*, *m*) only when hubs are established in these two nodes. Constraint (9) guarantees that the values of *Z* are binary variables. Finally, (10) represents the values that the *X* variable could take.

Kim and O'Kelly [2] presented a procedure to compute the reliability of a path based on single reliabilities of its arcs. However, it can be argued that in some cases, it is unable to represent the reliability properly.

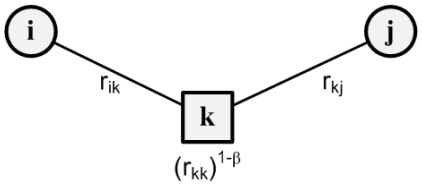
It is known that in a hub-and-spoke network, to reach a destination, the flow must pass hubs and arcs. Therefore, the reliability of each hub is of high importance, along with the reliability of arcs. This paper adds the reliabilities of hubs to the procedure of reliability calculation by presenting a procedure to sequential multiplication of single reliabilities of hubs and arcs. Moreover, it is assumed that same as the arcs, there should be a discount factor associated with hubs which will be shown as β in the sequel. It should be noted that this value could be completely different from the arcs discount factor. Fig. 2 shows two common types of flows in a hub-and-spoke network. The reliabilities of these two types of flows could be found as:

$$(I) R_{ij}^{km} = r_{ik} * (r_{kk})^{1-\beta} * (r_{km})^{1-\alpha} * (r_{mm})^{1-\beta} * r_{mj} \quad (11)$$

$$(II) R_{ij}^{km} = r_{ik} * (r_{kk})^{1-\beta} * r_{kj} \quad (12)$$



(I) Two-hub case



(II) One-hub case

Figure 2. The two common types of flows in hub-and-spoke networks

IV. FUZZY GOAL PROGRAMMING

Goal Programming (GP), first introduced by Charnes and Cooper [21], has been studied for many years as an efficient tool for multi-objective decision making (MODM) problems. Using a GP, decision maker(s) define aspiration levels and seeks an optimal solution where the undesirable deviations are minimized. However, determining precise aspiration levels for each objective in real world problems is a difficult task for decision makers (Yaghoobi et al. [22]).

Fuzzy Goal Programming (FGP) is a variant of the conventional GP, dealing with the imprecision came across by the DM, while expressing one's aspiration levels. The use of Fuzzy set theory (FST), proposed by Zadeh [23] to assist DMs to deal with this imprecise situation and uncertainties in GP was first proposed by Narasimhan [24] and then improved by Hannan [25].

Definition 2 (Zimmermann [26]). Assume that we are given a fuzzy goal $\widetilde{G}$ and a fuzzy constraint $\widetilde{C}$ in a space of alternatives X. Then $\widetilde{G}$ and $\widetilde{C}$ combine to form a decision $\widetilde{D}$ which is a fuzzy set resulting from intersection of $\widetilde{G}$ and $\widetilde{C}$. Bellman and Zadeh [27] proposed the min-operator to obtain a decision by intersection of the fuzzy sets of all objective functions.

DMs often need to know the crisp optimal solution, so it seems appropriate to suggest the highest degree of membership in the fuzzy set decision. Therefore, by using "maximizing solution", we have:

$$Max_{x\geq 0} Min_i\{\mu_i(x)\} = Max_{x\geq 0}\mu_{\widetilde{D}}(x) \quad (13)$$

Introducing a new variable, λ, this conventional linear programming problem can be formulated as follows:

$$Max\ \lambda \quad (14)$$

$$\mu_i(x) \geq \lambda \quad i = 1,\ldots,K \quad (15)$$

$$Ax \leq b \quad (16)$$

$$x \geq 0 \quad (17)$$

$$\lambda \in [0,1] \quad (18)$$

V. THE PROPOSED INTERACTIVE FUZZY FOAL PROGRAMMING (IFGP)

Many real-world problems are associated with a degree of uncertainty about goals and constraints. Recently, many academicians and practitioners have realized that uncertainty is an inevitable element in decision making. In addition, usually there is not enough historical data, or it is extremely difficult to gather reliable data, or even there is no underlying statistical model to build the model. Therefore, traditional probabilistic approaches are futile in many cases. In these sorts of problems, fuzzy logic has been proven to be a great tool. This paper will present how IFGP could be used to solve RHLP. Like any other MODM approach, IFGP is separated in two distinct stages. First, efficient solutions are found and then, a search is followed to find a compromise solution.

In the standard IFGP, one assumes that the DM can specify preference function with respect to the combination of the individual objective functions in advance, either as weights (utilities) or as distance functions.

Werners [28] presented a "fuzzy-and" operator which could be used in IFGP and is a strongly monotonically increasing function. It is presented as follows:

$$\mu_D(X) = Max\left\{\gamma\ Min_i\{\mu_i(x)\} + (1-\gamma)\left(\frac{1}{K}\right)\sum_i^K \mu_i(x)\right\} \quad (19)$$

where, $\mu_i(x)$ is the corresponding membership functions of *K* fuzzy objectives and constraints. DMs can interact with the

model to obtain preferred compromise solution by using γ as the coefficient of compensation defined within the interval [0, 1]. Later, Selim and Ozkarahan [29] modified the model by adding w_i as the relative weights for the membership functions of the objectives in (20):

$$\mu_D(X) = Max\left\{\gamma\ Min_i\{\mu_i(x)\} + (1-\gamma)\sum_i^K w_i\mu_i(x)\right\} \quad (20)$$

Results of using the Selim and Ozkarahan's [29] operator shows that the modified operator may provide different and even more preferable results compared to the Werners's "fuzzy and" approach. We will examine the usefulness of this operator on RHLP and analyze results.

The IFGP-based solution approach for solving RHLP is described as follows: First, individual best solutions are found using the single objective optimization and the CPLEX solver. Then, the decision maker is asked to determine if she/he is satisfied with the solution. If the results are not satisfactory, then using the payoff table (which contains the optimal values of objectives), membership functions are determined for objectives. Then, changing the values of γ gradually from 1 to 0, different solutions are obtained and presented to the decision maker. This process is followed until finding a preferred solution by the decision maker.

VI. COMPUTATIONAL EXPERIMENTS

In order to generate test problems, it was assumed that the reliability of a link is a function of its length. Therefore, the CAB dataset was modified to address the need to generate reliability values. To do so, the search was restricted to nodes 11 through 20. The set of cities is comprised of eastern, central, and western USA and include the following nodes.

- Kansas City
- Los Angeles
- Memphis
- Miami
- Minneapolis
- New Orleans
- New York
- Philadelphia
- Phoenix
- Pittsburg

Thus, it can be concluded that the dataset is sparse enough.

Then, reliability of each link was found as a function of its length. In other words, reliability value of each arc was considered to be a value between 0.5 and 0.9 based on its length. Then, the hub reliabilities (which are diagonal values in the reliability matrix) were generated uniformly between 0.9 and 1. Moreover, arc and hub discount factors were considered to be 0.95 and 0.9 respectively.

Fig. 3 shows the normalized fitness values of solutions for the test problem. Obviously, there is a tradeoff between the two objectives of the problem. Moreover, fig. 4 shows the behavior of both objectives and the aggregate function versus γ. It has been shown that although objectives change considerably by changes in γ, after a threshold (γ =0.3), the aggregated value remains almost steady.

To show the dissimilarities among the three models, fig. 5 depicts the solutions found using various values of γ. It clearly shows how the outputs differ in the locations of hubs and assignment of spokes to hubs.

Fig. 5 soundly confirms that there is an apparent discrepancy between solutions which can be attributed to changes in the value of γ. A rigorous analysis of results shows that New York is the only city which is present in all the solutions. Moreover, other cities which have been included in these solutions are Miami, Memphis, Phoenix, and Los Angeles. Since we assumed the reliabilities of arcs as a function of their length, it could be verified that the hubs are sparse in order to be able to cover the flows throughout the network.

VII. CONCLUSION AND FUTURE RESEARCH

At this point, to bring the study to a close, a conclusion is given. This paper presented a new method to compute the reliability of paths in a hub-and-spoke network. Moreover, it showed how IFGP could be used to solve RHLP. Results showed that IFGP could be a worthwhile tool to find solutions of RHLP in an interactive way with the decision maker. Another advantage of using IFGP is the fact that solutions could be found even if there is not a unanimous agreement between decision makers.

RHLP is still immature and needs more attention among academicians. An appealing future research could be considering the same problem in a stochastic environment. One may go through the performance of IFGP on other HLP variants such as incomplete hub networks or even hierarchical hub location problem. In addition, other variants of IFGP could be developed and their performance is to be assessed. Another interesting avenue for future research is building a model in which both cost and reliability are considered. Such an assumption makes the problem more realistic and in worth consideration in future Last, but not least, is the possibility of considering multiple-allocation in the HLP.

I. INTRODUCTION

This is new kinds of Web apps on network connection manager of force that will be more ubiquitous and smarter than current applications and will be accessible anytime, anywhere. This will require us to development a multi-network how to switch and decision. Faced with the new wave of mobile device applications for service wide range of use, seamless network access is an important issue. Nowadays, mobile service software contains some techniques form artificial intelligence (AI) research. As for a connection manager of intelligence system (or Connection Manager of Intelligence Agent, CMIA) interaction with the owner becomes important. However, the interaction is usually limited to the predefined command or few typewriting. We propose a way for the user to define a new behavior to enhance the interaction. This human-machine interaction multi-attributes for the user to define a new degree of rating scales such [1] as received signal strength indicator (RSSI), energy consumption, traffic, throughput and other attributes of wireless devices must be based on knowledge and action mechanism of this fuzzy analytic hierarchy process (Fuzzy AHP).

This paper describes the experiences that we learned from building such devices. Based on the observation of real connected devices and their relationship with their owners, the goal that we set is to create a CMIA that may grow in its relationship with the owner. The goal of the research is to give the CMIA the following ability:

Autonomous interaction. The CMIA is to interact with the user without pre-written scripts.

Learning ability. The CMIA is to become more mature by learning skills through the training provided by the user.

Dynamic ranking. The CMIA is to adjust the three parts of attribute (RSSI, energy consumption, traffic, throughput) of behaviors dynamically through networking environment and interaction changes.

The concept of multi-attributes is the most important issue in this research. Our idea is based on the APH architecture proposed by Thomas L. Saaty in the 1990s [2] (Figure 1.), where the goal and condition input from the user environment (Figure 2.) and prepares the input attributes degree to finding Importance of rating scales for user experience. The results from the classifier module are then passed to the multi-attributes for each of classes to produce a set of use cases array comparison. After decided is switch the network connection of a use case.

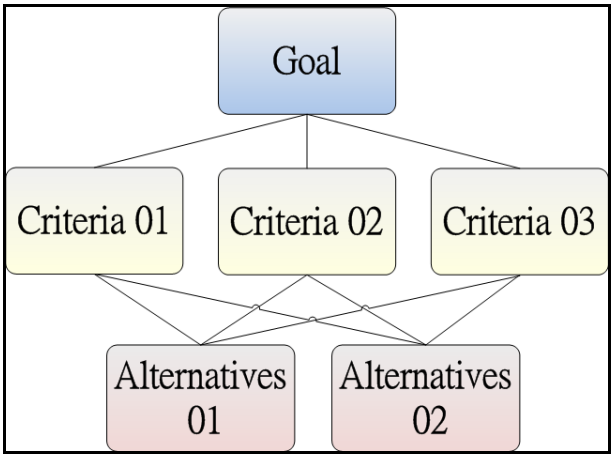

Figure 1. A sample architecture for AHP

The prototype system is described and the conclusion is given. The approach involves introduction of fuzzy theory into the Analytic Hierarchy Process developed by Saaty (1980) in

order to assess the weights of various assessed items and to sort their importance.

The rest of the paper is organized as follows. The next section explains the system concept. That is followed by the detail discussion on ranking and Fuzzy AHP.

II. SYSTEM CONCPET AND BACKGRAND

A. System Concpet

Based on the observation of Fuzzy AHP and its relationship with owner attributes, the goal was to create a use-case that enables the connection manager to find attributes automatically in its relationship with the attribute pattern-based model. The CMIA consists has five sublevel of depicted in Figure 2. : the target of sublevel, the network link type of sublevel, devices of sublevel and attribute of sublevel.

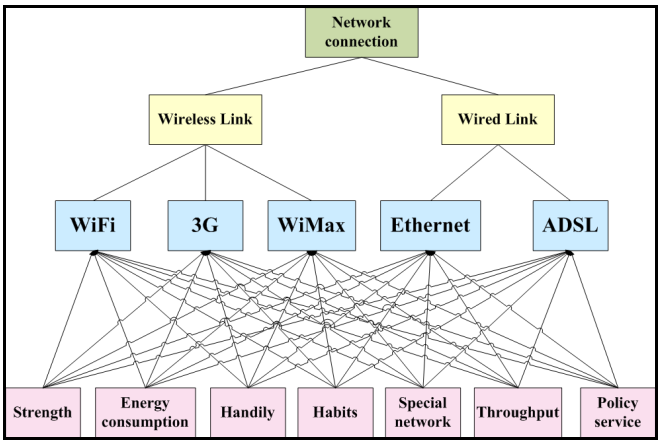

Figure 2. The five levels architecture for CMIA

However, the CMIA has combined modeling subsystem is based on the previous result for Fuzzy AHP and weighted-product model (WPM) processing which accepts the each all level weighted for WPM uses multiplication to rank alternatives with gesture of the user as the input for each kinds of levels weights in series.

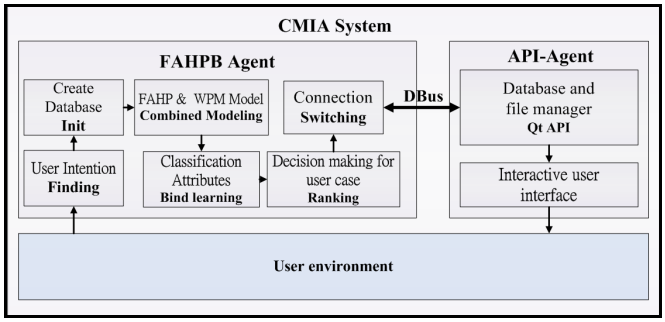

Figure 3. The System parts for CMIA

However, the implemented system contains five main modules of the elements, the input will be sent to the modeling subsystem which is the main topic reported in this paper. Within such system, learning and modeling are used for building the behavior definitions. The ranking subsystem is to carry out the behavior sequence produced by the connection switching subsystem. Such high-level behaviors are collection of basic actions that the CMIA can perform.

The attributes are processed in the combined modeling subsystem where those attributes are transformed to the user case for the CMIA to follow. The CMIA has the basic attributes (alternatives) and network devices (criteria or network classes) already defined. Thus, the main work of the combined modeling subsystem is to use such basic attributes and to construct more complicated behaviors to meet the network devices associated with the attributes. For such process, we use classification learning techniques to process the decomposition of goals to sublevels and to find the relationships associated of sublevels to the basic attributes for user case class.

The ranking subsystem is responsible for ranking the attributes (alternatives) of network class sublevel and connection link sublevel which are the collection of each levels weight in series to provide network connection recommended. The switching system (Qt API User Interface, QAUI) which shows the network device connected information of the CMIA in ConnManager list table. The interface between the switching subsystem and the QAUI is defined with ConnManager components to represent the basic connected device. This is sometimes proposed system provides the list of devices with the connMan for MeeGo network devices are currently repeat, we must establish a more updated list and delete list data. We used a state diagram approach to define the rational action relationship, which is reported in Section IV.

B. System Problems

This section describes the designing problem that system automated the processes of the dynamic parameters is difficult for convergence in CMIA. Thus, use classifier to filter a larger-scale problem given solving which can be dynamic space reduction. The storage unit is stores a network connection class, operating item, and network connection option. The processing unit performs of learning approach was self-control a dynamic parameters for classifier which in controller system can be establish an automatic network link mode. CMIA can through the user to operating some of function given a connected in network device of list table, generates a network classification link model according to the network connection class, the operating item in the network connection option which in system adopt this approach of obtained after weight calculation are ranking each all network device within user-case after classification of case of attributes in serial weights value. System have following encountered some problems:

- The characteristics of network devices are different attributes to quantify the process can not use the same method. For example, units of radiation measurement is a logarithmic expression, the user habits can simply attribute used to score.
- The environment must be immediately real-time updated parameters, the system is the application of a technology in mobile devices, the device is necessary to address the demand uncertainty and environmental

factors of space, these attributes will affect the degree of decision-making processes.

- Classification, however, parameters to be set for different connection modes will be connected by different device. Unless the user has considerable knowledge and specialty in the network and can set the connection modes by himself/herself to configuration. This network configuration is complex and difficult to install for general user. Also, they are unfamiliar connected with the network how to grasp setting manners of various network for connection modes. Which in usually because a user does not know how to set the network connection mode, an error occurs in the setting of the network connection mode so that network resources cannot be used, or a long time is required to research the setting manner, which causes trouble to the user.

III. FAHP AND CLASSIFIER

Michele Grimaldi (2011)[10] have presents a framework based on the analytic hierarchy process (AHP) methodology to select the most appropriate set of Knowledge Management (KM) tools to support the innovation and complex processes in organizations. In this study, multi-network connection mechanism is a complex of problem, which in structure will be use hierarchical architecture to solve complex problems associated with the level. The problem affected is the user of intend for interactive elements of weight-based number, we use the AHP framework to solve complex problems relationship of class and user case, there are simplify classification processes but also has affected relations between hierarchy structure.

A. FAHP and PSM Methods

We use the Fuzzy technique is used for different attributes to quantify the process include the RSSI, .When the decision maker considers the problem of ranking the m alternatives A_1,A_2,...,Am with respect to the N criteria C_1,C_2,...,C_N , it will feel great difficulty in assigning numbers, or ratios of numbers to alternatives[1] . The merit of using a fuzzy approach is to assign the relative importance of attributes using fuzzy numbers instead of crisp numbers. For numbers we use triangular fuzzy number (TFN), because they are step order for measurement data unit have dBm, mA, package rate, etc.

$$M = \{A_1, A_2, ..., A_M\} \tag{1}$$

The fuzzy weighted-product model (PWM) [3] is best alternative according to this mode is one which satisfies (2), and for the fuzzy version of this model the corresponding formula [1] is (3) :

$$R\left(\frac{A_K}{A_L}\right) = \prod_{j=1}^{N}\left(\frac{a_{Kj}}{a_{Lj}}\right)^{w_j} \tag{2}$$

where $\hat{a}_{Kj}, \hat{a}_{Lj}$, and $\hat{w}_j$ are TNF numbers. Alternative attribute A_K dominates alternative A_L if and only if the numerator (3) is greater than the denominator. We have instance in the following example:

$$R\left(\frac{A_K}{A_L}\right) = \prod_{j=1}^{N}\left(\frac{\hat{a}_{Kj}}{\hat{a}_{Lj}}\right)^{w_j} \tag{3}$$

The weighted-sum model (WSM) is a the weight of the public will use the sum of methods for decision-making [3]. A previous research discusses the notion of additive utilities in the expected-utility context when the set of consequences M can be written as the product of n other sets: $M = M1 \times M2 \times ... \times Mn$. where M is a subset of the product of n other sets: $M \subset M1 \times M2 \times ... \times Mn$. Under a finiteness restriction, an additivity axiom leads to an additive utility representation for the elements in M. The potential usefulness of the theory in connection with incomplete product sets is demonstrated with priority orderings and assignments [4]. There are M is alternatives and N criteria in a decision making problem. Then the best alternative, A^*, is the one which satisfies the following expression[3][4] :

$$P^*_{WSM} = \max_{M \geq i \geq 1} \sum_{i=1}^{N} a_{ij} W_j \tag{4}$$

There are weights in the maximization case, in each category of network devices, we find the best alternative according to (4). Currently, the performance values of the ith alternative for network devices attributes in terms of jth network device class that is a triangular fuzzy number denoted as $\hat{a}_{ij} = (a_{ijl}, a_{ijm}, a_{iju})$. Similarly, it is assumed that decision makers will use the triangular fuzzy number to express the importance of weight standards. These weights are denoted as $\hat{w}_{ij} = (w_{jl}, w_{jm}, w_{ju})$. The PSM model values of the fuzzy triangular numbers which represent the criterion weights for network device of class. It follows that best alternative is the one which satisfies the following relation [1]:

$$P^*_{WSM} = \max \sum_{j=1}^{N} \hat{a}_{ij} \hat{w}_j \text{ for } \quad i = 1,2,3,...,M . \tag{5}$$

m_l is that the lower value, m_m is that the median, m_u is located at a higher value. , show in Figure 4.

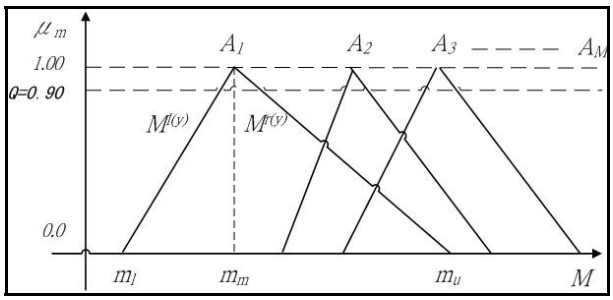

Figure 4. The fuzzy alternatives AM

So we can define each attribute fuzzy number step order for attributes scale degree mapping list, the RSSI and Energy attributes of scale degree samples such as TABLE I. In our system can be real-time update attributes values for RSSI, energy consumption, traffic, throughput. Through the reference TABLE I, we are also use a fuzzy number M on $R \in (-\infty, +be)$ is defined to be a fuzzy triangular number if its membership function $\mu_m : R \rightarrow [0, 1]$ is equal to :

$$\mu_m(x)=\begin{cases}\dfrac{1}{m-l}x-\dfrac{l}{m-l}, & x\in[l,m],\\ \dfrac{1}{m-u}x-\dfrac{l}{m-u}, & x\in[m,u],\\ 0 & otherwise,\end{cases} \tag{6}$$

A fuzzy triangular number, as denoted by (*l*,*m*,*u*).

TABLE I. ATTRIBUTES SCALE DRGREE FOR TFM TABLE LIST

Scale degree	A triangular fuzzy numbers
Weak strength	$\tilde{1}$ = (1,1,1) ≅ (1,10,20)
Degree of between	$\tilde{2}$ = (1,2,3) ≅ (21,25,30)
Low strength	$\tilde{3}$ = (2,3,4) ≅ (31,35,40)
Degree of between	$\tilde{4}$ = (3,4,5) ≅ (41,45,50)
Strength	$\tilde{5}$ = (4,5,6) ≅ (51,55,60)
Degree of between	$\tilde{6}$ = (5,6,7) ≅ (61,65,70)
Very strength	$\tilde{7}$ = (6,7,8) ≅ (71,75,80)
Degree of between	$\tilde{8}$ = (7,8,9) ≅ (81,85,90)
Higher strength	$\tilde{9}$ = (8,9,10) ≅ (91,95,100)

Finally, in this section will presents of the extent analysis method on fuzzy AHP are given and then the method classification applied to supplier selection problem. The CMIA is an AHP-Based system that goal is define and non-define for user free. The relationship between the various properties and weight (importance), we usually are based on pairwise comparison matrix properties used to calculate the average number of attributes of all weights.

Building pair-wise comparison matrix : the system have suppose classification function when the decision maker is asked to compare the nine attributes for network devices to classification these attributes to correct class.

- First: We are input a rating scale value of variables from each of attribute then use the fuzzy membership function to determine the matching variables of pair-wise comparison matrix about the ownership level degree, the process such as Figure 5.
- In this research, in synthesizing experts' opinions, the geometric mean method(GMM) proposed by Buckley (1985) [8] the average of the proposed method to integrate the views of respondents, integration formula, using the arithmetic mean method (AMM), you can calculate the ratio between the weight of property.

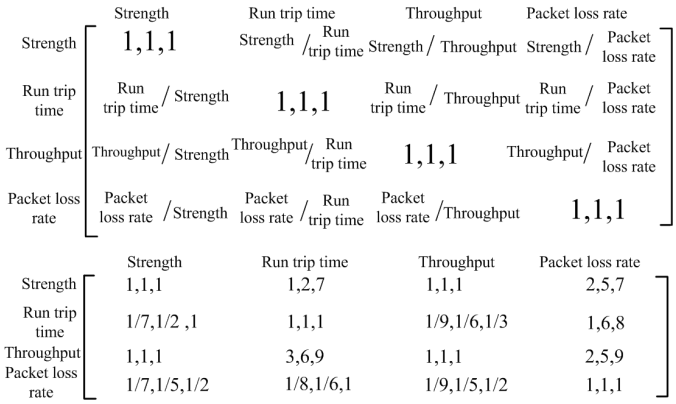

Figure 5. Using pairwis comparisons method

The fuzzy eigenvector of the above matrix is estimated. Recall that given a crisp reciprocal matrix then according with Saaty's matrix of right upper half of principal eigenvector of the matrix is expresses the importance of the attributes. We calculate the properties of the vertical for column is the average, show in Figure 6.

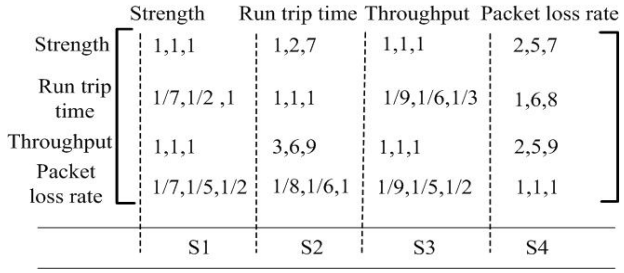

Figure 6. Vertical column for reciprocal judgment matrix of property

- And the properties of pair-wise comparison of the level of the multiplication of the sum of the field.

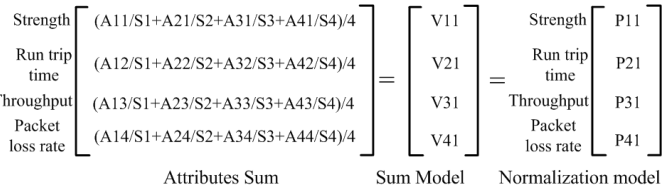

Figure 7. A pairwise comparison of the multiplication of the sum

- Above the results of the steps, only know the extent attributable to the pairing property can not be used for decision-making, with the judge to obtain measures of value, must use the fuzzy approach, a common center of gravity method (CGM), the largest collection with minimal set and so on, so before using this ambiguity to determine the value of the decision-making.
- Defuzzication :

According to the method of Teng&Tzeng(1993)[7], the DF_{ij} solution for fuzzy weight calculation process is:

$$DF_{ij}=\left[\left(R_{ij}-L_{ij}\right)+\left(M_{ij}-L_{ij}\right)\right]/3+L_{ij} \tag{7}$$

These are finished properties matching matrix, followed by the cascade (series level weight, SLW) calculation of the weight level, the process is to Class un-normalization weights and attribute sum model for the sum of the product , the fuzzy eigenvectors of the pair-wise comparisons when the four attributes are compares in the terms of each of the remaining criteria are also derived in a similar manner, along with the weights of importance of five classes, and form the vectors in the following fuzzy matrix , such as follows Figure 8. .

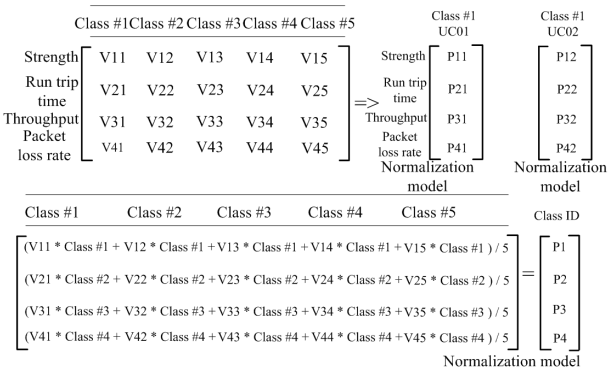

Figure 8. A pairwise comparison of the multiplication of the sum

Our approach, is based on (4) after the weights to different categories User-Case, this method is used to solve (The same device conflict., When simultaneously the occurrence of a category have more than one access point (AP), must be decision-making.

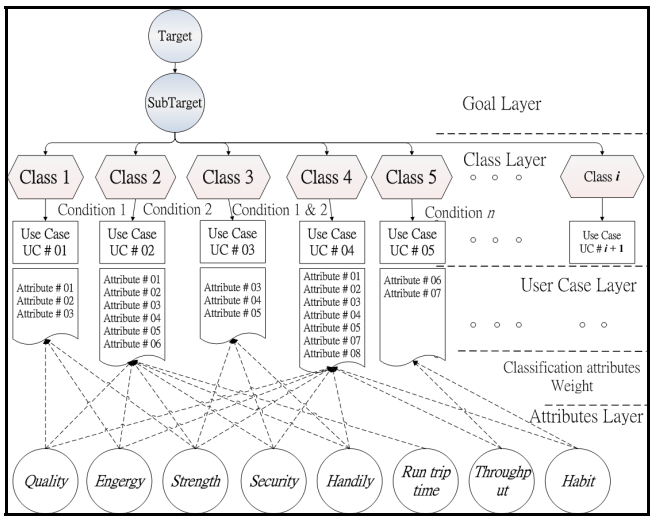

Figure 9. Fig A pairwise comparison

However, example have a decision problem with five criteria of classes (in user case, UC and include the WiFi, 3G, WiMax, Ethernet, ADSL and other classes) and four attributes in terms of first criterion by using pairwise comparisons.

We use the FAHP to building hierarchical structure for CMIA, shown in Figure 2. We are research by the FAHP [6], and modified an algorithm from fuzzy pairwise to describe our approach. The main purpose is to determine the user behavior intention as training data (TD) while satisfying constraints. The parameters, $\tilde{M}$ is a fuzzy triangular number (FTN), $1/\tilde{M}$ is a establish value of fuzzy matrix is inverted M. The FAHPTD is a training data form survey of questionnaire for 120 copies. The ConnMan is connection manager list table that record about each all devices of network device information data. Given user procession input data set:

$FAHPTD=\{(A_1,\textbf{Class}(C_1),(A_2,\textbf{Class}(C_2),\ldots,(A_N,\textbf{Class}(C_N)\}$, where A_i is a user input sample from the GD table, $\boldsymbol{Y(A_i)} \in y=\{C_1,C_2,...Class_L\}$ denotes the classes ($\boldsymbol{A_i}$) belongs to $\boldsymbol{L}$ is the number of the different classes (as like fowler formula : $Class(C_j) \in y=\{WiFi,3G,WiMax,Ethernet,ADSL,...Class_L\}$).

$\boldsymbol{N}$ is the number of training samples from to FAHPTD table for 100 questionnaires single. $\boldsymbol{i=1,2,\ldots,N}$ numbers.

procedure FAHPB (*FAHPTD,A,T*)

$FAHPTD_{Table}[i,j]$ for all $\boldsymbol{i=1,2,\ldots N}$; set for all $\boldsymbol{j=1,2,\ldots N}$;

$ConnMan_{Table}[i,j]$ for all $\boldsymbol{i=1,2,\ldots N}$; set for all $\boldsymbol{j=1,2,\ldots N}$;

//Building Comparison matrix :

$$FAHPTD_{Table}[i,j]=\frac{w_i}{w_j}=\frac{1}{FAHPTD_{Table}}>0,\forall i,j$$

//Building a fuzzy value matrix is inverted

//the value of fuzzy matrix is inverted M.

$M=[\tilde{M}_{ij}]$; $\tilde{M}_{ij}=(L_{ij},M_{ij},R_{ij})$; $\tilde{M}_{ij}=1/\tilde{M}_{ji}$,

$\forall i,j=1,2,\ldots,n$

//Groups combined

$$\tilde{m}_{ij}=(1/N)\otimes(\tilde{m}_{ij}^{\ 1}\oplus\tilde{m}_{ij}^{\ 2}\oplus\ldots\oplus\tilde{m}_{ij}^{\ N})$$

//Calculate the fuzzy weight

//Obtained by the following calculus of $\tilde{w}_i$ weight:

$$\tilde{Z}_i=(\tilde{a}_{i1}\otimes\tilde{a}_{i2}\otimes\ldots\otimes\tilde{a}_{in})^{\frac{1}{n}},\forall i=1,2,\ldots,n$$

$$\tilde{w}_i=\tilde{Z}_i\otimes(\tilde{Z}_1\oplus\tilde{Z}_2\oplus\ldots\tilde{Z}_n)^{-1}$$

//Defuzzication

DF_{ij} solution for fuzzy weight calculation process is:

$DF_{ij}=[(R_{ij}-L_{ij})+(M_{ij}-L_{ij})]/3+L_{ij}$ //Normalization

//Normalization weights for DFW_{ij} calculation process

$$DFW_{Ni}=\frac{DF_{ij}}{\sum DF_{ij}}$$

// Calculate the weight of level series, SLW

$$w_k=w_i+w_{ij}+w_{ijk}$$

//Running the Classifier core

if Rules R2 THEN UC02 update core process

if Rules Rn THEN UC0n update core process

//return the final hypothesis with weights for solving the //classifier

Reading $ConnMan_{Table}[i, j]$

//Update RSSI, energy consumption, traffic, throughput

Update user_parameter_weightTable[i,j]

return FAHPB process

end FAHPB

B. Classification of Approach

The Bayesian approach to classification estimates the probability that an instance Attributes (*Ai*) belongs to a class (*Cj*). Given the observed attribute values is the instance. There are L is the class labels $\{Cj\}$, $j = 1,2,\ldots,L$ numbers. When making a conditional than probabilistic classification, the class with the highest estimated posterior probability is selected. For the general problem of the user connection, each once have different conditions, there will have different the posterior probability.

The technology classified is to used for classifying different attribute and is classified in the cases of different users. According to the method of (8),(9) and [9], we can then derive the following relationship :

$$p(Y = y_i \mid X = x_i) = \frac{n_{ij}}{c_i} \tag{8}$$

$$p(Y = y_i, X = x_i) = \frac{n_{ij}}{N} = \frac{n_{ij}}{c_i} \cdot \frac{c_i}{N} = p(Y = y_i \mid X = x_i) p(X = x_i) \tag{9}$$

,which in the generating rule of probability. Conditional Probabilities of the principle with our paper is: Having constructed the GD network nodes, we will define the conditional probabilities which quantify the arcs of the GD network. We request define the second layer have two nodes are wireless link and wired link. We are reference form (8) and (9) can written (11) as follows:

$$P(WirelessLink \mid 3G) = \frac{P(3G \mid WirelessLi\ nk) P(WirelessLi\ nk)}{P(3G)} \tag{11}$$

In our system applied about the wireless link or wired link of posterior probability for connection is as flows:

Suppose there is a mixed network having 60% WiFi connection and 40% 3G link as connection switch. The wireless link 3G or WiFi in equal numbers; the wired link all Ethernet connection. An observer sees a (random) connection from a distance; all the observer can see is that this connection is 3G. What is the probability this connection is a wireless link The correct answer can be computed using Bayes' theorem.

- P(*WirelessLink*), or the probability that the wireless link is a 3G of any other information. Since the observers sees a random wireless link, meaning that all connection links have the same probability of being observed, and the percentage of connection among the wireless links is 40%, this probability equals 0.4.
- P(*WirlessLink*'), or the probability that the Wireless link connection is a WiFi regardless of any other information (*A*' is the complementary event to *A*). This is 60%, or 0.6.
- P(*3G*|*WirelessLink*), or the probability of the connection for habits given that the connection is a wireless link. As they are as likely to habits as energy consumption, this is 0.5.
- P(*3G*|W*irelessLink*'), or the probability of the wireless link to habits given that the connection is a link. This is given as 1.
- P(*3G*), or the probability of a (randomly selected) connection to 3G regardless of any other information. Since P(*3G*)=P(*3G*|*WirelessLink*)×P(*WirelessLink*)+ P(*3G*|*WirelessLink*')×P(*WirelessLink*'),this is 0.5×0.4 + 1×0.6 = 0.2+0.6=0.8.

Given all this information, the probability of the observer having spotted a 3G connection given that the observed network connection is habits can be computed by substituting these values in the formula about the entropy is by (11) posterior probability model given the features observed as show in Fig. 10.

$$P(WirelessLi\ nk \mid 3G) = \frac{P(3G \mid WirelessLi\ nk) P(WirelessLi\ nk)}{P(3G)} = \frac{0.5 \times 0.4}{0.8} = 0.25$$

We observe the values of the variables for a set of wireless link and wire link session examples. A given quantization into k of the entropy is by (11) for interval case labels, Bayesian inference for the Gaussian distribution.

The maximum likelihood framework gave point estimates for the parameters Σ. Now we develop a Bayesian treatment by introducing prior distributions over these parameters. Where Class for *i*=0,1,….,*L* and *j*=0,1,…,*L*.

$$p(Class_J \mid Attribute_i) = P(Class_J) \prod_{i=1}^{n} \prod_{j=1}^{L} P(Attribute_i \mid Class_J) \tag{12}$$

p(*Attribute*) given by a Gaussian distribution. Case profile learn method for connection manager. In this implementation, User finding to using wireless link device via the Bayesian Network probability is $P(Wireless\ link \mid \tilde{M})$ can be re-expressed as the entropy is by (12). The PTFAHP is probability for EM (Mathematical Expectation) of class, the best alternative according to this model is one which satisfies (13). For the Fuzzy AHP method of Bayesian classifier model the corresponding formula is Figure 10.

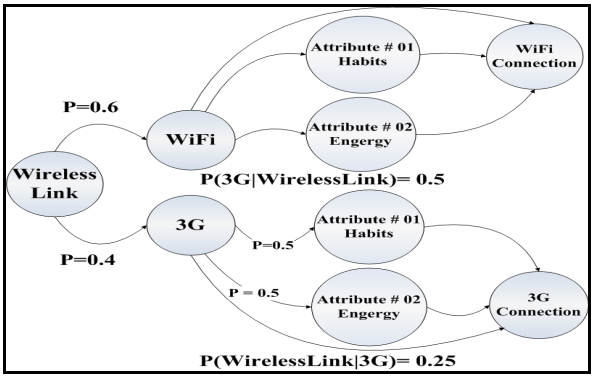

Figure 10. Connection Classifier model

$$PT_{FAHP} = \arg\max_{c \in C} P(Class) \prod_{i=1}^{n} P(\tilde{M}_i | Class) \quad (13)$$

IV. PROTOTYPE SYSTEM

The network devices connectivity of problems is currently facing in the embedded mobile device management, of multi-network connection manager problems. However, how to choose of accordance with past experience of capture user needs for system is currently an important problem, in our system will solve these technical difficulties.

A. System Architecture

We focused on the survey of questionnaire for 120 copies to build questionnaires table (*QT*a), the use of network devices for the intent of the process, after the computation of statistical methods FAHP be Training data, once again, the form through the user interface allows users to operate the network device operation process and then after FAHP understand user intent. Then, after repeated classification of learning to learn and update environment variables, classification of the property to meet the characteristics of the users of the device within the case, update the environment variables constant repeat users with FAHP operation user case *QT*a. The description to the components in is as follows, Figure 11. :

1) For Connection Manager on Intelligent System (CMIA): There are have concept of multi-attributes is the most important issue in this research. Our idea is based on the Fuzzy APH architecture by CMIA system.

a) Policy rule select: User can be selection or added this function to execution device precedence policy.

b) User input: S Selection *QT*a function will through a questionnaire to capture user intended..

c) Building relational table: Building the goal and attributes between relational values.

d) Condition rule of Pre-process: According to the user any choice the policy rules select of component, and *QT*a table input. These will be the result of user selection, back to the condition rule changes the each all weight for attributes and classes.

8	Special	0.042312	Special	0.058074	Special	0.042329
9	Policy Service	0.009773	Policy Service	0.013414	Policy Service	0.009769
	Total weighting	0.296512	Total weighting	0.406973	Total weighting	0.296515

WiFi link: 0.043515+0.042312+0.056396 = 0.142223
3G link: 0.059726+0.058074+0.077406 = 0.195206
Wired link: 0.043515+0.042312+0.056398= 0.142225
Ranking : 3G > Wired link > WiFi

Using by FAHPB approach (Red line) is the rate which the WSM(blue line) , WPM(Green line) and FAHPB fuzzy method disagree in the indication of the best attribute. In Figure 12. the fuzzy AHP by WSM, fuzzy WPM and FAHPD respectively.

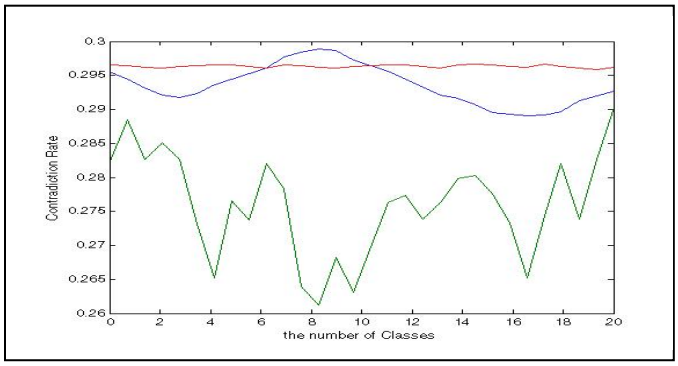

Figure 12. Contradiction rate when the number of attributes is classification

V. CONCLUSIONS

This research focuses on the connection manager of network equipment using fuzzy analytic hierarchy process in decision-making and classification classes for CMIA. The main contribution of this paper is to propose a flexible policy implementation model, including the training of classification and ranking of the optimal scheduling mechanism.

ACKNOWLEDGMENT

The authors thank the colleagues at the Institute for Information Industry (III) for providing the intelligence connection manager for Meego platform. The analysis is based on a pair-wise comparison among the user and then putted to matrix to resolve the ranking via Bayesian classifier model to selected user case.

Abstract— **The impreciseness happens in the quality control same as other statistical problems. In quality control where specification limits are better expressed by fuzzy sets, the generalized process capability indices $C_{\tilde{p}}$, $C_{\widetilde{pk}}$ and $C_{\widetilde{pm}}$ can be helpful and necessary for measuring the capability. We propose a generalized form of Taguchi index $C_{\widetilde{pm}}$ to assess the ability of the fuzzy process to be clustered around the target value. An approximate $100(1-\gamma)\%$ confidence interval for the generalized process capability index $C_{\widetilde{pm}}$ by using fuzzy specification limits is also presented.**

Keywords- Fuzzy quality; Taguchi process capability index; Confidence interval cmponent

I. BACKGROUND

Traditional process capability indices (PCIs) can be classified into two major kinds. The first one, such as index C_p, deals solely with the process variation in relation to a specified tolerance region. The second one, such as indices C_{pk} and C_{pm}, considers not only the process variation relative to the tolerance region but also the deviation of process mean from target value. In [3] it is pointed out that the exact sampling properties of the estimates of C_{pk} were more complex than those for C_{pm}. The process capability index C_{pm}, named Taguchi capability index, is defined as $C_{pm}=\frac{USL-LSL}{6\sqrt{E(X-T)^2}}=\frac{USL-LSL}{6\sigma_T}=\frac{USL-LSL}{6\sqrt{\sigma^2+(\mu-T)^2}}$ [1, 3, 20]. Here, T, LSL and USL are the target value, lower and upper specification limits (SLs), respectively.

In quality control, we may confront imprecise concepts. Ordinary capability indices cannot measure the capability if for example upper and lower SLs are imprecise. The impreciseness exists in SLs can be express by fuzzy terms. Recently, several PCIs developed deal with impreciseness [9, 19, 24, 25, 26, 27, 28, 32, 34, 38, 42] and they are applied in real cases [12, 13, 14, 15, 21]. We further investigate the point and interval estimators of the generalized capability index C_{pm} which has been introduced in [16, 17, 18].

In this paper, the problems of point and interval estimations of the generalized process capability index $C_{\widetilde{pm}}$ are considered which are based on the observed random sample for an in-control fuzzy process. Statistical inference based on fuzzy arithmetic is used to introduce a $100(1-\gamma)\%$ confidence interval for generalized capability index $C_{\widetilde{pm}}$, where we have two membership functions for SLs.

The organization of this paper is as follows. In Section II, some preliminaries on fuzzy arithmetic are presented and then generalized PCIs are introduced. Tow point estimators and an interval estimator is introduced in Section III for $C_{\widetilde{pm}}$. The final section is the conclusions part.

II. ARITHMETIC OPERATIONS ON FUZZY SPECIFICATION LIMITS

Let R be the set of all real numbers and $F(R)=\{\tilde{A}\mid \tilde{A}:R\to[0,1],\ \tilde{A}$ is a continuous function$\}$ be the set of all fuzzy sets on R. The α-cut of $\tilde{A}\in F(R)$ is the crisp set defined by $\tilde{A}_\alpha=\{x\mid \tilde{A}(x)\geq\alpha\}$, for any $\alpha\in[0,1]$. Although fuzzy SLs are introduced in [24], but we introduce new flexible formulas for the fuzzy SLs in Definition 2.1, inspired LR fuzzy numbers [7, 23]. The motivation of introducing fuzzy SLs in fuzzy processes is already introduced in [24].

Definition 2.1 Let $\widetilde{USL}$ and $\widetilde{LSL}$ be two fuzzy sets with membership functions

$$\widetilde{USL}(x)=\begin{cases}1 & \text{if} \quad x<q\\ U(\frac{x-q}{b}) & \text{if} \quad x\geq q\end{cases}$$

and

$$\widetilde{LSL}(x)=\begin{cases}L(\frac{p-x}{a}) & \text{if} \quad x\leq p\\ 1 & \text{if} \quad x>p\end{cases}$$

in which reference functions $L, U : [0,+\infty] \longrightarrow [0,1]$ are non-increasing functions, $U(0) = L(0) = 1$, and the upper and lower spreads a, $b > 0$. Then, $\widetilde{USL}$ and $\widetilde{LSL}$ are called upper fuzzy specification limit and lower fuzzy specification limit, and symbolically are denoted by $(q,b)_U$ and $(p,a)_L$, respectively. Also, $F_U(R)$ and $F_L(R)$ denote two sets of all upper and lower fuzzy SLs, respectively.

In Definition 2.1, the reference function L (or similarly U) can be described by any of the following functions:

(1) $L(x) = 1$ for $x \in [0,1]$ and 0 outside,

(2) $L(x) = \max\{0, 1 - |x|^r\}$,

(3) $L(x) = e^{-|x|^r}$,

(4) $L(x) = \dfrac{1}{1+|x|^r}$,

(5) $L(x) = \dfrac{1}{1+r|x|}$,

in which $r > 0$.

Remark 2.1 The fuzziness increases in $(p,a)_L$ and $(q,b)_U$, with the increase in the spreads a and b.

Definition 2.2 A process with fuzzy SLs $(q,b)_U$ and $(p,a)_L$, which we call a fuzzy process for short, is one which satisfies the normal distribution condition, that is $X_1, \ldots, X_n$ are independent, identically distributed random variables with $N(\mu, \sigma^2)$.

Definition 2.3 Let $\widetilde{USL} \in F_U(R)$ and $\widetilde{LSL} \in F_L(R)$ are the upper and the lower fuzzy SLs, such that $p \le q$. Then

$$\widetilde{USL} \oplus \widetilde{LSL} = \int_0^1 g(\alpha)(u_\alpha + l_\alpha) d\alpha$$

and

$$\widetilde{USL} \ominus \widetilde{LSL} = \int_0^1 g(\alpha)(u_\alpha - l_\alpha) d\alpha,$$

are called addition and subtraction of $\widetilde{USL}$ and $\widetilde{LSL}$, respectively, in which

$$\widetilde{USL}_\alpha = (-\infty, u_\alpha], \ \widetilde{LSL}_\alpha = [l_\alpha + \infty), \quad (1)$$

u_0, l_0 are finite real numbers and g is a real valued non-decreasing function on [0,1] with $g(0) = 0$ and $\int_0^1 g(\alpha)\, d\alpha = 1$ (for instance $g(\alpha) = (m+1)\alpha^m$ where $m = 1, 2, 3, \ldots$).

Note that in Definition 2.3, $u_\alpha + l_\alpha$ is the addition and $u_\alpha - l_\alpha$ is the subtraction of the left and the right end points of the α-cut of $\widetilde{USL}$ and $\widetilde{LSL}$. The value of $g(\alpha)$ can be understood as the weight of $u_\alpha \pm l_\alpha$, and the non-decreasing property of g means that the higher the membership of α-cut, the more important it is in determining the addition and subtraction of $\widetilde{USL}$ and $\widetilde{LSL}$. These defined operations synthetically reflect the information on every membership degree. The application of the arithmetic operations given in Definition 2.3 on fuzzy SLs allows different α-cuts to play different roles.

For observing some properties of the arithmetic operations on fuzzy SLs and numerical examples on fuzzy SLs, see [24]. Now, by extending the addition and subtract operations on fuzzy SLs, one can use $\ominus$ and $\oplus$ operations to generalize the classical PCIs, when the SLs are fuzzy rather than crisp [24].

Definition 2.4 Let in a fuzzy process $\widetilde{USL} \in F_U(R)$ and $\widetilde{LSL} \in F_L(R)$ be the engineering upper and lower fuzzy SLs, respectively, where $p \le q$. Then the extended process capability indices are defined as follows:

$$C_{\tilde{p}} = \frac{\widetilde{USL} \ominus \widetilde{LSL}}{6\sigma}, \quad (2)$$

$$C_{\widetilde{pk}} = \frac{\widetilde{USL} \ominus \widetilde{LSL} - 2\left|\mu - \dfrac{\widetilde{USL} \oplus \widetilde{LSL}}{2}\right|}{6\sigma} \quad (3)$$

and

$$C_{\widetilde{pm}} = \frac{\widetilde{USL} \ominus \widetilde{LSL}}{6\sqrt{E(X-T)^2}} = \frac{\widetilde{USL} \ominus \widetilde{LSL}}{6\sqrt{\sigma^2 + (\mu - T)^2}}, \quad (4)$$

where T is the target value. Note that $C_{\tilde{p}}$ is useful when $\mu = m$ in which $m = \dfrac{\widetilde{USL} \oplus \widetilde{LSL}}{2}$.

In the next section, we will discuss on the point and interval estimations of $C_{\widetilde{pm}}$.

III. Estimation of the Generalized Taguchi Index

A. Point estimation of $C_{\widetilde{pm}}$

The rationale behind the point estimation is quite simple. When sampling is from a population described by a Probability Density Function (PDF) or Probabiliy Mass Function (PMF) f_θ, knowledge of unknown parameter θ yields knowledge of the entire population. Hence it is natural to seek a good estimator of the unknown point θ, that is a good estimator as a function of sample. In this subsection, we

are going to obtain two point estimators for unknown parameter $C_{\widetilde{pm}}$.

The sample mean of random sample $X_1,...,X_n$ from a process is $\overline{X} = \sum_{i=1}^{n} X_i \big/ n$ and the sample variances are $S_{n-1}^2 = \frac{1}{n-1}\sum_{i=1}^{n}(X_i - \overline{X})^2$ and $S_n^2 = \frac{n-1}{n} S_{n-1}^2$. The estimators for $\sigma_T{}^2 = E(X-T)^2$ are $S_{T(n-1)}^2 = \frac{1}{n-1}\sum_{i=1}^{n}(X_i - T)^2$ and $S_{T(n)}^2 = \frac{n-1}{n} S_{T(n-1)}^2$.

Substituting the estimators of $\sigma_T{}^2$ in the formula of the Taguchi capability index will provides two point estimators for C_{pm} index. Therefore, the original estimate of C_{pm} is defined as $\hat{C}_{pm(n-1)} = \frac{USL - LSL}{6S_{T(n-1)}}$ in [3]. Another estimator is defined in [1] as

$$\hat{C}_{pm(n)} = \frac{USL - LSL}{6S_{T(n)}} = \sqrt{\frac{n}{n-1}}\hat{C}_{pm(n-1)}. \quad (5)$$

Considering the above discussion for the point estimations of C_{pm} and using Definition 2.4, one can easily define two fuzzy estimators for $C_{\widetilde{pm}}$. The below estimators (6) and (7) are computed by substituting two estimators $S_{T(n-1)}^2$ and $S_{T(n)}^2$ of $\sigma_T{}^2$ in the formula of $C_{\widetilde{pm}}$.

$$\hat{C}_{\widetilde{pm}(n-1)} = \frac{\widetilde{USL} \ominus \widetilde{LSL}}{6S_{T(n-1)}}, \quad (6)$$

$$\hat{C}_{\widetilde{pm}(n)} = \frac{\widetilde{USL} \ominus \widetilde{LSL}}{6S_{T(n)}} = \sqrt{\frac{n}{n-1}}\hat{C}_{\widetilde{pm}(n-1)}. \quad (7)$$

Like to traditional PCIs, for each of these generalized indices, a large value of estimate implies a better distribution of the quality characteristic. In sequel subsection, we only discuss the inference of the generalized index $C_{\widetilde{pm}(n)}$, since the case of $C_{\widetilde{pm}(n-1)}$ can be treated similarly.

B. Confidence interval for $C_{\widetilde{pm}}$

In this subsection, we obtain a confidence interval for the unknown parameter $C_{\widetilde{pm}}$, based the sampling distributions of the corresponding estimators.

Substituting $S_{T(n)}^2$ and $S_{T(n-1)}^2$ in $C_{\widetilde{pm}}$ will provide two fuzzy estimates for $C_{\widetilde{pm}}$, which we denote them by $\hat{C}_{\widetilde{pm}(n)}$ and $\hat{C}_{\widetilde{pm}(n-1)}$, respectively. Like other statistics $\hat{C}_{\widetilde{pm}(n)}$ is also subject to sampling variation and it is critical to compute a confidence interval. The confidence level provides a range which includes the true $C_{\widetilde{pm}}$ with high probability. The confidence interval for $C_{\widetilde{pm}}$ is based on the distribution of $S_{T(n)}^2$, where $S_{T(n)}^2$ is a uniformly minimum variance unbiased estimator of $E(X-T)^2$ [35], and $\hat{C}_{\widetilde{pm}(n)}$ is defined as a simple function of $S_{T(n)}^2$ in (7). Hence, to obtain any $100(1-\gamma)\%$ confidence interval for $C_{\widetilde{pm}}$ index, we need a statistical distribution of $S_{T(n)}^2$. This statistical distribution is presented in Chapter 29 of [10].

The approximate confidence interval for $C_{\widetilde{pm}}$ is given in Theorem 3.1.

Theorem 3.1 If $X_1,...,X_n$ is a random sample set from normal distribution with mean μ and variance σ^2, then the approximate equal-tailed $100(1-\gamma)\%$ confidence interval for $C_{\widetilde{pm}}$ is

$$\left[\hat{C}_{\widetilde{pm}(n)}\sqrt{\chi^2_{\frac{\alpha}{2},\hat{\nu}_n}\big/\hat{\nu}_n}\ ,\ \hat{C}_{\widetilde{pm}(n)}\sqrt{\chi^2_{1-\frac{\alpha}{2},\hat{\nu}_n}\big/\hat{\nu}_n}\right],$$

where $\hat{\nu}_n = n(1+\hat{\delta}_n{}^2)^2\big/(1+2\hat{\delta}_n{}^2)$, $\hat{\delta}_n = (\bar{x}-T)\big/s_n$ and $\chi^2_{\alpha,\hat{\nu}_n}$ is the 100α percentile of a central chi-square variable with $\hat{\nu}_n$ degree of freedom.

IV. Conclusions

This paper further improves the fuzzy process where it is more appropriate to define SLs by two fuzzy sets. In this paper, we presented two point estimators for $C_{\widetilde{pm}}$. But as they are not exactly equal to the true value of parameter, so $100(1-\gamma)\%$ confidence interval for the generalized process capability index $C_{\widetilde{pm}}$ is proposed and an approximate $100(1-\gamma)\%$ confidence interval for $C_{\widetilde{pm}}$ is presented. For future research one can consider the following topics: (1) Generalizing the point and interval estimations of other precise process capability indices, (2) testing hypotheses on the generalized process capability indices, (3) validating of the generalized process capability indices for real-world industrial applications.

***Abstract*—In this paper, a generalized intuitionistic fuzzy soft set (GIFSS) is introduced and its various properties are presented. The generalized intuitionistic soft fuzzy relations on GIFSS have been defined and their properties are discussed. We have also devised a new scoring function to compare two intuitionistic fuzzy numbers. An application of GIFSS, generalized intuitionistic soft fuzzy relations on GIFSS and the novel score function are demonstrated through a practical example of a multi-criteria medical diagnosis problem.**

Keywords-intuitionistic; fuzzy; soft; generalized; score function; multi criteria decision making; Sanchez diagnosis; medical diagnosis; relation

I. INTRODUCTION

The concept of intuitionistic fuzzy set characterized by a novel hesitancy function has been introduced by Atnassov [1, 2]. Molodtsov [3] has introduced the theory of soft sets characterized by parameterization tools for modelling the vagueness and uncertainties. The soft set theory finds wide range of applications in complex medical sciences, engineering, management, economics and social sciences, primarily due to its flexibility without restrictions on approximate description of the situation. Maji et al. [4-6] have extended the theory by proposing the concept of fuzzy soft sets and intuitionistic fuzzy soft sets, and their properties. Kong et al. [7-8] have demonstrated the application of soft set theory in decision making problems. Majumdar et al. [9-10] have explored the methods to find similarity measurement between the fuzzy soft sets, and proposed the notion of generalized fuzzy soft sets.

In this paper, we propose generalized intuitionistic fuzzy soft set (GIFSS). An intuitionistic degree is attached to the intuitionistic fuzzy soft set (IFSS) to indicate the degree of possibility of belongingness of the elements of the universal set in the IFSS. This adds to the second level of uncertainty in IFSS indicating the credibility of the values of IFSS. Relations and properties of GIFSS have been defined. A novel score function to compare intuitionistic fuzzy numbers (IFNs) has also been proposed. Finally Sanchez's method [11] of medical diagnosis is extended to demonstrate a practical medical application of GIFSS and novel score function.

The hesitancy parameter in Atnassov's [1] IFS is a feature of one's own perception, and hence itself ambiguous. It is insufficient to convey a unique meaning imperative for the correct medical diagnosis. For example, a patient might report the symptoms to a doctor as per his perceptions, and the real information might get distorted in its reporting. Unless this misrepresentation is factored in by a doctor, it would lead to wrong diagnosis. The extra generalization parameter that we introduce normalizes an IFSS with an expert's opinion which indicates the credibility of the information presented to him. For example, a doctor reposes more confidence in the symptoms reported by an educated adult patient than that reported by a child.

The paper is organized in seven sections. In section II, a few preliminaries and useful definitions are given. In section III, GIFSS and its properties are introduced. In section IV, a novel score function is introduced, designed specifically for the medical diagnosis applications. In the next section, relations on GIFSS are defined and its properties are discussed. In section VI, an application of GIFSS is shown in the area of medical diagnosis extending Sanchez's approach. And finally in Section VII, conclusions are presented.

II. PRELIMINARIES

Before describing GIFSS, a few definitions regarding intuitionistic fuzzy sets (IFS) and fuzzy soft sets are presented here.

Definition 2.1 [1]: Let $X = \{x_1, x_2, ..., x_n\}$ be a fixed finite non-empty set. Then a IFS $A = \{x_i, t_A(x_i), f_A(x_i) | x_i \in X\}$ where the functions $t_A: X \rightarrow [0,1]$ and $f_A: X \rightarrow [0, 1]$ denote the degree of membership and the degree of non-membership of the element $x \in X$ to A respectively, such that for every $x \in X$: $0 \leq t_A(x) + f_A(x) \leq 1$. Also $h_A(x) = 1 - (t_A(x) + f_A(x))$ is called the degree of hesitation or indeterminacy of x to A. For convenience, we call $\tilde{a} = (t_{\tilde{a}}, f_{\tilde{a}})$ as an intuitionistic fuzzy number (IFN), where $t_{\tilde{a}} \in [0, 1]$, $f_{\tilde{a}} \in [0, 1]$, and $t_{\tilde{a}} + f_{\tilde{a}} \leq 1$.

Definition 2.2 ([3]): Let U denote an initial universal set and E be a set of parameters. Let P (U) be the power set of U. Then pair (F, E) is called a soft set over U iff F is a mapping given by $F : E \rightarrow P(U)$.

Definition 2.3 ([4]): Let U denote an initial universal set and E be a set of parameters. Let I^U denote the power set of all

fuzzy subsets of U. Let A ⊂ E. A pair (F, E) is called a fuzzy soft set over U, where F is a mapping given by F : A → I^U.

Definition 2.4 ([4]) Let U denote an initial universal set and E be a set of parameters. Let IF^U denote the collection of all intuitionistic fuzzy subsets of U. Let A □ E. A pair (F, A) is called intuitionistic fuzzy soft set (IFSS) over U, where F is a mapping given by $\tilde{F} : A \rightarrow IF^U$.

Example 2.1: Let U={c_1, c_2, c_3, c_4} be the set of popular bicycles and E ={cost (e_1), colour (e_2), weight (e_3)} be the set of parameters. Let A ⊆ E denotes the list of select parameters that would determine Tom's buying decision. Let A = {e_1, e_3} ⊂ E.

Then, (C,A) = [C(e_1) = {c_1, c_3, c_4}, C(e_3)={c_2,c_3}] is the crisp soft set over U that describes the bicycles which Tom may buy.

Instead, if we have a fuzzy mapping, F: A → I^U with each criteria having a fuzzy membership for each sample of U, then an example of fuzzy soft set, (F, A), could be [F(e_1) = {c_1|0.8, c_2|0.2, c_3|0.5, c_4|0.4}, F(e_3)={ c_1|0.7, c_2|0.5, c_3|0.3, c_4|0.8}].

(F, A) is the fuzzy soft set over U that describes the cycles which Tom may buy.

If we have a mapping $\tilde{F} : A \rightarrow IF^U$ with each criteria having a intuitionistic fuzzy membership for each sample of U, then an example of IFSS, (I, A), could be [I(e_1) = {c_1|(0.8, 0.1), c_2|(0.2, 0.6), c_3|(0.5, 0.3), c_4|(0.4, 0.5)}, F(e_3)={c_1|(0.7, 0.1), c_2|(0.5, 0.2), c_3|(0.3, 0.6), c_4|(0.8, 0.0)}].

(I, A) is the IFSS over U that describes the cycles which Tom may buy.

Definition 2.5 ([1]): If A and B are two IFSs of the set E of form {x_i, t(x_i), f(x_i)> | x_i∈ X}, then

$$A \subset B \; iff \; \forall x \in E, [t_A(x) \leq t_B(x) \; and \; f_A(x) \geq f_B(x)] \quad (1)$$

$$A \supset B \; iff \; B \subset A \quad (2)$$

$$A = B \; iff \; \forall x \in E, [t_A(x) = t_B(x) \; and \; f_A(x) = f_B(x)] \quad (3)$$

$$\overline{A} = \{x, f_A(x), t_A(x) | x \in E\} \quad (4)$$

$$A \cup B = \{(x, \max(t_A(x), t_B(x)), \min(f_A(x), f_B(x)) | \; x \in E\} \quad (5)$$

$$A \cap B = \{(x, \min(t_A(x), t_B(x)), \max(f_A(x), f_B(x)) | \; x \in E\} \quad (6)$$

Definition 2.6 ([1])**:** An intuitionistic fuzzy relation (IFR) R from two IFSs X to Y is an IFS of $X \times Y$ characterized by the membership function t_R and non-membership function f_R, and denoted as R (X → Y)

Definition 2.7 ([11])**:** Let A be IFS in X. Let R (X → Y) be an IFR from X to Y. Then max-min-max composition of the IFR R (X → Y) with A would result in another IFS B of Y, denoted by B = R o A. The membership function of B is defined as

$$t_{R \circ A}(y) = \bigvee_x [t_A(x) \wedge t_R(x, y)] \quad (7)$$

Similarly, the non-membership function is defined as

$$f_{R \circ A}(y) = \bigwedge_x [f_A(x) \vee f_R(x, y)] \quad (8)$$

∀y ∈ Y (where $\bigvee = max, \bigvee = min$).

III. Generalized Intuitionistic Fuzzy Soft Set (GIFSS)

We hereby present a generalized version of IFSS with an extra parameter, indicating an expert's opinion regarding the authenticity of the IFSS values.

A. Basic Definitions

A few basic definitions of GIFSS are defined, and illustrated through examples.

Definition 3.1: Let U denote the universal set of elements and E = {e_1, e_2, ..., e_m} be the universal set of parameters. The pair (U, E) is called a soft universe. Let A ⊆ E and $\tilde{F}: A \rightarrow IF^U$ and $\tilde{\alpha}$ be an intuitionistic fuzzy subset of E, i.e., $\tilde{\alpha} \rightarrow IF = (t_{\tilde{a}}, f_{\tilde{a}})$, where $t_{\tilde{\alpha}} \in [0,1], f_{\tilde{\alpha}} \in [0,1], \; t_{\tilde{\alpha}} + f_{\tilde{\alpha}} \leq 1$, and IF^U is the collection of all intuitionistic fuzzy subsets of U. Mapping $\tilde{F}_{\tilde{\alpha}}: A \rightarrow IF^U \; X \; IF$ is defined as follows:

$$\tilde{F}_{\tilde{\alpha}}(e) = \left(\tilde{F}(e), \tilde{\alpha}(e)\right), \quad where \; \tilde{F}(e) \in IF^U, and \; \tilde{\alpha}(e) \in IF \quad (9)$$

$\tilde{F}_{\tilde{\alpha}}$ is called generalized intuitionistic fuzzy soft set (GIFSS in short) over the soft universe (U, E), where $\tilde{F}(e)$ refers to the elements of U in the IFSS, and the extra generalization parameter $\tilde{\alpha}(e)$ indicates degree of possibility of belongingness of the elements of U in $\tilde{F}(e_i)$.

Example 3.1: Let U={c_1, c_2, c_3, c_4} be the set of popular cycles and E ={cost (e_1), colour (e_2), weight (e_3)} be the set of parameters. Let A ⊆ E denote the list of select parameters that would determine Tom's buying decision. Let A = {e_1, e_3} ⊂ E.

Let $\tilde{\alpha} : E \rightarrow IF$ be defined as follows:
$\tilde{\alpha}(e_1) = (0.6, 0.3), \tilde{\alpha}(e_3) = (0.3, 0.5)$

So, if we assume the values of a member of IF^U, the function

$\tilde{F}_{\tilde{\alpha}}: A \rightarrow IF^U \; X \; IF$ is defined as follows:-

$\tilde{F}_{\tilde{\alpha}}(e_1)$ = {{c_1|(0.8, 0.1), c_2|(0.2, 0.6), c_3|(0.5, 0.3), c_4|(0.4, 0.5)}, (0.6, 0.3)}

$\tilde{F}_{\tilde{\alpha}}(e_3)$ = {{c_1|(0.7, 0.1), c_2|(0.5, 0.2), c_3|(0.3, 0.6),

$c_4|(0.8, 0.0)\}, (0.3, 0.5)\}$

Here, $\tilde{F}_{\tilde{\alpha}}$ is a GIFSS over (U, E). Here the value $\tilde{\alpha}(e)$ indicates an expert's confidence in the values of IFSS with regards to their correctness.

Definition 3.2: Let $\tilde{F}_{\tilde{\alpha}}$ and $\tilde{G}_{\tilde{\delta}}$ be two GIFSS over soft universe (U, E). Now, $\tilde{F}_{\tilde{\alpha}}$ would be called as generalized intuitionistic fuzzy soft subset of $\tilde{G}_{\tilde{\delta}}$, i.e., $\tilde{F}_{\tilde{\alpha}} \subseteq \tilde{G}_{\tilde{\delta}}$, if

i) $\tilde{\alpha}$ is an intuitionistic fuzzy subset of $\tilde{\delta}$.
ii) $\tilde{F}(e)$ is a intuitionistic fuzzy subset of $\tilde{G}(e)$, $\forall e \in E$.

Example 3.2: Let us consider the GIFSS, $\tilde{F}_{\tilde{\alpha}}$ as in Example 3.1. Let $\tilde{G}_{\tilde{\delta}}$ be another GIFSS over (U, E) defined as follows:

$\tilde{G}_{\tilde{\alpha}}(e_1) = \{\{c_1|\ (0.3, 0.5), c_2|\ (0.2, 0.7), c_3|\ (0.3, 0.5), c_4|\ (0.2, 0.6)\}, (0.5, 0.4)\}$
$\tilde{G}_{\tilde{\alpha}}(e_3) = \{\{c_1|\ (0.6, 0.3), c_2|\ (0.4, 0.4), c_3|\ (0.1, 0.8), c_4|\ (0.5, 0.3)\}, (0.1, 0.8)\}$

In the light of definition 3.2, the GIFSS, $\tilde{G}_{\tilde{\alpha}}$, is a intuitionistic fuzzy subset of $\tilde{F}_{\tilde{\alpha}}$.

Definition 3.3: Let $\tilde{F}_{\tilde{\alpha}}$ be a GIFSS over soft universe (U, E). Then the inverse of $\tilde{F}_{\tilde{\alpha}}$, $\tilde{F}^{i}_{\tilde{\alpha}} = \tilde{G}_{\tilde{\delta}}$ where

i) $\tilde{\delta}(e) = \tilde{\alpha}^{i}(e)$
ii) $\tilde{G}(e) = \tilde{F}^{i}(e)$, $\forall e \in E$.

Example 3.3: Find the inverse of the GIFSS, $\tilde{F}_{\tilde{\alpha}}(e_1)$ as in Example 3.1.

$\tilde{F}^{i}_{\tilde{\alpha}}(e_1) = \{\{c_1|\ (0.1, 0.8), c_2|\ (0.6, 0.2), c_3|\ (0.3, 0.5), c_4|\ (0.5, 0.4)\}, (0.3, 0.6)\}$

Definition 3.4: Let $\tilde{F}_{\tilde{\alpha}}$ be a GIFSS over soft universe (U, E). Then the complement of $\tilde{F}_{\tilde{\alpha}}$ is defined as

$$\tilde{F}^{c}_{\tilde{\alpha}} = \tilde{G}_{\tilde{\delta}}$$

where

i) $\tilde{\delta}(e) = \tilde{\alpha}^{c}(e)$
ii) $\tilde{G}(e) = \tilde{F}^{c}(e)$, $\forall e \in E$.

Definition 3.5: Let $\tilde{F}_{\tilde{\alpha}}$ and $\tilde{G}_{\tilde{\delta}}$ be two GIFSS over soft universe (U, E). Union of $\tilde{F}_{\tilde{\alpha}}$ and $\tilde{G}_{\tilde{\delta}}$, denoted by $\tilde{F}_{\tilde{\alpha}} \tilde{\cup} \tilde{G}_{\tilde{\delta}}$, would yield GIFSS $\tilde{H}_{\tilde{\nu}} : E \rightarrow IF^{U}\ X\ IF$, where

i) $\tilde{H}_{\tilde{\nu}}(e) = \left(\tilde{H}(e), \tilde{\nu}\ (e)\right), where\ \tilde{H}(e) \in IF^{U}, \tilde{\nu}\ (e) \in IF\ \tilde{F}(e)$
ii) $\tilde{H}(e) = \tilde{F}(e) \circ \tilde{G}(e)$
iii) $\tilde{\nu}(e) = \tilde{\alpha}(e) \circ \tilde{\delta}(e)$
iv) $\circ$ is a suitable t-conorm operator
v) $\tilde{\cup}$ is the union operator adapted for GIFSS.

Definition 3.6: Let $\tilde{F}_{\tilde{\alpha}}$ and $\tilde{G}_{\tilde{\delta}}$ be two GIFSS over soft universe (U, E). Then the intersection of $\tilde{F}_{\tilde{\alpha}}$ and $\tilde{G}_{\tilde{\delta}}$, denoted by $\tilde{F}_{\tilde{\alpha}} \tilde{\cap} \tilde{G}_{\tilde{\delta}}$, would yield GIFSS $\tilde{K}_{\tilde{\nu}} : E \rightarrow IF^{U}\ X\ IF$, where

i) $\tilde{K}_{\tilde{\nu}}(e) = \left(\tilde{K}(e), \tilde{\nu}\ (e)\right), \tilde{K}(e) \in IF^{U}, \tilde{\nu}\ (e) \in IF$
ii) $\tilde{K}(e) = \tilde{F}(e) * \tilde{G}(e)$
iii) $\tilde{\nu}(e) = \tilde{\alpha}(e) * \tilde{\delta}(e)$
iv) $*$ is a suitable t-norm operator
v) $\tilde{\cap}$ is the intersection operator adapted for GIFSS.

Example 3.4: Find the union of the two GIFSS, specified in examples 3.1 and 3.2. The t-conorm ($\circ$) operator is the standard union operator, as defined in (5).

Let $\tilde{F}_{\tilde{\alpha}}(e)\ \tilde{\cup}\ \tilde{G}_{\tilde{\delta}}(e) = \tilde{H}_{\tilde{\nu}}(e)$, $\forall e \in E$. Then,

$\tilde{H}_{\tilde{\nu}}(e_1) = \{\{c_1|\ (0.8, 0.1), c_2|\ (0.2, 0.6), c_3|\ (0.5, 0.3), c_4|\ (0.4, 0.5)\}, (0.6, 0.3)\}$
$\tilde{H}_{\tilde{\nu}}(e_3) = \{\{c_1|\ (0.7, 0.1), c_2|\ (0.5, 0.2), c_3|\ (0.3, 0.6), c_4|\ (0.8, 0.0)\}, (0.3, 0.5)\}$

Example 3.5: Find the intersection of the two GIFSS, as taken in examples 3.1 and 3.2. The t-norm ($*$) operator is the standard intersection operator, as defined in (6).

Let $\tilde{F}_{\tilde{\alpha}}(e)\ \tilde{\cap}\ \tilde{G}_{\tilde{\delta}}(e) = \tilde{K}_{\tilde{\nu}}(e)$, $\forall e \in E$. Then,

$\tilde{K}_{\tilde{\nu}}(e_1) = \{\{c_1|\ (0.3, 0.5), c_2|\ (0.2, 0.7), c_3|\ (0.3, 0.5), c_4|\ (0.2, 0.6)\}, (0.5, 0.4)\}$
$\tilde{K}_{\tilde{\nu}}(e_3) = \{\{c_1|\ (0.6, 0.3), c_2|\ (0.4, 0.4), c_3|\ (0.1, 0.8), c_4|\ (0.5, 0.3)\}, (0.1, 0.8)\}$

Definition 3.7: A GIFSS is said to be a generalized intuitionistic null fuzzy soft set, $\tilde{\Phi}_{\tilde{\theta}}: E \rightarrow IF^{U} \times IF$, if

$$\tilde{\Phi}_{\tilde{\theta}}(e) = \left(\tilde{F}(e), \tilde{\theta}\ (e)\right), where\ \tilde{F}(e) = (0.0, 1.0), and\ \tilde{\theta}\ (e) = (0.0, 1.0), \forall\ e\ \in E.$$

Definition 3.8: A GIFSS is said to be a generalized intuitionistic absolute fuzzy soft set, $\tilde{A}_{\tilde{\alpha}}: E \rightarrow IF^{U} \times IF$, if

$$\tilde{A}_{\tilde{\alpha}}(e) = \left(\tilde{F}(e), \tilde{\alpha}\ (e)\right), where\ \tilde{F}(e) = (1.0, 0.0), and\ \tilde{\alpha}\ (e) = (1.0, 0.0), \forall\ e\ \in E.$$

B. Properties of GIFSS

A few properties of GIFSS are stated in the following theorems.

Theorem 3.1: Let $\tilde{F}_{\tilde{\gamma}}$ be a GIFSS over (U, E), then the following holds:

i) $\tilde{F}_{\tilde{\gamma}}$ is a subset of $\tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{F}_{\tilde{\gamma}}$
ii) $\tilde{F}_{\tilde{\gamma}} \tilde{\cap} \tilde{F}_{\tilde{\gamma}}$ is a subset of $\tilde{F}_{\tilde{\gamma}}$
iii) $\tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{\Phi}_{\tilde{\theta}} = \tilde{F}_{\tilde{\gamma}}$
iv) $\tilde{F}_{\tilde{\gamma}} \tilde{\cap} \tilde{\Phi}_{\tilde{\theta}} = \tilde{\Phi}_{\tilde{\theta}}$
v) $\tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{A}_{\tilde{\alpha}} = \tilde{A}_{\tilde{\alpha}}$
vi) $\tilde{F}_{\tilde{\gamma}} \tilde{\cap} \tilde{A}_{\tilde{\alpha}} = \tilde{F}_{\tilde{\gamma}}$
vii) $\tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{F}_{\tilde{\gamma}}^{c} = \tilde{A}_{\tilde{\alpha}}$
viii) $\tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{F}_{\tilde{\gamma}}^{c} = \tilde{\Phi}_{\tilde{\theta}}$

Proof: The results follow trivially from definitions 3.1 to 3.7.

Theorem 3.2: Let $\tilde{F}_{\tilde{\gamma}}$, $\tilde{G}_{\tilde{\delta}}$ and $\tilde{H}_{\tilde{\nu}}$ be any three GIFSS over (U, E), then the commutative and associative properties hold:-

$$\text{i)}\quad \tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{G}_{\tilde{\delta}} = \tilde{G}_{\tilde{\delta}} \tilde{\cup} \tilde{F}_{\tilde{\gamma}} \tag{10}$$
$$\text{ii)}\quad \tilde{F}_{\tilde{\gamma}} \tilde{\cap} \tilde{G}_{\tilde{\delta}} = \tilde{G}_{\tilde{\delta}} \tilde{\cap} \tilde{F}_{\tilde{\gamma}} \tag{11}$$
$$\text{iii)}\quad \tilde{F}_{\tilde{\gamma}} \tilde{\cup} \left(\tilde{G}_{\tilde{\delta}} \tilde{\cup} \tilde{H}_{\tilde{\nu}}\right) = \left(\tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{G}_{\tilde{\delta}}\right) \tilde{\cup} \tilde{H}_{\tilde{\nu}} \tag{12}$$
$$\text{iv)}\quad \tilde{F}_{\tilde{\gamma}} \tilde{\cap} \left(\tilde{G}_{\tilde{\delta}} \tilde{\cap} \tilde{H}_{\tilde{\nu}}\right) = \left(\tilde{F}_{\tilde{\gamma}} \tilde{\cap} \tilde{G}_{\tilde{\delta}}\right) \tilde{\cap} \tilde{H}_{\tilde{\nu}} \tag{13}$$

Proof: The properties of commutativity and associativity of $\tilde{\cup}$ and $\tilde{\cap}$ trivially follows from the definitions.

Theorem 3.3: Let $\tilde{F}_{\tilde{\gamma}}$, $\tilde{G}_{\tilde{\delta}}$ and $\tilde{H}_{\tilde{\nu}}$ be any three GIFSS over (U, E), and the t-conorm (°) and t-norm ($*$) operators are the standard union (max) and intersection operators (min) (as defined in (5) and (6) respectively), then the distributive property holds:-

$$\text{i)}\quad \tilde{F}_{\tilde{\gamma}} \tilde{\cup} \left(\tilde{G}_{\tilde{\delta}} \tilde{\cap} \tilde{H}_{\tilde{\nu}}\right) = \left(\tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{G}_{\tilde{\delta}}\right) \tilde{\cap} \left(\tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{H}_{\tilde{\nu}}\right) \tag{14}$$
$$\text{ii)}\quad \tilde{F}_{\tilde{\gamma}} \tilde{\cap} \left(\tilde{G}_{\tilde{\delta}} \tilde{\cup} \tilde{H}_{\tilde{\nu}}\right) = \left(\tilde{F}_{\tilde{\gamma}} \tilde{\cap} \tilde{G}_{\tilde{\delta}}\right) \tilde{\cup} \left(\tilde{F}_{\tilde{\gamma}} \tilde{\cap} \tilde{H}_{\tilde{\nu}}\right) \tag{15}$$

Proof: Since the standard $\cup$ (max/union) and $\cap$ (min/intersection) operators as defined in (5) and (6) are commutative and associative, the above properties hold good, when these standard operators are used for t-conorm and t-norm.

Note: - If the t-conorm and t-norm operators are different from the standard union and intersection operators, the above rules may not hold good.

Theorem 3.4: Let $\tilde{F}_{\tilde{\gamma}}$, $\tilde{G}_{\tilde{\delta}}$ be any two GIFSS over (U, E), then the following holds:-

$$\text{i)}\quad \left(\tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{G}_{\tilde{\delta}}\right)^{c} = \tilde{F}_{\tilde{\gamma}}^{c} \tilde{\cap} \tilde{G}_{\tilde{\delta}}^{c} \tag{16}$$
$$\text{ii)}\quad \left(\tilde{F}_{\tilde{\gamma}} \tilde{\cap} \tilde{G}_{\tilde{\delta}}\right)^{c} = \tilde{F}_{\tilde{\gamma}}^{c} \tilde{\cup} \tilde{G}_{\tilde{\delta}}^{c} \tag{17}$$

Proof: The above results follow from definitions 3.3, 3.4 and 3.5.

Theorem 3.5: Let $\tilde{F}_{\tilde{\gamma}}$ be any GIFSS over (U, E) with $\tilde{G}_{\tilde{\delta}}$ being its generalized intuitionistic fuzzy soft subset, and the t-conorm (°) and t-norm ($*$) operators are the standard union (max) and intersection operators (min) (as defined in (5) and (6) respectively), then the following holds:-

$$\text{i)}\quad \tilde{F}_{\tilde{\gamma}} \tilde{\cup} \tilde{G}_{\tilde{\delta}} = \tilde{F}_{\tilde{\gamma}} \tag{18}$$
$$\text{ii)}\quad \tilde{F}_{\tilde{\gamma}} \tilde{\cap} \tilde{G}_{\tilde{\delta}} = \tilde{G}_{\tilde{\delta}} \tag{19}$$

Proof: The above results follow trivially from definitions 3.4 and 3.5, and (5) and (6).

IV. Novel Score Function

A novel score function is devised here to compare two intuitionistic fuzzy numbers (IFNs) by emphasizing the membership value over the non-membership value. Xu [12] has developed a ranking method based on the score function value and accuracy function value of interval-valued intuitionistic fuzzy numbers. Ye [13] has ranked the interval-valued intuitionistic fuzzy numbers based on a novel accuracy function. However, in particular applications, the proposed techniques using a score function and an accuracy function are not suitable to compare IFNs. Therefore, it is necessary to devise application specific score functions

Definition 4.1: Let $\tilde{F} = (t_f, f_f)$, $\tilde{G} = (t_g, f_g)$ be two IFNs. Then scores of $\tilde{F}$ and $\tilde{G}$ are given as $\Delta\tilde{F} = t_f^2 - f_f^2$, and $\Delta\tilde{G} = t_g^2 - f_g^2$ respectively. The accuracy degrees of $\tilde{F}$ and $\tilde{G}$ are given as $H_f = t_f^2 + f_f^2$, and $H_g = t_g^2 + f_g^2$ respectively.

- If $\Delta\tilde{F} < \Delta\tilde{G}$, $then\ \tilde{F} < \tilde{G}$;
- If $\Delta\tilde{F} = \Delta\tilde{G}$, $then$
  - If $H_f = H_g$, $then\ \tilde{F} = \tilde{G}$;
  - If $H_f < H_g$, $then\ \tilde{F} < \tilde{G}$; (20)

V. Relation on GIFSS

The notion of intuitionistic fuzzy soft relation is defined and generalized in the context of GIFSS.

Definition 5.1 : An intuitionistic fuzzy soft relation (IFSR) $\tilde{R}$ between two IFSS, $\tilde{F}$ and $\tilde{G}$ over soft universe (U, E) and (U, F) respectively, is defined as $\tilde{R}(e,f) = \tilde{F}(e) \tilde{\cap} \tilde{G}(f)$, $\forall e \in E\ and\ \forall f \in F$, where $\tilde{R}: K \rightarrow IF^{U}$ is an IFSS over (U, K), where K $\subseteq E \times F$.

Definition 5.2: A generalized intuitionistic fuzzy soft relation (GIFSR) $\tilde{R}_{\tilde{\tau}}$ between two GIFSS, $\tilde{F}_{\tilde{\alpha}}$ and $\tilde{G}_{\tilde{\delta}}$ over soft universe (U, E) and (U, F) respectively, is defined as:

$$\tilde{R}_{\tilde{\tau}}(e,f) = \tilde{F}_{\tilde{\alpha}}(e) \,\tilde{\cap}\, \tilde{G}_{\tilde{\delta}}(f),\ \forall e \in E \text{ and } \forall f \in F,$$

where, $\tilde{R}_{\tilde{\tau}}: K \to IF^U \times IF$ is a GIFSS over (U, K),

$K \subseteq E \times F$.

Definition 5.3: Let $\tilde{R}_1$ be GIFSR between two GIFSS, $\tilde{F}_{\tilde{\alpha}}$ and $\tilde{G}_{\tilde{\delta}}$ over soft universe (U, E) and (U, K) respectively. Let $\tilde{R}_2$ be GIFSR between GIFSS, $\tilde{G}_{\tilde{\delta}}$ and $\tilde{H}_{\tilde{\kappa}}$ over soft universe (U, K) and (U, L) respectively. Then composition of $\tilde{R}_1$ and $\tilde{R}_2$ is defined as:-

$$(\tilde{R}_1 \, composition \, \tilde{R}_2)(\mathrm{e},\mathrm{l}) = \tilde{R}_1(e,k) \,\tilde{\cap}\, \tilde{R}_2(k,l)$$

where, $\tilde{R}_1: E \times K \to IF^U \times IF$

$\tilde{R}_2: K \times L \to IF^U \times IF$ (21)

Definition 5.4: Let $\tilde{R}_1$ and $\tilde{R}_2$ be two GIFSRs between two GIFSS, $\tilde{F}_{\tilde{\alpha}}$ and $\tilde{G}_{\tilde{\delta}}$ over soft universe (U, A) and (U, B) respectively. Then the standard operations of union, intersection and inverse are defined as follows:

$$(\tilde{R}_1 \cup \tilde{R}_2)(\mathrm{a},\mathrm{b}) = \max\{\tilde{R}_1(a,b), \tilde{R}_2(a,b)\} \quad (22)$$

$$(\tilde{R}_1 \cap \tilde{R}_2)(\mathrm{a},\mathrm{b}) = \min\{\tilde{R}_1(a,b), \tilde{R}_2(a,b)\} \quad (23)$$

$$\tilde{R}_1^{-1}(\mathrm{a},\mathrm{b}) = \tilde{R}_1^{-1}(\mathrm{b},\mathrm{a}), \forall(\mathrm{a},\mathrm{b}) \in \mathrm{A} \times \mathrm{B} \quad (24)$$

where, $\tilde{R}_1: A \times B \to IF^U \times IF$

$\tilde{R}_2: A \times B \to IF^U \times IF$

VI. An Application of GIFSS in Medical Diagnosis

We present a practical example of an expert system to diagnose the disease of multiple patients among multiple diseases, deploying the proposed GIFSS and GIFSR and the score function. A medical expert system with intuitionistic medical knowledge as a GIFSR from S (set of symptoms) to D (set of diagnosis) as $S \times D$ is defined.

A. Case-Study 6.1

Tom, Bob, Ram and Edwin are four class-mates, and display the symptoms: fever, headache, body-pain, cough, and loss-of-appetite. The possible diseases could be Typhoid, Malaria, Flu, Jaundice or Throat infection.

Step 1: The symptoms of patients are noted in first five columns of table I. The last column is the newly proposed generalization parameter provided by a moderator indicating his trust in the fuzzy data furnished by the patients.

Step 2: Table II indicates standard medical knowledge relating symptoms with the set of diseases under consideration. The rows indicate the symptoms while the columns correspond to various diseases.

Step 3: In Table III, we obtain patients' diagnosis applying Sanchez's approach as per (7) and (8) to each row-column pair of the two matrices in order to arrive at patients' diagnosis. For ex., Tom's symptoms are composed with Typhoid symptoms as below:-

For membership function: $(0.5 \wedge 0.3) \vee (0.8 \wedge 0.4) \vee (0.8 \wedge 0.8) \vee (0.1 \wedge 0.1) \vee (0.6 \wedge 0.9) \vee (0.6 \wedge 1.0) = 0.8$

For non-membership function: $(0.4 \vee 0.7) \wedge (0.2 \vee 0.5) \wedge (0.1 \vee 0.1) \wedge (0.8 \vee 0.9) \wedge (0.2 \vee 0.1) \wedge (0.3 \vee 0.0) = 0.1$

Thus, the value obtained, (0.8, 0.1) gives the possibility of Tom, having Typhoid. Similarly other values of table III are obtained.

Step 4: The IFNs in Table III are compared, applying score function, as per (20), so as to find the maximum number that indicates the most probable diagnosis of the patients. The score values are populated in Table IV.

Result: The maximum score in a row indicates the diagnosis for each patient. Hence Tom (with score 0.63) and Ram (with score 0.63) suffer from Typhoid, Bob (with score 0.63) and Edwin (0.32) suffer from Malaria.

B. Validation of Results

A few additional steps, as given below, may also be performed so as to be more certain about the results obtained above.

Step 5: Obtain the inverse of the entries of Table II, and populate the values in Table V.

Step 6: Perform the composition of Table I and Table V, as explained in Step 3.

Step 7: Calculate the score of each number in the Table VI, and populate the values in Table VII.

Step 8: Calculate the difference between entries in Table IV and Table VII, to arrive at the net score, as given in Table

VIII. The higher the score, higher is the possibility of the patient affected with the respective disease.

Result: Again, it can be concluded that Tom and Ram suffers from Typhoid, Bob and Edwin suffer from Malaria.

C. Discussion of the Result

The new generalization parameter, indicating an expert's level of trust in the credibility of information, significantly makes the approach quite close to real-life situations. This helps in removing the individual bias from the input data and brings more credibility to the final decision arrived at.

The generalization parameter facilitates the decision making process by including the degree of possibility of correctness of the information presented. In the above example, the doctor appears to be more confident about the reporting by Tom, Ram and Bob (as seen by high values of the generalization parameter), while he is least sure about Edwin's reporting.

For standard medical knowledge, used as the basic rule engine, the generalization parameter is taken as (1, 0), indicating the absolute belief. The results obtained are also validated by performing the composition of non-symptoms of diseases with patients' symptoms so as to obtain the score that indicates non-possibility of a particular disease. The two scores are merged to arrive at the final diagnosis.

TABLE I. PATIENTS AND THEIR SYMPTOMS

Patients	Fever	Headache	Bodypain	Cough	Loss-of-Appetite	Degree of Belonging
Tom	(0.5, 0.4)	(0.8,0.2)	(0.8,0.1)	(0.1, 0.8)	(0.6, 0.2)	(0.6, 0.3)
Bob	(0.8, 0.1)	(0.9, 0.1)	(0.7, 0.2)	(0.1, 0.9)	(0.2, 0.7)	(0.4, 0.2)
Ram	(0.1, 0.8)	(0.3, 0.7)	(0.8, 0.1)	(0.6, 0.2)	(0.1, 0.8)	(0.5, 0.1)
Edwin	(0.6, 0.2)	(0.6, 0.2)	(0.5, 0.3)	(0,1)	(0.2, 0.7)	(0.2, 0.6)

TABLE II. SYMPTOMS AND RELATED DISEASES

Symptoms	Typhoid	Malaria	Flu	Jaundice	Throat-Infection
Fever	(0.3, 0.7)	(0.8,0.1)	(0.5,0.4)	(0.3, 0.5)	(0.5, 0.2)
Headache	(0.4, 0.5)	(0.6, 0.3)	(0.5, 0.2)	(0.2, 0.7)	(0.2, 0.7)
Bodypain	(0.8, 0.1)	(0.7, 0.2)	(0.2, 0.7)	(0.3, 0.5)	(0.4, 0.4)
Cough	(0.1, 0.9)	(0.3, 0.6)	(0.9, 0.1)	(0.2,0.7)	(0.8, 0.1)
Loss-of-Appetite	(0.9, 0.1)	(0.4, 0.5)	(0.1, 0.8)	(0.8,0.2)	(0.2, 0.7)
Degree of Belonging	(1,0)	(1,0)	(1,0)	(1,0)	(1,0)

TABLE III. PATIENTS AND THEIR DIAGNOSIS (TABLE I o TABLE II)

Patients	Typhoid	Malaria	Flu	Jaundice	Throat-Infection

VII. CONCLUSIONS

Information often gets distorted from the reality during its representation. This may happen due to lack of domain knowledge, vagueness of information, or similar reasons. In order to address the problem, we have introduced an extra generalization parameter in IFSS. This is another IFS, which is the perception of an expert, indicating the credibility of the information presented. The GIFSS is defined and its properties are studied in detail. Various relations on GIFSS are given and its properties are discussed. A novel score function is also devised specifically for medical diagnosis applications, strengthening the effect of the membership function and limiting that of the non-membership function.

Finally a new approach is developed applying the GIFSS and the novel score function with a view to evolve an expert system for the diagnosis of multiple patients. This approach takes the existing medical diagnosis methods using fuzzy sets to a higher level, being empowered with normalizing factor that indicates the quality of the input information. The approach could be the basis for development of an expert system for medical diagnosis that takes as input the symptoms of patient, and the doctor's opinion about the quality of the input furnished by the patients.

***Abstract*—In order to get correct results using the model predictive control, one must find the suitable values of its tuning parameters. In many case this task is achieved by empirical methods. It's sufficient to control a physical system which internal parameters remain the same. The chosen controller parameters continue to provide satisfactory performances against small system variations. They become quickly inappropriate when strong variations occur in the process. One of the classical approaches consists to identify online the system model to update its controller based on this model. This solution doesn't ensure always best results. In this paper, we show how one can perform a suitable control to a system with variable parameters applying a fuzzy-logic-supervised predictive control. The fuzzy logic supervisor fulfills the online tuning of the predictive control parameters. Thus, we carry out a comparison between these two strategies.**

Keywords- MPC, Augmented state space model, Fuzzy Logic Supervisor, LTV system

I. INTRODUCTION

Model predictive control (MPC) is a powerful tool used to control a large range of physical systems. There are currently many industrial applications where the MPC has proved its efficiency having various difficulty complexities [1]. However, these good results depend on the best appropriate values of the MPC parameters which are the horizons of prediction, control and the weighting factor.

Many previous studies on this topic show that the MPC parameters values are chosen offline [2, 3]. Some methods use algorithms based on traditional stability criteria such as the gain and phase margins [2, 3]. Others intend to determine them by online tedious algorithms based on genetic [4] and mixed-integer linear program [5] optimizations. [6] proposes to build the adaptive MPC by achieving the online process identification to update the process model and compute the optimal control sequence after. In [7], the *Indirect Adaptive MPC (IAMPC)* approach is proposed. Nevertheless, when certain process parameters vary strongly in the time, this method is not able to respect the desired performances.

In this paper we will intend to overcome its limits thanks to the fuzzy-logic. Our approach determines the suitable values of the MPC parameters thanks to a fuzzy logic supervisor which input variables are the measurable performance criteria. From [8], we elaborate this control strategy in which predictive control is based on a state-space model and the supervisor gets a decision logic less complex. In addition, we reformulate two of the above criteria to reduce the computational load.

The paper is outlined as follows: section II presents the classical *IAMPC* while section III highlights the *IAMPC supervised by Fuzzy Logic*. In section IV, we carry out a comparative study of the obtained performances by applying both approaches on a Linear Time-Variant (LTV) system.

II. INDIRECT ADAPTIVE MODEL PREDICTIVE CONTROL

A. Discrete-time augmented state-space model

Let us consider a single-input and single-output (SISO) system represented by its discrete-time state-space model

$$\begin{aligned} x(k+1) &= A_d x(k) + B_d u(k), \\ y(k) &= C_d x(k), \end{aligned} \tag{1}$$

where k is the sampling instant assumed to be positive. [3] introduces the differences of the state vector and control variable such as

$$\begin{aligned} \Delta x(k+1) &= x(k+1) - x(k), \\ \Delta u(k+1) &= u(k+1) - u(k). \end{aligned}$$

Let us rewrite the state equation in (1) as follows

$$\begin{aligned} \Delta x(k+1) &= A_d \left(x(k) - x(k-1) \right) + B_d \left(u(k) - u(k-1) \right) \\ &= A_d \Delta x(k) + B_d \Delta u(k). \end{aligned} \tag{2}$$

Which leads to create the new state variable vector defined by

$$x_a(k) = \left[\Delta x(k) \quad y(k) \right]^T.$$

When one includes $\Delta x(k+1)$ in the second equation of (1), the measurement equation becomes

$$\begin{aligned} y(k+1)-y(k) &= C_d\left(x(k+1)-x(k)\right) = C_d\Delta x(k+1) \\ &= C_d A_d \Delta x(k) + C_d B_d \Delta u(k) \end{aligned} \tag{3}$$

The combinason of (1) and (3) leads to the following discrete-time state-space model:

$$\begin{aligned} x_a(k+1) &= Ax_a(k) + B\Delta u(k) \\ y(k) &= Cx_a(k), \end{aligned} \tag{4}$$

where

$$x_a(k+1) = \begin{bmatrix} \Delta x(k+1) \\ y(k+1) \end{bmatrix}, x_a(k) = \begin{bmatrix} \Delta x(k) \\ y(k) \end{bmatrix},$$

$$A = \begin{bmatrix} A_d & O_d^T \\ C_d A_d & 1 \end{bmatrix}, B = \begin{bmatrix} B_d \\ C_d B_d \end{bmatrix}, C = \begin{bmatrix} O_d & 1 \end{bmatrix},$$

$$O_d = \begin{bmatrix} 0 & 0 & \cdots & 0 \end{bmatrix}.$$

O_d is a row matrix of size n_A such as $(n_A \times n_A)$ are the dimensions of square matrix A_d. The set of matrices (A, B, C) forms the discrete-time augmented state-space model [3].

B. Predictive control formulation

Let be $HI, HP, HC,$ and λ the horizons of initialization, prediction, control and the weighting factor respectively. The control sequence ΔU and the sets of desired Y_{des} and predicted $\hat{Y}$ outputs are represented under a vector form as follows:

$$\Delta U^T = \begin{bmatrix} \Delta u(k) & \Delta u(k+1) & \cdots & \Delta u(k+HC-1) \end{bmatrix},$$

$$Y_{des}^T = \begin{bmatrix} y_{des}(k+1) & y_{des}(k+2) & \cdots & y_{des}(k+HP) \end{bmatrix},$$

$$\hat{Y}^T = \begin{bmatrix} \hat{y}(k+1|k) & \hat{y}(k+2|k) & \cdots & \hat{y}(k+HP|k) \end{bmatrix},$$

To obtain the control signal, we need to minimize the following cost function [3]:

$$J = (Y_{des} - \hat{Y})^T (Y_{des} - \hat{Y}) + \Delta U^T \bar{R} \Delta U, \tag{5}$$

where $\bar{R} = \lambda I$ and I is the identity matrix of dimension $(HP \times HP)$. It's possible to express the vector $\hat{Y}$ such as

$$\hat{Y} = Fx_a(k) + \Phi\Delta U, \tag{6}$$

where

$$F = \begin{bmatrix} CA \\ CA^2 \\ CA^3 \\ \vdots \\ CA^{HP} \end{bmatrix}, \Phi = \begin{bmatrix} CB & 0 & 0 & \cdots & 0 \\ CAB & CB & 0 & \cdots & 0 \\ CA^2B & CAB & CB & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ CA^{HP-1}B & CA^{HP-2}B & CA^{HP-3}B & \cdots & CA^{HP-HC}B \end{bmatrix}$$

Putting (6) in (5), we obtain a complete form of the criterion which the partial derivative with respect to ΔU gives :

$$\frac{\partial J}{\partial \Delta U} = -2\Phi^T\left(Y_{des} - Fx_a(k)\right) + 2\left(\Phi^T\Phi + \bar{R}\right)\Delta U. \tag{7}$$

We find the optimal control sequence ΔU by solving the following equation:

$$\frac{\partial J}{\partial \Delta U} = 0, \tag{8}$$

what leads to

$$\Delta U = (\Phi^T\Phi + \bar{R})^{-1}\Phi^T(Y_{des} - Fx_a(k)). \tag{9}$$

According to the receding horizon principle, the control signal applied to the process will be:

$$\begin{aligned} u(k) &= u(k-1) + \Delta U \\ u(k) &= u(k-1) + (\Phi^T\Phi + \bar{R})^{-1}\Phi^T(Y_{des} - Fx_a(k)) \end{aligned} \tag{10}$$

The state vector $x_a(k)$ constitutes the current plant information required to estimate the optimal control signal.

C. Recursive least square method

We illustrate the online model identification [9] by writing the discrete-time model of the plant such as

$$y_{\text{mod}}(k) = -\sum_{i=1}^{n_1} a_i y(k-i) + \sum_{i=1}^{n_2} b_i u(k-d-i) \tag{11}$$

where a_i and b_i are the unknown parameters. The model output $y_{\text{mod}}(k)$ can be also written under the form of a scalar product between the unknown parameter vector

$$\theta^T = \begin{bmatrix} a_1, \ldots, a_{n_1}, b_1, \ldots, b_{n_2} \end{bmatrix}$$

and the vectors of measurements called the plant model regressor vector

$$\phi(k)=\begin{bmatrix} -y(k-1) \\ \vdots \\ -y(k-n_1) \\ u(k-d-1) \\ \vdots \\ u(k-d-n_2) \end{bmatrix}.$$

What leads to

$$y_{\text{mod}}(k)=\theta^T\phi(k). \tag{12}$$

One can define now the prediction error (a priori) as

$$\varepsilon^o(k)=y(k)-\theta^T(k-1)\phi(k-1). \tag{13}$$

The minimization of the cost function

$$J_\theta=\sum_{i=1}^{k}\left(\varepsilon^o(k)\right)^2 \tag{14}$$

gives the optimal parameter vector

$$\theta(k)=P(k)\sum_{i=1}^{k}y(i)\phi(i-1) \tag{15}$$

where

$$P(k)=\left[\sum_{i=1}^{k}\phi(i-1)\phi^T(i-1)\right]^{-1}.$$

The recursive least squares (RLS) steps can be expressed by

$$\varepsilon(k+1)=\frac{y(k)-\theta^T(k)\phi(k)}{1+\phi(t)^T P(k)\phi(t)} \tag{16}$$

$$P(k+1)=P(k)-\frac{P(k)\phi(t)\phi(t)^T P(k)}{1+\phi(t)^T P(k)\phi(t)} \tag{17}$$

$$\theta(k+1)=\theta(k)+P(k+1)\phi(k)\varepsilon(k+1). \tag{18}$$

D. Parameter adaptation algorithm

The recursive formula of the adaptation gain $P(k+1)$ given by (17) is generalized by introducing two weighting sequences $\lambda_1(k)$ and $\lambda_2(k)$, as indicated below:

$$P(k+1)=\frac{1}{\lambda_1(k)}\left[P(k)-\frac{P(k)\phi(t)\phi(t)^T P(k)}{\alpha(k)+\phi(t)^T P(k)\phi(t)}\right] \tag{19}$$

where

$$0<\lambda_1(k)\le 1,\ 0<\lambda_2(k)\le 2,\ P(0)>0 \text{ and } \alpha(k)=\frac{\lambda_1(k)}{\lambda_2(k)}.$$

To improve the results of the previous identification method, [9] associates it to the constant trace technique as parameter adaptation algorithm (PAA). The principle is to move in the optimal direction of the RLS by maintaining the trace of matrix *P* approximately constant.

Imposing the ratio $\alpha(k)$, the two factors $\lambda_1(k)$ and $\lambda_2(k)$ are automatically calculated at each step to ensure

$$tr(P(k+1))=tr(P(k))=tr(P(0))=(n_1+n_2)P_0 \tag{20}$$

in which *GI* is the initial gain and $P(0)=P_0 I$ with *I* the identity matrix of dimension $((n_1+n_2)\times(n_1+n_2))$.

Fig. 1 helps us to visualize and understand well the *IAMPC* strategy wholeness. For simplicity reasons, we include the PAA in the block named RLS.

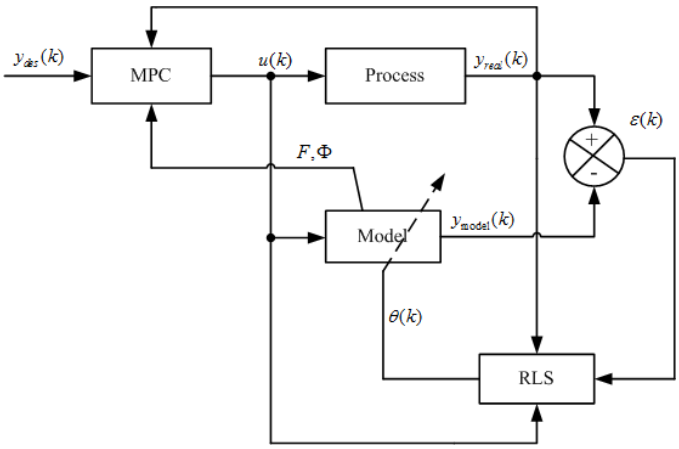

Figure 1. Equivalent structure of the IAMPC.

III. INDIRECT ADAPTIVE MODEL PREDICTIVE CONTROL SUPERVISED BY FUZZY LOGIC

Inspired by [8], it is possible to modify directly the tuning parameters of the predictive controller according to precise performance criteria. We consider four criteria estimated from controlled plant and model data. These four criteria are the inputs of the fuzzy-logic supervisor and the MPC parameters its outputs.

A. Performance criteria

We choose to evaluate the controlled plant rapidity by the controlled output convergence time (OCT). Considering the controlled output y_{cont} as a percentage γ of the desired output y_{des}, we can establish a relative error threshold (RET). It is defined such as

$$RET = \frac{y_{cont} - y_{des}}{y_{des}} = \frac{y_{des}(\gamma - 1)}{y_{des}} = \gamma - 1$$

OCT is the time interval from which the below inequality is verified:

$$\left| \left(y_{cont} - y_{des} \right) / y_{des} \right| \le RET, \tag{21}$$

Subsequently, it remains close to 0, if y_{cont} approaches y_{des}. It remains equal to -0.01, if y_{cont} is not close to y_{des}.

The controlled process stability is measured by the stability degree indicator (SDI). It is the difference between the radius of the unit circle and the modulus of the pole most remote from the unit circle center. What gives

$$SDI(k) = 1 - \max\left(|p_1|, |p_2|, \ldots, |p_{n_A}| \right), \tag{22}$$

where $p_1, p_2, \ldots, p_{n_A}$ are the eigenvalues of matrix A_d. When $0 < SDI < 1$, the system is stable. It will be in limit of stability if $SDI = 0$. It will become unstable if $SDI < 0$.

The control signal variance (VARU) allows observing the mean value of the square deviations of $u(k)$ from its average. It's expressed by

$$VARU(k) = \overline{u(k)^2} - \left[\overline{u(k)} \right]^2 \tag{23}$$

with

$$\overline{u(k)^2} = \overline{u(k-1)^2} + \frac{1}{2}\left(u(k)^2 - u(k-1)^2 \right),$$

and

$$\left[\overline{u(k)} \right]^2 = \left[\overline{u(k-1)} + \frac{1}{2}\left(u(k) - u(k-1) \right) \right]^2.$$

The trace of $\Phi^T\Phi$ provides an excellent tool to evaluate the computation conditioning of the optimal control signal [2, 8].

B. Normalization

Generally speaking, there is a difference between the real values of the mentioned performance criteria and the admissible values of the fuzzy input variables in their respective discourse universes from 0 to 1. One notices the same difference for the MPC parameters which are the fuzzy output variables. Thereby, one needs to normalize the values of these criteria and the obtained MPC horizons.

Let us add the subscript *n* to the criteria abbreviations OCT_n, SDI_n, $VARU_n$, $trace(\Phi^T\Phi)_n$ as their normalized values. Assigning them maximal and minimal values that fixe the expected performance ranges, SDI_n is evaluated by the simple operation (available for the other criteria)

$$SDI_n(k) = \left(SDI(k) - SDI_{\min} \right) / SDI_{\max}. \tag{24}$$

While the normalized supervisor outputs are designated by HP_n and HC_n respectively for *HP* and *HC*. Supposing they have maximal and minimal values that include the suitable horizons, the proposed control horizon is

$$HC(k) = round\left[HC_n(k)(HC_{\max} - HC_{\min}) + HC_{\min} \right], \tag{25}$$

where *round* is the function which rounds the real number to its nearest integer. We use the same calculus for *HP*. [8] shows how one can find the right numerical range of *HP*

$$HP_{\min} = 2\sup\left\{ n_2 + d; n_1 + 1 \right\},$$
$$HP_{\max} = HP_{\min} + 10.$$

And those of HC

$$HC_{\min} = n_1,$$
$$HC_{\max} = HP - HI.$$

C. Fuzzy logic supervisor

The purpose of the supervisor is to propose the appropriate values of *HP*, *HC* and λ depending on the plant variations. This supervisor is made of three sub-systems.

The first suggests the *HP* value based on the variance of $u(k)$ and the controlled OCT. The second gives the *HC* value according to the previous criteria. The third offers the λ value

in function of the trace of $\Phi^T\Phi$ and the controlled SDI. We illustrate this on fig. 2.

To be able to make proposals, the fuzzy logic supervisor involves the if-then rules using the Mamdani's fuzzy inference system. Thus, each linguistic input has three fuzzy sets and each linguistic output owns five fuzzy sets. All the membership functions are triangular. Tab. I, II and II present the inference tables corresponding to each supervisor sub-system.

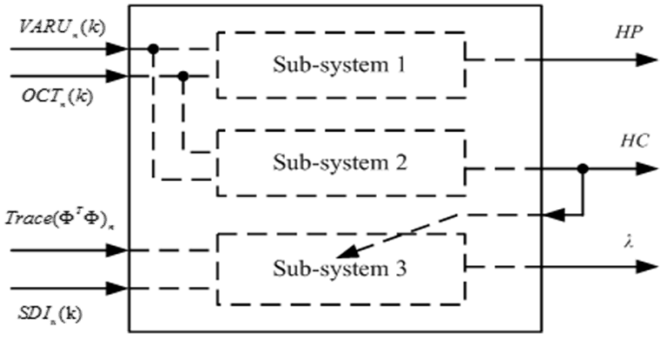

Figure 2. Sub-systems of the fuzzy logic supervisor.

D. *Control architecture*

The elaborated control architecture consists of the *IAMPC* control law enhanced by the fuzzy logic supervisor (FLS). To fulfill it this global strategy to a process, one requires to coordinate the activations of each task. The modeling error $\varepsilon(k)$ compares the real and the model outputs to guarantee good predictions. The model will track well the plant output when this error remains null. Otherwise, we take into account two adaptation cases through two positive thresholds called S_1 and S_2 $(S_1 < S_2)$.

Firstly, the condition $\varepsilon(k)$ upper than or equals to S_1 activates the RLS method enhanced by the PAA. It updates the former model parameters.

Secondly, when $\varepsilon(k)$ becomes greater than or equals to S_2, we activate the supervisor while the first adaptation still works (see fig. 3). This second updating suggests the best appropriate MPC parameters. As soon as $\varepsilon(k)$ becomes lower than or S_2, we take back the original values of *HP*, *HC* and λ.

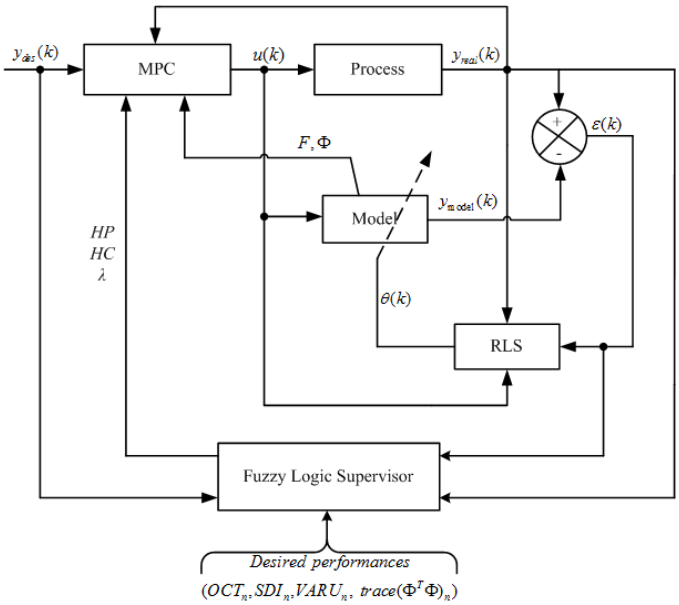

Figure 3. Equivalent structure of the IAMPC with fuzzy logic supervisor.

IV. APPLICATION AND COMPARISON

In this section we will focus on an academic application. Both detailed control strategies will be look at the overshoot or undershoot stability and rapidity. All simulations are derived via Matlab Simulink R2006b. For the computing environment set up, the solver used is "Discrete (no continuous states)" having a fixed step equals to 5 ms.

A. *System description*

The system considered is an electrical application that takes into account a flexible transmission with important variations of load inertia, which corresponds to typical applications in the machine tool area [10]. The transmission and load are modeled as a second order transfer function given in the continuous-time domain by:

$$H(s) = \frac{K}{J_n s^2 + f_n s + C} \quad with \quad \begin{cases} K = 2\ , J_n = 0.002 \\ f_n = 0.006, C = 2 \end{cases} \tag{26}$$

This SISO model is characterized by its natural pulsation and its damping factor:

$$\omega_n = \sqrt{C/J} = 31.623\ rad/s,\ \xi = f/\left(2\omega_n J\right) = 0.4743.$$

With a sampling period T_s of 5 ms, the discrete-time model coming from (26) including the digital to analogue and analogue to digital converters is given by:

$$H(q^{-1}) = \frac{0.01187q^{-1} + 0.01129q^{-2}}{1 - 1.838q^{-1} + 0.8607q^{-2}}. \qquad (27)$$

From [2], we set the original MPC parameters that produce correct results: $HI = 1$, $HC = 1$, $HP = 8$ and $\lambda = 0.42$. This set up respects the below performance criteria during the process control:

$$0 \le OCT \le 1,\ 0 \le SDI \le 1,\ 0 \le VARU \le 0.2, \left|Overshoot\right| \le S_1 \le S_2$$
$$0 \le trace(\Phi^T\Phi) \le 1.5, S_1 = 2.5\%,\ S_2 = 5\%.$$

How does the controlled plant react against the load inertia changes for a square reference signal (fig. 4)?

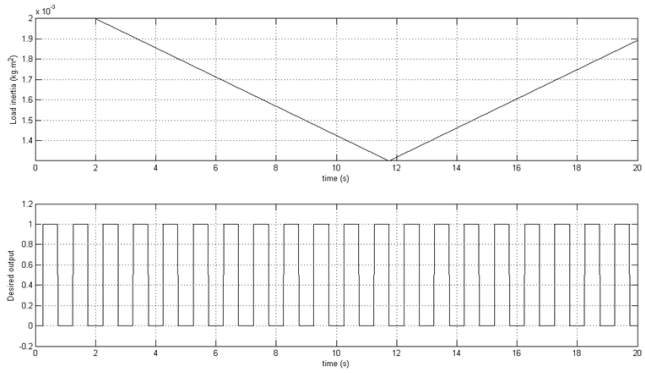

Figure 4. J profile and desired output.

B. Simulation results

1) Results with IAMPC : the plot of MPC output in fig. 5 shows us that the original controller MPC has difficulty in tracking correctly the reference signal. From 8 s to 16 s, where J reaches its lower value, the absolute overshoot is strictly greater than 5% and sometimes greater than 10% (fig. 6). In the same time, this gap increasing to $\varepsilon(k)$ activates the plant model reconfiguration (see fig. 7).

The *IAMPC* gets through to enhance the incapacities of MPC. One notices the reduction of the absolute overshoot, a smaller OCT in fig. 8 than before which prooves that the process became quicker. *IAMPC* control signal curve has decreasing and rising peaks which looks like the J profile. While MPC control signal keeps the same aspect (fig. 9).

However, an important peak of 1.21 is located around 11 s and 12 s when we use the first adaptive control law. We must solve this problem.

2) Results with fuzzy-logic-supervised IAMPC: Considering fig. 6 as the zoom of *IAMPC* output, one can observe various sudden peaks. They are limeted to 5% or 6% except between 11 s and 12 s. One visible effect of *fuzzy-logic-supervised IAMPC* is the drastic cancellation of these indisirable elements. Which leads to the smallest absolute overshoot (fig. 11). In fact, there is a modulus increase of the current control signal according to *IAMPC* control. The control signals plot shows that maximal values of control signal using FLS reach approximatively 4.3 (fig. 12).

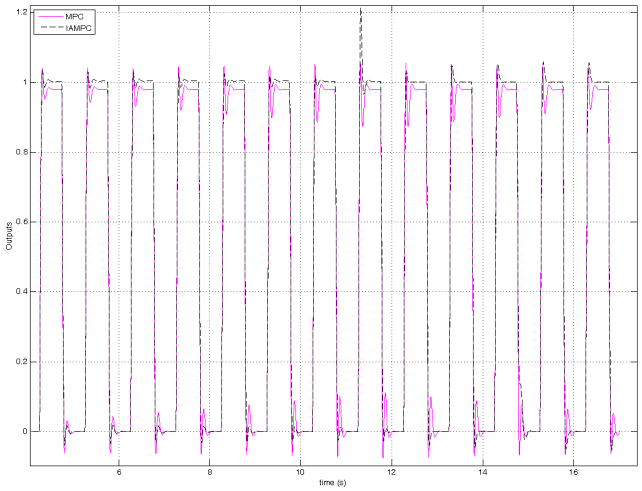

Figure 5. Output results of MPC vs IAMPC.

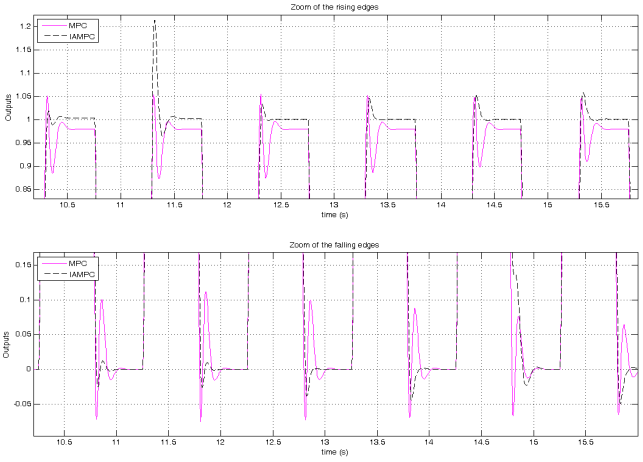

Figure 6. Output zooms of MPC vs IAMPC.

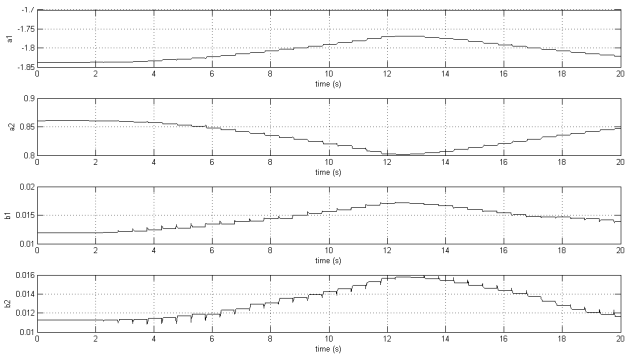

Figure 7. New estimated parameter vector.

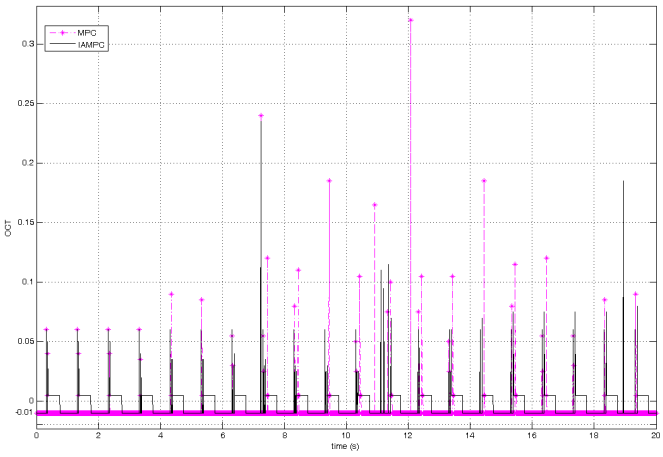

Figure 8. OCT results of MPC vs IAMPC.

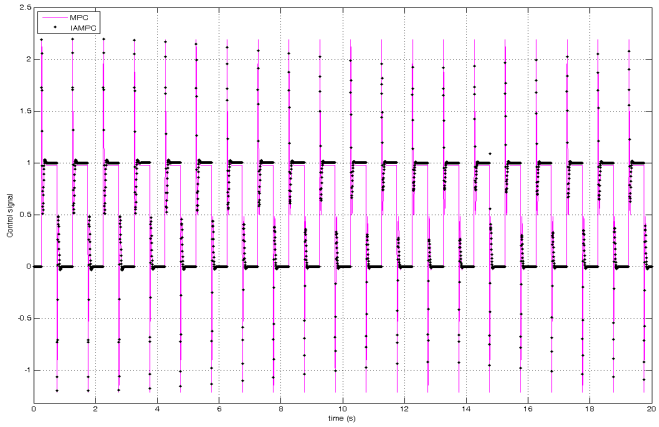

Figure 9. Control signals of MPC vs IAMPC.

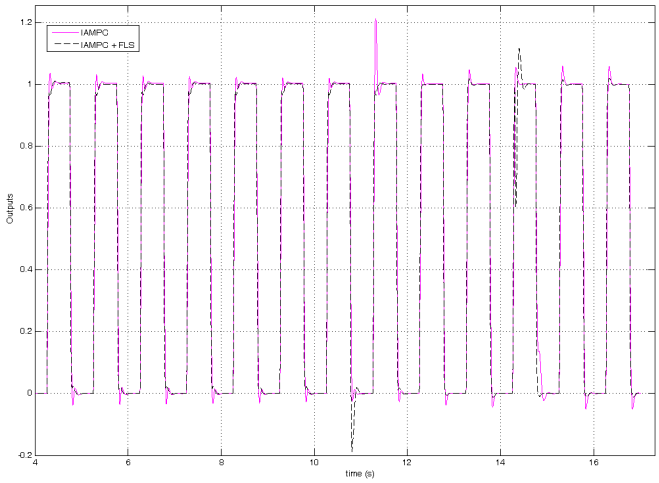

Figure 10. Output results of IAMPC vs IAMPC with FLS.

Concerning the rapidity criterion, the approach based FLS leads to a plant as quick as the process using the *IAMPC* strategy. In the above OCT plots (fig. 13), *IAMPC* proposes sometimes lower values than *IAMPC* enhanced by FLS. Otherwise, it's the opposite e.g near 7 s and from 15 s to 20 s. We perform the same analysis for SDI criterion.

During the first period i.e up to 13 s, *IAMPC* enhanced by FLS provides a better stability, while IAMPC strategy takes the advantage after (fig. 14).

This comment recalls the traditional dilemma between rapidity and stability: fluctations of one affects negatively the other.

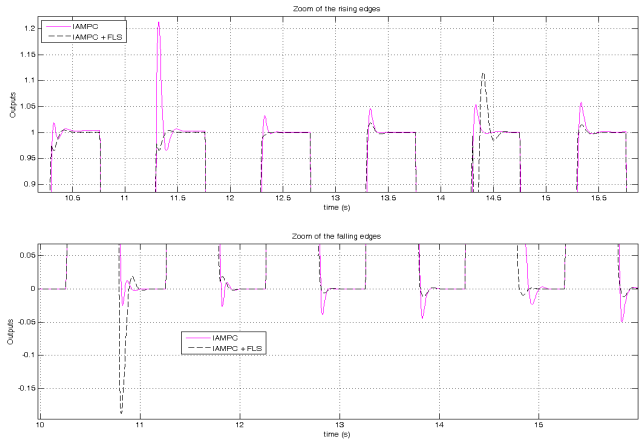

Figure 11. Output zoom of IAMPC vs IAMPC with FLS.

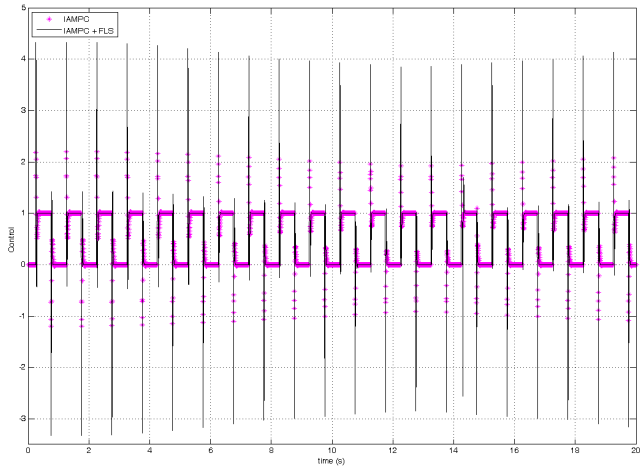

Figure 12. Control signals of IAMPC vs IAMPC with FLS.

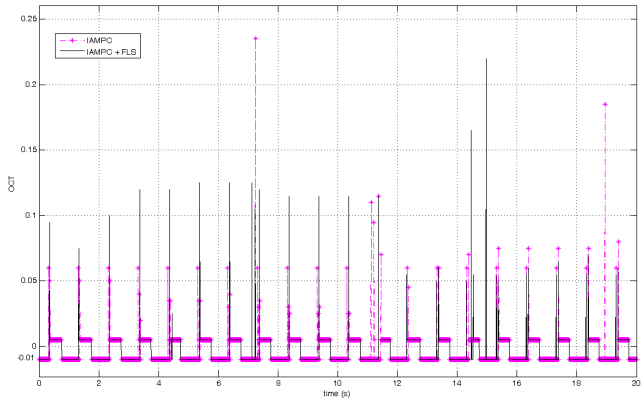

Figure 13. OCT results of IAMPC vs IAMPC with FLS.

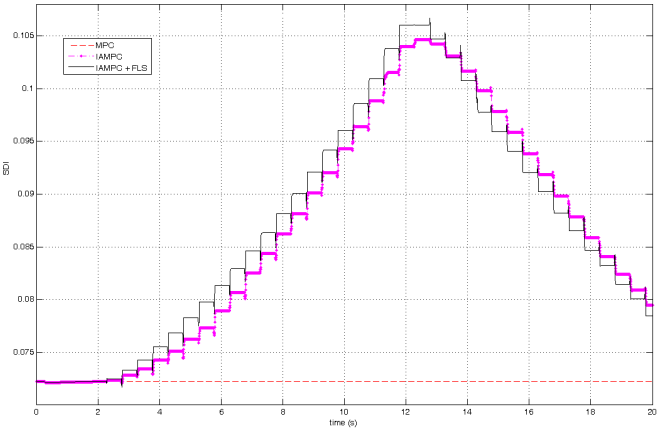

Figure 14. SDI results of IAMPC vs IAMPC with FLS.

Let us note that both reconfiguration strategies improve substantially the original stability getting an indicator closer to zero than theirs results.

All these improvements are due to the double capacity of *fuzzy-logic-supervised IAMPC* to conjugate in parallel the modifications of *HC*, *HP*, λ (see fig. 15) with the online model identification. Nevertheless, even if the irregular peak of *IAMPC* in [11 s, 12 s] disappeared, two perticular peaks (resp. -0.19 and 1.12) appear at 10.8 s and 14.4 s.

V. CONCLUSION

This paper presents an indirect adaptive MPC using fuzzy logic supervisor for which two simultaneous adaptations can be activated automatically. The first is based on the discrete-time augmented model reconfiguration thanks to RLS combining PAA. While the second provides suitable values of *HP*, *HC* and λ via a logic decision carried by the proposed supervisor.

Important abilities of IAMPC enhanced by FLS are highlighted when a Linear Time-Variant system is confronted to strong parameter variations. It gets through to repulse several limits encountered with MPC and IAMPC. The majority of performance criteria are respected. Nonetheless, two undesirable peaks appeared even if their values are lower than previously. It seems possible to eliminate these anomalies by imposing inequality constraints on the control and output signals. After that, it would be also very interesting to study how we can implement and test this enhanced control law on a real-time application.

Abstract— **An acknowledged interpretation of possibility distributions in quantitative possibility theory is in terms of families of probabilities that are upper and lower bounded by the associated possibility and necessity measures. This paper proposes a likelihood function for possibility distributions that agrees with the above-mentioned view of possibility theory in the continuous and in the discrete cases. Especially, we show that, given a set of data following a probability distribution, the optimal possibility distribution with respect to our likelihood function is the distribution obtained as the result of the probability-possibility transformation that obeys the maximal specificity principle. It is also shown that when the optimal distribution is not available, a direct application of this possibilistic likelihood provides more faithful results than approximating the probability distribution and then applying the probability possibility transformation. We detail the particular case of triangular and trapezoidal possibility distributions and we show that any unimodal unknown probability distribution can be faithfully upper approximated by a triangular distribution obtained by optimizing the possibilistic likelihood.**

keywords : possibility theory, probability-possibility transformation, maximum-likelihood principle.

I. Introduction

Possibility theory, based on max-decomposable set-functions, associated with possibility distributions, may have either a qualitative or a quantitative understanding, depending on the nature of the scales used for possibility degrees. Quantitative possibility theory corresponds to the case where the interval $[0, 1]$ is a ratio scale. In qualitative possibility theory, only the ordering of the possibility values makes sense. In this paper, we deal with quantitative possibility theory. Quantitative possibility measures can be viewed as upper bound of probabilities. Then, a possibility distribution represents a family of probability distributions [3]. This view was first suggested by Zadeh [10] based on the idea that what is probable must be possible. Following this intuition a probability-possibility transformation has been proposed [5]. This transformation associates a probability distribution with the maximally specific possibility distribution which is such that the possibility of any event is indeed an upper bound of the corresponding probability.

The maximum-likelihood principle is a basis for building a probability distribution from a set of data. Given a set of parameterized probability distributions and a set of data, a likelihood function is used for optimizing the choice of the parameters in order to determine the best suited distribution with respect to the data. However, this approach supposes that the shape of the distribution is apriori known or that we have a large number of data at our disposal. Moreover, due to the constraints on the probability distributions, induced by their additive nature, there are no simple distribution that allows for the faithful description of any set of data.

There exist different kinds of methods for eliciting possibility distributions from data. For instance, some approaches directly build the possibility distribution on the basis of a proximity relation defined on the universe of the data [4]. G. Mauris proposes a method for constructing a possibility distribution when only very few pieces of data are available (even only one or two) based on probability inequalities [8]. This latter method is justified in the probabilistic view of possibility theory. These methods, how different they are, have in common to build the distributions directly. In this paper, we investigate another road based on the optimization of an appropriate likelihood function. The proposed likelihood function is in agreement with the view underlying the probability-possibility transformation.

The paper is organized as follows. Section 2 provides the necessary background about possibility distributions and their interpretation in terms of families of probabilities. Section 3 presents likelihood measures for probabilities and especially a non-classical one, not based on logarithm, that can be used for approximating unbounded distributions with bounded ones. Sections 4 and 5 respectively deal with the discrete and continuous definitions of possibilistic likelihood and the specific cases of triangular or trapezoidal distributions. Finally, we provide some examples of the construction of a possibility distribution from data using the proposed possibilistic likelihood, and we discuss the usability of the approach in Section 6.

II. Background

A. Possibility distribution

Possibilty theory, introduced Zadeh [10], was initially created in order to deal with imprecision and uncertainty due

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

to incomplete information. This kind of uncertainty may not be handled by probability theory, especially when a priori knowledge about the nature of the probability distribution is lacking. A possibility distribution π is a mapping from Ω to $[0,1]$ (Ω may be a discrete universe, i.e. $\Omega = \{C_1, \ldots, C_q\}$, or a continuous one, i.e. $\Omega = \mathbb{R}$). The value $\pi(x)$ is called possibility degree. For any subset of Ω, the possibility measure is defined as follows:

$$\forall A \subseteq \Omega, \Pi(A) = max\{\pi(x), x \in A\}.$$

If it exists a single value $x \in \Omega$ for which we have $\pi(x) = 1$, the distribution is normalized. We can distinguish two extreme cases of information situations:

- complete knowledge: $\exists x \in \Omega$ such as $\pi(x) = 1$ and $\forall y \in \Omega, y \neq x, \pi(y) = 0$
- total ignorance: $\forall x \in \Omega, \pi(x) = 1$.

The necessity is the dual measure of the possibility measure. We have:

$$\forall A \subseteq \Omega, N(A) = 1 - \Pi(\overline{A}).$$

Finally, α-cuts of π are subsets of Ω such that:

$$A_\alpha = \{x \in \Omega, \pi(x) \geq \alpha\}.$$

It can be checked that, if $\Omega = \mathbb{R}$ and the distribution is continuous and normalized, we have $\forall \alpha \in [0,1], \Pi(A_\alpha) = 1$ and $N(A_\alpha) = 1 - \alpha$.

B. Possibility distribution as a family of probability distributions

Possibility distributions have two types of interpretations. The first one, that is related to fuzzy set theory, is the description of gradual properties. For instance, the definition of linguistic expressions such that "long", "old" or "expensive" does not refer to a specific value, but to a set of possible values in a particular context. For instance, a possibility distribution may describe the concept "expensive" for an house in a given area. In such a case, each price will be associated with a possibility degree which quantifies how much this price is typical with respect to this particular use of the concept "expensive".

Another type of interpretation is to consider a possibility distribution as a family of probability distributions (see [1] for an overview). Thus, a possibility distribution π will represent the family of the probability distributions for which the measure of each subset of Ω will be bounded by its necessity and its possibility measures. More formally, if $\mathcal{P}$ is the set of all probability distributions defined on Ω, the family of probability distributions $\mathcal{P}_\pi$ associated with π is defined as follows:

$$\mathcal{P}_\pi = \{p \in \mathcal{P}, \forall A \in \Omega, N(A) \leq P(A) \leq \Pi(A)\}. \quad (1)$$

In this scope, the situation of total ignorance corresponds to the case where all probability distributions are possible. This type of ignorance can not be described by a single probability distribution. The case of complete knowledge corresponds to the case where only one value is possible and then where there are no randomness nor imprecision. Obviously, if π is not normalized, $\mathcal{P}_\pi$ is empty (since then $N(A) \leq \Pi(A)$ is no longer guaranteed for any A).

When $\Omega = \mathbb{R}$, this family of probability distributions can also be described in terms of confidence intervals. Given a probability distribution p, a confidence interval I_α is a subset of Ω such as $P(I_\alpha) = \alpha$. We define I^*_α, also referred as quantile, as the smallest confidence interval with probability measure equal to α. Thus, when π is continuous, an alternative to the equation (1) is:

$$\mathcal{P}_\pi = \{p \in \mathcal{P}, \forall I^*_\alpha \in \Omega, I^*_\alpha \subseteq A_{1-\alpha}\} \quad (2)$$

where $A_{1-\alpha}$ is the $(1-\alpha)$-cut of π. Thus, the possibility distribution π contains the probability distributions for which the confidence intervals associated to the α's are bounded by the $(1-\alpha)$-cuts.

C. Probability to possibility transformation

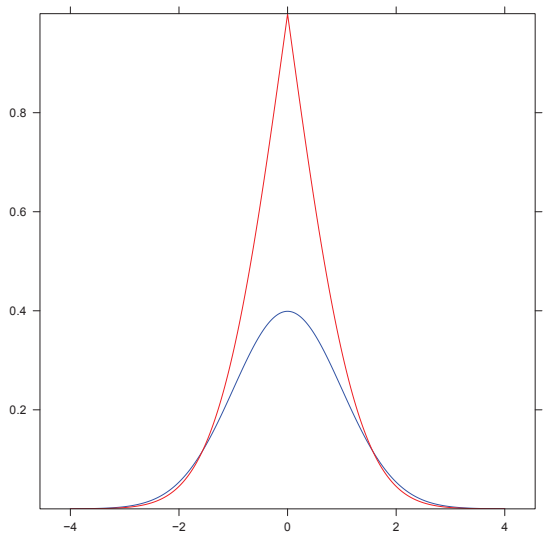

Fig. 1. probability to possibility transformation of a Gaussian distribution

According to this probabilistic interpretation, a method from transforming probability distributions into possibility distributions has been proposed in [5]. The idea behind this proposal is to consider the most informative possibility distribution, i.e. the tightest one (i.e. the smallest one in each point) that contains the probability distribution. Let us consider a probability distribution p, the possibility distribution π^* is defined in the following way:

$$\forall x \in \Omega, \pi^*(x) = max_{\alpha, x \in I_\alpha}(1-\alpha). \quad (3)$$

Then, in the spirit of equation (2), given p and its transformation π^* we have:

$$A^*_{1-\alpha} = I^*_\alpha$$

where $A^*_{1-\alpha}$ is the $(1-\alpha)$-cut of π^*. Thus, if p has a finite number of modes, π^* is the possibility distribution for which each $(1-\alpha)$-cut corresponds to the quantile of p. When p is

unimodal, the unique value x such that $\pi^*(x) = 1$ is the mode of p.

III. Probabilistic likelihood measure

Likelihood measures have been introduced in order to evaluate the adequateness of a probability distribution with respect to a set of data. Let us consider a set of data $X = \{x_1, \ldots, x_n\}$ belonging to a discrete universe $\Omega = \{C_1, \ldots, C_q\}$. We name $\alpha_1, \ldots, \alpha_q$ the frequency of the elements of X that belong respectively to $\{C_1, \ldots, C_q\}$. Given a probability distribution p on the discrete space $\Omega = \{C_1, \ldots, C_q\}$, we define $p_1, \ldots, p_q$ the probability of belonging to the unitary element of Ω, i.e. $p(x \in C_i) = p_i$. The values $p_1, \ldots, p_q$ entirely define p, and are then the parameters of p. The maximum-likelihood principle is used for estimating the parameters of a probability distribution. In the continuous case, the shape of the distribution has to be known, and the parameters are obtained through an optimization procedure with respect to the likelihood measure. In the discrete case, the parameters are $p_1, \ldots, p_q$, and obey the constraint $\sum_1^q p_i = 1$. The most used likelihood function is the logarithmic-based likelihood defined as follows (under the strict constraint $\sum_1^q p_i = 1$):

$$\mathcal{L}_{log}(p|x_1, \ldots, x_n) = -\sum_{i=1}^{n} log(p(x_i))$$

or, when considering frequency directly

$$\mathcal{L}_{log}(p|x_1, \ldots, x_n) = -\sum_{i=1}^{q} \alpha_i log(p_i).$$

It is equivalent to compute the joint probability of the elements of x with respect to p. This definition of the likelihood has a strong limitation, since it gives a very high weight to the error when probability is very low. This is especially true when Ω is continuous. Since $\mathcal{L}_{log}$ is not defined when $p(x_i) = 0$, an unbounded density cannot be approximated by a bounded one by optimization of $\mathcal{L}_{log}$. We propose another likelihood function that overcomes these limitations:

$$\mathcal{L}_{surf}(p|x_1, \ldots, x_n) = (\sum_{i=1}^{n} p(x_i)) - \frac{1}{2} * \sum_{i=1}^{q} p_i^2$$

or, when considering frequency directly

$$\mathcal{L}_{surf}(p|x_1, \ldots, x_n) = (\sum_{i=1}^{q} \alpha_i * p_i) - \frac{1}{2} * \sum_{i=1}^{p} p_i^2.$$

Roughly speaking, L_{surf} favors the probability distributions that are close to the optimal one in terms of surface. Thus, when, Ω is continuous, it allows for the approximation of unbounded densities by bounded ones.

Proposition 1: Given a set of data $X = \{x_1, \ldots, x_n\}$ belonging to a discrete universe $\Omega = \{C_1, \ldots, C_q\}$, we have

$$argmax_{p \in \mathcal{P}}(\mathcal{L}_{log}(p|x_1, \ldots, x_n)) = argmax_{p \in \mathcal{P}}(\mathcal{L}_{surf}(p|x_1, \ldots, x_n)).$$

Proof: Let $p_{log} = argmax_{p \in \mathcal{P}}(\mathcal{L}_{log}(p|x_1, \ldots, x_n))$ be the optimal probability distribution given X. This distribution is such as the probability of an event C_i is equal to the frequency of element of X in C_i, i.e. $p_{log}(x \in C_i) = p_i = \alpha_i$. We now look for the probability distribution p_{surf} that maximizes $\mathcal{L}_{surf}$. We have:

$$\forall i = 1 \ldots q, \frac{\delta \mathcal{L}_{surf}(p|x_1, \ldots, x_n)}{\delta p_i} = \alpha_i - p_i$$

thus

$$\forall i = 1 \ldots q, \frac{\delta \mathcal{L}_{surf}(p|x_1, \ldots, x_n)}{\delta p_i} = 0 \Leftrightarrow p_i = \alpha_i.$$

Since the derivative of $\mathcal{L}_{surf}(p|x_1, \ldots, x_n)$ with respect to p_i (the parameters of p) does not depend on the other parameters p_j, $j \neq i$, we obtain $p_{surf}(x \in C_i) = p_i = \alpha_i$. Thus $p_{surf} = p_{log}$ ■

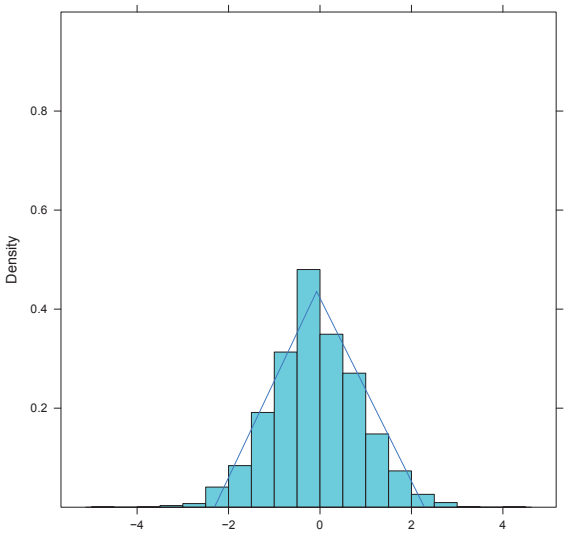

Fig. 2. Approximation of a Gaussian density with a triangular density by maximization of $\mathcal{L}_{surf}$

This proposition shows that, given X, the probability distribution that maximizes $\mathcal{L}_{log}$ is the same as the one that maximizes $\mathcal{L}_{surf}$.

$\mathcal{L}_{surf}$ can be extended to the case of $\Omega = \mathbb{R}$ in the following way:

$$\mathcal{L}_{surf}(p|x_1, \ldots, x_n) = (\sum_{i=1}^{n} p(x_i)) - \frac{1}{2} * \int_{\mathbb{R}} p(t)^2 dt.$$

Proposition 1 remains true when $\Omega = \mathbb{R}$. Figure 2 shows the triangular density that maximizes $\mathcal{L}_{surf}$ given a set of 3000 values that are generated by a Gaussian distribution with mean equal to 0 and standard derivation equal to 1. This triangular probability distribution is parametrized by m,

l and r which are respectively the mode, the left and the right spread of the probability distribution. We have used an optimization procedure in order to find the parameters that maximizes $\mathcal{L}_{surf}$. What we obtain is the triangular probability distribution that shares the maximum of surface with the histogram computed from the sample set. If we have used $\mathcal{L}_{log}$, the support of the triangle would have grow to infinity as the number of values increases.

IV. Possibilistic likelihood: discrete case

In this section we show how to use the $\mathcal{L}_{surf}$ likelihood function in order to define a likelihood function for a possibility distribution that supports the interpretation of a possibility distribution in terms of a family of probability distributions. Roughly speaking, the idea is to have a likelihood function that is maximal for the result of the probability-possibility transformation of the distribution and that favors the approximations of the distribution that share the maximum of surface with the optimal one (as for $\mathcal{L}_{surf}$ in the probabilistic case). We first consider the case of a discrete universe, i.e. $\Omega = \{C_1, \ldots, C_q\}$.

We now assume that the frequencies of examples in the different classes C_i are put in increasing order ($\alpha_1 \geq \ldots \geq \alpha_q$). In this case, the probability distribution p^* that maximizes the likelihood is such that $p(x \in C_i) = p_i = \alpha_i$. In the following, given a possibility distribution π, we note π_i the value $\pi(x \in C_i)$. It has been shown in [5] that the transformation of p^* into a possibility distribution π^* that satisfies the maximal specificity requirement, is:

$$\forall i \in \{1, \ldots, q\}, \pi_i^* = \sum_{j=i}^{q} \alpha_j. \tag{4}$$

This possibility distribution is one of the cumulated functions of p^*. It is worth noticing that it is the tightest one. What we expect from possibility likelihood is that the maximum of this function is reached for π^*. In the following, we assume that $\pi_1 \geq \ldots \geq \pi_q$ (and not necessarily $\alpha_1 \geq \ldots \geq \alpha_q$). We propose the following function:

$$\begin{aligned}\mathcal{L}_{pos}(\pi|x_1, \ldots, x_n) =& (\sum_{i=1}^{q}(1-\pi_i) * (1 - (\sum_{j=i}^{q} \alpha_i))) \\ & - \sum_{i=1}^{q} \frac{(1-\pi_i)^2}{2}\end{aligned} \tag{5}$$

which can be rewritten as this:

$$\begin{aligned}\mathcal{L}_{pos}(\pi|x_1, \ldots, x_n) =& \sum_{i=1}^{q}(-\alpha_i * \sum_{j=1}^{i}(1-\pi_j)) \\ & - \sum_{i=1}^{q} \frac{(1-\pi_i)^2}{2} \\ & + \sum_{i=1}^{q}(1-\pi_i)\end{aligned} \tag{6}$$

If we only consider one piece of data, we obtain:

$$\begin{aligned}\mathcal{L}_{pos}(\pi|x) =& \sum_{j=1}^{i|x\in C_i}(1-\pi_j)) \\ & - C * \sum_{i=1}^{q} \frac{(1-\pi_i)^2}{2} \\ & + C * \sum_{i=1}^{q}(1-\pi_i)\end{aligned} \tag{7}$$

where C is a constant (usually $\frac{1}{n}$, where n is the number of independent data considered). The rationale behind this is to evaluate the cumulated distribution in the spirit of $\mathcal{L}_{surf}$. Thus, the terms $((1-\pi_i) * (1 - (\sum_{j=i}^{q} \alpha_i))) - \frac{(1-\pi_i)^2}{2}$ correspond to the evaluation of $\mathcal{L}_{surf}$ for the set $\overline{C_i \cup \ldots \cup C_q}$. Note that, if you consider $C_i \cup \ldots \cup C_q$ instead of $\overline{C_i \cup \ldots \cup C_q}$, what is obtained is the largest cumulative distribution instead of the tightest one.

Proposition 2: Given a set of data $X = \{x_1, \ldots, x_n\}$ belonging to a discrete universe $\Omega = \{C_1, \ldots, C_q\}$, the possibility distribution π^* that maximizes the function $\mathcal{L}_{pos}$ is the transformation of the probability distribution p^*, according to equation (4), which maximizes $\mathcal{L}_{surf}$ ($\forall i \in \{1, \ldots, q\}, p_i^* = \alpha_i$).

Proof: We look for the probability distribution π^* that maximizes $\mathcal{L}_{surf}$.
We have:

$$\forall i = 1 \ldots q, \frac{\delta \mathcal{L}_{pos}(\pi|x_1, \ldots, x_n)}{\delta \pi_i} = -1 + \sum_{j=i}^{q} \alpha_i - \pi_i + 1$$

thus

$$\forall i = 1 \ldots q, \frac{\delta \mathcal{L}_{pos}(\pi|x_1, \ldots, x_n)}{\delta \pi_i} = 0 \Leftrightarrow p_i = \sum_{j=i}^{q} \alpha_i.$$

Since the derivative of $\mathcal{L}_{pos}(\pi|x_1, \ldots, x_n)$ with respect to π_i (the parameters of π) does not depend on the other operator π_j, $j \neq i$, we obtain $\pi_i^* = p_i = \sum_{j=i}^{q} \alpha_i$ which exactly corresponds to Equation (4). ■

This proposition shows that $\mathcal{L}_{pos}$ is an acceptable likelihood function for possibility distributions viewed as families of probabilities. As for $\mathcal{L}_{surf}$ the likelihood depends on the surface shared between the considered possibility distribution and the optimal one.

It is worth noticing that, when optimal distributions can only be approximated, finding the best approximation with respect to $\mathcal{L}_{pos}$ is not equivalent to find the best probability approximation with respect to $\mathcal{L}_{surf}$ and then turn it into a possibility distribution. For instance, we consider X that leads to the frequency $\alpha_1 = 0.5, \alpha_2 = 0.3, \alpha_3 = 0.2$. We know require that $p_3 = 0$ and $\pi_3 = 0$. In this context, the optimal p with respect to $\mathcal{L}_{surf}$ ($\mathcal{L}_{log}$ is not applicable here) is $p_1 = 0.6$, $p_2 = 0.4$, $p_3 = 0$. The optimal π with respect to $\mathcal{L}_{poss}$ is

$\pi_1 = 1$, $\pi_2 = 0.5$, $\pi_3 = 0$. The transformation π' of p is $\pi'_1 = 1$, $\pi'_2 = 0.4$, $\pi'_3 = 0$. We observe that π' is different than π and that π is a better approximation of the optimal possibility distribution.
This result is fundamental since it illustrates that using a probabilistic likelihood and then the probability-possibility transformation is not an effective approach for constructing a possibility distribution from data. The maximization of $\mathcal{L}_{pos}$ is more adapted in this scope.

V. Possibilistic likelihood: continuous case

We now consider the continuous case where $\Omega = \mathbb{R}$.

A. Definition

In the continuous case, the assumption of the values put in an increasing order of π is naturally replaced by the consideration of α-cuts. We adapt the equation (6) as follows:

$$\begin{aligned}\mathcal{L}_{pos}(\pi|x_1,\ldots,x_n) = &-(\sum_{i=1}^{n}\int_{A_{\pi(x_i)}}(1-\pi(t))dt)\\ &-\int_{\mathbb{R}}\frac{(1-\pi(t))^2}{2}dt\\ &+\int_{\mathbb{R}}(1-\pi(t))dt\end{aligned} \tag{8}$$

where $A_{\pi(x_i)}$ is the $\pi(x_i)$-cut of π. If we only consider one piece of data, we obtain:

$$\begin{aligned}\mathcal{L}_{pos}(\pi|x) = &-\int_{A_{\pi(x)}}(1-\pi(t))dt\\ +C*(&-\int_{\mathbb{R}}\frac{(1-\pi(t))^2}{2}dt+\int_{\mathbb{R}}(1-\pi(t))dt)\end{aligned} \tag{9}$$

where C is a constant (usually $\frac{1}{n}$, where n is the number of independent data considered). Property 2 remains true in the continuous case. The possibilistic counterpart of likelihood being defined, we will now considered the particular cases of triangular and trapezoidal distributions.

B. Triangular distribution

We define a triangular possibility distribution as the triple $\pi_{tri} = (m, l, r)$ where m is the mode of the triangle and l and r the left and the right spread respectively. Since the 0-cut is infinite for a triangular distribution, we assume that X is bounded and has a maximal size equal to the constant MAX_{size}.
We consider a piece of data $x \in X$. We note $\mu = \pi_{tri}(x)$ the possibility degree of x and $[a, b]$ the μ-cut of π_{tri}. There are two cases for the term that depends on $\pi_{tri}(x)$ in (9). We consider the case of $x \in]m-l, m+r[$. We have:

$$\begin{aligned}MemSurf(\pi_{tri}|x) &= -\int_{A_{\pi_{tri}(x)}}(1-\pi_{tri}(t))dt\\ &= -\int_a^b(1-\pi_{tri}(t))dt\\ &= -\int_a^m(1-\pi_{tri}(t))dt+\int_m^b(1-\pi_{tri}(t))dt\\ &= -\int_a^m(1-(1-\frac{m-t}{l}))dt-\int_m^b(1-(1-\frac{t-m}{r}))dt\\ &= -\int_a^m\frac{m-t}{l}dt-\int_m^b\frac{t-m}{r}dt\\ &= -(1-\mu)^2*\frac{l}{2}-(1-\mu)^2*\frac{r}{2}\\ &= -(1-\mu)^2*\frac{l+r}{2}.\end{aligned}$$

In the case of $x \notin]m-l, m+r[$, with the bounding assumption, we obtain:

$$MemSurf(\pi_{tri}|x) = -MAX_{size}+\frac{l+r}{2}.$$

Note that a more flexible approach on the bounding can be used, for instance by considering that the weight MAX_{size} depends on the distance between x and the triangle. The other part of the equation (9) is computed such as:

$$\begin{aligned}&-\int_{\mathbb{R}}\frac{(1-\pi_{tri}(t))^2}{2}dt+\int_{\mathbb{R}}(1-\pi(t))dt=\\ &\int_{m-l}^{m+r}-\frac{(1-\pi_{tri}(t))^2}{2}+(1-\pi_{tri}(t))dt\\ &+\int_{R/[m_l,m+r]}-\frac{(1-\pi_{tri}(t))^2}{2}+(1-\pi_{tri}(t))dt=\\ &-\frac{l+r}{6}-\frac{MAX_{size}}{2}.\end{aligned}$$

The terms MAX_{size} depends neither on π_{tri} and nor on x and can then be omitted. Finally, we obtain:

$$\mathcal{L}_{pos}(\pi_{tri}|x) = MemSurf(\pi_{tri}|x) - C*\frac{l+r}{6}. \tag{10}$$

C. trapezoidal distribution

We define a trapezoidal possibility distribution as the quadruple $\pi_{trap} = (a, b, c, d)$ where $[a, d]$ and $[b, c]$ are respectively the support and the core of the distribution. As in the triangular case, we assume that X is bounded and has a maximal size equal to the constant MAX_{size}. We note $\mu = \pi_{trap}(x)$ the possibility degree of x. There are three cases for the term that depends on $\pi_{tri}(x)$ in Equation (9).

- $x \in]b, c[$:
$$MemSurf(\pi_{trap}|x) = 0$$
- $x \in]a, b[$ or $x \in]c, d[$:
$$MemSurf(\pi_{trap}|x) = -(1-\mu)^2*\frac{b-a+d-c}{2}$$

- $x \notin]a, d[$:

$$MemSurf(\pi_{trap}|x) = -MAX_{size} + \frac{-b-a+d+c}{2}.$$

The other part of the equation (9) is computed such as:

$$-\int_{\mathbb{R}} \frac{(1-\pi_{trap}(t))^2}{2} dt + \int_{\mathbb{R}} (1-\pi(t))dt = -\frac{b-a+d-c}{6} - \frac{c-b}{2} - \frac{MAX_{size}}{2}.$$

As in the triangular case, the terms $-\frac{MAX_{size}}{2}$ can be omitted. Finally, we obtain:

$$\mathcal{L}_{pos}(\pi_{trap}|x) = MemSurf(\pi_{tri}|x) - C*(\frac{b-a+d-c}{6} - \frac{c-b}{2}). \quad (11)$$

Note that, having the likelihood function defined for triangular (resp. trapezoidal) distribution, we can obtain the optimal triangular (resp. trapezoidal) by finding the parameters that maximizes $\mathcal{L}_{pos}$. Since this problem cannot be solved analytically, we have to use a meta heuristic such as simulated annealing [7] or particle swarm optimization [6].

VI. Illustrations and Discussion

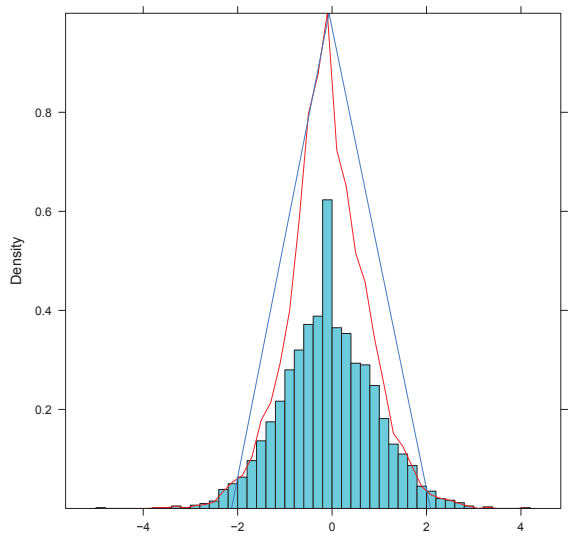

Fig. 3. Possibility transformation that maximizes $\mathcal{L}_{pos}$ with respect to a set of data that follows a Gaussian distribution

In this section, we will use possibilistic likelihood in order to build a possibility distribution from a set of data. Figure 3 represents the triangular possibility distribution obtained from a set of 3000 data that obey a Gaussian distribution with a mean equal 0 and a standard deviation equals to 1. The possibility distribution obtained from a probability-possibility transformation of the histogram is in red. It corresponds to the optimal possibility distribution with respect to data. The triangular possibility distribution that maximizes $\mathcal{L}_{pos}$ is in blue. We can first notice that the mode of the triangular distribution corresponds to the mode of the Gaussian distribution. The triangular distribution is very close to the optimal one and dominates its on the majority of the data. The support contains 96% of the data. Figure 4

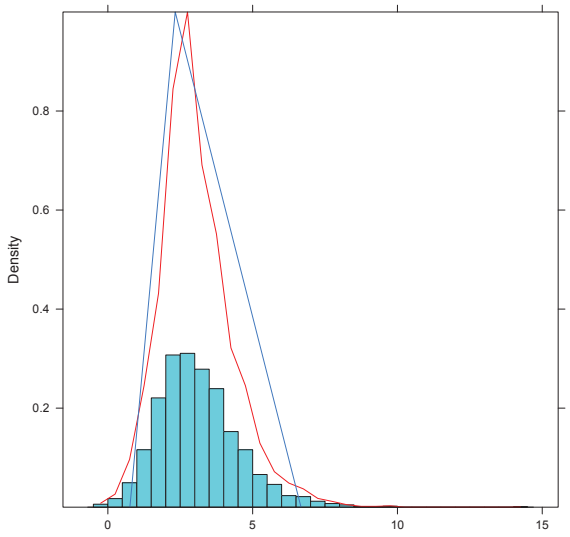

Fig. 4. Possibility transformation that maximize $\mathcal{L}_{pos}$ with respect to a set of data that follow a Student distribution

represents the triangular possibility distribution obtained from a set of 3000 data that follow a non central student distribution with 5 degrees of freedom. Although the distribution is not symmetric, we can observe similar results to the one observed with the Gaussian distribution. The support contains 96% of the data. In Figure 5, the distribution is multi modal. Here

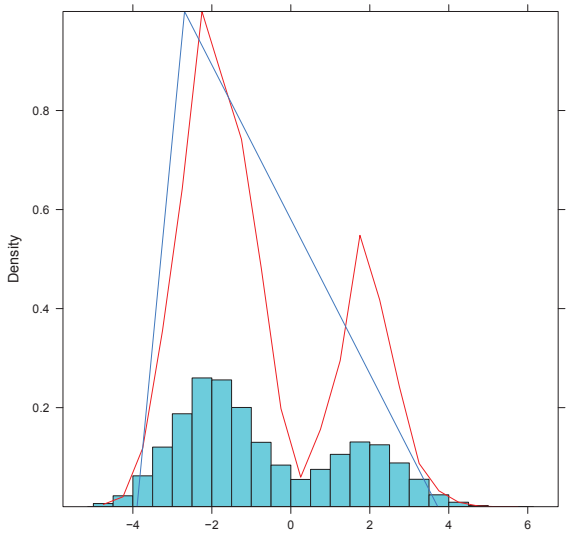

Fig. 5. Possibility transformation that maximizes $\mathcal{L}_{pos}$ with respect to a set of data that follows a multimodal distribution

we can observe that the mode of the triangular distribution is the highest mode of the probability distribution. However, it underestimates the second mode. The support still contains 96% of the data.

These results illustrates the following property, proved in [2]:

Proposition 3: The triangular symmetric possibility distribution of support $[x_1, x_2]$ and of mode $\frac{x_1+x_2}{2}$ is the least upper bound of all the possibility transforms of symmetric probability distributions of support $[x_1, x_2]$ and of mode $\frac{x_1+x_2}{2}$.

This proposition shows that triangular distributions may approximate any possibility transformation of bounded symmetric unimodal distributions. We have shown in Section 4 that approximating a possibility distribution by maximizing $\mathcal{L}_{pos}$ is more efficient that approximating the probability distribution and then turning it into a possibility distribution. It validates the use of possibilistic likelihood for building triangular distributions from data. Even Proposition 3 is not always true if the distribution is asymmetric, triangular possibilistic distribution performs well in general for any type of unimodal distribution. Thus, the use of triangular possibility distributions and of $\mathcal{L}_{pos}$ is a good alternative for bounding densities when the shape of the probability distribution is not known. Results are less good if the distribution is multimodal, but the mode of the triangular possibilistic distribution always identifies the highest mode of the probability distribution. Note that we do not present a result with a trapezoidal distribution because triangular distributions (which are a particular case of trapezoidal distributions) are always obtained.

VII. Conclusion

In this paper we have proposed a definition of possibilistic likelihood that agrees with the view of possibility distributions as families of probability distributions and with the probability-possibility transformation based on the maximum-specificity principle. This function can be used for evaluating and comparing a possibility distribution with respect to data or can be embedded into an optimization process in order to build a possibility distribution from a set of data. We have defined the possibilistic likelihood function both for discrete and for continuous universes. In the continuous case, we have shown that, in spite of its sophisticated definition, it is easy to compute for triangular and trapezoid distributions. Lastly, the good properties of triangular possibility distributions for bounding unimodal probability distributions make the building of possibility distributions by optimization of $\mathcal{L}_{pos}$ a good approach when no a priori information on the type of distribution is available. This optimization approach may be interesting in a machine learning context, for instance for Bayesian learning or for a k-nearest neighbor approach where distributions have to be computed from data. It can be also used as quality function for imprecise regression [9].

In the future, it may be interesting to define a possibilistic likelihood that allows us to obtain genuine trapezoidal distributions. Moreover, the proposed approach does not take into account the quantity of data available. Indeed, if only one value is available, the best possibility distribution is a Dirac, and there will be no difference with the case where a thousand of identical values are available. Less data should lead to less specific distributions. This should be taken into account in representations.
