FUZZ-IEEE 2011

2011 IEEE International Conference On Fuzzy Systems

Grand Hyatt Taipei, Taipei, Taiwan

June 27-30, 2011

Proceedings

Organized by:

Institute of Electrical and Electronics Engineers (IEEE)

IEEE Computational Intelligence Society (CIS)

National Chiao Tung University, Taiwan, R. O. C.

National University of Tainan, Taiwan, R. O. C.

National Cheng Kung University, Taiwan, R. O. C.

Osaka Prefecture University, Japan

Sponsored by:

National Science Council, Taiwan, R. O. C.

Ministry of Education, Taiwan, R. O. C.

Bureau of Foreign Trade, Taiwan, R. O. C.

A Message from the Conference Organizers

2011 IEEE International Conference on Fuzzy Systems

It is our great privilege to welcome you to the ***2011 IEEE International Conference on Fuzzy Systems*** (***FUZZ-IEEE 2011***) held in Taipei, Taiwan, June 27-30, 2011. Like the previous conferences in this series, we are confident that FUZZ-IEEE 2011 will provide a forum for fruitful interaction and exchange of ideas between the participants coming from around the world. FUZZ-IEEE 2011 covers all major facets of computational intelligence, but as usual, the primary emphasis will be on fuzzy sets and systems. We are glad to note that 58 different countries from around the world are represented by the authors, thereby making it a truly international event.

The technical program covers four days of presentations including three keynote speeches, two plenary speeches, three invited talks, one Human vs. Computer Go competition, five tutorials, five workshops, two panel sessions, and forty three special sessions given by well-known world class researchers in various fuzzy related subject areas. As for the papers, a total of 358 papers were accepted for oral presentation and 82 for poster presentation out of 618 submissions. So, we expect you to have a great time during these four days. However, we would like to express our sincere gratitude to all the authors and reviewers who have made so many effects for the preparation of their latest researches and all the tutorial and invited speakers who kindly accepted sharing their expertise with the attendees.

No conference can be successful without excellent teamwork and ours is no different. Our special appreciations also go to the sacrifices and perspirations of our colleagues and organizing committee members, for example, Wei-Yen Wang (Local Arrangement Chair), I-Fang Chung (Finance Chair), Shun-Feng Su (Finance Co-Chair), Chia-Feng Juang (Publication Chair), Hani Hagras (Special Sessions Chair), Naoyuki Kubota (Special Sessions Co-Chair), Jyh-Yeong Chang (Registration Chair), Vincenzo Loia (Workshop Chair), Shyi-Ming Chen (Publicity Chair), Mei-Hui Wang (Secretary), Ya-Wen Lin (Secretary), and Hung-Miau Chen (Secretary) in making this conference a smooth process. Most of all, thank you for attending FUZZ-IEEE 2011. We hope this conference will benefit all of us in advancing research activities and building new friendship.

General Chair
Chin-Teng Lin
NCTU, Taiwan

General Co-Chair
Yau-Huang Kuo
NCKU, Taiwan

Program Chair
Chang-Shing Lee
NUTN, Taiwan

Program Co-Chair
Hisao Ishibuchi
OPU, Japan

Program Co-Chair
Wen-June Wang
NCU, Taiwan

Committees

- **Organizing Committee**

Honorary Co-Chairs

Chung-Yu Wu (National Chiao Tung University, Taiwan)
Hsiu-Shuang Huang (National University of Tainan, Taiwan)
Hwung-Hweng Hwung (National Cheng Kung University, Taiwan)
Taketoshi Okuno (Osaka Prefecture University, Japan)

General Chair

Chin-Teng Lin (National Chiao Tung University, Taiwan)

General Co-Chair

Yau-Huang Kuo (National Cheng Kung University, Taiwan)

Program Chair

Chang-Shing Lee (National University of Tainan, Taiwan)

Program Co-Chairs

Hisao Ishibuchi (Osaka Prefecture University, Japan)
Wen-June Wang (National Central University, Taiwan)

Tutorials Chair

Jerry Mendel (University of Southern California, USA)

Keynotes Chair

Jim Keller (University of Missouri-Columbia, USA)

Panels Chair

Nikhil Pal (Indian Statistical Institute, India)

Invited Sessions Chair

Pau-Choo Chung (National Cheng Kung University, Taiwan)

Invited Sessions Co-Chais

Yueh-Min Huang (National Cheng Kung University, Taiwan)
Chih-Min Lin (Yuan Ze University, Taiwan)

Special Sessions Chair

Hani Hagras (University of Essex, UK)

Special Sessions Co-Chair

Naoyuki Kubota (Tokyo Metropolitan University, Japan)

Workshops Chair

Vincenzo Loia (University of Salerno, Italy)

Workshops Co-Chairs

Tzung-Pei Hong (National University of Kaohsiung, Taiwan)
Shi-Jim Yen (National Dong Hwa University, Taiwan)

Fuzzy Competition Chair

Hao Ying (Wayne State University, USA)

Computer Go Competition Chair

Chang-Shing Lee (National University of Tainan, Taiwan)

Computer Go Competition Co-Chairs

Martin Muller (University of Alberta, Canada)
Olivier Teytaud (INRIA-Futurs, TAO, France)
Shun-Chin Hsu (Chang Jung Christian University, Taiwan)

Publicity Chair

Shyi-Ming Chen (National Taiwan University of Science and Technology, Taiwan)

Publicity Co-Chairs

Gary Feng (City University of Hong Kong, Hong Kong)
Francisco Herrera (University of Granada, Spain)
Kok Wai Kevin Wong (Murdoch University, Australia)
Li-Wei Ko (National Chiao Tung University, Taiwan)
Frank Chung-Hoon Rhee (Hanyang University, Korea)
Richard Weber (University of Chile, Chile)
Vladik Kreinovich (University of Texas, USA)
Valentina Balas (Aurel Vlaicu University of Arad, Romania)

Finance Chair

I-Fang Chung (National Yang-Ming University, Taiwan)

Finance Co-Chair

Shun-Feng Su (National Taiwan University of Science and Technology, Taiwan)

Publication Chair

Chia-Feng Juang (National Chung Hsing University, Taiwan)

Publication Co-Chairs

Cheng-Jian Lin (National Chin-Yi University of Technology, Taiwan)
Shin-Mu Tseng (National Cheng Kung University, Taiwan)

Registration Chair

Jyh-Yeong Chang (National Chiao Tung University, Taiwan)

Registration Co-Chairs

Wen-Chieh Lin (National Chiao Tung University, Taiwan)
Sheng-Fu Liang (National Cheng Kung University, Taiwan)

Student Activities Chair

Faa-Jeng Lin (National Central University, Taiwan)

Student Activities Co-Chair

Rong-Ming Chen (National University of Tainan, Taiwan)

Local Arrangement Chair

Wei-Yen Wang (National Taiwan Normal University, Taiwan)

Local Arrangement Co-Chairs

Jin-Tsong Jeng (National Formosa University, Taiwan)
Ching-Hung Lee (Yuan Ze University, Taiwan)
Chun-Fei Hsu (Chung Hua University, Taiwan)
Jiann-Shu Lee (National University of Tainan, Taiwan)
Shing-Tai Pan (National University of Kaohsiung, Taiwan)

Website Chair

Fu-Shine Pai (National University of Tainan, Taiwan)

Website Co-Chair

Ming-Yi Ju (National University of Tainan, Taiwan)

Secretary

Mei-Hui Wang (National University of Tainan, Taiwan)
Yuan-Liang Wang (National University of Tainan, Taiwan)
Ya-Wen Lin (National University of Tainan, Taiwan)
Yi-Ting Fu (Ting) (National Chiao Tung University, Taiwan)
Hung-Miau Chen (NAO) (National Chiao Tung University, Taiwan)

Website maintenance

Hui-Min Wang (National University of Tainan, Taiwan)
Hui-Ju Yang (National University of Tainan, Taiwan)
Yan-Liang Chen (National University of Tainan, Taiwan)

- **Advisory Committee**

James Bezdek (University of West Florida, USA)
Zeungnam Bien (Korea Advanced Institute of Science and Technology, Korea)
Piero Bonissone (GE Global Research, USA)
Bernadette Bouchon-Meunier (University Paris VI, France)
Bor-Sen Chen (National Tsing Hua University, Taiwan)
Jyh-Horng Chou (National Kaohsiung First University of Science and Technology, Taiwan)
Dimitar Filev (Ford Motor Company, USA)
Kaoru Hirota (Tokyo Institute of Technology, Japan)
Laszlo Koczy (Budapest University of Technology and Economics, Hungary)
Enrique H. Ruspini (European Centre for Soft Computing, Spain)
Kay Chen Tan (National University of Singapore, Singapore)
Gwo-Hshiung Tzeng (Kainan University, Taiwan)
Ronald Yager (Iona College, USA)
Gary Yen (Oklahoma State University, USA)
Lotfi A. Zadeh (University of California, USA)

- **Program Committee**

Area Co-Chairs

Intelligent agents and smart environment
Hani Hagras (University of Essex, UK)
Fuzzy control
Jeen-Shing Wang (National Cheng Kung University, Taiwan)
Fuzzy AI - knowledge discovery, reasoning, knowledge representation
Marek Reformat (University of Alberta, Canada)
Basic concepts and mathematics
Qiang Shen (University of Wales Aberystwyth, UK)
Mathematical foundations of fuzzy systems
Baoding Liu (Tsinghua University, China)
Fuzzy robotics
Tzuu-Hseng Li (National Cheng Kung University, Taiwan)
Fuzzy hardware, sensors and architectures
Kaoru Hirota (Tokyo Institute of Technology, Japan)
Fuzzy information processing - information extraction and retrieval, fusion
Witold Pedrycz (University of Alberta, Canada)
Web mining and text mining
Jung-Hsien Chiang (National Cheng Kung University, Taiwan)
Soft computing and hybrid systems - adaptive, hierarchical, evolutionary, neural and nature-inspired systems
Yaochu Jin (University of Surrey, UK)
Software engineering and applications
Jonathan Lee (Chair) (National Central University, Taiwan)
Alan Liu (Co-Chair) (National Chung Cheng University, Taiwan)
Memetic computing
Yew Soon Ong (Nanyang Technological University, Singapore)
Machine learning and cloud computing
Shie-Jue Lee (National Sun Yat-Sen University, Taiwan)
Fuzzy optimization and design, decision support
Hideki Katagiri (Hiroshima University, Japan)
Granular computing
Churn-Jung Liau (Academia Sinica, Taiwan)
Computing with words
Robert John (De Montfort University, UK)
Rough sets, fuzzy human computer interaction
Yo-Ping Huang (National Taipei University of Technology, Taiwan)
Type 2 fuzzy sets and systems
Woei Wan Tan (National University of Singapore, Singapore)
Industrial, financial and medical applications, business intelligence
Fernando Gomide (University of Campinas, Brazil)

Smart interaction and multimedia processing
Hajime Nobuhara (University of Tsukuba, Japan)
Fuzzy reinforcement learning
Hamid Berenji (Intelligent Inference Systems Corp, USA)
Fuzzy systems and Internet - semantic web, ontologies, searching, networks and routing, intrusion detection
Trevor Martin (University of Bristol, UK)
Fuzzy decision making and risk analysis
Didier Dubois (Paul Sabatier University, France)
Genetic fuzzy systems
Rafael Alcalá (University of Granada, Granada, Spain)
Fuzzy image, speech, vision and signal processing
Oscar Cordon (DECSAI, University of Granada, Spain)

Program Committee Members

Rafael Alcalá (University of Granada, Spain)
Plamen Angelov (Lancaster University, UK)
Sansanee Auephanwiriyakul (Chiang Mai University, Thailand)
Robert Babuska (Delft University of Technology, Netherlands)
Gleb Beliakov (Deakin University, Australia)
Oscar Castillo (Tijuana Institute of Technology, Mexico)
Shyi-Ming Chen (National Taiwan University of Science and Technology, Taiwan)
Yung-Yaw Chen (National Taiwan University, Taiwan)
Martine De Cock (Ghent University, Belgium)
Yutaka Hata (University of Hyogo, Japan)
Janusz Kacprzyk (Polish Academy of Science, Poland)
Okyay Kaynak (Bogazici University, Turkey)
Son Kuswadi (Polytechnic Institute of Surabaya, Indonesia)
Yongming Li (Shaanxi Normal University, China)
Kuang-Yow Lian (National Taipei University of Technology, Taiwan)
Radko Mesiar (Slovak University of Technology Bratislava, Slovakia)
Detlef Nauck (Intelligent Systems Research Centre, UK)
Andreas Nürnberger (University of Magdeburg, Germany)
Leszek Rutkowski (Technical University of Czestochowa, Poland)
Mika Sato-Ilic (University of Tsukuba, Japan)
Joao Miguel da Costa Sousa (Technical University of Lisbon, Portugal)
Juhng-Perng Su (National Yunlin University of Science and Technology, Taiwan)
Chin-Wang Tao (National Ilan University, Taiwan)
Nipon Theera-Umpon (Chiang Mai University, Thailand)
Kuo-Yang Tu (National Kaohsiung First University of Science and Technology, Taiwan)
Chi-Hsu Wang (National Chiao Tung University, Taiwan)
Fei-Yue Wang (University of Arizona, USA)
Rahmat Widyanto (University of Indonesia, Indonesia)
Hongwei Wu (Georgia Institute of Technology, USA)

Special Session Organizers

SS01: Fuzzy Ontologies and FML Applications
Organizers: Giovanni Acampora and Chang-Shing Lee

SS02: Evolutionary Fuzzy Systems
Organizers: Yusuke Nojima, Rafael Alcalá, Hisao Ishibuchi, and Francisco Herrera

SS03: Uncertainty and the Semantic Web
Organizers: Fernando Bobillo and Umberto Straccia

SS04: Soft Computing for Operations Research and Optimization
Organizers: Hideki Katagiri, Takashi Hasuike, and M. K. Luhandjula

SS05: Fuzzy Robotics
Organizers: Naoyuki Kubota, Honghai Liu, and Chee Seng Chan

SS06: Intelligent Agents
Organizers: Vincenzo Loia and Hani Hagras

SS07: Metaheuristics and Its Applications
Organizer: Chun-Wei Tsai

SS08: Innovative Fuzzy Approaches to Management Engineering
Organizer: Junzo Watada

SS09: Applications of Fuzzy Logic to Awareness Promotion
Organizers: Kiyota Hashimoto and Shingo Aoki

SS10: Medical and Wellness Engineering
Organizer: Yutaka HATA

SS11: Large-Scale Clustering
Organizer: Timothy Havens

SS12: Recent Advances in Fuzzy-Model-Based Control Systems
Organizers: J. C. Lo and H. K. Lam

SS13: Fuzzy Multiple Criteria Decision Making
Organizer: Gwo-Hshiung Tzeng

SS14: Advances in Fuzzy Theory and their Applications
Organizers: Shyi-Ming Chen and Huey-Ming Lee

SS15: Type-2 Fuzzy Logic Theory
Organizers: Christian Wagner and Robert John

SS16: Fuzzy Interpolation
Organizers: Qiang Shen, László Koczy, and Shyi-Ming Chen

SS17: Practical and Applications Aspects of Type-2 Fuzzy Logic Systems
Organizers: Hani Hagras and Simon Coupland

SS18: Recent Advances in Fuzzy Logic in Image Processing
Organizers: Mike Nachtegael and Gerald Schaefer

SS19: Fuzzy Inference Systems-Theory and Applications
Organizer: Hirosato Seki

SS20: Universal Contents Creation/Distribution and Intelligent System
Organizer: Katsuhiro Honda

SS21: Fuzzy Control in Industrial and Application
Organizer: Shun-Hung Tsai

SS22: Fuzzy Methods in Machine Learning and Data Mining
Organizers: Eyke Huellermeier and Daniel Sanchez

SS23: Industrial Applications of Evolving Fuzzy Systems
Organizers: Kit Yan Chan, Hak Keung Lam, and Steve S. H. Ling

SS24: Hybrid Learning for Fuzzy Systems
Organizer: Jin-Tsong Jeng

SS25: Evolving and Adaptive Fuzzy Systems
Organizers: Plamen Angelov, Dimitar Filev, and Nik Kasabov

SS26: Inter-Relation between Interval and Fuzzy Techniques
Organizers: Eunjin Kim and Vladik Kreinovich

SS27: Communication Robotics and Computational Intelligence Co-creation
Organizers: Yoichi Yamazaki and Fangyan Dong

SS28: Current Development in Pattern Classification-Kernelization, Pairwise Constraints, and Classifiers
Organizer: Yasunori Endo

SS29: Software Engineering with Computational Intelligence
Organizers: Jonathan Lee, Nien-Lin Hsueh, and Chiung-Hon Leon Lee

SS30: Computing With Words
Organizers: Sergio Guadarrama and Jerry Mendel

SS31: Human Symbiotic Systems
Organizers:Yoichiro Maeda and Daisuke Katagami

SS32: Adaptive Fuzzy Logic Control
Organizers:Valentina E. Balas and Tsung-Chih Lin

SS33: Fuzzy and Paraconsistent Intelligent Systems
Organizers: Valentina E. Balas, Jair Minoro Abe, and Kazumi Nakamatsu

SS34: Brain and Learning
Organizers:Isao Hayashi and Toshihiko Watanabe

SS35: Fuzzy Regression Analysis and Its Applications
Organizers: M. Hadi Mashinchi, Mehmet A. Orgun, Witold Pedrycz, Mashaalah Mashinchi, and Chi-Tsuen Yeh

SS36: Fuzzy Systems on Renewable Energy
Organizers: Faa-Jeng Lin and Hong-Tzer Yang

SS37: Fuzzy Logic Based Computer Vision and Its Applications to Guidance and Control
Organizer: Kuo-Hsien Hsia

SS38: Fuzzy Knowledge Discovery and Its Applications
Organizers: Yue-Shi Lee and Rung-Ching Chen

SS39: Fuzzy Based Computation on Biomedical Systems
Organizers: Shing-Tai Pan, Sheng-Fu Liang, and Tzung-Pei Hong

SS40: Fuzzy Approach for Information Security Management
Organizers: Tzung-Nan Chuang, Che-Hung Liu, and Chang-Shing Lee

SS41: Neuro Fuzzy Systems and Their Real World Application
Organizers: Sungshin Kim, Euntai Kim, Kweebo Sim, and Jinwoo Jung

SS42: Fuzzy Cognitive Maps-Theory and Applications
Organizers: Elpiniki I. Papageorgiou and Jose L. Salmeron

SS43: Fuzzy Systems of Unknown Nonlinear Complex Systems
Organizers: Wei-Yen Wang and Hsum Li

Tutorials

T01: Evolutionary Multi-Objective Design of Fuzzy Rule-Based Systems

Instructor: Rafael Alcala

T01-1: Monday, June 27, 2011 (9:00 AM- 10:30 AM) Room: Peacock

T01-2: Monday, June 27, 2011 (11:00 AM- 12:30 PM) Room: Peacock

T02: Interpolative Fuzzy Rule Bases

Instructor: László Koczy

T02-1: Monday, June 27, 2011 (9:00 AM- 10:30 AM) Room: Phoenix

T02-2: Monday, June 27, 2011 (11:00 AM- 12:30 PM) Room: Phoenix

T03: Theoretical and Practical Aspects of Type-2 Fuzzy Systems: Part 1

Instructor: Jerry Mendel

T03-1: Monday, June 27, 2011 (9:00 AM- 10:30 AM) Room: Crane

T03-2 Monday, June 27, 2011 (11:00 AM- 12:30 PM) Room: Crane

T04: Theoretical and Practical Aspects of Type-2 Fuzzy Systems: Part 2

Instructor: Hani Hagras

T04-1: Monday, June 27, 2011 (01:30 PM- 03:00 PM) Room: Peacock

T04-2: Monday, June 27, 2011 (03:30 PM- 05:00 PM) Room: Peacock

T05: Towards a Unified Framework for Intelligent Robotics

Instructors: Honghai Liu and Naoyuki Kubota

T05-1: Monday, June 27, 2011 (01:30 PM- 03:00 PM) Room: Phoenix

T05-2: Monday, June 27, 2011 (03:30 PM- 05:00 PM) Room: Phoenix

Workshops

W01: Fuzzy Approaches to Ambient Intelligent Agents

Organizers:Vincenzo Loiaand Hani Hagras

W01-1: Monday, June 27, 2011 (9:00 AM- 10:30 AM) Room: Egret

W01-2: Monday, June 27, 2011 (11:00 AM- 12:30 PM) Room: Egret

W02: Standards in Computational Intelligence

Organizers:Giovanni Acampora, PlamenAngelov, and Bruno Di Stefano

W02: Monday, June 27, 2011 (9:00 AM- 10:30 AM) Room: Swallow

W03: Computational Intelligence Techniques for Smart Grids

Organizers:Alfredo Vaccaroand Vladimir Terzija

W03-1: Monday, June 27, 2011 (01:30 PM- 03:00 PM) Room: Crane

W03-2: Monday, June 27, 2011 (03:30 PM- 05:00 PM) Room: Crane

W04: Computer Game and Fuzzy-based Game Applications

Organizers:Shun-Chin Hsu, I-Chen Wu, and Shi-Jim Yen

W04-1: Monday, June 27, 2011 (01:30 PM- 03:00 PM) Room: Egret

W04-2: Monday, June 27, 2011 (03:30 PM- 05:00 PM) Room: Egret

W05: Hybrid Computational Intelligence Applications

Organizers:Chuan-Kang Ting and Tzung-Pei Hong

W05-1: Monday, June 27, 2011 (01:30 PM- 03:00 PM) Room: Swallow

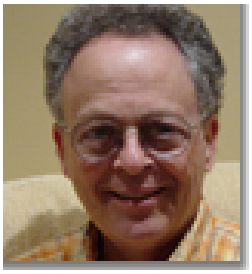
W05-2: Monday, June 27, 2011 (03:30 PM- 05:00 PM) Room: Swallow

Plenary Speech I

Date/Time: Tuesday, June 28, 2011 /1:30 PM- 2:30 PM

Room: Grand Ballroom I, Chair: Chang-Shing Lee

Type-2 Fuzzy Sets and Systems: Challenges and Misconceptions.



Prof. Jerry M. Mendel

University of Southern California, USA

Abstract

Type-2 fuzzy sets and systems have now moved into the mainstream of world-wide research and should no longer be viewed as an "emerging" research area. During the latter part of 2009 and the first half of 2010 a small group of type-2 researchers created a jointly-authored CI Magazine article, whose title is that of this talk. In addition, in April 2011 there were two panel sessions at the Advances in Type-2 Fuzzy Sets and Systems Symposium, that was a part of the IEEE CIS Symposium Series on CI, held in Paris, France. These panel sessions were also on the topics in the title of this talk. In this talk, I will summarize the main conclusions from the magazine article and the two panels (and ensuing discussions) about the challenges and misconceptions of type-2 fuzzy sets and systems. This should be of great interest to researchers who want to know the directions of the vectors of most promising type-2 research.

Biography

Jerry M. Mendel is Professor of Electrical Engineering and Systems Architecting Engineering at the University of Southern California in Los Angeles, where he has been since 1974. He has published over 480 technical papers and is author, co-author and/or editor of nine books, including Uncertain Rule-based Fuzzy Logic Systems: Introduction and New Directions and Perceptual Computing: Aiding People in Making Subjective Judgments (2010). His present research interests include: type-2 fuzzy logic systems and their applications to a wide range of problems, including smart oil field technology and computing with words. He is a Life Fellow of the IEEE, a Distinguished Member of the IEEE Control Systems Society, and a Fellow of the International Fuzzy Systems Association (2009). He was President of the IEEE Control Systems Society in 1986. He was a member of the Administrative Committee of the IEEE Computational Intelligence Society (2004-2009) and was Chairman of its Fuzzy Systems Technical Committee. He is presently Chair of

the Computing With Words Task Force of the IEEE Computational Intelligence Society. Among his awards are the 1983 Best Transactions Paper Award of the IEEE Geoscience and Remote Sensing Society, the 1992 Signal Processing Society Paper Award, the 2002 Transactions on Fuzzy Systems Outstanding Paper Award, a 1984 IEEE Centennial Medal, an IEEE Third Millenium Medal, and a Fuzzy Systems Pioneer Award (2008) from the IEEE Computational Intelligence Society.

Plenary Speech II

Date/Time: Wednesday, June 29, 2011 /1:30 PM- 2:30 PM

Room: Grand Ballroom I, Chair: Faa-Jeng Lin

Soft Computing in Prognostics and Health Management (PHM) Applications: A Case Study in Anomaly Detection

Dr. Piero Bonissone

GE Global Research, USA

Abstract

Soft Computing (SC) is a term that has evolved, since its inception in 1991, to represent a methodology and a set of techniques covering the aspects of data-driven models design, domain knowledge integration, model generation, and model tuning. We distinguish between offline Meta-heuristics (MH's), used for model design and tuning, and online MH's, used for models selection or aggregation. This view suggests the use of hybrid SC at each MH's level as well as at the object level. We manage model complexity by finding the best model architecture to support problem decomposition, generate local models with high-performance in focused applicability regions, provide smooth interpolations among local models, and increase robustness to imperfect data by aggregating diverse models. We illustrate this concept with a case study in anomaly detection for a fleet of physical assets (such as an aircraft engines or a gas turbines.) Anomaly detection typically uses unsupervised learning techniques to extract the underlying structural information from the data, define normal structures and regions, and identify departures from such regions. We focus on one of the most common causes for anomalies: the inadequate accuracy of the anomaly detection models, which are prone to create false alarms. To address this issue, we propose a hybrid approach based on a fuzzy supervisory system and an ensemble of locally trained auto associative neural networks (AANN's.) The design and tuning of this hierarchical model is performed using evolutionary algorithms. In our approach we interpolate among the outputs of the local models (AANN's) to assure smoothness in operating regime transition and provide continuous condition monitoring to the system. Experiments on simulated data from a high bypass, turbofan aircraft engine model demonstrated promising results.

Biography

Piero Bonissone A Chief Scientist at GE Global Research, Dr. Bonissone has been a pioneer in the field of fuzzy logic, AI, soft computing, and approximate reasoning systems applications

since 1979. He is a Coolidge Fellow at GE Global Research (1993). He is also a Fellow of the Association for the Advancement of Artificial Intelligence (1996), the IEEE (2004), and the International Fuzzy Systems Association (2005). He served as Editor in Chief of the International Journal of Approximate Reasoning for 13 years (1993-2005). He co-edited six books and co-authored 150 publications. He received 54 patents issued from the USPTO (plus 50 pending). He has co-chaired 12 scientific conferences and symposia focused on Multi-Criteria Decision-Making, Fuzzy sets, Diagnostics, Prognostics, and Uncertainty Management in AI. In 2002, he was President of the IEEE Neural Networks Society (now Computational Intelligence Society). He has been an Executive Committee member of NNC/NNS/CIS society since the past 16 years and an IEEE CIS Distinguished Lecturer since 2004. In 2008 he received the II Cajastur International Prize for Soft Computing, from CajAstur and the Foundation for the Advancement of Soft Computing. He is the Chair of the Scientific Committee of the European Centre of Soft Computing.

Inferring Disease Related Gene-Gene Interactions: A Fuzzy Logic Based Approach

Prof. Nikhil Pal

Indian Statistical Institute, India

Abstract

There have been many attempts to infer gene-gene interactions from microarray data based on different approaches such as mutual information, Bayesian networks, and differential equations. The gene-gene interactions identified by such methods reveal important and interesting biological functions, but all of these may not be related to a phenotype, say, a particular cancer. In this talk we shall focus on identification of gene-gene interactions, which are related to a particular disease. Two genes individually may be related to a particular cancer but we are not interested in such pairs. The objective here is to identify pairs of genes whose cooperative behavior make them related to the disease. There have been a few attempts to address this problem based on information theoretic concepts. In this talk first we shall discuss the main philosophy behind such approaches and some associated issues/problems. Then we shall present a very simple fuzzy set theoretic method for inferring gene-gene interactions associated to a particular type of disease/cancer. Our method is based on a set of fuzzy rules. The advantages of this fuzzy approach over the existing ones will be discussed. Finally, we shall demonstrate the effectiveness of our method on a benchmark data set.

Biography

Nikhil R. Pal is a Professor in the Electronics and Communication Sciences Unit of the Indian Statistical Institute. He has also served as a Chair Professor at the National Chiao Tung University, Taiwan and as a visiting professor at other universities. He has coauthored, edited/co-edited several books. His current research interest includes bioinformatics, brain science, fuzzy logic, image and pattern analysis, neural networks, and evolutionary computation. He serves on the editorial /advisory board/ steering committee of several journals including the International Journal of Approximate Reasoning, Applied Soft Computing, Neural Information

Processing—Letters and Reviews, International Journal of Knowledge-Based Intelligent Engineering Systems, International Journal of Neural Systems, Fuzzy Sets and Systems ,International Journal of Intelligent Computing in Medical Sciences and Image Processing, Fuzzy Information and Engineering : An International Journal, and the IEEE Transactions on Systems Man and Cybernetics—B. He has been serving as the Editor-in-Chief of the IEEE Transactions on Fuzzy Systems since 2005. He has given many plenary/keynote speeches in different premier international conferences in the area of computational intelligence. He was the president of the Asia Pacific Neural Net Assembly. He was the Program Chair of the 4th International Conference on Advances in Pattern recognition and Digital Techniques, December 1999, Calcutta, India and was a co-program chair of 2005 IEEE International Conference on Fuzzy Systems and 2006 IEEE International Conference on Fuzzy Systems. He was the General Chair of 2002 AFSS International Conference on Fuzzy Systems, Calcutta, 2002 and the 11th International Conference on Neural Information Processing, ICONIP 2004. He is a Fellow of the National Academy of Sciences, India, a Fellow of the Indian National Academy of Engineering, a Fellow of the International Fuzzy Systems Association (IFSA), and a Fellow of the IEEE, USA.

Fuzzy Approaches to Information Fusion

Prof. Bernadette Bouchon-Meunier

University Paris VI, France

Abstract

Fusion is a major issue in all steps of the management of information, from data representation to data mining and decision-making, from basic granules of information to consensus of opinions or semantic interpretation of situations. The complexity of data is due to various factors : heterogeneous media, large size available data on the web or provided by all kinds of sensors, incomplete data bases, imprecise or subjective information granules, the reliability of sources, to mention a few of them. Fuzzy approaches provide interesting solutions to cope with such problems. We will address two main levels in information fusion. The first one is technical and concerns basic needs in image processing, prototype construction or classifier fusion. The second one is more abstract and deals with the interpretation of results, the recognition of high level features in images or videos, or the issue of information scoring.

Biography

Bernadette Bouchon-Meunier is a director of research at the National Center for Scientific Research, head of the department of Databases and Machine Learning in the Computer Science Laboratory of the University Paris 6. Graduate from the Ecole Normale Superieure at Cachan, she received the degrees of B.S. in Mathematics and Computer Science, Ph.D. in Applied Mathematics and D. Sc. in Computer Science from the University of Paris. She is the Editor-in-Chief of the International Journal of Uncertainty, Fuzziness and Knowledge-based Systems (World Scientific), She is also a member of the editorial board of the International Journal of Approximate Reasoning, Fuzzy Sets and Systems, International Journal of Fuzzy Systems, International Journal of Information Technology and Intelligent Computing, Journal of Uncertain Systems. She is the (co)-editor of 21 books and the (co)-author of four books in French and one in vietnamese on Fuzzy Logic and Uncertainty Management in Artificial Intelligence. She is a co-founder and co-executive

director of the International Conference on Information Processing and Management of Uncertainty in Knowledge-based Systems (IPMU) held every other year since 1986. She is an IEEE senior member and an International Fuzzy Systems Association fellow. Her present research interests include approximate and similarity-based reasoning, as well as the application of fuzzy logic and machine learning techniques to decision-making, data mining, risk forecasting, information retrieval and user modelling.

Keynote Speech III

Soft Computing for Hard Pattern Recognition Problems

Prof. Paul Gader

University of Florida, USA

Abstract

A survey of research and development of fuzzy set related approaches for use in difficult applications involving pattern recognition. Approaches include fuzzy clustering, fuzzy k-nearest neighbors, ordered weighted averaging operators, fuzzy integrals, and random sets. Applications will be drawn from medical image and signal analysis, landmine detection, language processing, and hyperspectral image analysis for remote sensing, face recognition, and trace material detection.

Biography

Paul Gader received his Ph.D. in Mathematics for image processing related research in 1986 from the University of Florida. He has worked as a Senior Research Scientist at Honeywell's Systems and Research Center, as a Research Engineer and Manager at the Environmental Research Institute of Michigan, and as a faculty member at the University of Wisconsin - Oshkosh, the University of Missouri - Columbia, and the University of Florida, where he is currently a Professor of Computer and Information Science and Engineering. His research has spanned a number of areas related to image analysis and pattern recognition including applied mathematics, parallel image processing, mathematical morphology, fuzzy and random sets, handwriting recognition, bio-medical image analysis, automatic target recognition, landmine detection, hyperspectral image analysis, and information fusion. He enjoys trying to devise theoretical approaches and translate them into applications and trying to understand what the important issues are in that process.

Invited Talk I

Casual Communication between Robots and Humans based on Robot Technology Middleware and Multimedia Recognition

Prof. Kaoru Hirota

Tokyo Institute of Technology, Japan

Abstract

The Mascot Robot System has been developed by the author's group as a part of the "Development Project for a Common Basis of Next-Generation Robots" sponsored by NEDO (New Energy and industrial technology Development Organization). The main purpose of the mascot robot system is to perform casual communication between robots and humans mainly based on the speech recognition module mounted on household robots. The system is implemented as a network of multi-robots freely connected by RT middleware (RTM). It consists of 5 robots, i.e., 4 fixed robots (placed on a TV, a darts game machine, an information terminal, and a mini-bar) and 1 mobile robot. Each of them includes an eye robot, a speech recognition module, and a notebook PC that controls the robot and the speech recognition module. These robots connect together with a server through the internet by RTM, thus constituting the Robot System. The Mascot Robot System's functioning is demonstrated in an ordinary living room, where casual communication between 5 robots and 4 human beings (1 host, 2 guests, and 1 walk-in) is conducted based on speech recognition and mentality expression of eye robots. The experimental results are shown by DVD files.

The NEDO project is extended to JSPS (Japan Society for Promotion of Science) project ongoing, where computational intelligence based gesture recognition method is proposed and embedded in the mascot robot system to realize casual communication between robots and humans. It utilized both video image data from web camera, voice information by microphone, and motion data given by a wearable 3D acceleration sensor on human wrists to identify the intentions and emotions, i.e., multi media recognition technology. To demonstrate the validity, the proposed method is now applied to a part of a mascot robot system, where a home party scenario performed

by five eye robots and four human participants. On going results show the possibility that the proposed method may be used to improve the interaction between human and robotic systems.

Biography

Kaoru HIROTA received Dr. E. degrees from Tokyo Institute of Technology in 1979. After his career at Sagami Institute of Technology and Hosei University, he has been with Tokyo Institute of Technology. His research interests include fuzzy systems, intelligent robot, and image understanding. He experienced president-elect and fellow of IFSA (International Fuzzy Systems Association), and president of SOFT (Japan Society for Fuzzy Theory and Systems.) He is a chief editor of J. of Advanced Computational Intelligence and Intelligent Informatics. Banki Donat Medal, Henri Coanda Medal, Grigore MOISIL Award, SOFT best paper award, Acoustical Society of Japan best paper award, honorary professorships from de La Salle University and Changchun Univ. of Science & Technology, and Honoris Causa from Bulacan state university, Budapest Technical University, and Szechenyi Istvan University were awarded to him. He organized more than 10 international conferences/symposiums as a founding/general/program chair. He has been publishing about 250 journal papers, 50 books, and 450 conference papers.

Invited Talk II

Date/Time: Wednesday, June 29, 2011 /05:00 PM- 06:00 PM

Room: Swan, Chair: Li-Wei Ko

Acceleration and Scalability for c-Means Clustering

Prof. James Bezdek

University of West Florida, USA

Abstract

This talk begins with characterization the three canonical problems of clustering: tendency assessment (does the data have cluster substructure?); clustering (how do we find partitions of the data?); and validation (are the partitions we find accurate and/or useful?). I identify the four types of models used in clustering: partition only (single linkage); prototype only (self-organizing maps); partition and prototypes (hard, fuzzy and possibilistic c-means); and (partition, prototype, other parameter) models (EM algorithm for Gaussian mixture decomposition). I will give a brief account of the basic models and algorithms for hard, fuzzy, possibilistic c-means. These algorithms are reliable, but can be slow, and may not scale well for very large data sets. So, the main issues when dealing with huge data sets are acceleration and scaling.

There have been many ideas for acceleration of FCM advanced over the years. I will review eight methods that can be used to speed up clustering with FCM when the entire data set is loadable. Included are AFCM, mrFCM, brFCM and a method for acceleration that depends on mounting the algorithm on a GPU instead of a conventional computer. Reported improvements in speed range from 2:1 to 100:1.

The final part of the talk covers two approaches for (approximate) FCM clustering in VL data. First I will discuss two methods that are based on incremental, distributed clustering (spFCM and oFCM). The second set of three methods considers approaches to approximating FCM clusters for VL data by a much different method – viz., sampling followed by non-iterative extension. This general technique can be used for EM and many other algorithms that are not discussed in this talk. The three algorithms are eFFCM (efficient fast FCM for image data); geFFCM (for feature vector data); and eNERF (for relational data). We will have time to look at only eFFCM here.

Biography

James Bezdek Jim received the PhD in Applied Mathematics from Cornell University in 1973. Jim is past president of NAFIPS (North American Fuzzy Information Processing Society), IFSA (International Fuzzy Systems Association) and the IEEE CIS (Computational Intelligence Society): founding editor the Int'l. Jo. Approximate Reasoning and the IEEE Transactions on Fuzzy Systems: Life fellow of the IEEE and IFSA; and a recipient of the IEEE 3rd Millennium, IEEE CIS Fuzzy Systems Pioneer, and IEEE technical field award Rosenblatt medals. Jim's interests: woodworking, optimization, motorcycles, pattern recognition, cigars, clustering in very large data, fishing, visual methods for clustering, blues music, wireless sensor networks, poker and co-clustering in rectangular relational data. Jim retired in 2007, and will be coming to a university near you soon (especially if there is fishing nearby).

Invited Talk III

Date/Time: Wednesday, June 29, 2011 /06:00 PM- 07:00 PM

Room: Swan, Chair: Li-Wei Ko

Activity Summarization from 3D Video Systems in an Eldercare Environment

Prof. Jim Keller

University of Missouri-Columbia, USA

Abstract

This talk concerns eldercare. Older adults are living longer and more fulfilled lives, and they desire to live as independently as possible in the home of their choice. However, independent lifestyles come with risks that are complicated by chronic illness and impairments in mobility, cognition, and the senses. In response to this trend, the University of Missouri has been investigating new approaches in caring for the elderly. This research focus has resulted in TigerPlace, an apartment complex for seniors that opened in Columbia, Missouri in 2004. A joint venture between MU's Sinclair School of Nursing and Americare Systems Inc., TigerPlace is one of four projects granted state approval to operate under the "aging in place" model of care giving. Under that model, residents who would otherwise be required by state law to live in nursing homes may have health services brought to them in their apartments instead. One focus of our large multidisciplinary research team, including faculty and students from Engineering, Nursing, Health Management and Informatics, Medicine, Social Work, and Physical Therapy, is the creation of intelligent systems that use sensors to uncover patterns of activity helpful to caregivers, especially targeting mobility and cognitive impairment. Details can be found at http://eldertech.missouri.edu.

The larger research program fits perfectly into the concept of Recognition Technology, as defined by L. Zadeh, to be current or future systems that have the potential to provide a "quantum jump in the capabilities of today's recognition systems", and includes systems that incorporate new sensors, novel signal processing and soft computing. In this talk, I will concentrate on generating linguistic activity summarization for large amounts of multiple camera video data, depicting activities that might take place in a single person apartment. Using 2 cameras, a 3-D "voxel person" is constructed (made possible by our high speed GPU construction of silhouettes from image sequences), and sophisticated position and shape features are calculated. A hierarchical fuzzy logic system is built to determine memberships in various states, followed by another set of rules to classify activities (early focus on fall detection). Extensions to a fuzzy voxel person to model the

uncertainty of reconstruction in some areas of the field of view will be discussed. Additionally, we have recently investigated and constructed a real time multiple stereo camera system that produces true depth-based 3-D objects, providing comprehensive models of the environment and the human within it. This representation is completely insensitive to (even abrupt) lighting changes and shadows, incorporates a human detector that provides false alarm reduction for change detection regarding movement of nonhuman objects (e.g. chairs) and objects manipulated by a person, and has a natural way to address tracking and updating, i.e. not adapting stationary humans into the background while still absorbing moved objects even under significant lighting variations.

Biography

Jim Keller James M. Keller received the Ph.D. in Mathematics in 1978. He holds the University of Missouri Curators' Professorship in the Electrical and Computer Engineering and Computer Science Departments on the Columbia campus. He is also the R. L. Tatum Professor in the College of Engineering. His research interests center on computational intelligence: fuzzy set theory and fuzzy logic, neural networks, and evolutionary computation with a focus on problems in computer vision, pattern recognition, and information fusion including bioinformatics, spatial reasoning in robotics, geospatial intelligence, sensor and information analysis in technology for eldercare, and landmine detection. His industrial and government funding sources include the Electronics and Space Corporation, Union Electric, Geo-Centers, National Science Foundation, the Administration on Aging, The National Institutes of Health, NASA/JSC, the Air Force Office of Scientific Research, the Army Research Office, the Office of Naval Research, the National Geospatial Intelligence Agency, the Leonard Wood Institute, and the Army Night Vision and Electronic Sensors Directorate. Professor Keller has coauthored over 350 technical publications.

Jim is a Fellow of the Institute of Electrical and Electronics Engineers (IEEE) for whom he has presented live and video tutorials on fuzzy logic in computer vision, is an International Fuzzy Systems Association (IFSA) Fellow, an IEEE Computational Intelligence Society Distinguished Lecturer, a national lecturer for the Association for Computing Machinery (ACM) from 1993 to 2007, and a past President of the North American Fuzzy Information Processing Society (NAFIPS). He received the 2007 Fuzzy Systems Pioneer Award and the 2010 Meritorious Service Award from the IEEE Computational Intelligence Society. He finished a full six year term as Editor-in-Chief of the IEEE Transactions on Fuzzy Systems, is an Associate Editor of the International Journal of Approximate Reasoning, and is on the editorial board of Pattern Analysis and Applications, Fuzzy Sets and Systems, International Journal of Fuzzy Systems, and the Journal of Intelligent and Fuzzy Systems. Jim was the Vice President for Publications of the IEEE Computational Intelligence Society from 2005-2008, and is currently an elected Adcom member. He was the conference chair of the 1991 NAFIPS Workshop, program co-chair of the 1996 NAFIPS meeting, program co-chair of the 1997 IEEE International Conference on Neural Networks, and the program chair of the 1998 IEEE International Conference on Fuzzy Systems. He was the general chair for the 2003 IEEE International Conference on Fuzzy Systems.

Panel Sessions

PASI: Interpolation and Approximation in Fuzzy Rule Bases

Organizer and Chair: Laszlo Koczy

Panelists: Kaoru Hirota, Qiang Shen, Christophe Marsala, Mathieu Serrurier, Laszlo Koczy

Tuesday, June 28, 2011 (8:00 AM- 10:20 AM) Room: Grand Ballroom I

Human vs. Computer Go Competition

Description

The technique of Monte Carlo Tree Search (MCTS) has revolutionized the field of computer game-playing, and is starting to have an impact in other search and optimization domains as well. In past decades, the dominant paradigm in game algorithms was alpha-beta search. This technique, with many refinements and game-specific engineering, lead to breakthrough performances in classic board games such as chess, checkers and Othello. After Deep Blue's famous victory over Kasparov in 1996, some of the research focus shifted to games where alpha-beta search was not sufficient. Most prominent among these games was the ancient Asian game of Go. During the last few years, the use of MCTS techniques in Computer Go has really taken off, but the groundwork was laid much earlier. In 1990, Abramson [1] proposed to model the expected outcome of a game by averaging the results of many random games. In 1993, Bruegmann [2] proposed Monte-Carlo techniques for Go using almost random games, and developed the refinement he termed all-moves-as-first (AMAF). Ten years later, a group of French researchers working with Bruno Bouzy took up the idea [3]. Bouzy's Indigo program used Monte-Carlo simulation to decide between the top moves proposed by a classical knowledge-based Go engine [4]. RemiCoulom's Crazy Stone [5] was the first to add the crucial second element, a selective game tree search controlled by the results of the simulations. he last piece of the puzzle was the Upper-Confidence Tree (UCT) algorithm of Kocsis and Szepesvari [6], which applied ideas from the theory of multi-armed bandits to the problem of how to selectively grow a game tree. Gelly and Wang developed the first version of MoGo [7], which among other innovations combined Coulom's ideas, the UCT algorithm, and pattern-directed simulations. AMAF was revived and extended in Gelly and Silver's Rapid Action Value Estimate (RAVE), which computes AMAF statistics in all nodes of the UCT tree. Rapid progress in applying knowledge and parallelizing the search followed. Today, programs such as MoGo/MoGoTW, Crazy Stone, Fuego, Many Faces of Go, and Zen have achieved a level of play that seemed unthinkable only a decade ago. These programs are now competitive at a professional level for 9×9 Go and amateur Dan strength on 19×19 [4], [8].

One measure of success is competitions. In Go, Monte-Carlo programs now completely dominate classical programs on all board sizes (though no one has tried boards larger than 19×19). Monte-Carlo programs have achieved considerable success in play against humans. An early sign of things to come was a series of games on a 7×7 board between Crazy Stone and professional 5th Dan Guo Juan. Crazy Stone demonstrated almost perfect play. Since 2008, National University of Tainan (NUTN) in Taiwan and other academic organizations have hosted or organized several human vs. computer Go-related events, including the 2008 Computational Intelligence Forum & World 9×9 Computer Go Championship [8], and 2009 Invited Games for MoGo vs. Taiwan Professional Go Players (Taiwan Open 2009) [9]. Besides, the FUZZ-IEEE 2009: Panel, Invited Sessions, and Human vs. Computer Go Competition [10] was held at the 2009 International Conference on Fuzzy Systems in Aug. 2009. This event was the first human vs. computer Go competition hosted by the IEEE Computational Intelligence Society (CIS) at the IEEE CIS flag conference. In 2010, MoGo and Many Faces of Go achieved wins against strong amateur players on 13×13 with only two handicap stones. On the full 19×19 board, programs have racked up a number of wins (but still a lot more losses) on 6 and 7 handicap stones against top professional Go players [11], [12]. Also, computer Go Programs have won both as White and Black against top players in 9×9 game [13]. Additionally, in April 2011, MoGoTW broke a new world record by winning the first 13×13 game against the 5th Dan professional Go player with handicap 3 and reversed komi of 3.5. It also won 3 out of 4 games of Blind Go in 9×9.

Date
June 27-June 29, 2011

Place
Magpie Room

Human
More than 10 Taiwanese Professional Go Players will join this competition

- Chun-Hsun Chou (9P)
- Ping-Chiang Chou (5P)
- Joanne Missingham (5P)
- Other 10 professional Go players

Computer Go Program

- MoGo/MoGoTW (France / Taiwan)
- Fuego (Canada)
- Many Faces of Go (USA)
- Zen (Japan)

Organizers

- IEEE / IEEE Computational Intelligence Society (CIS)
- National University of Tainan (NUTN), Taiwan
- INRIA, France
- National Science Council (NSC), Taiwan
- Grid 5000 Project, France
- Taiwanese Association for Artificial Intelligence (TAAI), Taiwan
- Taiwan Association of Cloud Computing (TACC), Taiwan

Co-Chairs

- Chang-Shing Lee, National University of Tainan, Taiwan
- Martin Mueller, University of Alberta, Canada
- Olivier Teytaud, TAO-Inria, France
- Shun-Chin Hsu, Chang Jung Christian University, Taiwan

Potential List of Panelists: (tentative)

- Chang-Shing Lee, National University of Tainan, Taiwan
- Martin Mueller, University of Alberta, Canada

- Wen-Yang Lin, National University of Kaohsiung, Taiwan
- Olivier Teytaud, TAO-Inria, France
- Kuo-Ning Chiang, National Center for High-Performance Computing, Taiwan
- Hani Hagras, University of Essex, UK
- Tzung-Pei Hong, National University of Kaohsiung, Taiwan
- Vincenzo Loia, University of Salerno, Italy
- Shi-Jim Yen, National Dong Hwa University, Taiwan
- Gary Yen, Oklahoma State University, USA
- Shun-Chin Hsu, Chang Jung Christian University, Taiwan
- Piero Bonissone, GE Global Research, USA
- Shang-Rong Tsai, Chang Jung Christian University, Taiwan
- Giovanni Acampora, University of Salerno, Italy
- Yeh-Ching Chung, National TsingHua University, Taiwan
- Fabien Teytaud, TAO-Inria, France
- Chun-Nan Hsu, Academia Sinica, Taiwan
- Yau-Hwang Kuo, National Cheng-Kung University, Taiwan

Fuzzy Competition

Date

11:00 AM-12:30 PM, June 27, 2011

Place

Swallow Room

Organizers

- IEEE / IEEE Computational Intelligence Society (CIS)
- Task Force on Competitions of the IEEE CIS's Fuzzy Systems Technical Committee

Co-Chairs

- Hao Ying, Wayne State University, USA
- Plamen Angelov, Lancaster University, UK
- Mohammad Biglarbegian, Ryerson University, Canada
- Asli Celikyilmaz, Microsoft Research, USA
- Xinyu Du, Wayne State University, USA
- Dimitar Filev, Ford Motor Company, USA
- Yanqing Ji, Gonzaga University, USA
- Zhao Lu, Tuskegee University, USA
- Edwin Lughofer, Johannes Kepler University of Line, Austria
- Fazal U. Syed, Ford Motor Company, USA
- Tadanari Taniguchi, Tokai University, Japan
- Xiao-Jun Zeng, University of Manchester, UK
- Haibo Zhou, Central South University, China

General Information

Conference Location

The registration, tutorials, workshops, plenary speeches, keynotes, invited talks, competition, and technical sessions are all held at 3F, Grand Hyatt Taipei, Taipei, Taiwan.

Social Programs

- Welcome Reception: 6:00 PM- 9:00 PM, Monday, June 27, 2011
  Venue: Gordon Biersch (GB) Brewery Restaurant, 2F, No.11, Songshou Rd., Xinyi District, Taipei City
- Opening Ceremony: 10:50 AM, Tuesday, June 28, 2011
  Room/Venue: Grand Ballroom I, 3F, Grand Hyatt Taipei Hotel
- Banquet: 7:30 PM-10:00 PM, Wednesday, June 29, 2011
  Room/Venue: Grand Ballroom II, 3F, Grand Hyatt Taipei Hotel

Internet Access

Free internet access is available at 3F, Grand Hyatt Taipei Hotel. There will be tables and chairs for delegates to relax and have discussions.

Conference Venue

- **Introduction to Taiwan**

Taiwan is a medium-sized archipelago in East Asian. It is located off the southeastern coast of China, at the western edge of the Pacific Ocean, between Japan and the Philippines. The Central Mountain Range divides the east and west coasts and stretches from north to south. A wonderful variety of geo-graphical contrasts exist: mountains, hills, plateaus, plains, basins, and coastline, all in which a diversity of unique flora and fauna thrive. Taipei is the capital of Taiwan. Fig. 1 shows basic information of Taiwan. Taiwan was first known to the West as Ilha Formosa or Beautiful Island.

Fig. 1. Taiwan geographical location.

Taiwan has many tourist attractions such as (1) Taipei 101: The world's tallest certified building; (2) Yushan National Park: the highest mountain in Northeast Asia (Yushan means Mt. Jade); (3) National Palace Museum: one of the five top museums in the world; (4) Taroko National Park: the world-class natural landscapes. We also have some of the friendliest people in the world, 24-hour bookstores and convenience shops, and hustling and bustling night markets—all of which imprint indelible memories in the minds of visitors. Taiwan also has the advantage of convenient transportation and an excellent travel environment that you will want to enjoy again and again. For example, Taiwan High Speed Rail (THSR) makes the tourists easier extend their journey from Taipei to Kaohsiung (the biggest city in southern Taiwan) and it only takes 90 minutes by THSR. For more detailed tourist attractions in Taiwan, the FUZZ-IEEE 2011 attendances can connect to Taiwan Tourism Bureau.

- **Introduction to Taipei**

Taipei is located in the valley of the Danshui River in northern Taiwan. It is Taiwan's capital, as well as Taiwan's busy center of commerce, government, and culture. Taipei itself has a population of almost 3 million and it has 12 administrative districts, listed in Fig. 2. In addition, Taipei also provides Taipei Metro with eight lines: Muzha Line, Danshui Line, Zhonghe Line, Xindian Line, Banqiao Line, Nangang Line, Tucheng Line, and Xiaonanmen Line. Fig. 3 shows the Map of Taipei Metro and also indicates some of the Taipei's most popular attraction areas' locations, including Taipei 101, National Palace Museum, Longshan Temple, ShiLin Night Market, Yangmingshan National Park, Beitou Hot Springs, Danshui Fisherman's Wharf, and Bitan Scenic Area.

Fig. 2. District Map of Taipei.

Fig. 3. Map of Taipei Metro.

- **Introduction to Grand Hyatt Taipei**

The conference venue is Grand Hyatt Taipei, which is situated in the foothills of eastern Taipei's XinYi District, an area where the modern face of Taipei shines with glass and steel skyscrapers, one of the tallest buildings in the world (Taipei 101), wide boulevards, and the Taipei World Trade Center complex.The Grand Hyatt Taipei is located in heart of the Taipei, a burgeoning business, shopping and entertainment district, and it is 45 minutes drive from the Taoyuan International Airport. As the political, economic, and cultural center of Taipei, the district houses many landmark buildings, including the Taipei City Hall, Taipei City Council, Sun Yat-Sen Memorial Hall, and Taipei 101. Additionally, the local attractions include National Palace Museum, Shihlin Night Market, Yangmingshan National Park, Lungshan Temple, and Chiang Kai-shek Memorial Hall. Taipei is the capital of Taiwan and is its largest city. Located to the north, its proximity and accessibility to Taiwan's business and production regions is just as appealing as the national parks and eco-reserves that surround and exist within the city itself. Fig. 4 shows the map near Grand Hyatt Taipei.

Fig. 4. Map near Grand Hyatt Taipei.

Transportation Information

Venue: Grand Hyatt Taipei

Address: 2, Songshou Rd., Taipei 11051, Taiwan

Tel: +886-2-2720-1234

Fax: +886-2-2720-1111

Email: taipei.grand@hyatt.com

Website: http://taipei.grand.hyatt.com

From Taiwan Taoyuan International Airport

TPE Airport offers you various direct connections to downtown Taipei. You may select one of the following transportation to arrive at Grand Hyatt Taipei.

Airport Bus

It offers an easy access to the Taiwan Taoyuan International Airport. Fig. 5 shows the Toward You Air Bus (East Line) transportation how to get to the Grand Hyatt Taipei from the Taiwan Taoyuan International Airport and it's about 45-minute ride.

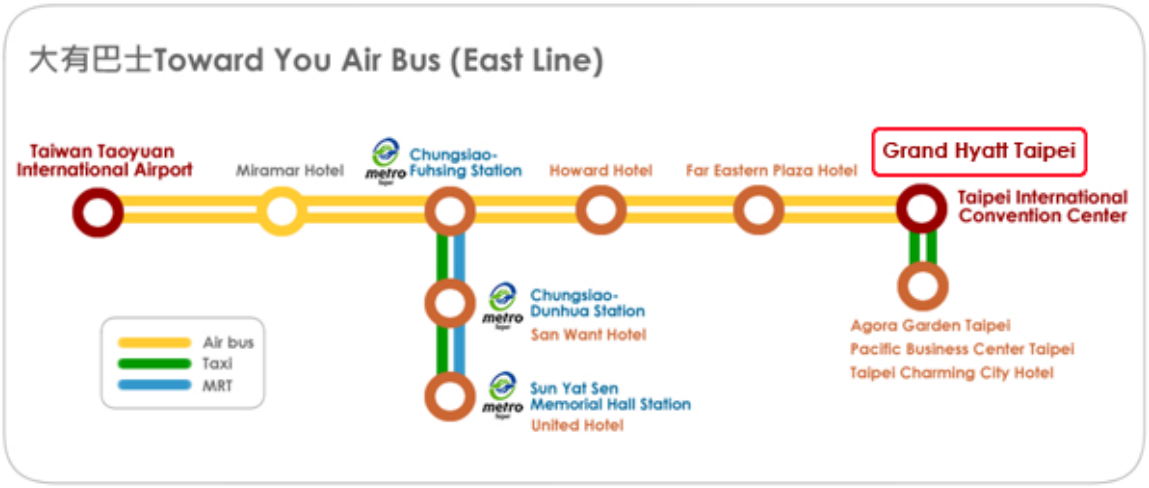

Fig. 5. Toward You Air Bus (East Line) transportation to Grand Hyatt Taipei hotel.

Airport Taxi

Taxi queues are outside the Arrival Halls of both terminals. To ensure the safety of passengers, only the taxis approved by the Aviation Police Bureau are permitted to operate in Taoyuan Airport. The average fare (plus surcharge) to Taipei is about NT$1,200.

Access Grand Hyatt Taipei

By Bus

1. Take bus No. 207, 537, or Blue 5 to TWTC stop, and walk toward Jilong (Keelung) Road.
2. Take bus No. 1, 284, 292, 611, or 650 to TWTC stop, and walk toward Xinyi Road.

By Metro

Take Metro Banqiao Nagang Line (Blue Line) to Taipei City Hall Station, exit at Exit 2 and take Keelung Rd., join onto Songgao Rd., and turn right to Shihfu Rd., then walk toward Xinyi Road. You will see Grand Hyatt Taipei (please refer to Fig. 6 Location Map of Grand Hyatt Taipei).

Fig. 6. Location Map of Grand Hyatt Taipei hotel.

2011 IEEE International Conference on Fuzzy Systems (FUZZ-IEEE 2011)
Timetable

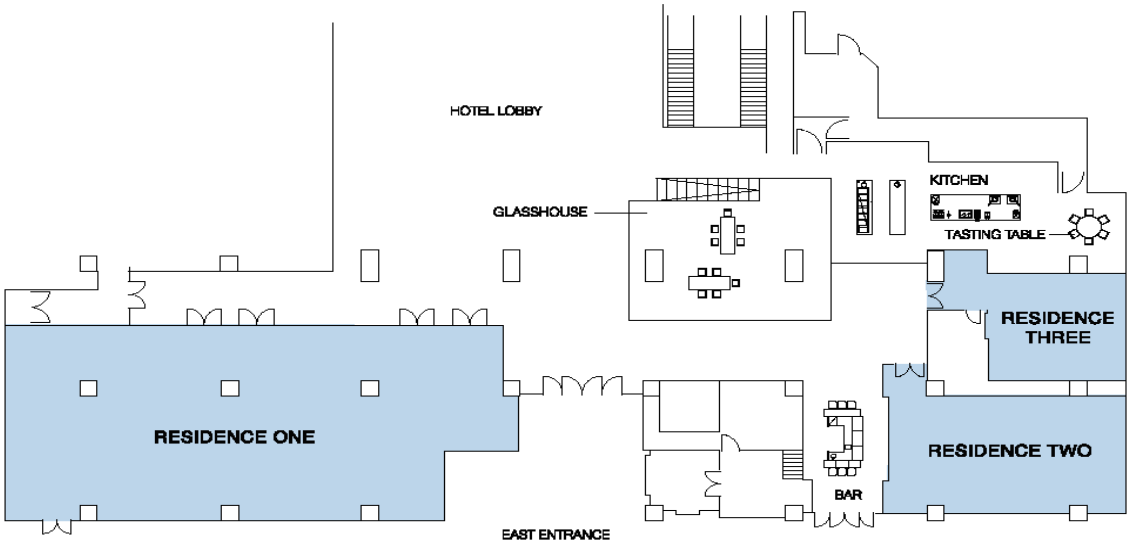
Monday, June 27, 2011						
Time	**Peacock**	**Phoenix**	**Crane**	**Egret**	**Swallow**	**Magpie**
8:00 AM **5:00 PM**	Registration					
9:00 AM **10:30 AM**	**T01-1** Evolutionary Multi-Objective Design of Fuzzy Rule-Based Systems **Rafael Alcala**	**T02-1** Interpolative Fuzzy Rule Bases **László Koczy**	**T03-1** Theoretical and Practical Aspects of Type-2 Fuzzy Systems: Part 1 **Jerry Mendel**	**W01-1** Fuzzy Approaches to Ambient Intelligence **SS06** Intelligent Agents	**W02** Standards in Computational Intelligence	**HCGC-1** Human vs. Computer Go Competition
10:30 AM **11:00 AM**	Coffee Break					
11:00 AM **12:30 PM**	**T01-2** Evolutionary Multi-Objective Design of Fuzzy Rule-Based Systems **Rafael Alcala**	**T02-2** Interpolative Fuzzy Rule Bases **László Koczy**	**T03-2** Theoretical and Practical Aspects of Type-2 Fuzzy Systems: Part 1 **Jerry Mendel**	**W01-2** Fuzzy Approaches to Ambient Intelligence **SS06** Intelligent Agents	**FC** Fuzzy Competition	
12:30 PM **1:30 PM**	Lunch Break					
1:30 PM **3:00 PM**	**T04-1** Theoretical and Practical Aspects of Type-2 Fuzzy Systems: Part 2 **Hani Hagras**	**T05-1** Towards a Unified Framework for Intelligent Robotics **Honghai Liu** **Naoyuki Kubota**	**W03-1** Computational Intelligence Techniques for Smart Grids	**W04-1** Computer Game and Fuzzy-based Game Applications	**W05-1** Hybrid Computational Intelligence Applications	
3:00 PM **3:30 PM**	Coffee Break					
3:30 PM **5:00 PM**	**T04-2** Theoretical and Practical Aspects of Type-2 Fuzzy Systems: Part 2 **Hani Hagras**	**T05-2** Towards a Unified Framework for Intelligent Robotics **Honghai Liu** **Naoyuki Kubota**	**W03-2** Computational Intelligence Techniques for Smart Grids	**W04-2** Computer Game and Fuzzy-based Game Applications	**W05-2** Hybrid Computational Intelligence Applications	
6:00 PM	Welcome Reception					

	Tuesday, June 28, 2011								
Time	**Swan**	**Peacock**	**Phoenix**	**Crane**	**Egret**	**Swallow**	**Grand Ballroom I**	**Grand Ballroom II**	**Magpie**
8:00 AM 5:00 PM	Registration								
8:00 AM 10:20 AM	**SS02-1** Evolutionary Fuzzy Systems	**SS12-1** Recent Advances in Fuzzy-Model-Based Control Systems	**SS14** Advances in Fuzzy Theory and their Applications	**SS28-1** Current Development in Pattern Classification-Kernelization, Pairwise Constraints, and Classifiers	**SS16** Fuzzy Interpolation **SS11** Large-Scale Clustering	**T2FL & FPR** Type-2 Fuzzy Logic and Fuzzy Pattern Recognition	**Panel Session I** Interpolation and Approximation in Fuzzy Rule Bases	**FA-1** Fuzzy Applications	**HCGC-2** Human vs. Computer Go Competition
10:20 AM 10:50 AM	Coffee Break								
10:50 AM 12:00 PM	**Opening Ceremony & Keynote Speech I** Inferring Disease Related Gene-Gene Interactions: A Fuzzy Logic Based Approach **Nikhil Pal** Place: Grand Ballroom I Chair: Jyh-Yeong Chang								
12:00 PM 1:30 PM	Lunch Break IEEE TFS AE Lunch Meeting (TFS AE only) IEEE WCI Lunch Meeting								
1:30 PM 2:30 PM	**Plenary Speech I** Type-2 Fuzzy Sets and Systems: Challenges and Misconceptions **Jerry M. Mendel** Place: Grand Ballroom I Chair: Chang-Shing Lee								
2:30 PM 2:50 PM	Break							**PS01** Poster Session I	
2:50 PM 4:30 PM	**SS05** Fuzzy Robotics	**SS18** Recent Advances in Fuzzy Logic in Image Processing	**SS27** Communication Robotics and Computational Intelligence Co-creation	**SS28-2** Current Development in Pattern Classification-Kernelization, Pairwise Constraints, and Classifiers	**SS42-1** Fuzzy Cognitive Maps-Theory and Applications	**SS21-1** Fuzzy Control in Industrial and Application	**Invited Panel Session** Birth and Evolution of Fuzzy Logic		
4:30 PM 5:00 PM	Coffee Break							**PS02** Poster Session II	
5:00 PM 7:00 PM	**SS10-1** Medical and Wellness Engineering	**SS09** Applications of Fuzzy Logic to Awareness Promotion	**SS08** Innovative Fuzzy Approaches to Management Engineering	**SS37** Fuzzy Logic Based Computer Vision and Its Applications to Guidance and Control	**SS17-1** Practical and Applications Aspects of Type-2 Fuzzy Logic Systems	**SS19** Fuzzy Inference Systems-Theory and Applications	**Panel Session II** Computing With Words		

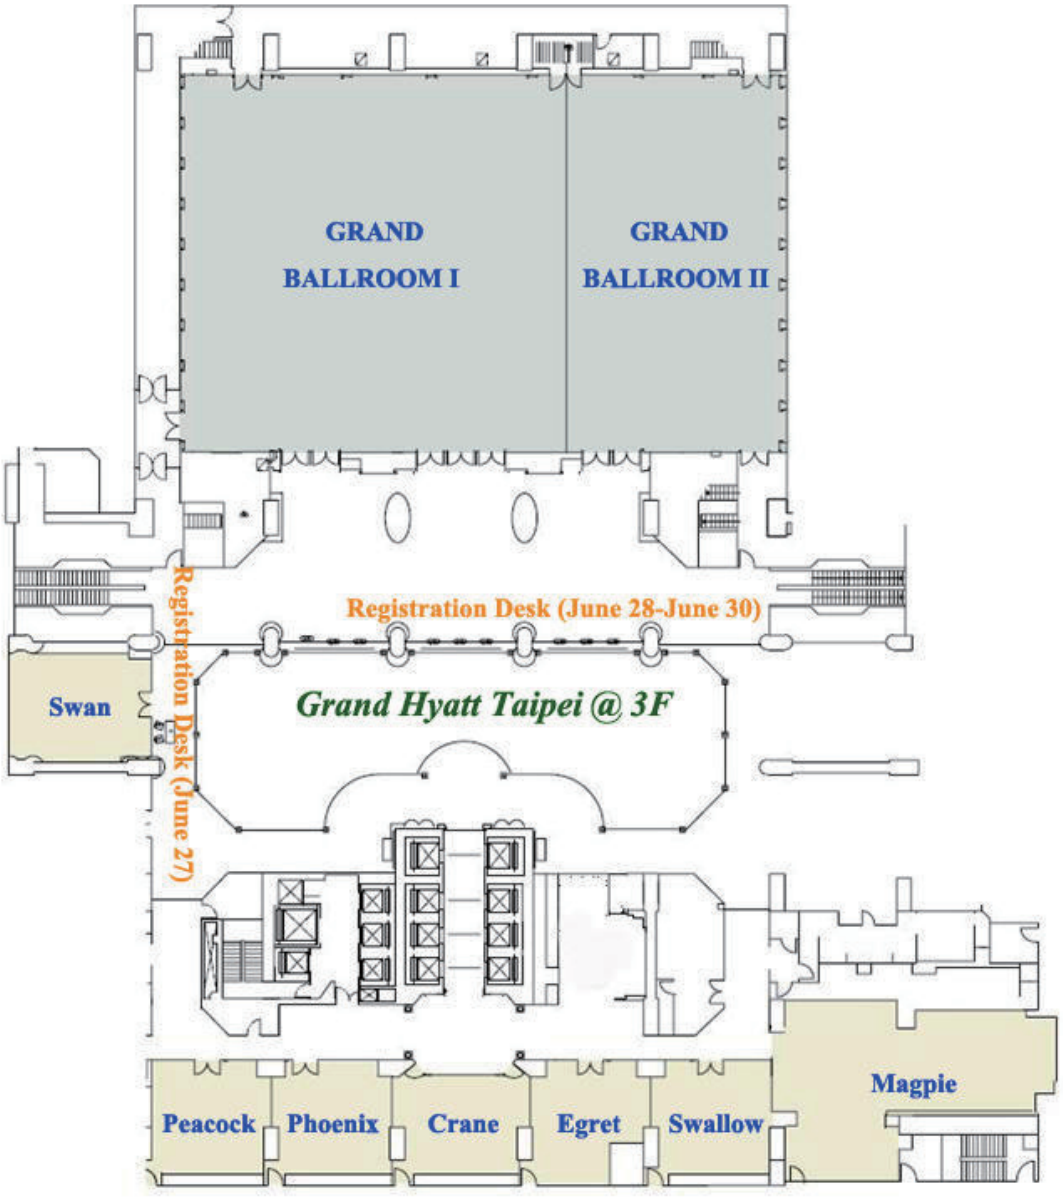
	Wednesday, June 29, 2011								
Time	**Swan**	**Peacock**	**Phoenix**	**Crane**	**Egret**	**Swallow**	**Grand Ballroom I**	**Grand Ballroom II**	**Magpie**
8:00 AM 5:00 PM	Registration								
8:00 AM 9:00 AM	**SS02-2** Evolutionary Fuzzy Systems	**SS12-2** Recent Advances in Fuzzy-Model-Base d Control Systems	**SS31** Human Symbiotic Systems	**FC&IS** Fuzzy Control and Intelligent Systems	**SS10-2** Medical and Wellness Engineering	**SS13-1** Fuzzy Multiple Criteria Decision Making	**Invited Talk I** Casual Communication between Robots and Humans based on Robot Technology Middleware and Multimedia Recognition **Kaoru Hirota** Chair: Yau-Hwang Kuo	**FA-2** Fuzzy Applications	**HCGC-3** Human vs. Computer Go Competition
9:00 AM 10:20 AM									
10:20 AM 10:50 AM	Coffee Break								
10:50 AM 12:00 PM	**Keynote Speech II** Fuzzy Approaches to Information Fusion **Bernadette Bouchon-Meunier** Place: Grand Ballroom I Chair: Chia-Feng Juang								
12:00 PM 1:30 PM	Lunch Break IEEE FSTC Lunch Meeting								
1:30 PM 2:30 PM	**Plenary Speech II** Soft Computing in Prognostics and Health Management (PHM) Applications: A Case Study in Anomaly Detection **Piero Bonissone** Place: Grand Ballroom I Chair: Faa-Jeng Lin								
2:30 PM 2:50 PM	Break							**PS03** Poster Session III	
2:50 PM 4:30 PM	**SS20** Universal Contents Creation/Distribution and Intelligent System	**SS03** Uncertainty and the Semantic Web	**SS04** Soft Computing for Operations Research and Optimization	**SS01** Fuzzy Ontologies and FML Applications	**SS42-2** Fuzzy Cognitive Maps-Theory and Applications	**SS21-2** Fuzzy Control in Industrial and Application			
4:30 PM 5:00 PM	Coffee Break							**PS04** Poster Session IV	
5:00 PM 6:00 PM	**Invited Talk II** Acceleration and Scalability for c-Means Clustering **James Bezdek** Chair: Li-Wei Ko	**SS40** Fuzzy Approach for Information Security Management	**SS38** Fuzzy Knowledge Discovery and Its Applications	**SS39** Fuzzy Based Computation on Biomedical Systems	**SS17-2** Practical and Applications Aspects of Type-2 Fuzzy Logic Systems	**SS30** Computing With Words **SS43** Fuzzy Systems of Unknown Nonlinear Complex Systems			
6:00 PM 7:00 PM	**Invited Talk III** Activity Summarization from 3D Video Systems in an Eldercare Environment **Jim Keller** Chair: Li-Wei Ko								
7:30 PM		Conference Banquet Place: Grand Ballroom I							

Thursday, June 30, 2011							
Time	**Swan**	**Peacock**	**Phoenix**	**Crane**	**Egret**	**Swallow**	**Magpie**
8:00 AM **5:00 PM**	Registration						
8:00 AM **10:20 AM**	**SS23** Industrial Applications of Evolving Fuzzy Systems	**MFI & RWA** Medical, Financial, Industrial and Other Real World Applications	**FSM & IS** Fuzzy Systems Modeling and Intelligent Systems	**FST & GC** Fuzzy Set Theory and Granular Computing	**SS36-1** Fuzzy Systems on Renewable Energy	**FS & FDM** Fuzzy Clustering and Fuzzy Data Mining	**HA** Hybrids and Other Applications
10:20 AM **10:50 AM**	Coffee Break						
10:50 AM **12:00 PM**	**Keynote Speech III** Soft Computing for Hard Pattern Recognition Problems **Paul Gader** Place: Grand Ballroom I Chair: Jung-Hsien Chiang						
12:00 PM **1:30 PM**	Lunch Break						
1:30 PM **2:30 PM**	**FOD** Fuzzy Optimization and Design	**FO & FEC** Fuzzy Optimization and Fuzzy Emotional Computing	**RS & RDA** Rough Sets and Rough Data Analysis	**T2FL** Type-2 Fuzzy Logic	**SS36-2** Fuzzy Systems on Renewable Energy	**FDM&DSS-1** Fuzzy Decision Making and Decision Support Systems	**HFS** Hybrid Fuzzy Systems
2:30 PM **2:50 PM**	Break						
2:50 PM **4:30 PM**	**SS29** Software Engineering with Computational Intelligence	**SS34** Brain and Learning	**SS35** Fuzzy Regression Analysis and Its Applications	**SS41** Neuro Fuzzy Systems and Their Real World Application	**SS25** Evolving and Adaptive Fuzzy Systems	**SS24** Hybrid Learning for Fuzzy Systems	**SS32** Adaptive Fuzzy Logic Control
4:30 PM **5:00 PM**	Coffee Break						
5:00 PM **6:00 PM**	**SS22** Fuzzy Methods in Machine Learning and Data Mining	**FCW & PT** Fuzzy Computing with Words and Possibility Theory	**SS07** Metaheuristics and Its Applications **SS33** Fuzzy and Paraconsistent Intelligent Systems	**IA** Informatics and Analytics	**SS13-2** Fuzzy Multiple Criteria Decision Making	**FDM&DSS-2** Fuzzy Decision Making and Decision Support Systems	

Venue Floor Plan



THE GRAND RESIDENCE – LOBBY LEVEL



All Session Rooms Are at 3rd Floor, Grand Hyatt Taipei

Technical Program Schedule

DETAILED PROGRAM

Monday, June 27, 9:00AM-10:30AM

(T01-1) Tutorial: Evolutionary Multi-Objective Design of Fuzzy Rule-Based Systems
Monday, June 27, 9:00AM-10:30AM, Room: Peacock, Instructor: Rafael Alcala

(T02-1) Tutorial: Interpolative Fuzzy Rule Bases
Monday, June 27, 9:00AM-10:30AM, Room: Phoenix, Instructor: László Koczy

(T03-1) Tutorial: Theoretical and Practical Aspects of Type-2 Fuzzy Systems: Part 1
Monday, June 27, 9:00AM-10:30AM, Room: Crane, Instructor: Jerry Mendel

(W01-1/SS06) Workshop: Fuzzy Approaches to Ambient Intelligence/Intelligent Agents
Monday, June 27, 9:00AM-10:30AM, Room: Egret, Chair: Vincenzo Loia and Hani Hagras

9:00AM ***Gesture-Based Hybrid Approach for HCI in Ambient Intelligent Environments*** *[#543]*
Stefano Carrino, Elena Mugellini, Omar Abou Khaled and Rolf Ingold

9:20AM ***Understanding the Unknown: Unattested Input Processing in Natural Language*** *[#446]*
Julia M. Taylor and Victor Raskin

9:40AM ***A Fuzzy Agent-based Approach to Trust-based Competency Management*** *[#424]*
Matteo Gaeta, Francesco Orciuoli, Sabrina Senatore and Vincenzo Loia

10:00AM ***Open discussion on current and future trends on Fuzzy Approaches to Ambient Intelligence and Intelligent Agents***

(W02) Workshop: Standards in Computational Intelligence
Monday, June 27, 9:00AM-10:30AM, Room: Swallow, Chair: Plamen Angelov, Giovanni Acampora and Bruno Di Stefano

9:00AM ***New Evolution Algorithm Based On The Standard Particle Swarm Optimization*** *[#166]*
Lipeng Wang, Yangjie Cheng and Liu Dong C

(HCGC-1) Competition: Human vs. Computer Go Competition
Monday, June 27, 9:00AM-10:30AM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Monday, June 27, 11:00AM-12:30PM

(T01-2) Tutorial: Evolutionary Multi-Objective Design of Fuzzy Rule-Based Systems
Monday, June 27, 11:00AM-12:30PM, Room: Peacock, Instructor: Rafael Alcala

(T02-2) Tutorial: Interpolative Fuzzy Rule Bases
Monday, June 27, 11:00AM-12:30PM, Room: Phoenix, Instructor: László Koczy

(T03-2) Tutorial: Theoretical and Practical Aspects of Type-2 Fuzzy Systems: Part 1
Monday, June 27, 11:00AM-12:30PM, Room: Crane, Instructor: Jerry Mendel

(W01-2/SS06) Workshop: Fuzzy Approaches to Ambient Intelligence/Intelligent Agents
Monday, June 27, 11:00AM-12:30PM, Room: Egret, Chair: Vincenzo Loia and Hani Hagras

11:00AM ***Intrusion Detection Systems Adapted from Agent-based Artificial Immune Systems*** *[#375]*
Chung-Ming Ou, Yao-Tien Wang and C.R. Ou

11:20AM ***An Adaptive Multi-Agent Memetic System for Personalizing e-Learning Experiences*** *[#309]*
Giovanni Acampora, Matteo Gaeta, Enrique Munoz and Autilia Vitiello

11:40AM ***A hybrid context aware system for tourist guidance based on collaborative filtering*** *[#425]*
Giuseppe Fenza, Enrico Fischetti, Domenico Furno and Vincenzo Loia

12:00AM ***Trainable Estimators for Indirect People Counting: A Comparative Study*** *[#473]*
Giovanni Acampora, Vincenzo Loia, Gennaro Percannella and Mario Vento

(FC) Competition: Fuzzy Competition
Monday, June 27, 11:00AM-12:30PM, Room: Swallow, Chair: Hao Ying

11:00AM ***A TSK Neuro-Fuzzy Approach for Modeling Highly Dynamic Systems*** *[#475]*
Giovanni Acampora

(HCGC-2) Competition: Human vs. Computer Go Competition
Monday, June 27, 11:00AM-12:30PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Monday, June 27, 1:30PM-3:00PM

(T04-1) Tutorial: Theoretical and Practical Aspects of Type-2 Fuzzy Systems: Part 2
Monday, June 27, 1:30PM-3:00PM, Room: Peacock, Instructor: Hani Hagras

(T05-1) Tutorial: Towards a Unified Framework for Intelligent Robotics
Monday, June 27, 1:30PM-3:00PM, Room: Phoenix, Instructor: Honghai Liu and Naoyuki Kubota

(W03-1) Workshop: Computational Intelligence Techniques for Smart Grids
Monday, June 27, 1:30PM-3:00PM, Room: Crane, Chair: Alfredo Vaccaro

1:30PM ***A Bacterial Foraging PSO - DE Algorithm for Solving Reserve Constrained Dynamic Economic Dispatch Problem*** *[#286]*
Praveena Pillala, Vaisakh Kanchapogu and Rama Mohana Rao Sanchana

1:50PM ***A Noisy Data Regression Model Based on General Regression Neural Networks*** *[#384]*
Shih-Chun Shao, Wen-Hui Chen and Jun-Horng Chen

2:10PM ***Estimation of Load Model Parameters from Instantaneous Voltage and Current*** *[#431]*
Pawel Regulski, Francisco Gonzalez-Longatt and Vladimir Terzija

(W04-1) Workshop: Computer Game and Fuzzy-based Game Applications
Monday, June 27, 1:30PM-3:00PM, Room: Egret, Chair: Shun-Chin Hsu, I-Chen Wu, and Shi-Jim Yen

1:30PM ***Apply Different Fuzzy Integrals in Unit Selection Problem of Real Time Strategy Game*** *[#170]*
Y.J. Li, Peter H.F. Ng, H.B. Wang, S.C.K. Shiu and Y. Li

1:50PM ***Unit Formation Planning in RTS game by using Potential Field and Fuzzy Integral*** *[#479]*
Ng Peter, Li Y. J. and Shiu Simon

2:10PM ***Elimination Search for puzzle games : An Application for Hashi Solver*** *[#505]*
Shi-Jim Yen, Shih-Yuan Chiu, Cheng-Wei Chou and Tsan-Cheng Su

2:30PM ***An efficient algorithm for solving Fillomino*** *[#507]*
Shi-Jim Yen, Tsan-Cheng Su and Shun-Chin Hsu

(W05-1) Workshop: Hybrid Computational Intelligence Applications
Monday, June 27, 1:30PM-3:00PM, Room: Swallow, Chair: Chuan-Kang Ting and Tzung-Pei Hong

1:30PM ***Symbiotic Neuron Evolution of a Neural-Network-Aided Grey Model for Time Series Prediction*** *[#302]*
Shih-Hung Yang and Yon-Ping Chen

1:50PM ***A Hybrid Computational Intelligence Approach for Automatic Music Composition*** *[#315]*
Giovanni Acampora, Jose Manuel Cadenas, Roberto De Prisco, Vincenzo Loia, Enrique Munoz and Rocco Zaccagnino

2:10PM ***A Study of a Hybrid Evolutionary Fuzzy Model for Stock Selection*** *[#503]*
Chien-Feng Huang, Chih-Hsiang Chang, Bao Rong Chang and Dun-Wei Cheng

2:30PM ***Upper-Bound Multiple Fuzzy Frequent-Pattern Trees*** *[#526]*
Tzung-Pei Hong, Chun-Wei Lin, Tsung-Ching Lin and Shing-Tai Pan

(HCGC-3) Competition: Human vs. Computer Go Competition
Monday, June 27, 1:30PM-3:00PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Monday, June 27, 3:30PM-5:00PM

(T04-2) Tutorial: Theoretical and Practical Aspects of Type-2 Fuzzy Systems: Part 2
Monday, June 27, 3:30PM-5:00PM, Room: Peacock, Instructor: Hani Hagras

(T05-2) Tutorial: Towards a Unified Framework for Intelligent Robotics
Monday, June 27, 3:30PM-5:00PM, Room: Phoenix, Instructor: Honghai Liu and Naoyuki Kubota

(W03-2) Workshop: Computational Intelligence Techniques for Smart Grids
Monday, June 27, 3:30PM-5:00PM, Room: Crane, Chair: Alfredo Vaccaro

3:30PM ***Exploiting Timed Automata Based Fuzzy Controllers for Voltage regulation in Smart Grids*** *[#441]*
Giovanni Acampora, Vincenzo Loia and Autilia Vitiello

3:50PM ***A Novel Fuzzy System for Wind Turbines Reactive Power Control*** *[#411]*
Geev Mokryani, Pierluigi Siano, Antonio Piccolo, Vito Calderaro and Carlo Cecati

4:10PM ***Terminal Sliding Mode Controlled CVCF Inverters*** *[#282]*
En-Chih Chang, Li-Peng Yin, Rong-Ching Wu and Lung-Sheng Yang,

(W04-2) Workshop: Computer Game and Fuzzy-based Game Applications
Monday, June 27, 3:30PM-5:00PM, Room: Egret, Chair: Shun-Chin Hsu, I-Chen Wu, and Shi-Jim Yen

(W05-2) Workshop: Hybrid Computational Intelligence Applications
Monday, June 27, 3:30PM-5:00PM, Room: Swallow, Chair: Chuan-Kang Ting and Tzung-Pei Hong

3:30PM ***Differential Evolution to Enhance Localization of Mobile Robots*** *[#584]*
Michael Lisowski, Zhun Fan and Ravn Ole

3:50PM ***Fuzzy C-Means Clustering Based Construction And Training For Second Order RBF Network*** *[#571]*
Kanishka Tyagi, Xun Cai and Michael Manry

(HCGC-4) Competition: Human vs. Computer Go Competition
Monday, June 27, 3:30PM-5:00PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Tuesday, June 28, 8:00AM-10:20AM

(SS02-1) Special Session: Evolutionary Fuzzy Systems
Tuesday, June 28, 8:00AM-10:20AM, Room: Swan, Chair: Rafael Alcalá

8:00AM ***Evolutionary Learning of a Laser Pointer Detection Fuzzy System for an Environment Control System*** *[#320]*
Chavez de la O Francisco, Fernandez de Vega Francisco, Alcala Fernandez Rafael, Alcala Fernandez Jesus and Herrera Trigeros Francisco

8:20AM ***A Meta-Fuzzy Classifier for Specifying Appropriate Fuzzy Partitions by Genetic Fuzzy Rule Selection with Data Complexity Measures*** *[#606]*
Yusuke Nojima, Shinya Nishikawa and Hisao Ishibuchi

8:40AM ***Assessing The Effects Of Zero Abundance Data On Habitat Preference Modelling Using A Genetic Takagi-Sugeno Fuzzy Model*** *[#586]*
Shinji Fukuda

9:00AM ***A Multiple-Level Genetic-Fuzzy Mining Algorithm*** *[#512]*
Chun-Hao Chen, Tzung-Pei Hong and Yeong-Chyi Lee

9:20AM ***An Architecture for Constructing Fuzzy Regression Tree Forests Using Opt-aiNet*** *[#314]*
Fathi Gasir, Zuhair Bandar and Keeley Crockett

9:40AM ***Fuzzy C-Means Clustering and Partition Entropy for Species-Best Strategy and Search Mode Selection in Nonlinear Optimization by Differential Evolution*** *[#456]*
Tetsuyuki Takahama and Setsuko Takahama

(SS12-1) Special Session: Recent Advances in Fuzzy-Model-Based Control Systems
Tuesday, June 28, 8:00AM-10:20AM, Room: Peacock, Chair: H. K. Lam

8:00AM ***LMI-Based Stability Conditions for Interval Type-2 Fuzzy-Model-Based Control Systems*** *[#228]*
H.K. Lam, Mohammad Narimani and L.D. Seneviratne

8:20AM ***Robust H-infinite Fuzzy Observer for A Class of Time-Delay Discrete Fuzzy Bilinear Systems with Parameter Uncertainties*** *[#54]*
Shun-Hung Tsai, Ta-Tau Chen, Ming-Ying Hsiao and Chin-Sheng Chen,

8:40AM ***Sum of Squares Solutions Assuring Non-quadratic Discrete Stability*** *[#39]*
Ji-Chang Lo and Jhen-Shun Kao

9:00AM ***Output Feedback Control for Discrete-Time Takagi-Sugeno Fuzzy Systems*** *[#122]*
Nao Ueno, Yuzu Uchida and Jun Yoneyama

9:20AM ***Decentralized control of large scale switched Takagi-Sugeno systems*** *[#156]*
Dalel Jabri, Kevin Guelton and Noureddine Manamanni

9:40AM ***Some Refinements for Non quadratic Stabilization of continuous TS Models*** *[#381]*
Thierry Marie Guerra, Abdelhafidh Jaadari, Juntao Pan and Antonio Sala

10:00AM ***Adaptive fault estimation design for T-S fuzzy systems with interval time varying delay*** *[#496]*
Hamdi Gassara, Ahmed EL Hajjaji and Mohamed Chaabane

(SS14) Special Session: Advances in Fuzzy Theory and their Applications
Tuesday, June 28, 8:00AM-10:20AM, Room: Phoenix, Chair: Shyi-Ming Chen

8:00AM ***Fast Extracting of Change Area from Remote Sensing Image by Fuzzy Theory and Case Base Reasoning*** *[#399]*
Ting-shiuan Wang and Teng-to Yu

8:20AM ***Weights-Learning for Weighted Fuzzy Rule Interpolation in Sparse Fuzzy Rule-Based Systems*** *[#253]*
Shyi-Ming Chen and Yu-Chuan Chang

8:40AM ***On The Type-2 Fuzzy Thresholding Protocol For Event-Driven Wireless Sensor Networks*** *[#458]*
Chung-Ming Own

9:00AM ***A Theoretical Approach to Liu's Generalized Lambda-Fuzzy Measure*** *[#350]*
Hsiang-Chuan Liu and Tung-Sheng Liu

9:20AM ***A Fuzzy Intelligent Decision Support System for Typhoon Disaster Management*** *[#387]*
Wang-Kun Chen, GuangJun Sui and DangLing Tang

9:40AM ***A Robust Fuzzy Trajectory Estimation Design of High Speed Reentry Vehicles*** *[#190]*
Yung-Yue Chen and Chung-Shi Tseng

10:00AM ***Data-driven Based 3-D Fuzzy Logic Controller Design Using Nearest Neighborhood Clustering and Linear Support Vector Regression*** *[#535]*
Zhang Xianxia, Jiang Ye, Zou Tao, Qi Chenkun and Cao Guitao

(SS28-1) Special Session: Current Development in Pattern Classification-Kernelization, Pairwise Constraints, and Classifiers

Tuesday, June 28, 8:00AM-10:20AM, Room: Crane, Chair: Yasunori Endo

8:00AM ***A Method of Explicit Mappings for Kernel Data Analysis and Applications*** *[#276]*
Sadaaki Miyamoto and Keisuke Sawazaki

8:20AM ***Comparison of Scaling Behavior Between Fuzzy c-Means Based Classifier with Many Parameters and LibSVM*** *[#77]*
Hidetomo Ichihashi, Katsuhiro Honda and Akira Notsu

8:40AM ***Ellipse Detection with Hard c-Regression Models and Random Initializations*** *[#106]*
Hidetomo Ichihashi, Li Chieu Lam, Katsuhiro Honda and Akira Notsu

9:00AM ***Trajectory Anonymization From a Time Series Perspective*** *[#141]*
Sergi Martinez-Bea and Vicenc Torra

9:20AM ***On Some Clustering Approaches For Graphs*** *[#205]*
Klara Stokes and Vicenc Torra

9:40AM ***A Study on Regularization Effects of Fuzzified Memberships in FCM Clustering*** *[#57]*
Katsuhiro Honda, Yui Matsumoto, Akira Notsu and Hidetomo Ichihashi

10:00AM ***Constrained Agglomerative Hierarchical Clustering Algorithms with Penalties*** *[#75]*
Sadaaki Miyamoto and Akihisa Teram

(SS16 & SS11) Special Session: Fuzzy Interpolation & Large-Scale Clustering

Tuesday, June 28, 8:00AM-10:20AM, Room: Egret, Chair: Qiang Shen and Timothy Havens

8:00AM ***Adaptive Fuzzy Interpolation with Prioritized Component Candidates*** *[#226]*
Longzhi Yang and Qiang Shen

8:20AM ***Fuzzy Rule Interpolation in Embedded Behaviour-based Control*** *[#558]*
Szilveszter Kovacs

8:40AM ***An Evolutionary-Based Similarity Reasoning Scheme for Monotonic Multi-Input Fuzzy Inference Systems*** *[#119]*
Tay Kai Meng and Lim Chee Peng

9:00AM ***Fuzzy Rule Interpolation Based on Interval Type-2 Gaussian Fuzzy Sets and Genetic Algorithms*** *[#326]*
Shyi-Ming Chen and Yu-Chuan Chang

9:20AM ***Double-Linear Fuzzy Interpolation Method*** *[#546]*
Marcin Detyniecki, Christophe Marsala and Maria Rifqi

9:40AM ***Speedup of Fuzzy and Possibilistic Kernel c-Means for Large-Scale Clustering*** *[#443]*
Timothy Havens, Radha Chitta, Anil Jain and Rong Jin

10:00AM ***Adaptive Fuzzy Interpolation with Uncertain Observations and Rule Base*** *[#397]*
Longzhi Yang and Qiang Shen

(T2FL & FPR) Type-2 Fuzzy Logic and Fuzzy Pattern Recognition

Tuesday, June 28, 8:00AM-10:20AM, Room: Swallow, Chair: Frank Chung-Hoon Rhee

8:00AM ***General Type-2 Fuzzy Membership Function Design and its Application to Neural Networks*** *[#590]*
Eun-A Shim and Frank Chung-Hoon Rhee

8:20AM ***Human Action Recognition via Sum-Rule Fusion of Fuzzy K-Nearest Neighbor Classifiers*** *[#510]*
Teck Wee Chua, Karianto Leman and Nam Trung Pham

8:40AM ***Fuzzy Clustering with Multiple Kernels*** *[#150]*
Naouel Baili and Hichem Frigui

9:00AM ***Kernel-Based Fuzzy Clustering of Interval Data*** *[#52]*
Bruno Pimentel, Anderson Costa and Renata Souza

9:20AM ***Short Term Load Forecasting Using Interval Type-2 Fuzzy Logic Systems*** *[#208]*
Abbas Khosravi, Saeid Nahavandi and Doug Creighton

9:20AM ***An Adaptive Type-2 Input Based Non-SingletonType-2 Fuzzy Logic System for Real World Applications*** *[#528]*
Nazanin Sahab and Hani Hagras

9:40AM ***Hospital Service Quality Evaluation: A Fuzzy Preference Relation Approach*** *[#72]*
Tsung-Han Chang

(HCGC-1) Competition: Human vs. Computer Go Competition
Tuesday, June 28, 8:00AM-10:20AM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Panel Session I: Interpolation and Approximation in Fuzzy Rule Bases
Tuesday, June 28, 8:00AM-10:20AM, Room: Grand Ballroom I, Chair: László Koczy

(FA-1) Fuzzy Applications
Tuesday, June 28, 8:00AM-10:20AM, Room: Grand Ballroom II, Chair: Hisao Ishibuchi

8:00AM ***Structural Analysis on Team Internal Soft Factors to Project Success*** *[#49]*
Jyh-Fu (Don) Jeng

8:20AM ***A Robust Portfolio Selection Problem based on a Confidence Interval with Investor's Subjectiviety*** *[#100]*
Takashi Hasuike and Hideki Katagir

8:40AM ***On Some Fuzzy Relations for Color Information*** *[#412]*
Daniel Sanchez, Jose Manuel Soto-Hidalgo, Jesus Chamorro-Martinez and Pedro Martinez-Jimenez

9:00AM ***The Positioning control of an Electro-Hydraulic Variable Rotational Speed Pump-Controlled System Using Adaptive Fuzzy Controller with Self-tuning Fuzzy Sliding Mode Compensation*** *[#463]*
Lian-Wang Lee, I-Hsum Li, Chung-Chieh Chen and Jun-Yi Huang

9:20AM ***Toward Quantitative Definition of Explanation Ability of Fuzzy Rule-based Classifiers*** *[#605]*
Hisao Ishibuchi and Yusuke Nojima

9:40AM ***Multi-level Multi-Objective Decision Problem through Fuzzy Random Regression based Objective Function*** *[#81]*
Nureize Arbaiy and Junzo Watada

Tuesday, June 28, 10:50AM-12:00PM

(HCGC-2) Competition: Human vs. Computer Go Competition
Tuesday, June 28, 10:50AM-12:00PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Keynote Speech I: Inferring Disease Related Gene-Gene Interactions: A Fuzzy Logic Based Approach
Tuesday, June 28, 10:50AM-12:00PM, Room: Grand Ballroom I, Speaker: Nikhil Pal

Tuesday, June 28, 1:30PM-2:30PM

(HCGC-3) Competition: Human vs. Computer Go Competition
Tuesday, June 28, 1:30PM-2:30PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Plenary Speech I: Type-2 Fuzzy Sets and Systems: Challenges and Misconceptions
Tuesday, June 28, 1:30PM-2:30PM, Room: Grand Ballroom I, Speaker: Jerry M. Mendel

Tuesday, June 28, 2:30PM-4:30PM

(PS01) Poster Session I
Tuesday, June 28, 2:30PM-4:30PM, Room: Grand Ballroom II

P101 ***A fuzzy hypothesis test based model for customer satisfaction measurement (Case study in PARS KHODRO CO.)*** *[#22]*
Naimeh Borjalilu, Mahdi Zowghi and Abdolhamid Eshraghniaye Jahromi

P102 ***Permutation Flow Shop Scheduling: Fuzzy Particle Swarm Optimization Approach*** *[#29]*
S. H. Ling, F. Jiang, H. T. Nguyen and K. Y. Chan

P103 ***Patent Valuation with a Fuzzy Binomial Model*** *[#67]*
Xiaolu Wang

P104 ***Natural Topology via Fuzzy Metric*** *[#70]*
Fagner Santana and Regivan Santiago

P105 ***Fault diagnosis of turbine using an improved intuitionistic fuzzy cross entropy approach*** *[#79]*
Hung Kuo-Chen, Lin Kuo-Ping and Weng Chia-Chun

P106 ***Fuzzy delta separation axioms*** *[#91]*
Seok Jong Lee and Sang Min Yun

P107 ***Clustering Data and Imprecise Concepts*** *[#101]*
Zengchang Qin and Weifeng Zhang

P108 ***Fuzzy Variable Structure Control for PWM Inverters*** *[#102]*
En-Chih Chang and Josep M. Guerrero

P109 ***An Adaptive Fuzzy Logic Controller based on Real Coded Quantum-Inspired Evolutionary Algorithm*** *[#103]*
Pintu Shill, Amjad Hossain, Faijul Amin and Kazuyuki Murase

P110 ***An Efficient Hybrid Particle Swarm Optimization for the Job Shop Scheduling Problem*** *[#116]*
Xue-Feng Zhang, Miyuki Koshimura, Hiroshi Fujita and Ryuzo Hasegawa

P111 ***A Framework of Multi-characteristics Fuzzy Dynamic Scheduling for Parallel Video Processing on MPSoC Architecture*** *[#117]*
Da Li, Yibin Hou, Zhangqin Huang and Chunhua Xiao

P112 ***The Drivation of the Analytical Structure of a class of Interval Type-2 fuzzy PD and PI controllers*** *[#127]*
Maowen Nie and Woei Wan Tan

P113 ***Estimation of the Asympototic Stability Region of Uncertain Fuzzy Systems with Bounded Controllers Using Variable Structure System Design Approach*** *[#138]*
Chung-Chun Kung, Ti-Hung Chen, Shuo-Chieh Chang and Chih-Chieh Chen

P114 ***A Study on Atanassov's Intuitionistic Fuzzy Graphs*** *[#157]*
Karunambigai M.G., Parvathi R. and Kalaivani O.K.

P115 ***Fuzzy Controller Based Output Power Leveling Enhancement for a Permanent Mangnet Synchronous Generator*** *[#159]*
Abdul Motin Howlader, Naomitsu Urasaki, Shantanu Chakraborty, Atsushi Yona, Tomonobu Senjyu and Ahmed Y. Saber

P116 ***Important Issues To Be Considered In Developing Fuzzy Cognitive Maps*** *[#548]*
Costas Neocleous, Christos Schizas and Maria Papaioannou

P117 ***A Fall Detection Study on the Sensors Placement Location and a Rule-Based Multi-Thresholds Algorithm Using Both Accelerometer and Gyroscopes*** *[#613]*
Donald Lie, Jerene Jacob and Nguyen Tam

P118 ***A Fuzzy Representation for Non-additive Weights of AHP*** *[#196]*
Shin-ichi Ohnishi, Takahiro Yamanoi and Hideyuki Imai

P119 ***A social cognitive framework of knowledge contribution in the online community*** *[#192]*
Fan-Chuan Tseng and Feng-Yuan Kuo

P120 ***Fuzzy Clustering of Large-Scale Data Sets Using Principal Component Analysis*** *[#188]*
Sassi Minyar and Arfaoui Olfa

P121 ***Soft Subspace Clustering with Competitive Agglomeration*** *[#168]*
Lin Zhu, Longbing Cao and Jie Yang

Tuesday, June 28, 2:50PM-4:30PM

(SS05) Special Session: Fuzzy Robotics
Tuesday, June 28, 2:50PM-4:30PM, Room: Swan, Chair: Honghai Liu

2:50PM ***Hand Motion Recognition via Fuzzy Active Curve Axis Gaussian Mixture Models: A Comparative Study*** *[#96]*
Ju Zhaojie and Liu Honghai

3:10PM ***Trajectory-based Control under ZMP Constraint for the 3D Biped Walking via Fuzzy Control*** *[#294]*
Hsiu-Ming Wu and Chih-Lyang Hwang

3:30PM ***Formation Behavior of Multiple Robots based on Tele-operation*** *[#565]*
Yuki Wagatsuma, Yuichiro Toda and Naoyuki Kubota

3:50PM ***Evaluation of Pointing Navigation Interface for Mobile Robot with Spherical Vision System*** *[#521]*
Kyohei Yoshida, Fuminori Hibino, Yasutake Takahashi and Yoichiro Maeda

4:10PM ***Fuzzy PID Controller Design for Artificial Finger based SMA Actuators*** *[#341]*
Alireza Khodayari, Mohammad Mahdi Kheirikhah and Maryam Talari

(SS18) Special Session: Recent Advances in Fuzzy Logic in Image Processing
Tuesday, June 28, 2:50PM-4:30PM, Room: Peacock, Chair: Mike Nachtegael

2:50PM ***Fuzzy shape Classification exploiting Geometrical and Moments Descriptors*** *[#557]*
Ugo Erra and Sabrina Senatore

3:10PM ***Piece-wise Convex Spatial-Spectral Unmixing of Hyperspectral Imagery using Possibilistic and Fuzzy Clustering*** *[#452]*
Alina Zare and Paul Gader

3:30PM ***Detection of Hyperintense Regions on MR Brain Images using a Mamdani Type Fuzzy Rule-Based System*** *[#603]*
F. Xavier Aymerich, Eduard Montseny, Pilar Sobrevilla and Alex Rovira

3:50PM ***On Fuzzy Partitions for Visual Texture Modelling*** *[#360]*
Jesus Chamorro-Martinez, Pedro Manuel Martinez-Jimenez and Jose Manuel Soto-Hidalgo

(SS27) Special Session: Communication Robotics and Computational Intelligence Co-creation
Tuesday, June 28, 2:50PM-4:30PM, Room: Phoenix, Chair: Yoichi Yamazaki

2:50PM ***Educational System with the Android Robot SAYA and Field Trial*** *[#176]*
Takuya Hashimoto, Naoki Kato and Hiroshi Kobayashi

3:10PM ***Multimodal Gesture Recognition Based on Choquet Integral*** *[#113]*
Kaoru Hirota, Hai An Vu, Phuc Quang Le, Chastine Fatichah and Zhentao Liu

3:30PM ***Emotional States Based 3-D Fuzzy Atmosfield for Casual Communication between Humans and Robots*** *[#172]*
Zhentao Liu, Min Wu, Danyun Li, Fangyan Dong, Yoichi Yamazaki and Kaoru Hirota

3:50PM ***Presence Expression Using Eye Robot for Computer Go System*** *[#455]*
Yoichi Yamazaki, Masaya Hanada, Chang-Shing Lee, Takuya Hashimoto, Fangyan Dong, Makoto Motoki and Kaoru Hirota

4:10PM ***Emotion Recognition based on Human Gesture and Speech Information using RT Middleware*** *[#367]*
An Hai Vu, Yoichi Yamazaki, Fangyan Dong and Kaoru Hirota

(SS28-2) Special Session: Current Development in Pattern Classification-Kernelization, Pairwise Constraints, and Classifiers
Tuesday, June 28, 2:50PM-4:30PM, Room: Crane, Chair: Yasunori Endo

2:50PM ***FCMdd-type Linear Fuzzy Clustering for Incomplete Non-Euclidean Relational Data*** *[#108]*
Takeshi Yamamoto, Katsuhiro Honda, Akira Notsu and Hidetomo Ichihash

3:10PM ***Hybrid Objective Function of Fuzzy c-Varieties and Cross-shape Fuzzy Cluster Extraction*** *[#295]*
Daisuke Yoshida, Katsuhiro Honda, Akira Notsu and Hidetomo Ichihash

3:30PM ***Kernelized Fuzzy c-Means Clustering for Uncertain Data using Quadratic Penalty-Vector Regularization with Explicit Mappings*** *[#114]*
Yasunori Endo, Isao Takayama, Yukihiro Hamasuna and Sadaaki Miyamoto

3:50PM ***On Mahalanobis Distance Based Fuzzy c-Means Clustering for Uncertain Data Using Penalty Vector Regularization*** *[#125]*
Yukihiro Hamasuna, Yasunori Endo and Sadaaki Miyamoto

4:10PM ***On Hard and Fuzzy c-Means Clustering with Conditionally Positive Definite Kernel*** *[#177]*
Yuchi Kanzawa, Yasunori Endo and Sadaaki Miyamoto

(SS42-1) Special Session: Fuzzy Cognitive Maps-Theory and Applications
Tuesday, June 28, 2:50PM-4:30PM, Room: Egret, Chair: Chair: Elpiniki I. Papageorgiou and Sebastian Lozano

2:50PM ***Intuitionistic Fuzzy Reasoning with Cognitive Maps*** *[#477]*
Dimitris Iakovidis and Elpiniki Papageorgiou

3:10PM ***Review study on Fuzzy Cognitive Maps and their applications during the last decade*** *[#516]*
Elpiniki Papageorgiou

3:30PM ***Nonlinear Cause-Effect Relationships In Fuzzy Cognitive Maps*** *[#361]*
Maria Ketipi, Dimitrios Koulouriotis, Evangelos Karakasis, George Papakostas and Vassilios Tourassis

3:50PM ***Case Based Fuzzy Cognitive Maps (CBFCM) : New method for medical reasoning*** *[#567]*
Nassim Douali, Elpiniki Papageorgiou, Jos De Roo and Marie-Christine Jaulent

4:10PM ***Training Fuzzy Cognitive Maps by Using Hebbian Learning Algorithms: A Comparative Study*** *[#343]*
George Papakostas, Athanasios Polydoros, Koulouriotis Dimitrios and Tourassis Vasileios

(SS21-1) Special Session: Fuzzy Control in Industrial and Application
Tuesday, June 28, 2:50PM-4:30PM, Room: Swallow, Chair: Shun-Hung Tsai

2:50PM ***Applications of Fuzzy Classification with Fuzzy C-Means Clustering and Optimization Strategies for Load Identification in NILM Systems*** *[#126]*
Yu-Hsiu Lin, Men-Shen Tsai and Chin-Sheng Chen,

3:10PM ***Knowledge-Based Fuzzy Imbalanced Force Compensator Design for a Single Active Magnetic Bearing Suspended Rotor System*** *[#347]*
Yi Hua Fan and Ying Tsun Lee

3:30PM ***DSP-Based Cross-Coupled Synchronous Control for Dual Linear Motors via Functional Link Radial Basis Function Network*** *[#129]*
Chin-Sheng Chen, Po-Huan Chou and Faa-Jeng Lin,

3:50PM ***An Interactive Fuzzy Satisficing Method for Multiobjective Stochastic Defensive Location Problems*** *[#284]*
Takeshi Uno and Kosuke Kato

(HCGC-4) Competition: Human vs. Computer Go Competition
Tuesday, June 28, 2:50PM-4:30PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Tuesday, June 28, 4:30PM-7:00PM

(PS02) Poster Session II
Tuesday, June 28, 4:30PM-7:00PM, Room: Grand Ballroom II

P301 ***Robust Speed-Controlled Permanent Magnet Synchronous Motor Drive using Fuzzy Logic Controller*** *[#162]*
Gunawan Dewantoro and Yong-Lin Kuo

P302 ***Possibilistic Regression Analysis by Support Vector Machine*** *[#183]*
Pei-Yi Hao

P303 ***Cognitive Simulation-Based on Knowledge Evolution in Fuzzy Discrete Event Systems*** *[#199]*
Paul-Antoine Bisgambiglia, Paul Antoine Bisgambiglia and Jean-Sebastien Gualtieri

P304 ***A Fuzzy Tool for the Validation of Individual Risk Premia in High-Technology Venture Valuation*** *[#202]*
Lars Krueger, Peter Heydebreck and Ralf Salomon

P305 ***Soft-Core Implementation for Centre of Slice Area Average Defuzzifier*** *[#206]*
Antonio Hernandez Zavala, Oscar Camacho Nieto and Cornelio Yanez Marquez

P306 ***Fuzzy Integral-based Composite Facial Expression Generation for a Robotic Head*** *[#234]*
Bum-Soo Yoo, Se-Hyoung Cho and Jong-Hwan Kim

P307 ***Comparing soft clusters and partitions*** *[#243]*
Derek Anderson, James Keller, Ozy Sjahputera, James Bezdek and Mihail Popescu

P308 ***An Adaptive Hybrid Data Fusion Based Identification of Skeletal Muscle Force with ANFIS and Smoothing Spline Curve Fitting*** *[#245]*
Parmod Kumar, Cheng-Hung Chen, Anish Sebastian, Madhavi Anugolu, Chandrasekhar Potluri, Amir Fassih, Yimesker Yihun, Alex Jensen, Yi Tang, Steve Chiu, Ken Bosworth, D. S. Naidu, Marco P. Schoen, Jim Creelman and Alex Urfer

P309 ***A Functional-Link based Interval Type-2 Compensatory Fuzzy Neural Network for Nonlinear System modeling*** *[#249]*
Jyh-Yeong Chang, Yang-Yin Lin, Ming-Feng Han and Chin-Teng Lin

P310 ***Infrared Image Segmentation using Enhanced Fuzzy C-Means clustering for Automatic Detection Systems*** *[#251]*
Sitanshu Gupta and Asim Mukherjee

P311 ***Image-Correlation Data Association with Global Uncertainty Techniques*** *[#274]*
Stephen Stubberud and Kathleen Kramer

P312 ***A Non-Singleton Interval Type-2 Fuzzy Logic System for Universal Image Noise Removal using Quantum-Behaved Particle Swarm Optimization*** *[#291]*
Daoyuan Zhai, Minshen Hao and Jerry Mendel

P313 ***Fuzzy Folksonomy-based Index Creation for e-Learning Content Retrieval on Cloud Computing Environments*** *[#306]*
Wen-Chung Shih, Chao-Tung Yang and Shian-Shyong Tseng

P314 ***Relationship between Intuitionistic Fuzzy Similarity Measures*** *[#308]*
Leila Baccour, Adel M. Alimi and Robert I. John

P315 ***Decomposition of Term-Document Matrix Representation for Clustering Analysis*** *[#316]*
Jianxiong Yang and Junzo Watada

P316 ***Visual-Based Guiding Method for Unmanned Helicopter Approaching to Landmark*** *[#171]*
Kuo-Hsien Hsia, Shao-Fan Lien and Juhng-Perng Su

P317 ***On the Type-1 and Type-2 Fuzziness Measures for Thresholding MRI Brain Images*** *[#200]*
Rajesh R., Senthilkumaran N., Satheesh Kumar J., Shanmuga Priya B., Thilagavathy C. and Priya K

P318 ***A Fast Algorithm for Mining Frequent Closed Itemsets over Stream Sliding Window*** *[#587]*
Show-Jane Yen, Cheng-Wei Wu, Yue-Shi Lee, Vincent S. Tseng and Chaur-Heh Hsieh

P319 ***Neuro-Fuzzy System Design using Differential Evolution with Local Information*** *[#313]*
Lin Chin-Teng, Han Ming-Feng, Lin Yang-Yin, Liao Shih-Hui and Chang Jyh-Yeong

P320 ***Stability Analysis and Synthesis of Markovian Jump Nonlinear Systems with Incomplete Transition Descriptions via Fuzzy Control*** *[#325]*
Min Kook Song, Jin Bae Park and Young Hoon Joo

P321 ***Bio-inspired computing of vision - fuzzy and neurmorphic processing*** *[#426]*
Woo Joon Han and Il Song Han

Tuesday, June 28, 5:00PM-7:00PM

(SS10-1) Special Session: Medical and Wellness Engineering

Tuesday, June 28, 5:00PM-7:00PM, Room: Swan, Chair: Yutaka Hata

5:00PM ***A Testicular Tubule Evaluation Method by Ultrasonic Array Probe*** *[#89]*
Yuya Takashima, Kei Kuramoto, Kobashi Syoji, Hata Yutaka and Ishikawa Tomomoto

5:20PM ***Fuzzy RASP Determination by 1kHz Ultrasonic Probe for Total Hip Arthroplasty*** *[#98]*
Naomi Yagi, Yoshitetsu Oshiro, Osamu Ishikawa, Yutaka Hata and Nao Shibanuma

5:40PM ***A Fuzzy Logic Approach to Predict Human Body Weight Based on AR Model*** *[#88]*
Hideaki Tanii, Hiroshi Nakajima, Tsuchiya Naoki, Kei Kuramoto, Syoji Kobashi and Yutaka Hata

6:00PM ***Consideration of Invasion, Intrusion, and Consciousness in Biomedical Sensing with Uncertainty*** *[#209]*
Hiroshi Nakajima, Naoki Tsuchiya and Yutaka Hata

6:20PM ***Load Forecasting using Fuzzy Wavelet Neural Networks*** *[#273]*
Mahdi Amina and Vassilis Kodogiannis

6:40PM ***Fuzzy Modelling Using a New Compact Fuzzy System: A Special Application to the Prediction of the Mechanical Properties of Alloy Steels*** *[#593]*
Qian Zhang and Mahdi Mahfouf

(SS09) Special Session: Applications of Fuzzy Logic to Awareness Promotion

Tuesday, June 28, 5:00PM-7:00PM, Room: Peacock, Chair: Kiyota Hashimoto

5:00PM ***Agent Simulation for Contents Evaluation with User Models for Hierarchical Knowledge Relations*** *[#356]*
Kiyota Hashimoto and Kazuhiro Takeuchi

5:20PM ***Giving Awareness of Maturity by Capability Assessment*** *[#607]*
Yi-Ling Kuo, Yu Nakamura, Masayuki Sakoda, Hiroshi Tsuji and Chang-Shing Lee

5:40PM ***Medical Care System Evaluation Based on DEA Of Prefectures In Japan*** *[#335]*
Kenji Fukuoka, Shingo Aoki and Yukie Majima

6:00PM ***Structured DEA Model Considering Relation among Input and Output Elements*** *[#331]*
Yamasaki Shingo and Aoki Shingo

6:20PM ***Component-Based Search Engine for Blogs*** *[#490]*
Sachio Hirokawa, Chengjiu Yin and Tetsuya Nakatoh

6:40PM ***Influence of the Space Segmentation and its Adaptive Automation for Reinforcement Learning*** *[#290]*
Akira Notsu, Yuki Komori, Katsuhiro Honda and Hidetomo Ichihashi

(SS08) Special Session: Innovative Fuzzy Approaches to Management Engineering

Tuesday, June 28, 5:00PM-7:00PM, Room: Phoenix, Chair: Junzo Watada

5:00PM ***Learning with Imbalanced Datasets using Fuzzy ARTMAP-based Neural Network Models*** *[#43]*
Shing Chiang Tan, Junzo Watada, Zuwarie Ibrahim, Marzuki Khalid and Wen Jau Lee

5:20PM ***Re-Scheduling the Unit Commitment Problem in Fuzzy Environment*** *[#18]*
Bo Wang, You Li and Junzo Watada

5:40PM ***Building a Fuzzy Multi-objective Portfolio Selection model with Distinct Risk Measurements*** *[#19]*
You Li, Bo Wang and Junzo Watada

6:00PM ***Statistic Test on Fuzzy Portfolio Selection Model*** *[#65]*
Pei-Chun Lin, Junzo Watada and Berlin Wu

6:20PM ***An Approach Based on Takagi-Sugeno Fuzzy Inference System Applied to the Operation Planning of Hydrothermal Systems*** *[#279]*
Ricardo Rabelo, Ricardo Fernandes, Adriano Carneiro and Rosana Braga

6:40PM ***Fuzzy Cognitive Maps in estimating the repercussions of oil/gas exploration on politico-economic issues in Cyprus*** *[#495]*
Costas Neocleous, Maria Papaioannou and Christos Schizas

(SS37) Special Session: Fuzzy Logic Based Computer Vision and Its Applications to Guidance and Control

Tuesday, June 28, 5:00PM-7:00PM, Room: Crane, Chair: Kuo-Hsien Hsia

5:00PM ***The Picked and Placed Control of the Objects for a Pneumatic X-Y Servo Platform by Integrating Image Processing Techniques and a Fuzzy Sliding Mode Controller Design*** *[#390]*
Hong-Ming Chen, Yi-Ping Shyu, Chun-Sheng Shen and Hong-Jia Yang

5:20PM ***The Dynamic Measurement System Design for Stewart Platform by Using Digital Image Processing Method*** *[#161]*
Yu Ker-Wei and Zhou Yu-Quan

5:40PM ***Orientation control of hovercraft systems via an SMFLC and Image-Guided Techniques*** *[#318]*
Chun-Chieh Wang

6:00PM ***PSO-based Estimation for Gaussian Blur in Blind Image Deconvolution Problem*** *[#529]*
Yang-Chih Lai, Chih-Li Huo, Yu-Hsiang Yu and Tsung-Ying Sun

6:20PM ***Fuzzy integrals for the aggregation of confidence measures in speech recognition*** *[#494]*
Julie Mauclair, Laurent Wendling and David Janiszek

6:40PM ***Active Tracking Using Intelligent Fuzzy Controller and Kernel-Based Algorithm*** *[#400]*
Moteaal Asadi Shirzi and M.R. Hairi-Yazdi

(SS17-1) Special Session: Practical and Applications Aspects of Type-2 Fuzzy Logic Systems

Tuesday, June 28, 5:00PM-7:00PM, Room: Egret, Chair: Woei Wan Tan

5:00PM ***An Interval Type 2 Fuzzy Approach to Multilevel Image Segmentation*** *[#591]*
Debanga Raj Neog, Muhammad Amjad Raza and Frank Chung-Hoon Rhee

5:20PM ***Navigation System of Mobile Robot in an Uncertain Environment Using Type-2 Fuzzy Modelling*** *[#585]*
Sittichok Junratanasiri, Sansanee Auephanwiriyakul and Nipon Theera-Umpon

5:40PM ***Multi-attribute Decision Making Models under Interval Type-2 Fuzzy Environment*** *[#95]*
Weize Wang and Xinwang Liu

6:00PM ***A Perceptual Computer Based Method for Supplier Selection Problem*** *[#186]*
Han Shilian and Liu Xinwang

6:20PM ***A Comparison of Non-stationary, Interval Type-2 and Dual-Surface Interval Type-2 Fuzzy Control*** *[#423]*
Naisan Benatar, Uwe Aickelin and Jonathan M. Garibaldi

6:00PM ***A Fuzzy Toolbox for the R Programming Language*** *[#612]*
Christian Wagner, Simon Miller and Jonathan M. Garibaldi

(SS19) Special Session: Fuzzy Inference Systems-Theory and Applications
Tuesday, June 28, 5:00PM-7:00PM, Room: Swallow, Chair: Hirosato Seki

5:00PM ***Type-2 Fuzzy Functional Inference Method*** *[#573]*
Hirosato Seki and Masaharu Mizumoto

5:20PM ***On Extension of Consequent Parts of T-S Inference Model*** *[#553]*
Hirosato Seki and Masaharu Mizumoto

5:40PM ***Optimization of Gaussian Fuzzy Membership Functions and Evaluation of the Monotonicity Property of Fuzzy Inference Systems*** *[#118]*
Tay Kai Meng and Lim Chee Peng,

6:00PM ***Refinement CTIN for General Type-2 Fuzzy Logic Systems*** *[#417]*
Thanh Long Ngo

6:20PM ***On a Strengthening Connective for Flexible Database Querying*** *[#7]*
Patrick Bosc and Olivier Pivert

(HCGC-5) Competition: Human vs. Computer Go Competition
Tuesday, June 28, 5:00PM-7:00PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Panel Session II: Computing With Words
Tuesday, June 28, 5:00PM-6:30PM, Room: Grand Ballroom I, Chair: Nikhil R. Pal

Wednesday, June 29, 8:00AM-10:20AM

(SS02-2) Special Session: Evolutionary Fuzzy Systems
Wednesday, June 29, 8:00AM-10:20AM, Room: Swan, Chair: Rafael Alcalá

8:00AM ***Studying the Behavior of a Multiobjective Genetic Algorithm to design Fuzzy Rule-Based Classification Systems for Imbalanced Data-Sets*** *[#189]*
Pedro Villar, Alberto Fernandez and Francisco Herrera

8:20AM ***On the Cooperation of Interval-Valued Fuzzy Sets and Genetic Tuning to Improve the Performance of Fuzzy Decision Trees*** *[#258]*
Jose Antonio Sanz, Alberto Fernandez, Humberto Bustince and Francisco Herrera

8:40AM ***A Two-Step Approach of Feature Construction for a Genetic Learning Algorithm*** *[#388]*
David Garcia, Antonio Gonzalez and Raul Perez

9:00AM ***Using the Adaboost algorithm for extracting fuzzy rules from low quality data: some preliminary results*** *[#487]*
Ana Palacios, Luciano Sanchez and Ines Couso

9:20AM ***Checking Orthogonal Transformations and Genetic Algorithms for Selection of Fuzzy Rules based on Interpretability-Accuracy Concepts*** *[#324]*
M.Isabel Rey, Marta Galende, Gregorio I. Sainz and MariaJ. Fuente

9:40AM ***A Hierarchical Genetic Fuzzy Rule-Based Classifier for High-Dimensional Classification Problems*** *[#395]*
Dimitris Stavrakoudis, Ioannis Gitas and John Theocharis

10:00AM ***A New Approach to Handle High Dimensional and Large Datasets in Multi-objective Evolutionary Fuzzy Systems*** *[#432]*
Michela Antonelli, Pietro Ducange and Francesco Marcelloni

(SS12-2) Special Session: Recent Advances in Fuzzy-Model-Based Control Systems
Wednesday, June 29, 8:00AM-10:20AM, Room: Peacock, Chair: H. K. Lam

8:00AM ***Generalized Stabilizing Controllers for Fuzzy Systems via Circle Criterion -- LMI and SOS*** *[#40]*
Ji-Chang Lo and Wei-Cheng Liao

8:20AM ***T-S Fuzzy Systems Approach to Approximation and Robust Controller Design for General Nonlinear Systems*** *[#216]*
Qing Gao, Xiao-Jun Zeng, Gang Feng and Yong Wang

8:40AM ***A Polynomial Observer Design for a Wider Class of Polynomial Fuzzy Systems*** *[#62]*
Toshiaki Seo, Hiroshi Ohtake, Kazuo Tanaka, Ying-Jen Chen and Hua O. Wang

9:00AM ***A SVD Approach to $H_$ Decentralized Static Output Feedback Fuzzy Control Design for Nonlinear Interconnected Systems*** *[#45]*
Chung-Shi Tseng and Yung-Yue Chen

9:20AM ***Adaptive Fuzzy Sliding-Mode Control for a Class of Nonlinear Systems with Uncertainties*** *[#111]*
Hugang Han

9:40AM ***Mixed H2/H-Infinity Optimization with Discrete Smith Predictor for Fuzzy Decentralized Control of Nonlinear Interconnected Discrete Dynamic Systems with Large Delay*** *[#44]*
Chih-Lyang Hwang

10:00AM ***A Hybrid Fuzzy Sliding-Mode Control for a Class of Generalized, Under-Actuated and Uncertain Nonlinear Dynamic Systems*** *[#120]*
Chih-Lyang Hwang and Hsiu-Ming Wu

(SS31) Special Session: Human Symbiotic Systems
Wednesday, June 29, 8:00AM-10:20AM, Room: Phoenix, Chair: Daisuke Katagami

8:00AM ***Visualization and Analytical Support of Questionnaire Free-Texts Data based on HK Graph with Concepts of Words*** *[#365]*
Daisuke Kobayashi, Tomohiro Yoshikawa and Takeshi Furuhashi

8:20AM ***Development of Body Mapping from Human Demonstrator to Inverted-Pendulum Mobile Robot for Imitation*** *[#353]*
Takahashi Sataya, Takahashi Yasutake, Maeda Yoichiro and Nakamura Takayauki

8:40AM ***Social Interaction of Cooperative Communication and Group Generation in Multi-Agent Reinforcement Learning Systems*** *[#389]*
Kun Zhang, Yoichiro Maeda and Yasutake Takahashi

9:00AM ***Estimation Of Subjective Stress Via Finger Plethysmogram*** *[#255]*
Yusuke Kobashi, Genma Sano, Tsuyoshi Nakamura and Masayoshi Kanoh

9:20AM ***Human Preference Learning by Robot Partners Based on Multi-objective Behavior Coordination*** *[#560]*
Naoyuki Kubota, Aiko Yaguchi and Utaki Ishikawa

9:40AM ***A Report The Difference Features Of A Multi-agent Using An Overlay Knowledge In The Fire Panic Problem*** *[#554]*
Yukinobu Hoshino

10:00AM ***Group Pressure Generation of Multi-Agents on Cross-cultural Simulation Game*** *[#377]*
Daisuke Katagami and Tam Huynh van

(FC& IS) Fuzzy Control and Intelligent Systems

Wednesday, June 29, 8:00AM-10:20AM, Room: Crane, Chair: Li-Wei Ko

8:00AM ***H2 Guaranteed Cost of Uncertain Continuous T-S Fuzzy Systems by Multiple Lyapunov Function Approach*** *[#87]*
Wen-Ren Horng, Chun-Hsiung Fang, Ching-Hsiang Lee and Jyh-Horng Chou

8:20AM ***Higher Order Sliding Fuzzy Type-2 Interval Control for SISO Uncertain Nonlinear Systems*** *[#508]*
Malik Manceur, Essounbouli Najib and Hamzaoui Abdelaziz

8:40AM ***Output Regulation Using Integral Fuzzy Predictive Control with Piecewise Lyapunov Functions*** *[#248]*
Chien-Hung Liu and Kuang-Yow Lian

9:00AM ***Power Management of a Variable Speed Wind Turbine for Stand-Alone System using Fuzzy Logic*** *[#580]*
Minh Huynh Quang, Frederic Nollet, Najib Essounbouli and Abdelaziz Hamzaoui

9:20AM ***Robust stabilization for continuous fuzzy systems with time varying delay*** *[#550]*
Chedia Latrach, Mourad Kchaou, Ahmed Hajjaji and Ahmed Toumi

9:40AM ***Splitting K-means Generated Neural Fuzzy System with Support Vector Regression*** *[#406]*
Cheng-Da Hsieh and Chia-Feng Juang

10:00AM ***Fuzzy Reinforcement Learning Control for Decentralized Partially Observable Markov Decision Processes*** *[#523]*
Rajneesh Sharma and Matthijs T. J. Spaan

(SS10-2) Special Session: Medical and Wellness Engineering

Wednesday, June 29, 8:00AM-10:20AM, Room: Egret, Chair: Yutaka Hata

8:00AM ***A challenge to biometrics by sole pressure while walking*** *[#338]*
Takahiro Takeda, Kei Kuramoto, Syoji Kobashi and Yutaka Hata

8:20AM ***Six Degree of Freedom Calculation Based on Principal Component Analysis for the Knee Joint in MDCT Image*** *[#433]*
Yosuke Uozumi, Kouki Nagamune, Daisuke Araki, Tomoyuki Matsumoto and Takehiko Matsushita

8:40AM ***Nursing-care Text Classification using Additional Term Information from Web*** *[#336]*
Manabu Nii, Takafumi Yamaguchi, Yusuke Mori, Yutaka Takahashi and Atsuko Uchinuno

9:00AM ***A Development of Navigation System for MOSAIC PLASTY using Electromagnetic Sensor*** *[#413]*
Takayasu Toyoshima, Kouki Nagamune, Daisuke Araki, Tomoyuki Matsumoto and Seiji Kubo

9:20AM ***A Quantitative Measurement System of Endpoint during Lachman tTest with Force Sensor*** *[#379]*
Shogo Kawaguchi, Kouki Nagamune, Daisuke Araki, Tomoyuki Matsumoto and Seiji Kubo

9:40AM ***Human Motion Tracking for Cognitive Rehabilitation in Informationally Structured Space Based on Sensor Networks*** *[#569]*
Yuichiro Toda, Kodai Yuki, Eriko Hiwada and Naoyuki Kubota

10:00AM ***A Pervasive Multi-sensor Data Fusion for Smart Home Healthcare Monitoring*** *[#472]*
Hamid Medjahed, Dan Istrate, Jerome Boudy, Jean-Louis Baldinger and Bernadette Dorizzi

(SS13-1) Special Session: Fuzzy Multiple Criteria Decision Making
Wednesday, June 29, 8:00AM-10:20AM, Room: Swallow, Chair: Gwo-Hshiung Tzeng

8:00AM ***Value Driver Derivations for Embedded Memories by Fuzzy DEMATEL based Hybrid MCDM Methods*** *[#530]*
Chi-Yo Huang and Gwo-Hshiung Tzeng

8:20AM ***Fuzzy Multiple Attribute Decision Making Theory With The Balanced Scorecard Application In Mobile Industry*** *[#369]*
Chiu-Hung Su, Ying-Hsun Hung and Gwo-Hshiung Tzeng

8:40AM ***Fuzzy MCDM Application for Strategy Evaluation*** *[#383]*
Mei-Chen Lo and Gwo-Hshiung Tzeng

9:00AM ***Exploring the SPM System Structure Model by Using Fuzzy DEMATEL for NPD*** *[#342]*
Chang Yu-Yun, Kuan Meng-Jong, Chuang Yen-Ching and Tzeng Gwo-Hshiung

9:20AM ***Interdependent Multiple Objective Programming- A Monte Carlo Method*** *[#398]*
Jih-Jeng Huang and Chin-Yi Chen

9:40AM ***Handling Fuzzy Decision Making Problem based on Linguistic Information and Intersection Concept*** *[#93]*
Chen-Tung Chen, Ping-Feng Pai and Wei-Zhan Hung

10:00AM ***Evaluate and Identify Optimal Weapon Systems Using Fuzzy Multiple Criteria Decision Making*** *[#14]*
Ying Bai and Dali Wang

(HCGC-1) Competition: Human vs. Computer Go Competition
Wednesday, June 29, 8:00AM-10:20AM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Wednesday, June 29, 8:00AM-9:00AM

Invited Talk I: Casual Communication between Robots and Humans based on Robot Technology Middleware and Multimedia Recognition
Wednesday, June 29, 8:00AM-9:00AM, Room: Grand Ballroom I, Speaker: Kaoru Hirota

Wednesday, June 29, 8:00AM-10:20AM

(FA-2) Fuzzy Applications
Wednesday, June 29, 8:00AM-10:20AM, Room: Grand Ballroom II, Chair: Qiang Shen

8:00AM ***Fuzzy-rough Classifier Ensemble Selection*** *[#134]*
Ren Diao and Qiang Shen

8:20AM ***Kernel-Based Fuzzy-Rough Nearest Neighbour Classification*** *[#135]*
Yanpeng Qu, Changjing Shang, Qiang Shen, Neil MacParthalain and Wei Wu

8:40AM ***FAPOP: Feature Analysis Enhanced Pseudo Outer-Product Fuzzy Rule Identification System*** *[#240]*
Sau Wai Tung, Chai Quek and Cuntai Guan

9:00AM ***Tracking Control of Surface Vessels via Adaptive Type-2 Fuzzy Logic Control*** *[#256]*
Xue Tao Chen and Woei Wan Tan

9:20AM ***Relaxed Fuzzy Lyapunov Approach for Dynamic Local Model Networks*** *[#263]*
Christian Mayr, Christoph Hametner, Martin Kozek and Stefan Jakubek

9:40AM ***Vehicle Warning System for Land Departure and Collision Avoidance: Using Adaptive Fuzzy Decision Making*** *[#484]*
Chih-Li Huo, Yu-Hsiang Yu, Jhih-Cheng Syu and Tsung-Ying Sun

10:00AM ***Centroid Density of Interval Type-2 Fuzzy Sets: Comparing Stochastic and Deterministic Defuzzification*** *[#444]*
Ondrej Linda and Milos Manic

Wednesday, June 29, 10:50AM-12:00PM

(HCGC-2) Competition: Human vs. Computer Go Competition
Wednesday, June 29, 10:50AM-12:00PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Keynote Speech II: Fuzzy Approaches to Information Fusion
Wednesday, June 29, 10:50AM-12:00PM, Room: Grand Ballroom I, Speaker: Bernadette Bouchon-Meunier

Wednesday, June 29, 1:30PM-2:30PM

(HCGC-3) Competition: Human vs. Computer Go Competition
Wednesday, June 29, 1:30PM-2:30PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Plenary Speech II: Soft Computing in Prognostics and Health Management (PHM) Applications: A Case Study in Anomaly Detection
Wednesday, June 29, 1:30PM-2:30PM, Room: Grand Ballroom I, Speaker: Piero Bonissone

Wednesday, June 29, 2:30PM-4:30PM

(PS03) Poster Session III
Wednesday, June 29, 2:30PM-4:30PM, Room: Grand Ballroom II

P501 ***Statistical Scheme via AIC for Evaluating the Optimal Cut Off Level in Fuzzy Clustering*** *[#370]*
Shuya Kanagawa, Kimiaki Shinkai, Hsunhsun Chung and Kenichi Nagashima

P502 ***Genetic Algorithm Based Fully Automated and Adaptive Fuzzy Logic Controller*** *[#371]*
Pintu Shill, Kishore Pal, Faijul Amin and Kazuyuki Murase

P503 ***A Comparison of Distance-based Semi-Supervised Fuzzy c-Means Clustering Algorithms*** *[#373]*
Daphne Teck Ching Lai and Jonathan M. Garibaldi

P504 ***Applying MDL in PSO for Learning Bayesian Networks*** *[#382]*
Shu-Ching Kuo, Hung-Jen Wang, Hsiao-Yi Wei, Chih-Chuan Chen and Sheng-Tun Li

P505 ***Relational Structure Analysis of Fuzzy Node Fuzzy Graph and its Application*** *[#385]*
Hiroaki Uesu, Kenichi Nagashima, Hsunhsun Chung and Ei Tsuda

P506 ***On another approach to the definition of an L-fuzzy valued integral*** *[#419]*
Vecislavs Ruza and Svetlana Asmuss

P507 ***Evolving Fuzzy Image Segmentation*** *[#422]*
Ahmed Othman and Hamid Tizhoosh

P508 ***On spline methods of approximation under L-fuzzy information*** *[#430]*
Svetlana Asmuss and Alexander Sostak

P509 ***Local Non-Quadratic H-infinity Control For Continuous-Time Takagi-Sugeno Models*** *[#440]*
Miguel Bernal, Adolfo Soto-Cota, Joaquin Cortez, Jose Luis Pitarch and Abdelhafidh Jaadari

P510 ***Fuzzy Active Contour Models*** *[#451]*
Cesar Pereira, Carlos Bastos, Ren Tsang and George Cavalcanti

P511 ***Discretization of fuzzy transitive relations*** *[#470]*
D. Boixader and J. Recasens

P512 ***Tridimensional Fuzzy Pain Assessment*** *[#476]*
Ernesto Araujo and Suzana Miyahira

P513 ***Integrate Variable Precision Rough Sets and Modified PBMF Index Function for Partitioning and Classifying Complex Datasets*** *[#478]*
Kuang Yu Huang and Yu-Hsin Cheng

P514 ***Anti-Swing Control of A New Container Crane With Fuzzy Uncertainties Compensation*** *[#486]*
Weimin Xu, Wei Gu, Aidi Shen, Jianxin Chu and Wangqiang Niu

P515 ***A Robust Method for Image Segmentation of Noisy Digital Images*** *[#492]*
Prabhjot Kaur, I. M. S. Lamba and Anjana Gosain

P516 ***The Fuzzy DEMATEL based Job Accommodation Strategy Definitions for Operators with Hearing Impairments*** *[#534]*
Chi-Yo Huang and Gwo-Hshiung Tzeng

P517 ***A Fuzzy MCDM method to select the best company based on Financial Report Analysis****[#527]*
Jung-Yuan Kung, Tzung-Nan Chuang and Minh Ky Chau

P518 ***Improve Observation-Based Discrete Hidden Markov Model by Fuzzy Vector Quantization -- An example on electroencephalogram (EEG) signal recognition*** *[#572]*
Shing-Tai Pan, Sheng-Fu Liang, Tzung-Pei Hong and Jian-Hong Zeng

P519 ***Design of Interval Type-2 Fuzzy Logic Systems Using Prior Knowledge via Optimization Algorithms*** *[#92]*
Tiechao Wang and Jianqiang Yi

P520 ***Fuzzy Reinforcement Learning for System of Systems (SOS)*** *[#34]*
Hamid Berenji and Mo Jamshidi

Wednesday, June 29, 2:50PM-4:30PM

(SS20) Special Session: Universal Contents Creation/Distribution and Intelligent System
Wednesday, June 29, 2:50PM-4:30PM, Room: Swan, Chair: Katsuhiro Honda

2:50PM ***Partially Exclusive Condition for Sequential Fuzzy Co-cluster Extraction*** *[#48]*
Katsuhiro Honda, Akira Notsu and Hidetomo Ichihashi

3:10PM ***DEA based Hierarchical Structure Evaluation and Vissualization Method*** *[#323]*
Kazushige Inoue, Takeo Ichinotsubo and Shingo Aoki

3:30PM ***Group Decision Focusing on Outliers*** *[#115]*
Tomoe Entani

3:50PM ***PCA-guided k-Means Clustering With Incomplete Data*** *[#15]*
Katsuhiro Honda, Ryoichi Nonoguchi, Akira Notsu and Hidetomo Ichihashi

4:10PM ***Proposed Particle-Filtering Method for Reinforcement Learning*** *[#53]*
Akira Notsu, Katsuhiro Honda and Hidetomo Ichihashi

(SS03) Special Session: Uncertainty and the Semantic Web

Wednesday, June 29, 2:50PM-4:30PM, Room: Peacock, Chair: Fernando Bobillo

2:50PM ***Formalizing Object Membership in Fuzzy Ontology with Property Importance and Property Priority*** *[#298]*
Yi Cai and Ho-fung Leung

3:10PM ***Aggregation Operators and Fuzzy OWL 2*** *[#142]*
Fernando Bobillo and Umberto Straccia

3:30PM ***Are Fuzzy Description Logics with General Concept Inclusion Axioms Decidable?*** *[#310]*
Franz Baader and Rafael Penaloza

3:50PM ***Fuzzy Concept Lattice Construction: A Basis for Building Fuzzy Ontologies*** *[#454]*
Valerie Cross and Meenaskhi Kandasamy

4:10PM ***Fuzziness, OWA and Linguistic Quantifiers for Web Selection Processes*** *[#420]*
Ronald R. Yager, Marek Z. Reformat and Giray Gumrah

(SS04) Special Session: Soft Computing for Operations Research and Optimization

Wednesday, June 29, 2:50PM-4:30PM, Room: Phoenix, Chair: Takashi Hasuike

2:50PM ***Visual Stability Improvement of SOM's Feature Map by Initial Value Assignment*** *[#502]*
Shinji Momoi and Tsutomu Miyoshi

3:10PM ***Study of morphogenesis of a large-span roof that satisfies its form design requirements*** *[#61]*
Yuya Takeda and Kazutoshi Tsutsumi

3:30PM ***Multiobjective Two-Level 0-1 Programming through Distributed Genetic Algorithms*** *[#86]*
Keiichi Niwa, Tomohiro Hayashida and Masatoshi Sakawa

3:50PM ***Optimal Static Output Feedback Control of Fuzzy-Model-Based Control Systems*** *[#12]*
Wen-Hsien Ho, Chen Shinn-Horng, Chou Jyh-Horng and Shu Chun-Chin

4:10PM ***An Interactive Satisficing Method for Multiobjective Random Fuzzy Programming Problems through the Possibility-Based Probability Model*** *[#197]*
Hideki Katagiri, Masatoshi Sakawa and Takeshi Matsui

(SS01) Special Session: Fuzzy Ontologies and FML Applications

Wednesday, June 29, 2:50PM-4:30PM, Room: Crane, Chair: Giovanni Acampora

2:50PM ***Improving Ontology Alignment through Memetic Algorithms*** *[#307]*
Giovanni Acampora, Pasquale Avella, Vincenzo Loia, Salerno Saverio and Autilia Vitiello

3:10PM ***Genetic Fuzzy Markup Language for Diet Application*** *[#468]*
Chang-Shing Lee, Mei-Hui Wang, Zhi-Wei Chen, Chin-Yuan Hsu, Su-E Kuo, Hui-Ching Kuo, Hui-Hua Cheng and Akio Naito

3:30PM ***A Hierarchical Approach to Assess Keyword Dependencies in Fuzzy Keyword Ontologies*** *[#124]*
Christer Carlsson, Robert Fuller and Mario Fedrizzi

3:50PM ***Improving Disease Prediction Using ICD-9 Ontological Features*** *[#148]*
Mihail Popescu and Mohammed Khalilia

(SS42-2) Special Session: Fuzzy Cognitive Maps-Theory and Applications
Wednesday, June 29, 2:50PM-4:30PM, Room: Egret, Chair: Chair: Elpiniki I. Papageorgiou and Sebastian Lozano

2:50PM ***Software Maintenance Scenarios Simulation with Fuzzy Cognitive Maps*** *[#514]*
Cristina Lopez, Jose L. Salmeron and Sebastian Lozano

3:10PM ***Train Fuzzy Cognitive Maps by Gradient Residual Algorithm*** *[#262]*
Huiliang Zhang, Zhiqi Shen and Chunyan Miao

3:30PM ***Causal Modeling Approximations In The Medical Domain*** *[#556]*
Lawrence Mazlack

3:50PM ***Interactive fuzzy programming through possibility measures and probability maximization for two-level linear programming problems involving fuzzy random variable coefficients*** *[#163]*
Masatoshi Sakawa, Hideki Katagiri and Takeshi Matsui

(SS21-2) Special Session: Fuzzy Control in Industrial and Application
Wednesday, June 29, 2:50PM-4:30PM, Room: Swallow, Chair: Shun-Hung Tsai, Chin-Sheng Chen and Ming-Ying Hsiao

2:50PM ***Decentralized Fuzzy Fault Tolerant Control for Multiple Satellites Attitude Synchronization*** *[#265]*
Junquan Li and K. D. Kumar

3:10PM ***T-S Fuzzy Tracking and Synchronous Control in a Gantry Stage*** *[#128]*
Chin-Sheng Chen, Chao-Feng Lee, Po-Huan Chou, Faa-Jeng Lin and Shun-Hung Tsai

3:30PM ***Observer-Based Adaptive FNN Control of Robot Manipulators: PSO-SA Self Adjust Membership Approach*** *[#181]*
Kai-Shiuan Shih, Tzuu-Hseng S. Li and Shun-Hung Tsai

3:50PM ***Design of Digital Battery Charger System Based on PV-Module*** *[#137]*
Ta-Tau Chen, Ming-Ying Hsiao, Shun-Hung Tsai and Che-Nan Lin

4:10PM ***Fuzzy Approaches for Multiobjective Stochastic Linear Programming Problems Considering Both Probability Maximization and Fractile Optimization*** *[#217]*
Hitoshi Yano

(HCGC-4) Competition: Human vs. Computer Go Competition
Wednesday, June 29, 2:50PM-4:30PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Wednesday, June 29, 4:30PM-7:00PM

(PS04) Poster Session IV
Wednesday, June 29, 4:30PM-7:00PM, Room: Grand Ballroom II

P701 ***Performance Enhancement of Hierarchical Document Signature: A Comprehensive Study*** *[#497]*
Sukanya Manna and Tom Gedeon

P702 ***Sliding Adaptive Fuzzy Control for a Class of Time-Delayed Chaotic Systems*** *[#509]*
Negin Farzbod, Hassan Zarabadipour, Mahdi Aliyari Shoorehdeli and Faezeh Farivar

P703 ***Estimating Missing Value in Microarray Gene Expression Data*** *[#515]*
Amit Paul and Jaya Sil

P704 ***Interval Fuzzy Modeling Applied to Model Based Fault Detection of an Active Suspension System*** *[#537]*
Tayebe Sadat Ghiasi, Hassan Zarabadipour and Mahdi Aliyari Shoorehdeli

P705 ***Uncertainty Management in Type-2 Fuzzy Face-Space for Emotion Recognition*** *[#541]*
Rajshree Mandal, Anisha Halder, Pavel Bhowmik, Aruna Chakraborty, Amit Konar and Atulya K. Nagar

P706 ***Generation of Takagi-Sugeno Fuzzy Systems with Minimum Rules in Modeling and Identification*** *[#549]*
Feng Wan and Chenglin Hu

P707 ***Maximum Power Point Tracker for a PV Cell using a Fuzzy Agent adapted by the Fractional Open Circuit Voltage Technique*** *[#551]*
Moustafa Adly, Hisham El-Sherif and Mohamed Ibrahim

P708 ***Improvement of Digital Image Motion Compensation by Fuzzy Inference*** *[#597]*
Sheng-Che Hsu

P709 ***A Semisupervised Feature Extraction Method Based on Fuzzy-type Linear Discriminant Analysis*** *[#598]*
Hui-Shan Chu, Cheng-Hsuan Li, Bor-Chen Kuo and Chin-Teng Lin

P710 ***The Emotion Recognition System with Heart Rate Variability and Facial Image Features*** *[#599]*
Pei-Yang Hsieh and Chiun-Li Chin

P711 ***Fuzzy Control of a Bi-directional Inverter with Nonlinear Inductance for DC Microgrids*** *[#610]*
Gwo-Ruey Yu

P712 ***The Development of the Automatic Lane Following Navigation System for the Intelligent Robotic Wheelchair*** *[#611]*
Wen-Chang Cheng and Chia-Ching Chiang

P713 ***The Prediction of Trust Rating Based on the Quality of Services Using Fuzzy Linear Regression*** *[#614]*
Hadi Mashinchi, Lei Li, Mehmet Orgun and Yan Wang

P714 ***Observer-based Hybrid Fuzzy CMAC Controller for a Class of Uncertain Chaotic Systems*** *[#616]*
Chun-Sheng Chen

P715 ***Automated Boundary Extraction and Visualization System for Coronary Plaque in IVUS Image by Using Fuzzy Inference-based Method*** *[#271]*
Takanori Koga, Eiji Uchino and Noriaki Suetake

P716 ***Multi-source Knowledge Based Unnormalized Interval Type-2 Fuzzy Logic Systems Design*** *[#154]*
Tiechao Wang, Jianqiang Yi and Chengdong Li

P717 ***On the Properties of SIRMs Connected Type-1 and Type-2 Fuzzy Inference Systems*** *[#264]*
Chengdong Li, Guiqing Zhang, Jianqiang Yi and Tiechao Wang

P718 ***Digital controller design for fuzzy systems with packet loss: intelligent digital redesign approach*** *[#333]*
Geun Bum Koo, Jin Bae Park, Young Hoon Joo and Hyoung Seok Jeon

P719 ***Mixed-Time T-S Fuzzy Optimal Estimator for Target Tracking*** *[#517]*
Sun Young Noh, Jin Bae Park and Young Hoon Joo

P720 ***Generalized Projective Synchronization of Time-Delayed Chaotic Systems via Sliding Adaptive Fuzzy Control*** *[#540]*
Negin Farzbod, Hassan Zarabadipour, Mahdi Aliyari Shoorehdeli and Faezeh Farivar

Wednesday, June 29, 5:00PM-6:00PM

Invited Talk II: Acceleration and Scalability for c-Means Clustering
Wednesday, June 29, 5:00PM-6:00PM, Room: Swan, Speaker: James Bezdek

Wednesday, June 29, 5:00PM-7:00PM

(SS40) Special Session: Fuzzy Approach for Information Security Management
Wednesday, June 29, 5:00PM-7:00PM, Room: Peacock, Chair: Che-Hung Liu

5:00PM ***Knowledge Management, Education and Firm's Performance*** *[#416]*
Yen-Tzu Chen, Yun-Chia Yan, Hsiao-Wen Huang and Hua-Wei Huang

5:20PM ***Expert decision making method based on uncertain linguistic variables*** *[#525]*
Tzung-Nan Chuang, Jung-Yuan Kung, Yin-Fang Lin and Hsiang-Chun Ku

5:40PM ***Applying FML and Fuzzy Ontologies to Malware Behavioural Analysis*** *[#575]*
Hsien-De Huang, Giovanni Acampora, Vincenzo Loia, Chang-Shing Lee and Hung-Yu Kao

6:00PM ***Applying Fuzzy AHP to Study the KSFs of Information Security Management*** *[#401]*
Jen-Sheng Wang, Che-Hung Liu, Joseph Z. Shyu and Hsiao-Wen Huang

6:20PM ***An Extension of a Fuzzy Ontology for Flexible Querying*** *[#6]*
Nouredine Tamani, Ludovic Lietard and Daniel Rocacher

6:40PM ***A Computational Linguistic Approach for the Identification of Translator Stylometry using Arabic-English Text*** *[#329]*
Heba El-Fiqi, Eleni Petraki and Hussein A. Abbass

(SS38) Special Session: Fuzzy Knowledge Discovery and Its Applications
Wednesday, June 29, 5:00PM-7:00PM, Room: Phoenix, Chair: Rung-Ching Chen

5:00PM ***Genetic-Fuzzy Association Rules for Network Intrusion Detection Systems*** *[#364]*
Ming-Yang Su, Chun-Yuen Lin, Sheng-Wei Chien and Han-Chung Hsu

5:20PM ***Personalized Recommendation for Web-based Learning Based on Ant Colony Optimization with Segmented-goal and Meta-Control Strategies*** *[#459]*
Feng-Hsu Wang

5:40PM ***A novel fuzzy recommendation system integrated the experts' opinion*** *[#461]*
Li Chen Cheng and Hua An Wang

6:00PM ***Fuzzy Rule-Based Stock Trading System*** *[#464]*
I-Cheng Yeh and Che-hui Lien

6:20PM ***Towards Application of FML in Suspicion of Non-Common Diseases*** *[#582]*
Giovanni Acampora, Tatiana Kiseliova, Karaman Pagava and Autilia Vitiello

6:40PM ***Linguistic summarization of long-term trends for understanding change in human behavior*** *[#296]*
Maria Ros, Derek Anderson, James Keller, Manuel Pegalajar, Miguel Delgado, Amparo Vila and Mihail Popescu

(SS39) Special Session: Fuzzy Based Computation on Biomedical Systems
Wednesday, June 29, 5:00PM-7:00PM, Room: Crane, Chair: Shing-Tai Pan

5:00PM ***Fuzzy Knowledge Approach to Automatic Disease Diagnosis*** *[#281]*
Giuseppe Fenza, Vincenzo Loia, Carmen De Maio, Mariacristina Gallo, Roberto Linciano and Aldo Morrone

5:20PM ***Predicting Laboratory Testing in Intensive Care using Fuzzy and Neural Modeling*** *[#349]*
Federico Cismondi, Andre Fialho, Susana Vieira, Joao Sousa and Shane Reti

5:40PM ***A fuzzy inference system for sleep staging*** *[#109]*
Liang Sheng-Fu, Chen Ying-Huang, Kuo Chih-En, Chen Jyun-Yu and Hsu Sheng-Che

6:00PM ***Fusion of Fuzzy Logic and PD Control for a Five-Fingered Smart Prosthetic Hand*** *[#485]*
Cheng-Hung Chen and D. Subbaram Naidu

6:20PM ***Hierarchical-interpolative Fuzzy System Construction by Genetic and Bacterial Programming Algorithms*** *[#414]*
Krisztian Balazs and Laszlo T. Koczy

6:40PM ***Study on Various Defuzzification Methods for Fuzzy Clustering Algorithms to Improve ROIs Detection in Lung CTs*** *[#140]*
Alberto Rey, Bernardino Arcay and Alfonso Castro

(SS17-2 & SS15) Special Session: Practical and Applications Aspects of Type-2 Fuzzy Logic Systems & Type-2 Fuzzy Logic Theory
Wednesday, June 29, 5:00PM-7:00PM, Room: Egret, Chair: Hani Hagras and Christian Wagner

5:00PM ***Comparison and Practical Implementation of Type-Reduction Algorithms for Type-2 Fuzzy Sets and Systems*** *[#24]*
Dongrui Wu and Maowen Nie

5:20PM ***Interpreting Fuzzy Set Operations and Multi Level Agreement in a Computing with Words Context*** *[#602]*
Christian Wagner and Hani Hagras

5:40PM ***An Adaptive Type-2 Fuzzy Logic Controller for Dynamic Positioning*** *[#211]*
Xue Tao Chen and Woei Wan Tan

6:00PM ***Interval Type-2 Recurrent Fuzzy Neural System Desing via Stable Simultaneous Perturbation Stochastic Approximation Algorithm*** *[#269]*
Feng-Yu Chang and Ching-Hung Lee

6:20PM ***Efficient centroid computation of general type-2 fuzzy sets with linear secondary membership function*** *[#145]*
Liu Xinwang

6:40PM ***Type-2 Fuzzy Airplane Altitude Control: A Comparative Study*** *[#283]*
Sheir Afgen Zaheer and Jong-Hwan Kim

(SS30 & SS43) Special Session: Fuzzy Inference Systems-Theory and Applications &Fuzzy Systems of Unknown Nonlinear Complex Systems
Wednesday, June 29, 5:00PM-7:00PM, Room: Swallow, Chair: Chi-Hsu Wan and Shih-Yu Li

5:00PM ***Solving Zadeh's Magnus Challenge Problem on Linguistic Probabilities via Linguistic Weighted Averages*** *[#436]*
Mohammad Reza Rajati, Jerry Mendel and Dongrui Wu

5:20PM ***Linguistic Weighted Power Means: Comparison with the Linguistic Weighted Average*** *[#68]*
John T. Rickard, Janet Aisbett, Ronald R. Yager and Greg Gibbon

5:40PM ***Finding the Capacity of Fuzzy Neural Networks (FNNs) via Its Equivalent Fully Connected Neural Networks (FFNNs)*** *[#241]*
Jing Wang, Chi-Hsu Wang and C. L. Philip Chen

6:00PM ***On the Classification of Cancer Cell Gene via Expressive Value Distance (EVD) Algorithm and Its Comparison to the Optimally Trained ANN Method*** *[#589]*
Tong Zhang, Sik Chung Tam, Chi-Hsu Wang and C.L. Philip Chen

6:20PM ***Adaptive Neural-Fuzzy Inference System for Classification of Rail Quality Data with Bootstrapping-Based Over-Sampling*** *[#592]*
Yong Yao Yang, Mahdi Mahfouf, George Panoutsos, Steve Thornton and Qian Zhang

6:40PM ***Passive Fuzzy Control for Uncertain Noulinear Stochastic Inverted Pendulum Robot System*** *[#219]*
Wen-Jer Chang, Sin-Sian Jheng and Cheung-Chieh Ku

(HCGC-5) Competition: Human vs. Computer Go Competition
Wednesday, June 29, 5:00PM-7:00PM, Room: Magpie, Chair: Chang-Shing Lee, Martin Muller, Olivier Teytaud, and Shun-Chin Hsu

Wednesday, June 29, 6:00PM-7:00PM

Invited Talk III: Activity Summarization from 3D Video Systems in an Eldercare Environment
Wednesday, June 29, 6:00PM-7:00PM, Room: Swan, Speaker: Jim Keller

Thursday, June 30, 8:00AM-10:20AM

(SS23) Special Session: Industrial Applications of Evolving Fuzzy Systems

Thursday, June 30, 8:00AM-10:20AM, Room: Swan, Chair: Kit Yan Chan

8:00AM ***Economic Load Dispatch using Intelligent Optimization with Fuzzy Control*** *[#105]*
Johnny C.Y. Lai, Frank H. Leung, S. H. Ling and Edwin C. Shi

8:20AM ***Hypoglycemia Detection using Fuzzy Inference System with Genetic Algorithm*** *[#28]*
Sai Ho Ling, Hung Nguyen and F.H.F Leung

8:40AM ***An Approach for Stability Analysis of Polynomial Fuzzy Model-Based Control Systems*** *[#280]*
Mohammad Narimani, Hak-Keung Lam, Kaspar Althoefer, Reza Shams Dilmaghani, Charles Wolfe and Christian Deters

9:00AM ***A Distributed Smart Routing Scheme for Terrestrial Sensor Networks with Hybrid Neural Rough Sets*** *[#588]*
Frank Jiang and Steve Ling

9:20AM ***P2P Traffic Identification and Optimization Using Fuzzy C-means Clustering*** *[#435]*
Duo Liu and Chung-Horng Lung

9:40AM ***Determination Of Process Conditions Of Epoxy Dispensing Processes Using A Genetic Algorithm Based Neural Fuzzy Networks*** *[#30]*
K. Y. Chan, T.S. Dillon, S. H. Ling and C.K. Kwong

10:00AM ***Manufacturing Modeling Using An Evolutionary Fuzzy Regression*** *[#31]*
K.Y. Chan, T.S. Dillon, S.H. Ling and C.K. Kwong

(MFI & RWA) Medical, Financial, Industrial and Other Real World Applications

Thursday, June 30, 8:00AM-10:20AM, Room: Peacock, Chair: James Keller

8:00AM ***A Heuristic Search and its Roughness*** *[#153]*
Chun-Hung Tzeng and Fu-Shing Sun

8:20AM ***Linguistic description of adult skeletal age-at-death estimations from fuzzy integral acquired fuzzy sets*** *[#164]*
Derek Anderson, Melissa Anderson, James Keller and Daniel Wescott

8:40AM ***Moving Pattern-based Approach to Modeling of a Class of Complex Production Processes*** *[#491]*
Zhengguang Xu and Changping Sun

9:00AM ***Multiple Characterisation Modelling of Friction Stir Welding Using a Genetic Multi-objective Data-driven Fuzzy Modelling Approach*** *[#596]*
Qian Zhang, Mahdi Mahfouf, George Panoutsos, Kathryn Beamish and Ian Norris

9:20AM ***Fuzzy Modeling to Predict Administration of Vasopressors in Intensive Care Unit Patients*** *[#429]*
Andre Fialho, Federico Cismondi, Susana Vieira, Joao Sousa, Shane Reti, Leo Celi, Michael Howell and Stan Finkelstein

9:40AM ***Probing Performance Evaluation for NPD Process by Using MCDM Approach*** *[#354]*
Chia-Chun Hsiang, Meng-Jong Kuan and Gwo-Hshiung Tzeng

10:00AM ***Application of Adaptive Self-Organizing CMAC_GBF to Aircraft Landing System*** *[#221]*
Jih-Gau Juang

(FSM & IS) Fuzzy Systems Modeling and Intelligent Systems

Thursday, June 30, 8:00AM-10:20AM, Room: Phoenix, Chair: Honghai Liu

8:00AM ***Optimal Necessary Conditions for General SISO Mamdani Fuzzy Systems as Function Approximators within a Given Accuracy*** *[#522]*
Fuchun Sun, Jin Yang, Minnan Luo and Huaping Liu

8:20AM ***A fuzzy stochastic programming approach to solve the capacitated lot size problem under uncertainty*** *[#493]*
Navid Sahebjamnia and S.Ali Torabi

8:40AM ***Look-ahead intelligent energy management of a parallel hybrid electric vehicle*** *[#278]*
Behnam Ganji, Abbas Z. Kouzani and Hamid Khayyam

9:00AM ***Dynamic Window with Fuzzy Controller in Wireless Sensor Networks for Elliptic Curve Cryptography*** *[#38]*
Xu Huang, Dharmendra Sharma and Pritam Gajkumar Shah

9:20AM ***Regulation for Wind Generation System Using Ant System Based Takagi Sugeno Fuzzy PID*** *[#260]*
Ahmad Besheer and Abdo Tamer

9:40AM ***Actuator Delayed Active Vehicle Suspension Control: A T-S Fuzzy Approach*** *[#396]*
Hongyi Li, Honghai Liu and Huijun Gao

10:00AM ***Hinf Disturbance Attenuation of Fuzzy Large-Scale Systems*** *[#66]*
Mehdi Hosseinzadeh, Nasser Sadati and Iman Zamani

(FST & GC) Fuzzy Set Theory and Granular Computing

Thursday, June 30, 8:00AM-10:20AM, Room: Crane, Chair: Gwo-Hshiung Tzeng

8:00AM ***Dualities between Indistinguishabilities and Related Concepts*** *[#518]*
Gabriel Mattioli and Jordi Recasens

8:20AM ***Graded equipollence and fuzzy c-measures of finite fuzzy sets*** *[#559]*
Michal Holcapek

8:40AM ***On monotonicity of type <1,1> fuzzy quantifiers determined by fuzzy measures*** *[#437]*
Antonin Dvorak and Michal Holcapek

9:00AM ***Generalized Fuzzy Imaginary Ideals of Rings*** *[#104]*
Zuhua Liao, Shu Cao, Qinghe Tian, Miaohan Hu and Yang Zhang

9:20AM ***Cellular Fuzzy Networks*** *[#59]*
Koosha Sadeghi Oskooyee, Mohammad Mansour Riahi Kashani and Mehrdad Jangjou

9:40AM ***Expatriate Manager Selection for an Overseas Manufacturing Site by Using FMCDM Methods*** *[#568]*
Chi-Yo Huang, Chih-Wei Wan and Gwo-Hshiung Tzeng

10:00AM ***On the Geometry of Join and Meet Calculations for General Type-2 Fuzzy Sets*** *[#8]*
Jerry Mendel

(SS36-1) Special Session: Fuzzy Systems on Renewable Energy

Thursday, June 30, 8:00AM-10:20AM, Room: Egret, Chair: Faa-Jeng Lin

8:00AM ***A Fuzzy-Based Output Power Smoothing of WECS using Short-Term Ahead Prediction of Wind Speed*** *[#97]*
Yuya Izumi, Alok Pratap, Yoshihisa Kinjyo, Akie Uehara and Endusa Billy Muhando

8:20AM ***Frequency and Voltage Control by Decentralized Controllable Loads with Fuzzy Control*** *[#332]*
Yoshihisa Kinjyo, Tomonobu Senjyu, Atsushi Yona, Nomitsu Urasaki and Toshihisa Funabashi

8:40AM ***Short-Term Load Forecasting Via Fuzzy Neural Network With Varied Learning Rates*** *[#27]*
Rong-Jong Wai, Yi-Chang Chen and Yung-Ruei Chang

9:00AM ***A Fuzzy Control Maximum Power Point Tracking Photovoltaic System*** *[#133]*
Irwan Purnama, Lo Yu-Kang and Chiu Huang-Jen

9:20AM ***Fuzzy Control of MW-class PV Generation to Reduce Frequency and Tie-line Power Fluctuations in Three Control Area Power System*** *[#391]*
Manoj Datta, Tomonobu Senjyu, Atsushi Yona and Toshihisa Funabashi

9:40AM ***A Fuzzy-Rule Based Power Restoration Approach for a Distribution System with Renewable Energies*** *[#327]*
Hong-Tzer Yang, Jian-Tang Liao and Xiang-He Su

10:00AM ***Neuro-Fuzzy Predictive Model for PV Energy Production based on Weather Forecast*** *[#539]*
Francesco Grimaccia, Marco Mussetta and Riccardo E. Zich

(FS & FDM) Fuzzy Clustering and Fuzzy Data Mining
Thursday, June 30, 8:00AM-10:20AM, Room: Swallow, Chair: Tzung-Pei Hong

8:00AM ***Fuzzy Clustering Approach for Star-Structured Multi-Type Relational Data*** *[#165]*
Jian-Ping Mei and Lihui Chen

8:20AM ***Predicting Septic Shock Outcomes in a Database with Missing Data using Fuzzy Modeling*** *[#427]*
Ruben Pereira, Andre Fialho, Federico Cismondi, Susana Vieira, Joao Sousa, Rui Almeida, Uzay Kaymak, Shane Reti, Michael Howell and Stan Finkelstein

8:40AM ***A normalized soft window-based similarity measure to extend the Rand index*** *[#405]*
Romain Quere and Carl Frelicot

9:00AM ***Fuzzy Clustering With Learnable Cluster Dependent Kernels*** *[#149]*
Ouiem Bchir and Hichem Frigui

9:20AM ***The Interval Autoregressive Time Series Model*** *[#236]*
Xun Wang and Shoumei Li

9:40AM ***Feature Evaluation Based Fuzzy C-Mean Classification*** *[#229]*
Mostafa A. Salama, Aboul Ella Hassanien and Aly A. Fahmy

10:00AM ***A Clustering Method for Geometric Data based on Approximation using Conformal Geometric Algebra*** *[#386]*
Minh Tuan Pham, Kanta Tachibana, Tomohiro Yoshikawa and Takeshi Furuhashi

(HA) Hybrids and Other Applications
Thursday, June 30, 8:00AM-10:20AM, Room: Magpie, Chair: Bor-Sen Chen

8:00AM ***Improving Estimation Accuracy of the COCOMO II Using an Adaptive Fuzzy Logic Model*** *[#237]*
Iman Attarzadeh and Siew Hock Ow

8:20AM ***Fuzzy-Rough Set based Semi-Supervised Learning*** *[#259]*
Neil Mac Parthalain and Richard Jensen

8:40AM ***An Application of Genetic Fuzzy Systems for Wireless Sensor Networks*** *[#418]*
Liliam Leal, Marcus Lemos, Raimir Holanda, Ricardo Rabelo and Fabbio Borges

9:00AM ***On Predicting Learning Styles in Conversational Intelligent Tutoring Systems using Fuzzy Classification Trees*** *[#304]*
Keeley Crockett, Annabel Latham, Zuhair Bandar, James O'Shea and David Mclean

9:20AM ***Signal Transduction Ability Measurement of Signaling Pathways in Intracellular Communication via Fuzzy Method*** *[#501]*
Chia-Chou Wu and Bor-Sen Chen

9:40AM ***Long-term business cycle forecasting using intuitionistic fuzzy least-squares support vector regression*** *[#348]*
Kuo-Ping Lin, Kuo-Chen Hung and Ming-Chang Wu

Thursday, June 30, 10:50AM-12:00PM

Keynote Speech III: Soft Computing for Hard Pattern Recognition Problems
Thursday, June 30, 10:50AM-12:00PM, Room: Grand Ballroom I, Speaker: Paul Gader

Thursday, June 30, 1:30PM-2:30PM

(FOD) Fuzzy Optimization and Design
Thursday, June 30, 1:30PM-2:30PM, Room: Swan, Chair: Chia-Feng Juang

1:30PM ***Production Planning with Uncertain Demands*** *[#35]*
Guillaume Romain, Kobylanski Przemyslaw and Zielinski Pawel

1:50PM ***Min-Max and Two-Stage Possibilistic Combinatorial Optimization Problems*** *[#69]*
Kasperski Adam and Zielinski Pawel

2:10PM ***A Fuzzy Concept for Climate Management in Preventive Conservation*** *[#146]*
Christian Arnold, Steven Lambeck and Christoph Ament

(FO & FEC) Fuzzy Optimization and Fuzzy Emotional Computing
Thursday, June 30, 1:30PM-2:30PM, Room: Peacock, Chair: Chuan-Yu Chang

1:30PM ***Fuzzy Bipolar Conditions of Type "or else"*** *[#33]*
Ludovic Lietard, Nouredine Tamani and Daniel Rocacher

1:50PM ***Fuzzy Optimization Model Based Tolerance Approach to Timetable Rescheduling for High Speed Railway in China*** *[#130]*
Yong Qin, Li Wang, Huan Lian, Xuelei Meng, Xuewen Li, Fugui Shi and Limin Jia

2:10PM ***Online Neuro-Fuzzy CANFIS Hidden-Node Teaching*** *[#402]*
Eiji Mizutani and Jing-Yun Fan

(RS & RDA) Rough Sets and Rough Data Analysis
Thursday, June 30, 1:30PM-2:30PM, Room: Phoenix, Chair: Yo-Ping Huang

1:30PM ***Fuzzy Fusion Fairness Relations for the Evaluation of User Preference*** *[#358]*
Mario Koeppen, Jun Okamoto and Aoi Honda

1:50PM ***Multiple Criteria Group Decision Making with Triangular Interval Type-2 Fuzzy Sets*** *[#409]*
Kuo-Ping Chiao

2:10PM ***Noise Control in Document Classification Based On Fuzzy Formal Concept Analysis*** *[#207]*
Sheng-Tun Li and Fu-Ching Tsai

(T2FL) Type-2 Fuzzy Logic
Thursday, June 30, 1:30PM-2:30PM, Room: Crane, Chair: Hao Ying

1:30PM ***Deriving the Input-Output Mathematical Relationship for a Class of Interval Type-2 Mamdani Fuzzy Controllers*** *[#193]*
Haibo Zhou and Hao Ying

1:50PM ***Design of Interval of Type-2 Fuzzy Logic Controllers for Flocking Algorithm*** *[#231]*
Seung-Mok Lee, Jong-Hwan Kim and Hyun Myung

2:10PM ***Is it rational to partition a data set using Kernel-clustering?*** *[#536]*
Kaushik Sarkar and Nikhil R Pal

(SS36-2) Special Session: Fuzzy Systems on Renewable Energy
Thursday, June 30, 1:30PM-2:30PM, Room: Egret, Chair: Faa-Jeng Lin

1:30PM ***Fuzzy Quantum Computation Based Thermal Unit Commitment Strategy with Solar-battery System Injection*** *[#312]*
Shantanu Chakraborty, Tomonobu Senjyu, Atsushi Yona and Toshihisa Funabashi

1:50PM ***Control of Doubly-Fed Induction Generator System Using PFNN*** *[#46]*
Faa-Jeng Lin, Kuang-Hsiung Tan, Zong-Han Lu and Yung-Ruei Chang

(FDM & DSS-1) Fuzzy Decision Making and Decision Support Systems
Thursday, June 30, 1:30PM-2:30PM, Room: Swallow, Chair: Bao-Rong Chang

1:30PM ***Web User Identification with Fuzzy Fingerprints*** *[#203]*
Nuno Homem and Joao Carvalho

1:50PM ***Fuzzy Multiattribute Evaluation of Airport Performance*** *[#500]*
Chung-Hsing Yeh, Yu-Hern Chang and Yu-Liang Kuo

2:10PM ***An Intelligent Decision Support Tool Based on Belief Rule-Based Inference Methodology*** *[#305]*
Alberto Calzada, Jun Liu, Hui Wang, Luis Martinez and Kashyap Anil

(HFS) Hybrid Fuzzy Systems
Thursday, June 30, 1:30PM-2:30PM, Room: Magpie, Chair: I-Fang Chung

1:30PM ***Fuzzy Controller Design Using Group-Crossover Particle Swarm Optimization for Truck Reversing Control*** *[#225]*
Chia-Feng Juang, Yu-Cheng Chang, Chia-Hung Hsu and I-Fang Chung

1:50PM ***Evolving Ensemble of Fuzzy Models*** *[#85]*
Eng Yeow Cheu, Chai Quek and See Kiong Ng

2:10PM ***Long Term Bank Failure Prediction using Fuzzy Refinement-based Transductive Transfer Learning*** *[#467]*
Vahid Behbood, Jie Lu and Guangquan Zhang

Thursday, June 30, 2:50PM-4:30PM

(SS29) Special Session: Software Engineering with Computational Intelligence
Thursday, June 30, 2:50PM-4:30PM, Room: Swan, Chair: Nien-Lin Hsueh

2:50PM ***Developing a Fuzzy Search Engine Based on Fuzzy Ontology and Semantic Search*** *[#107]*
Lien-Fu Lai, Chao-Chin Wu, Pei-Ying Lin and Liang-Tsung Huang

3:10PM ***Multi-Agent Automatic Negotiation and Argumentation for Courses Scheduling*** *[#213]*
Jong Yih Kuo, Hsuan-KueiI Cheng, Yong-Yi FanJiang and Shang-Pin Ma

3:30PM ***Investment Decision Making by Using Fuzzy Candlestick Pattern and Genetic Algorithm*** *[#563]*
Chiung-Hon Lee, Lindroos Hsu and Yi-Ching Liaw

3:50PM ***Fuzzy Logic as a Basic for Use Case Point Estimation*** *[#577]*
Jonathan Lee, Wen-Tin Lee and Jong-Yih Kuo

4:10PM ***Fuzzy Lymphedema Assessment based on Clinical and Functional Criteria*** *[#524]*
Ernesto Araujo, Patricia Vicentini and Maria C. J. Perez

(SS34) Special Session: Brain and Learning
Thursday, June 30, 2:50PM-4:30PM, Room: Peacock, Chair: Toshihiko Watanabe

2:50PM ***Decision Making Based on Reinforcement Learning and Emotion Learning for Social Behavior*** *[#293]*
Atsushi Matsuda, Hideaki Misawa and Keiichi Horio

3:10PM ***Analysis of Relationship between Characteristics of Driver's Eye Movements and Visual Scene in Driving Events*** *[#561]*
Tetsuya Miyoshi and Hidetoshi Nakayasu

3:30PM ***Directional Control of an Omni-Directional Walker for Walking Support with Forearm Pressures*** *[#233]*
Yinlai Jiang, Shuoyu Wang, Kenji Ishida, Takeshi Ando and Masakatsu G. Fujie

3:50PM ***Construction of Collision Avoidance Behavior Model Induced by Visual Motion*** *[#457]*
Norifumi Watanabe, Hiroaki Mikado and Takashi Omori

4:10PM ***Instruction Knowledge Acquisition for Reinforcement Learning Scheme by PSO Algorithm*** *[#564]*
Toru Sawa and Toshihiko Watanabe

(SS35) Special Session: Fuzzy Regression Analysis and Its Applications
Thursday, June 30, 2:50PM-4:30PM, Room: Phoenix, Chair: M. Hadi Mashinchi

2:50PM ***A Formula for Fuzzy Linear Regression Analysis*** *[#374]*
Chi-Tsuen Yeh

3:10PM ***Real-Time Analysis of Granular Information: Some Initial Thoughts on a Convex Hull-based Fuzzy Regression Approach*** *[#175]*
Azizul Azhar Ramli, Witold Pedrycz, Junzo Watada and Nureize Arbaiy

3:30PM ***An Interval-Based Approach to Fuzzy Regression for Fuzzy Input-Output Data*** *[#215]*
Jalal Chachi, Taheri Seyed Mahmoud and Hojat Rezaei Pazhand

3:50PM ***Study of Dependency between the Input Noise and the Parameter in Fuzzy Linear Regression Model*** *[#372]*
Hongwei Ge, Shitong Wang and Wei Song

(SS41) Special Session: Neuro Fuzzy Systems and Their Real World Application
Thursday, June 30, 2:50PM-4:30PM, Room: Crane, Chair: Sungshin Kim

2:50PM ***Daily Reservoir Inflow Forecasting Using Fuzzy Inference Systems*** *[#542]*
Ivette Raymunda Luna Huamani, Rosangela Ballini, Ieda Geriberto Hidalgo, Paulo Sergio Franco Barbosa and Alberto Luiz Francato

3:10PM ***A Study on Hybrid Model of HMMs and GMMs for Mirror Neuron System Modeling using EEG Signals*** *[#289]*
Seung-Min Park, Junheong Park, Kwang-Eun Ko and Kwee-Bo Sim

3:30PM ***Optimal Input Selection for Neural Fuzzy Modelling With Application to Charpy Energy Prediction*** *[#601]*
Yong Yao Yang, Mahdi Mahfouf and Qian Zhang

3:50PM ***Stereo Vision-Based Self-Localization System for RoboCup*** *[#555]*
Jen-Shiun Chiang, Chih-Hsien Hsia, Hung-Wei Hsu and Chun-I Li

4:10PM ***Training Multilayer Perceptron By Using Optimal Input Normalization*** *[#488]*
Xun Cai, Kanishka Tyagi and Michael Manry

(SS25) Special Session: Evolving and Adaptive Fuzzy Systems
Thursday, June 30, 2:50PM-4:30PM, Room: Egret, Chair: Plamen Angelov

2:50PM ***Automatic Scene Recognition for Low-Resource Devices using Evolving Classifiers*** *[#583]*
Andreu Javier, Dutta Baruah Rashmi and Angelov Plamen

3:10PM ***Real Time Recognition of Human Activities from Wearable Sensors by Evolving Classifiers*** *[#415]*
Javier Andreu, Rashmi Dutta Baruah and Plamen Angelov

3:30PM ***Fuzzy Granular Evolving Modeling for Time Series Prediction*** *[#210]*
Daniel Leite, Fernando Gomide, Rosangela Ballini and Pyramo Costa

3:50PM ***Combustion Engine Modelling using an Evolving Local Model Network*** *[#84]*
Christoph Hametner and Stefan Jakubek

4:10PM ***Rough Set Approach to User Modeling*** *[#71]*
Binghui Helen Wu

(SS24) Special Session: Hybrid Learning for Fuzzy Systems
Thursday, June 30, 2:50PM-4:30PM, Room: Swallow, Chair: Jin-Tsong Jeng

2:50PM ***A Rough-based Robust Support Vector Regression Network for Function Approximation*** *[#212]*
Chih-Ching Hsiao, Shun-Feng Su and Chen-Chia Chuang

3:10PM ***An Immune Symbiotic Evolution Learning for Compensatory Neural Fuzzy Networks and Its Applications*** *[#32]*
Cheng-Hung Chen, Cheng-Jian Lin and Chin-Teng Lin

3:30PM ***Identification of Time-Delay Chaotic System with Outliers: Fuzzy Neural Networks Using Hybrid Learning Algorithm*** *[#214]*
Chia-Nan Ko, Yu-Yi Fu, Guan-Yu Liu and Cheng-Ming Lee

3:50PM ***A New Framework of Fuzzy Clustering Algorithm*** *[#99]*
Horng-Lin Shieh

4:10PM ***Modeling of Fuzzy Integral Based Nonlinear Multi-regressions Systems with QPSO-GS*** *[#270]*
You-Min Jau and Jin-Tsong Jeng

(SS32) Special Session: Adaptive Fuzzy Logic Control
Thursday, June 30, 2:50PM-4:30PM, Room: Magpie, Chair: Tsung-Chih Lin

2:50PM ***Direct Adaptive Fuzzy Control for Nonaffine Nonlinear Systems with Unknown Control direction*** *[#20]*
Salim Labiod and Thierry Marie Guerra

3:10PM ***An Observer Based Adaptive Iterative Learning Control for Robotic Systems*** *[#169]*
Ying-Chung Wang and Chiang-Ju Chien

3:30PM ***Synchronization of uncertain fractional order chaotic systems via adaptive interval type-2 fuzzy sliding mode control*** *[#80]*
Tsung-Chih Lin, Tun-Yuan Lee and Emilia Balas Valentina

3:50PM ***Fractional order chaotic system tracking design based on adaptive hybrid intelligent control*** *[#83]*
Tsung-Chih Lin, Chia-Hao Kuo and Emilia Balas Valentina

Thursday, June 30, 5:00PM-6:00PM

(SS22) Special Session: Fuzzy Methods in Machine Learning and Data Mining
Thursday, June 30, 5:00PM-6:00PM, Room: Swan, Chair: Shi-An Chen and Enrique Munoz

5:00PM ***Towards the Learning from Low Quality Data in a Fuzzy Random Forest ensemble*** *[#299]*
Jose M. Cadenas, M. Carmen Garrido, Raquel Martinez and Piero P. Bonissone

5:20PM ***Non-monotone averaging aggregation*** *[#480]*
Gleb Beliakov, Shui Yu and Daniel Paternain

5:40PM ***Linguistic Local Change Comparison Of Time Series*** *[#147]*
Rita Castillo-Ortega, Nicolas Marin and Daniel Sanchez

(FCW & PT) Fuzzy Computing with Words and Possibility Theory
Thursday, June 30, 5:00PM-6:00PM, Room: Peacock, Chair: Chin-Wang Tao

5:00PM ***Indirect Adaptive Model Predictive Control Supervised by Fuzzy Logic*** *[#434]*
Jerry Mamboundou and Nicolas Langlois

5:20PM ***Maximum likelihood principle for possibility distributions viewed as families of probabilities*** *[#319]*
Mathieu Serrurier and Henri Prade

(SS07 & SS33) Special Session: Metaheuristics and Its Applications & Fuzzy and Paraconsistent Intelligent Systems
Thursday, June 30, 5:00PM-6:00PM, Room: Phoenix, Chair: Chun-Wei Tsai and Shih-Yu Li

5:00PM ***Ant Colony Optimization with Dual Pheromone Tables for Clustering*** *[#378]*
Chun-Wei Tsai, Kai-Cheng Hu, Ming-Chao Chiang and Chu-Sing Yang

5:20PM ***Job Shop Scheduling Based on ACO with a Hybrid Solution Construction Strategy*** *[#376]*
Shih-Pang Tseng, Chun-Wei Tsai, Jui-Le Chen, Ming-Chao Chiang and Chu-Sing Yang

5:40PM ***The Sensing System for the Autonomous Mobile Robot Emmy III*** *[#321]*
Claudio Torres, Jair Abe, Germano Lambert-Torres and Joao da Silva Filho

(IA) Informatics & Analytics
Thursday, June 30, 5:00PM-6:00PM, Room: Crane, Chair: Janusz Kacprzyk and Lawrence Mazlack

5:00PM ***On a benchmark related assessment of the performance of mutual (investment) funds*** *[#297]*
Anna Wilbik and Janusz Kacprzyk

5:20PM ***Discerning Suicide Notes Causality Using Fuzzy Cognitive Maps*** *[#545]*
Ethan White and Lawrence Mazlack

(SS13-2) Special Session: Fuzzy Multiple Criteria Decision Making
Thursday, June 30, 5:00PM-6:00PM, Room: Egret, Chair: Gwo-Hshiung Tzeng

5:00PM ***Constant Penalty Functions to Simplify Optimization of the Choquet Integral under Constraints*** *[#235]*
Tanja Magoc

5:20PM ***Design of a reliable hub-and-spoke network using an interactive fuzzy goal programming*** *[#489]*
Mohammad Hossein Fazel Zarandi, Soheil Davari and Ali Haddad Sisakht

(FDM & DSS-2) Fuzzy Decision Making and Decision Support Systems
Thursday, June 30, 5:00PM-6:00PM, Room: Swallow, Chair: Kuang-Yow Lian

5:00PM ***Connection Manager : A FAHP-based System for Classifier and Decision-Making*** *[#198]*
Chih-Wei Hsu and Sheng-Tzong Cheng

***Abstract*—In this paper we propose a novel interaction approach, based on gestures, aiming to recognize and enhance interactions between augmented human beings and augmented environments. We explain how this model, we called ARAMIS, allows interaction designers to fill the gap between real and virtual worlds augmenting the human itself. An enhanced interaction is achieved exploiting a hybrid approach. This approach is defined hybrid since it is the combination of several complementary techniques: wearable and pervasive computing paradigms, brute force, fuzzy and ML methods, virtual and real worlds, optical and non-optical sensing technologies. A framework implementing this concept has been developed. Finally, in order to validate our approach, we present a first prototype implemented according to the ARAMIS concept.**

Keywords – HCI, Ambient Intelligence, gesture-based interaction, hybrid-approach

I. INTRODUCTION

People naturally communicate through the voice, gestures, expressions and movements. In HCI area several researches are addressing the design of natural user interfaces allowing the machine to understand the natural language of human beings [1]. In order to allow this kind of communication and bridge the gap between the human and the machine, natural interactions have to be understood by the system. With the same logic the system must provide a feedback as natural as possible. Although these are still opened research fields, at present AmI systems intrinsically have the potential to implement augmented natural-interaction[1]. For instances many of the manipulations used on multi-touch screens, such as the pinch, have no natural counterpart in our interactions with everyday life (it is not possible to pinch a piece of paper to make it smaller, while preserving its aspect ratio). This concept can be highly extended taking into account possibilities provided (at present or in the next years) by novel interaction vectors as smart, mixed reality environments and the approaching internet of things. In these cases the interaction experienced by the users can be extremely richer than the common interaction of every day [2].

The major contribution presented in this paper is the proposition of a hybrid interaction approach, called ARAMIS, aiming to enhance natural gesture-based interaction between humans and smart environments. Our approach is defined hybrid since it is based on four complementary approaches: environmental/wearable paradigms, brute force/fuzzy/machine learning methods, real/virtual worlds, optical/non-optical sensing technologies. ARAMIS uses this heterogeneity in order to exploit the strong points of individual approaches or technologies, and to overcome their weakness (such as light condition sensitivity in vision-based techniques or heavy training for neural network algorithms).

This paper is organized as follow: Section II presents some related work on the interaction between augmented human and smart environments. Section III briefly presents an envisioning scenario highlighting augmented interactions between the user and smart environments. Section IV describes the ARAMIS approach. Section V introduces how the ARAMIS framework handles the information. Section VI illustrates the implementation of the ARAMIS concept and a first prototype. Finally section VII concludes the paper.

II. RELATED WORKS

Studies on human augmentation through the technology have a long history in HCI domain. Since the works of Engelbart [3] the possibility to augment human capacities using the technology was taken into account. If the first studies focused on approaches to improve human abilities to deal with everyday issues, afterwards the problem changed with the years; technology evolved and from human-machine interaction scientific community starts to talk about human-machine cooperation [4], envisioning a kind of communication based on similitudes with the human-human interaction. Moreover, since the environment surrounding the human was progressively changing in something richer and at the same time more complex (in the interfaces, tools and objects), the

[1] Natural interaction is seen in this paper as the computers capability to exploit the perceptive abilities which so far have been a prerogative of human–human communication

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

need of an approach encompassing the wearable and pervasive dimension is becoming a central issue. Under this perspective Greenberg et al. [5] defines a novel interaction approach between users and pervasive devices based on their relative proximity (distance, orientation, identity, movement, and location). Pederson et al. [6] present an egocentric interaction model, in which wearable and pervasive paradigms are combined and interactions are classified based on human perceptual characteristic such as what can be observed and what can be manipulated. This model aimed at bridging the gap between real and mixed reality worlds. We differ from previous approaches by providing a perspective in which also the human has to be augmented in order to extend the interaction toward an augmented natural-interaction and, in addition, we focus on hybrid middleware able to take advantages from different techniques.

III. INTERACTION SCENARIO

This section briefly presents a scenario envisioning the augmented interactions possibilities offered by augmented human in smart environments.

Context: Human-computer interactions (HCI) taken into account in this project have as context a smart environment, with real and virtual interactive devices available inside, and a set of wearable devices woven seamlessly on the user. Alice, the system user, coming back home, is wearing her glasses (actually a head-mounted display). The house is an environment enriched by real and digital elements. Alice through gestures can interact with the surrounding environment in a natural, augmented way.

Interaction with virtual objects (virtual screen): Alice seats in her sofa and with a simple gesture (recognized through sensors woven in her clothes and sensors in the environments) a virtual screen appears in front of her. Passing a hand on the virtual screen, the hand changes shape becoming a mouse pointer and allowing an easier interaction with the screen (without the problem of occlusion, since the virtual objects can be superposed to the real hand). To watch a movie from her sofa she chooses to enlarge the screen and put it on the ceiling: she grabs the virtual screen corners and stretches her arms until the ceiling tuning the screen position, size and orientation (showed in Figure 1). After some time, enjoying the comfort of the sofa, she starts reading a book that is a virtual representation of a real, book that is physically placed in another room.

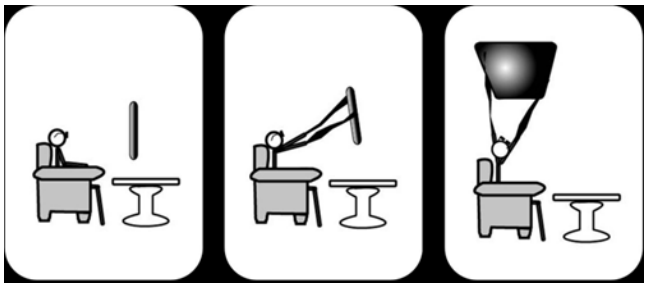

Figure 1. Interaction with a virtual screen

Virtual access to real objects: Alice decides to wear her precious earrings; hence, to open her strongbox, she has to digit the right password in a virtual display that is accessible only in the virtual dimension of the house. In this case the strongbox is a physical object in the real world whereas its command interface is in the digital world.

This scenario highlights the augmented interaction key points and the motivation behind the ARAMIS model. In the next sections it is explained how the presented augmented interactions are modeled in ARAMIS and how ARAMIS handles them.

IV. ARAMIS: BASIC CONCEPT AND BACKGROUND

Gestures are a natural way for a person to interact with the environment, tools and the objects around him [7]. For this reason ARAMIS is focused on gestures as main communication modality. However the ARAMIS approach can be used to model different type of modalities (e.g. voice, touch, etc.) and it can be easily extended toward multimodal approaches.

Since gestures lack in universality (gestures have not the same meaning everywhere) and in order to propose general principles, ARAMIS does not establish a gesture lexicon, but allows detecting different command gestures according to different application and usage contexts.

A. Why a Hybrid Approach

In this section the proposed hybrid approach is presented in its four components highlighting the advantages in the use of these complementary techniques.

Pervasive and Wearable paradigms

Coupling pervasive and wearable paradigms is possible to merge the advantages of both approaches. Table 1 presents the different features form the two approaches as presented in [8] and [9]).

Table 1. Features provided by the pervasive and the wearable approach

FEATURES	*PERVASIVE*	*WEARABLE*
Privacy		**X**
Personalization		**X**
Consistency		**X**
Localized information	**X**	
Localized control	**X**	
Resources	**X**	

Pervasive paradigm provides localized information, controls and resources; whereas wearable paradigm provides privacy, personalization and consistency. Using at the same time pervasive and wearable approaches some features, such as personalization and localized control can be combined to improve user interaction with the system. However the mutual improvement between these paradigms is further increased by our approach. For example information can be fitted and displayed for specified users according to their profiles and interaction context (information from the user and the environment); moreover exploiting virtual elements this

information is still private and personalized. Also the resource management will benefit of our hybrid approach. In ARAMIS data is elaborated in the wearable (mobile) system or/and in the environmental (fixed), according to the type of information to handle, the available devices and the quality of the connection. For instance, data that is troublesome to transfer, such as a high frequency data from the accelerometers, can be elaborated locally on the wearable machine and just the processed information (e.g. extracted features) is sent further. On the other hand information that is heavy to elaborate (e.g. images) can be elaborated at environmental side (more details can be found in [8] and [9]).

As stated above, the merging of these paradigms brings the combination of their related strong points. However to make this possible a lot of issues have to be faced (e.g. heterogeneous devices working asynchronously and with different data rates must be able to rapidly exchange information in order to effectively take advantage one from the other).

Mixed Reality

Gestures are performed in a mixed (real and virtual) world. As presented in the scenario, the presence of digital components is the enabling factor to enhance the interaction. It allows avoid physical constraints (object can be suspended in the air, people can stretch their arms, etc.) and defining new ways of interaction. In ARAMIS two entities are augmented by the technology: the human and the environment. A user avatar is used to represent a human being, and especially the body parts involved in the interaction, in a mixed world (e.g. in a system designed for hands and arms interaction only these parts will be augmented). Since the human representation is digital, the avatar is not tied to physical laws and not necessarily something of visible (e.g. the avatar is not an anthropomorphic digital representation of the user, an avatar can be a simple pointer representing the user hand). Hence, the user avatar can change considerably from an application to another since it depends on the gesture vocabulary, the context and the kind of mixed reality implemented for the interaction and the feedback. Finally the avatar has the goal of facilitating and enhancing the interaction.

Human augmentation becomes valuable in the case the surrounding environment provides rich interfaces of interaction and feedback modalities: we called such ambience augmented (or smart) environment. Our approach defines augmented environments as composed by two kinds of elements: objects and places. 1) Objects can be pure real, pure virtual or enhanced. With the adjective enhanced we classify objects that have the double nature: real and virtual. It means that it is possible to interact with them as normal or virtual objects. For example a book, that can be read directly (physically) or displayed on a screen (virtual representation), belongs to this category. Moreover the simultaneous existence of a real object, its digital counterpart and a suitable feedback interface helps the user in the interaction with tools solving part of the problems tied to the use of a ubiquitous, invisible computer [10]. 2) Places are mixed reality entities integrated in the ARAMIS system that describe interactive objects and their state (id, position, activation state, etc.).

Classification techniques

ARAMIS hybrid approach combines different classification techniques in order to implement decision tasks: brute force, machine learning, fuzzy logic, or neuro-fuzzy [11]. According to the interaction to be implemented and the context of use one or a combination of these techniques can be used.

With a brute force approach is possible to interpret simple data in order to have less computation and, therefore, improve performances [12]. Training is not needed and algorithms are generally simple. This improves speed in recognition but brings limitations in the gestures complexity that can be handled; additional complexity must be introduced in order to make the system user adaptive. With gesture of higher complexity, statistical model and machine learning approaches could be used. Analyzing complex gestures is often not possible or too complicated using brute force algorithms. Machine learning (ML) algorithms can be a solution (especially Hidden Markov Model (HMM) and Artificial Neural Networks (ANN) are used in the gesture recognition field) [13] . However ML solutions require often a large quantity of data to train and to learn the system (for example a neural network can be initialized with random values but it will need training sessions to update these values). Moreover to achieve good results, an algorithm structure may require several calibration sessions and user knowledge of the system can speed up this practice. However tuning such systems can take hours or days of computer time because networks may converge on an inappropriate solution or rule or may fail to converge at all [14]. Neural researchers have proposed hundreds of schemes to alleviate this problem, but none has removed it. Even after a lengthy tuning session, the final rules may not be much better than the first set. Moreover “an impediment to a more widespread acceptance of ANN’s is the absence of a capability to explain to the user, in a human-comprehensible form, how the network arrives at a particular decision. Neither can one say something about the knowledge encoded within the black-box” [11].

Facing these issues and aiming to improve the velocity of the computation is possible using a fuzzy logic (FL). Fuzzy sets are considered to be advantageous in handling higher order processing. Although generally faster than ML often FL systems require experience (of the system developer) in order to configure properly the system. In fact the goal of FL is to simulate the behavior of an expert addressing complex problems, instead of analyzing a problem in detail [15].

Rather than relying on an expert to supply a training set of data and correct a network in the process of learning, unsupervised neural networks learn simply by observing an expert's decisions. In this way, an adaptive fuzzy system can learn to spot rule patterns in the incoming data. In other words adaptive systems can help fuzzy systems learning rules and the merits of both neural and fuzzy systems can be integrated in a neuro–fuzzy approach (NFA). In fact NFA are used to realize a fuzzy system through the connectionist networks, with the advantage that is it possible to extract rules without the need of an expert [16].

The following diagram (in Figure 2) schematizes the strong points and the weakness of these four approaches. The parameters taken into account are: speed of the classification,

need of a large training dataset, capability to recognize complex gestures and need of experience to "tune" the algorithm.

The main idea if ARAMIS concept is to combine these methods flexibly, aiming to take advantage of the more suitable solution according the information to analyze.

Optical and Non-Optical sensing technologies

Combining more acquisition technologies brings several advantages. Different sensors, working with different technologies make possible to have a more robust and accurate dataset. So far, several technologies (vision-based, inertial and acoustic) have been considered. Researches highlighted advantages and drawbacks for any technology. Therefore an approach is usually adapted to specific use cases and contexts [17]. For example optical technologies give very useful information but are expensive in term of processing power if more than one sensor is considered. In addition, sensibility to lighting changes is still an open issue in computer vision domain. Otherwise inertial sensors are more resistant to environmental changes, can be easily embedded in small devices, but suffer for systematic and incremental errors, necessitating a recalibration phase for long measures.

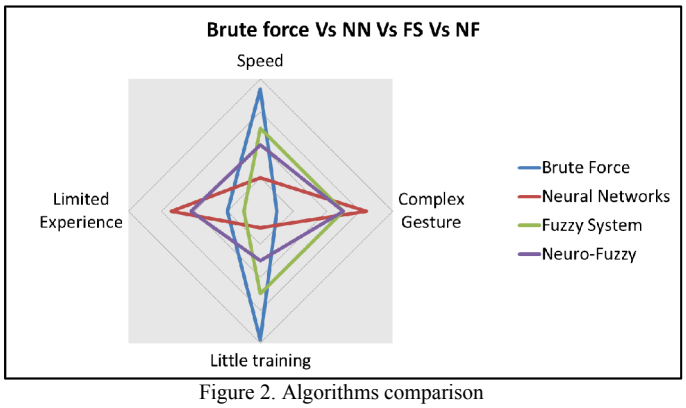

Figure 2. Algorithms comparison

B. *Working Configurations*

Thanks to the proposed hybrid approach ARAMIS is suitable for three working configurations from totally wearable (augmented human) to totally pervasive (augmented environment):

- Augmented human in augmented environment. This is the standard case of use of our system. Our model provides the maximum of augmentation in the interactions. Information provided at the two levels (pervasive and wearable) are merged and exploited to recognize the interaction and provide the feedback.

- Human (without wearable devices) in augmented environment. A reduced interaction lexicon will be recognized at the environment level (e.g. through fixed cameras), and the feedback is presented back to the user in different ways such as acoustic, or visual output.

- Augmented human in normal environment. Also in this case a reduced vocabulary is recognized and the interaction with the environment takes the form of contextual information provided by the wearable devices (e.g. approach used in smart-phones for some augmented reality applications).

The major issue in a combined wearable-environmental approach is the data transmission and fusion between the different entities. Data are heterogeneous and asynchronous. Hence, the elaboration can be complex and, above all, too slow to achieve real-time interaction. Therefore, in order to demonstrate the feasibility of our concept a concrete framework has been realized.

V. ARAMIS: THE FRAMEWORK

Figure 3 shows an overview of the ARAMIS framework and how it handles the information and the decision mechanisms. This framework is service-oriented; it means that each component exposes some method as service that can be flexibly used by other components running on the same machine or exploiting a network.

The framework representation in Figure 3 reflects the hybrid approach presented above separating the environmental and the wearable modules.

A. *Information handling*

Usually, environmental modules have more processing capabilities than wearable modules but the transfer of the information between the different devices can be quite expensive in term of time and bandwidth occupation. In order to optimize the elaboration task the ARAMIS framework allows the information from any sensors to be handled according to three different paths. Raw data that are expensive to be processed (e.g. data from accelerometers needing the extraction of several features) are transmitted to the environmental side and then elaborated (path 1). At the contrary, data that is heavy to transfer (e.g. high quality frames from the camera) has the main features extracted in the module in which is sensed and then sent ahead for further elaboration (such as features fusion according to the path 2). Whereas the information from the worn devices is enough to be analyzed autonomously, gesture can be recognized separately at environmental and wearable side and only the final decision

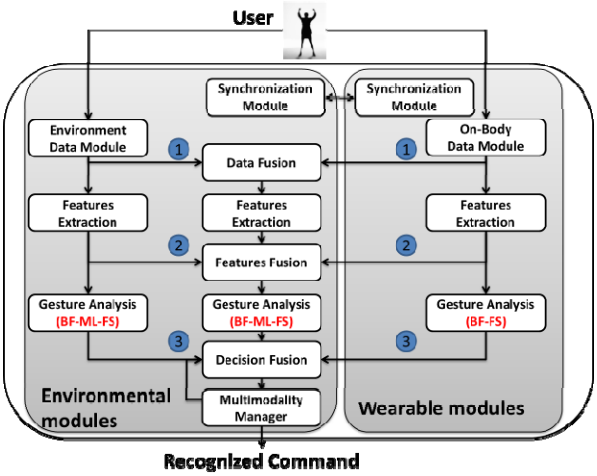

Figure 3. ARAMIS framework – Overview

(path 3) will be pondered and merged (more information about the framework can be bound in the paper [9]).

B. Decision algorithms handling

The gesture analysis modules analyze features in order to classify the input provided by the user. Once again because of the different capabilities between the wearable and pervasive modules it becomes interesting to differentiate and tune the algorithms to be adopted according the type of input and the used devices. At wearable side it will be better to use algorithms fast and requiring small training dataset such as brute force for simple gesture and fuzzy systems to more complex ones. At environmental side all possibilities are opened and also more complex algorithms could be furnished by the framework (Simple Vector Machine, Hidden Markov Model, Neural Networks, Decision Trees, etc.).

VI. ARAMIS: THE IMPLEMENTATION

The previous sections have introduced the ARAMIS approach and how it models the interaction between augmented human beings and the surrounding augmented environments. In this section is presented a first implementation of a system based on the ARAMIS model developed in order to demonstrate its feasibility and benefits. The prototype with the used algorithms, the set-up, and the test of use cases are presented in this section.

A. Gesture lexicon

The gesture lexicon we implemented is composed by several dynamic gestures performed with one arm: goUp, goDown, goLeft, goRight, shake left-right, shake up-down, shake back-forward, rollClockwise, rollCounterclockwise, rollClockwise-&Return. The rolls gestures have to be performed by the arm wearing the gyroscope in order to be recognized. Some more gesture representing numbers drawn in air by one hand are recognized in special context (see section D). In addition a pointing gesture has been introduced in order to indicate and select the device that is the second term of the interaction.
These gestures are been chosen for the sake of simplicity and the minimum effort (cognitive and physic to realize the gesture).

B. Algorithms

Several algorithms have been used in order to face the implementation of a first prototype demonstrating the feasibility of our approach. The complexity of the problem can be resumed in the following main challenges: gesture analysis (features extraction, gesture segmentation, and gestures classification), user recognition and tracking.

Table 2. Algorithms in wearable components

Algorithm	***Goal***
PTAMM	Pointing
PTAMM	World Creation and user tracking
Optical Flow	Dominant arm gesture recognition
Brute Force	Non-dominant arm gesture recognition

Table 3. Algorithms in environmental components

Algorithm	***Goal***
Haar cascade	Face recognition -> hand color extraction
Kalman/ CAMShift	Hand tracking
Speed threshold (or OCR-like)	Gesture Classification
Synchronization	Inspired from [18]

The choice of a simple gesture vocabulary allowed us to use simple classifiers based on brute force to perform recognition at wearable and environmental side. However, as stated before, the system can allow more complex classifiers; for example, at present, is equally possible to use an OCR-like classifier in order to recognize gestures performed facing the camera in the environment and that have reference to alphabet characters. In addition we plan to offer a Hidden Marcov Model (HMM) classifier in order to analyze the data captured by inertial sensors to analyze more complex gestures. However, our simple gesture vocabulary allows us to use simpler and faster brute force classification algorithms without significant changes in the recognition task. A simple vocabulary is possible since a gesture is interpreted differently according to the target of the interaction; this solution allows us to limit to five the number of gestures to be classified in parallel (reducing considerably the possibility of errors). The presence of the user on the in face of the environmental camera is detected by a face detection algorithm (also used to determine in which part of the image is possible to find skin colored elements, as shown in Figure 7).

The pointing gesture requires special effort since the position of the user and the target must be known. A customized version of PTAMM algorithm (presented by Castel et Al. [19] [20]) proved to be suitable for this goal. Moreover it offered the basis to build virtual maps on a real environment realizing the augmented world we need. In fact we use this method to initialize new environments and introducing the interactive objects in the system. A summary of the used algorithms is shown in Table 2 and Table 3 (classified according their use in the wearable or pervasive paradigm).

C. Set-up

Wearable Set-Up

In the implementation of our system we used the wearable devices as illustrated in Figure 4.

The user body is divided in two main parts: the dominant arm and the non-dominant arm. The first is the arm used for most pointing gestures, whereas the second is used for symbolic gestures and as feedback (haptic stimuli) [21]. As segmentation gesture we chose a double rotation of the non-dominant arm (rollClockwise&Return) that has the feature to be easily recognized by gyroscopes and accelerometers (99% of recognition rate with trained users, with negligible false po-

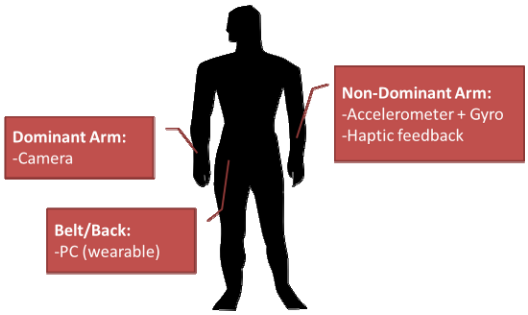

Figure 4. Wearable components set-up

sitives). In the dominant hand (on the upper side of the wrist) is placed a camera. At present the wearable processing part are done on a PC on the user; the use of the only PDA as input, output and processing device is taken into account for the next evolution of the system.

Environmental Set-Up

The augmented environment is realized inside a smart living room. The set-up consists in several pervasive components. A large display (projection on a wall) is used for a visual feedback for the interaction with virtual objects. Using a projection instead of a head mounted display decrease the burden on the user, simplifying the implementation of the scenario. A fixed camera is disposed in front of a couch; this turns the couch into an interactive area in which sensors on the user and in the room can be used at the same time. The enhanced object are a media center PC to play multimedia content, wireless-controlled switches to control some lamps in the room, and processing units hidden in the room performing data elaboration and message routing between elements in the system.

D. *Prototype*

According the working configuration (section IV.B) we developed three interaction scenarios and we present interaction supported by ARAMIS according to the three working configurations.

Case 1 (on Figure 5): augmented human in augmented environment. The user can point and select the media center and start interacting with the menu displayed on a small LCD (such as select the content of a DVD and control the sound).

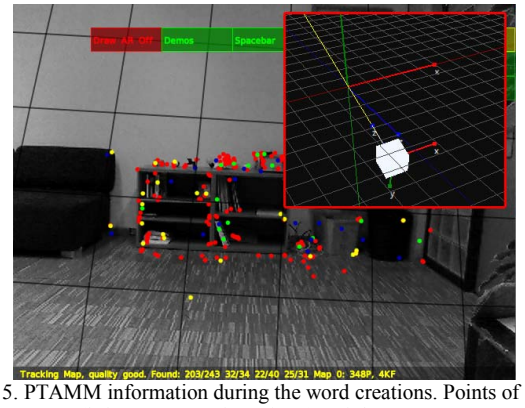

Figure 5. PTAMM information during the word creations. Points of interest (left). Camera orientation (up-right corner).

In addition, complex interactions are allowed, user can grasp a virtual representation of the LCD screen and move it on the wall by pointing at it, now the media center interface will be shown on the wall. With the same gestures the augmented user can point at remote switches and turn on and off the room lighting system. The same gesture is interpreted differently by the system according to the target of the interaction. Whereas the user sits on the couch, a vision-based system for gesture recognition is turned on and the user hands are tracked. Inputs from worn devices and the environment are merged enabling more gesture commands.

Case 2: augmented human in standard environment. The user enters in the environment for a first time. He can include it in the system (creating a new world, as shown in Figure 6) and add virtual objects, which are coupled with the environment only for the position in the space. Due to the lack of feedback (only sound or vibrations), the user should choose conveniently the position of the virtual objects (e.g. a virtual media center on the top of a real media center).

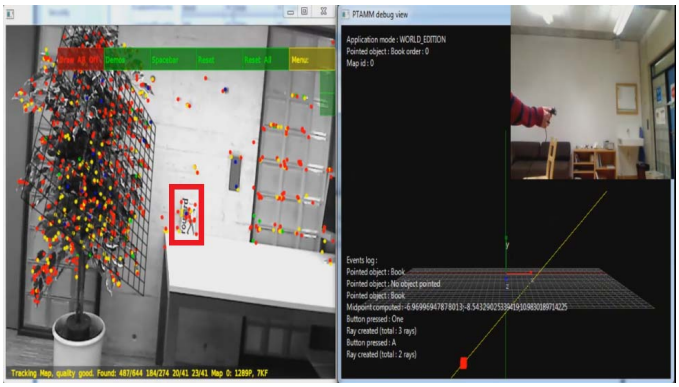

Figure 6. User creating a map. Left: user pointing a book (inside the red rectangle) to add it to the world. Right: ARAMIS perspective, the red cube is the book pointed by the camera.

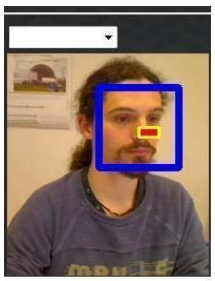
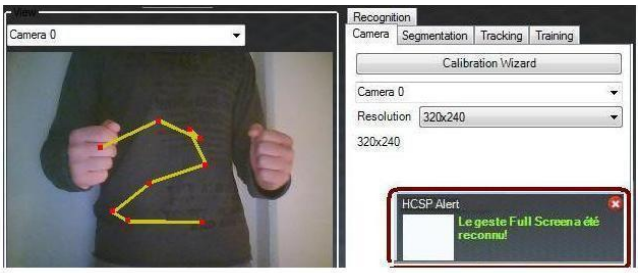
Case 3 (Figure 7): normal human in augmented environment. In this case the system offers one augmented interaction in a special spot of the room: the couch facing the camera. The interaction is similar to the case 1 with just the gestures from the environment and a simpler gesture vocabulary. Using only a camera an augmented interaction is still possible. Interaction output: only the environment.



a)



b)

Figure 7. A user facing the camera. a) Haar based face detection and skin color extraction. b) Hand tracking by the environmental camera and with Kalman tracker (working configuration 3)

E. Discussion

The realized scenario implements a part of the hybrid approach described in the section IV. Case 1 (the only having wearable and environmental modules working at the same time), after some speed tests in different configurations, has been implemented according the following principles:

- Wrist worn camera: images are elaborate at wearable side from the features extraction to the gesture analysis (path 3 in Figure 3).
- Worn accelerometers and gyroscopes: raw data is sent at environmental side for features extractions and elaboration (path 1)
- Environmental camera: features are extracted and the gesture analyzed at environmental side.

Data is finally merged at decision level.

It is interesting to highlight that the system is user-location aware: gestures performed in front of the camera are recognized exploiting both the accelerometers and the camera, whereas gestures performed elsewhere (with a reduced lexicon) are recognized only by the worn sensors. For this prototype we have designed a simple gesture vocabulary of ten commands that are interpreted in different ways according to the position of the user in the room and the target of the interaction. The gesture recognition task is made easier by the gesture protocol we used, with five classifiers running in parallel in the worst case (two-three in average).

We have concentrated our efforts to demonstrate the feasibility of the proposed approach. From a technical point of views we evaluate the systems paying attention to real-time issues. We achieved gesture recognition (from features extraction to gesture classification) in less than 250ms. The most of the time is spent by the system sending data (serialization, transfer, and deserialization) between devices on the user and in the environment. It was perceived as acceptable during the tests and it motivates us to proceed with usability tests. However, at this moment, also the proposed gesture language needs more assessments to be deeply evaluated independently of the worn devices (still too cumbersome).

VII. CONCLUSION

In order to achieve novel augmented interactions between human and smart environments, we propose to adopt a hybrid gesture-based approach. Different interaction paradigms and techniques are used at the same time:

- Pervasive and wearable computing paradigms;
- Mixed reality interactive environments;
- Brute force, neuronal, fuzzy or neuro-fuzzy classification approaches;
- Optical and non-optical sensing techniques.

To validate our concept of hybrid approach we realized a framework allowing the system to flexibly handle the information. Data from each sensor can be elaborated in the more suitable way at wearable or environmental side.

We have implemented key elements of the ARAMIS approach demonstrating how to augment the interactions of a user in three different working configurations. The prototype, used to perform feasibility evaluations has demonstrated the system can work in real-time modeling augmented interactions.

In the first prototype we implemented brute force algorithms for simple gesture recognitions, as next step we plan to extend our prototype including a fuzzy approach in order to recognize more complex gestures in real-time. Finally a quantitative evaluation comparing the different solutions (brute force, machine learning and fuzzy approaches) will be done to complete the formalization of the presented interaction.

***Abstract*—This paper describes the process of deriving the meaning of an unknown word within the framework of meaning based natural language processing. It uses the clues supplied by the rest of the sentence, taking into account various degrees of possibilities of what the unknown word can mean, according to the previously acquired knowledge resources. The process of finding the meaning is incremental, and thus the derived meaning can evolve as more knowledge is gathered. The paper describes the fuzzy approach to the problem within this framework with regard to the semantic and syntactic acceptability of a sentence.**

Unknown words; computing with words; ontological semantics; natural language understanding; sentence acceptability

I. Introduction

This paper attempts to bring attention to the understanding of previously unseen words based on the meaning of the rest of the sentence. We assume that such trait is necessary for any robust computer system that is capable of communicating intelligently with humans. The necessity is derived from the ongoing changes in natural languages, including constant addition of new terms or senses, i.e. the new meanings of the existing words (think, for instance, of the ever propagated government generated acronyms or of teenage slang terms).

The use of natural language in ambient intelligence seems to be a reasonable bet. This makes it necessary for computer systems to understand natural language at the human proficiency level. If guessing games are to be performed, they have to be built on the platform of solid content and context comprehension to be useful for any reasonable purpose.

We assume, therefore, that an effective computer system that is used to communicate naturally with humans must be equipped with the same ability to learn new terms in a familiar context as the ability that humans possess and utilize under the same circumstances. It is also reasonable to assume that such learning is based on the perception of the situation described in the text, and that, as with most perception-based mechanisms, it is fuzzy.

II. What Kind of Animal Is Unattested Input?

A. First Type: Annetested Input

Annetested input, along with ambiguity, is a major problem for systems attempting to understand natural language: no matter how many words the systems is supposed to be familiar with, there are hundreds of thousands words and senses that it has never encountered and is, therefore, not equipped to handle with the resources it has. However, in order to be robust, such a system must have such a capability.

Annetested input processing can only be meaningful when it happens among the words and in sentences that are well understood other than this one particular unknown occurrence. The task then becomes to guess the meaning of the annestested input on the basis of the fully understood information in the rest of the sentence. In a way, annestested input is being solved just like an inequality system in math is solved, by finding the possible intervals which satisfy it.

Non-meaning based approaches cannot proceed as far because they are not aware of the meaning of the other words or utterances in the sentence. The only reason the famous Jabberwocky poem [1] is understood somewhat by humans is that, besides the felicitous morphological and syntactic guesses, they fully understand quite a few words interspersed with the unknown ones.

The first stanza is, perhaps, the most artful one, because the only known words there are of a grammatical nature: conjunctions, prepositions, determiners and auxiliary verbs. As a result, the understanding is the vaguest and most surprising—in the sense of having any understanding at all:

> Twas brillig, and the slithy toves
> Did gyre and gimble in the wabe:
> All mimsy were the borogoves,
> And the mome raths outgrabe.

By contrast, in the most easily understood stanzas (third and fifth, respectively), the annetested input is limited to very few unknown non-proper-name words each:

> He took his vorpal sword in hand:
> Long time the manxome foe he sought –
> So rested he by the Tumtum tree,
> And stood awhile in thought.

> One, two! One, two! And through and through
> The vorpal blade went snicker-snack
> He left it dead, and with its head
> He went galumphing back.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Notice that the first occurrence of *vorpal* is broad: it can be any attribute of a sword. The second occurrence modifies the blade of a sword, thus reducing the set of possible senses of the annetested word. In a similar fashion, the fully familiar and well understood words in this section have compensated, we hope, for our deliberate misspelling of the word *unattested* as *annetested*.

B. *The Vagueness of Vorpal*

One leaves the Jabberwocky poem with a clear understanding that *vorpal* is an attribute of *blade*. This understanding is, however, vague in the sense of the coarsest possible grain size for a blade attribute: it can be such a physical property as sharp (primary function quality), steel (material), masterful (manufacturing execution), heavy (weight), long (dimension); it can also be a non-physical property, such as expensive (price), famous or legendary (extent of what is known about it), heroic (history of performance), merciless (effectiveness), etc. But we cannot yet treat the property as fuzzy because there is no basis for assigning a non-100% degree of membership to any one of the possibilities (cf. [2] on possibilistic theory and the Hartley measure of the uncertainty). So the captured meaning of *vorpal* is uncertain in the sense of vagueness but, perhaps, not yet fuzzy.

III. THE MEANING OF UNKNOWN WORDS

While the meaning of the sentence is not fully compositional in general, many sentence meanings can be put together from individual word meanings, provided that the syntax and semantics make sense. All words in the sentence are connected through some semantic relationships within the syntactic phrases to which they belong. We will assume that some two words in a syntactic phrase are connected through one or more relationships, and each word is connected to at least one other word in the sentence through such relationship. Moreover, there is a finite number of existing relationships. For simplicity, we will describe here binary relations that correspond to such semantic relationships. Such semantic relationships in natural language are fuzzy: we unlock a door with a key, with a code, or with a paper clip[1]. Clearly, $\mu_{\text{INSTRUMENT}}(\text{UNLOCK, KEY}) < \mu_{\text{INSTRUMENT}}(\text{UNLOCK, PAPER-CLIP})$.

Each such relation R(X, Y), where x∈X and y∈Y, has a domain and range, defined respectively as:

$$\mu_{\text{DOM R}}(x) = \max_{y \in Y} \mu_R(x,y), \text{ for each } x \in X.$$

$$\mu_{\text{RAN R}}(y) = \max_{x \in X} \mu_R(x,y), \text{ for each } y \in Y.$$

Furthermore, we assume that each relation has at least some (x, y) such that $\mu_R(x, y)=1$: $\max_{y \in Y} \max_{x \in X} \mu_R(x,y) = 1$.

Semantic relationships typically have well defined and easily calculated inverse relationships, with

$$\mu_{\text{DOM R}^{-1}}(y) = \max_{x \in X} \mu_{R^{-1}}(y,x), \text{ for each } y \in Y.$$

$$\mu_{\text{RAN R}^{-1}}(y) = \max_{y \in Y} \mu_{R^{-1}}(y,x), \text{ for each } x \in X.$$

The relationships are typically verb centered: agent(y, x_1), theme(y, x_2), beneficiary(y, x_3), etc. where y is a verb. Yet, they are rarely all interdependent and, hence, can be dealt with in pairs. When a relationship is object centered, the task is simpler, as the number of such relationships is smaller. As an example, consider the following sentence: *The man opened the door to his house with the key*. The following relationships are of interest: AGENT(OPEN, MAN), THEME(OPEN, DOOR), INSTRUMENT(OPEN, KEY), ENTRY-POINT(DOOR, HOUSE), OWNER(MAN, HOUSE). There are 3 verb centered relationships here, and 2 object centered ones, as shown in Fig. 1.

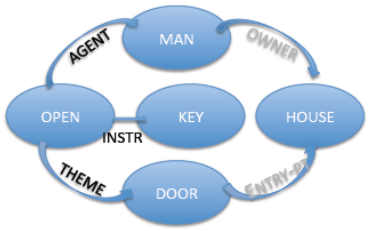

Figure 1. A linked representation of *The man opened the door to his house with the key*.

Whenever a sentence consists of compositional relationships between words, where the words are not interdependent, an unknown word can be calculated based on the domain or range of the relation that corresponds to the semantic relationship between the unknown and the known words. Thus, if in the example above, we don't know the word *man* but somehow know that it is an AGENT of OPEN, we can derive some knowledge of what *man* is from $\mu_{\text{AGENT}}(\text{OPEN, } man)$. Moreover, until more information is found we can approximate *man* as something that maximizes $\mu_{\text{AGENT}}(\text{OPEN, } z)$.

On the other hand, there are situations when an unknown word depends on more than one relationship. This can happen in several situations, some of which are shown in Figure 1. For instance, if the word *house* were unknown, its meaning would be derived from something that can be owned and from something that has a door as an entry. Similarly, if the word *door* was unknown, its meaning would have to be derived from something that is a theme of OPEN and that serves as an entry to HOUSE.

Assuming that there are at least two relations R1(X, Y) and R2(Y, X) such they there is a y∈Y where (x, y) ∈ R1 and (y, z) ∈ R2, a join can be formed between these two relations (R1*R2), such as

$$\mu_{R1*R2}(x,y,z) = \min[\mu_{R1}(x,y), \mu_{R2}(y,z)]$$

for each x∈X, y∈Y, z∈Z ([2], p. 77). Using this formula, the meaning of unknown words—as those in the examples of *door* and *house*—can be calculated.

The formula can be generalized to n relations:

$$\mu_{R1*R2*\ldots*RN}(x_1, x_2, \ldots, x_n, y) = \min[\mu_{R1}(x_1,y), \mu_{R2}(x_2,y), \ldots, \mu_{RN}(x_n,y)]$$

[1] http://www.ehow.com/how_4809693_unlock-locked-door-key.html.

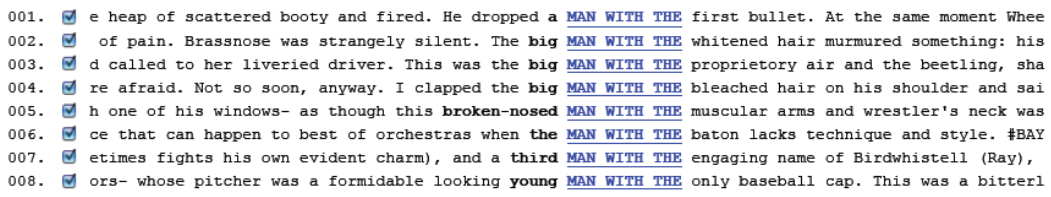

Figure 2. Results for *man with the* __

Figure 3. Results for *door with the* __

for each $x_i \in X_i$, $y \in Y$. Using this formula, if word *open* is unknown, its meaning can be derived by considering together its AGENT *man*, its INSTRUMENT *key* and its THEME *door*.

The situation gets more complicated when we consider unknowns that are dependent on other information from the sentence. For example, if we have *A cat opened the door with xyz,* we know that typical instruments of opening the door like keys and code are excluded. On the other hand, if it is a locksmith that opened the door, it is probably not the regular key that was used to open it. Intuitively, in such cases the join should not be done on a single concept but on as many as it takes to derive the correct meaning. Thus, in the case of *cat* or *locksmith*, the agent has to be considered on the join as well or membership functions has to be defined based on individual agents. We will abandon the notion of individual membership function of the INSTRUMENT of OPEN based on the agency for a time being, but note that it is not much different than defining sets for the height of a basketball player: it is easy to define them, but they are not practical from the point of view of natural language usage.

It is easy to see that for the cases of unknown words that are independent arguments of a binary relation, their meaning can be derived from a join of all pertinent relations contained throughout a text: *I lost the xyz that opened the door last time. It fell through the opening in front of the elevator door*. Here, not only do we know that *xyz* is something that opened the door, but it is also slim enough to fall through a centimeter (or so) wide opening. Thus, if somebody disambiguates a sentence, and assigns arguments to each relation, including which relation an unknown word will be in, it is mathematically possible to find the meaning of such word, especially, if it is used in many sentences that describe different functional characteristics. The next section will demonstrate what type of linguistic processes are needed do it automatically.

IV. What Does It Take To Open a Door?

Let us, again, consider the sentence *The man opened the door with the xyz*. In the sentence, *xyz* can be a number of things, including *key, combination code, card, two hanger wires*, or any other instrument with the use of which a lock on the door can be opened. Perhaps somewhat less obviously, *xyz* can be *mirror, picture, hole, ornament*, or any other detail or part of the door. Even less obviously, and somewhat syntactically awkward, *xyz* may stand for *friend, dog*, or any other accompanier for *the man*.

Without the explanation above, the sentence is three-way syntactically ambiguous, depending on the analysis of the prepositional phrase which may pertain to *man*, *open*, or *door*. Thus, similarly to the case of *vorpal*, indicated are the three vague sets of constituents that somehow modify the dominant entities above.

The task of unattested input processing is, then, to determine the semantic features that can satisfy *the man with the xyz*, *open with the xyz*, or *the door with the xyz*. It is here that understanding these phrases and the resulting sentence is necessary. The process of understanding the phrases when all words are known is outlined in Section V.

It is tempting to use the corpus-based approach and look for occurrences of *xyz* given *the man with the, open with the, the door with the xyz.* A brief search[2] of the Brown corpus for the first phrase yielded the results shown in Fig. 2. The results of the second phrase produced nothing, the results of the third phrase yielded one usage, shown in Fig. 3.

The lessons of this example are fast learned: none of the usages received for the first query work for the sentence *The man opened the door with the xyz*. The one usage in the third query is extremely limiting: there are many more possibilities for the detail or part of the door other than having a brass number.

It can be argued that the exact phrase search approach is too narrow and should be expanded to the conceptual search[3], at least of the dominant word. It is possible that it will somewhat enrich the results and give a somewhat higher quantity of the acceptable phrases, such as and beyond *brass number*. It would not, however, correct the situation with the first tried phrase, illustrated in Fig. 2, where none of the results were suitable for the example sentence.

Nirenburg & Raskin [3] sketch an early meaning-based procedure that can be used to find the prevalent crisp set associated with the sense of the one unknown word in a sentence. (See also references there and elsewhere on pre-semantic attempts to account for unattested input: for a representative sample, see [4-19]) Using a much simplified version of early Ontological Semantics, they demonstrate that non-existing word *keegh* can be understood as an instrument of locking/unlocking a door on the basis of the machine-

[2] http://conc.lextutor.ca/concordancers was used

[3] a primitive example of which could be the usage of hypernyms and hyponyms of WordNet.

understood definitions of *lock*, *door*, and the ontological knowledge of the most common artifact that is required to perform the unlocking.

Such an approach, especially on a single sentence, demonstrates that a solution can be found, without validating that it was the optimal solution (see [20] for empirical verification). Consider, for example, a sentence *he unlocked the car door with an xyz*. The range of possibilities here encompasses *key, keyless remote fob, code* (on the door), *wire*, *screwdriver*, *hanger*, *lock pick (Slim Jim)*. In a crisp treatment, *key, keyless remove fob, code*, or maybe *lock pick* and *hanger* will work. The *screwdriver*, on the other hand, will probably draw a blank.

Now suppose, the sentence that follows is *He always had the xyz with him to take the screws off laptops.* The screwdriver, then, an initially unlikely tool, becomes the leading candidate for the unattested input: while it is possible, although hard, to unlock a car door with a screwdriver, none of the other tools are purposefully used to take the screws off laptops.

It appears useful, then, to collect all interpretations, to the lowest possible degree (as unlikely as they may sound), of the tools that could imaginably open a car door. The set of all these interpretations will remain intact until and unless further information is perceived to narrow it down. If decisions have to be made prior to the moment when new, narrowing information is received, then it is natural to accept those tools that have the highest membership in the set as the interpretation of *xyz*. Moreover, it seems natural to select the most probable of them to be used for the interpretation as well. Thus, [3] concluded—or rather, stopped just short of concluding—that the unattested input was an instrument for opening a door, the likeliest of which is, of course, some sort of key.

V. A Meaning-Based Method for Guessing What xyz Is

In this section, we will demonstrate in somewhat simplified non-proprietary technical detail, how the meaning of an unknown word is determined on the basis of the full understanding of everything else in the sentence. The derived meaning will be calculated based on the fuzzy joins of relevant relations. This will be done with the methods and resources of the Ontological Semantic Technology (OST—see [21-23]).

At the core of OST are repositories of world and linguistic knowledge, acquired semi-automatically within the approach and used to disambiguate the different meanings of words and sentences and to represent them. These repositories, also known as the static knowledge resources, consist of the ontology, containing language-independent concepts and relationships between them; one lexicon per supported language (English, Russian, etc), containing word senses anchored in the language-independent ontology which is used to represent their meaning; the Proper Name Dictionary (PND), which contains names of people, countries, organizations, etc., and their description anchoring them in ontological concepts and interlinking them with other PND entries; and a common sense rules resource. A conforming lexicon and ontology, as well as – when needed -- PNDs and common sense rules, are used by the Semantic Text Analyzer (STAn), a software, developed by RiverGlass Inc., that produces Text Meaning Representations (TMRs) from the text that it reads. The format of TMRs conforms to the format and interpretation of the ontology. The processed TMRs are entered into InfoStore, a dynamic knowledge resource of OST, from which information is used for further processing and reasoning.

A. Lexicon

The substantive part of interpreting the sentence *The man opened the door with the xyz* starts with the search for the event of the single clause, and in this case, it is easy: *open* is the only word with any sense anchored in an ontological event concept. For illustrative purposes, we will work with the following senses of *open* as a verb that a semantic analyzer would find in a generic OST lexicon:

1. to allow access [*open the door*]
2. spread out, unfold (open out) [*open the wings*]
3. allow public access, permit access [*open the gallery to the public*]
4. establish [*open a new restaurant*]

…

The formal definition of the above senses is:

```
(open-v1
    (cat(v))
    …
    (syn-struc((subject((root($var1))(cat(np))))
        (root($var0))(cat(v))
        (directobject((root($var2))(cat(np))))
        (pp-adjunct((opt(+))(root(with by))(cat(prep))
            (obj((root($var3))(cat(np))))))
        (pp-adjunct((opt(+))(root(to into of))(cat(prep))
            (obj((root($var4))(cat(np))))))
    ))
    (sem-struc(open
        (agent(value(^$var1)))
        (theme(value(^$var2)))
        (instrument(value(^$var3)))
        (location(value(^$var4)))
    ))
)
(open-v2/v3/v4
    (cat(v))
    …
    (syn-struc((subject((root($var1))(cat(np))))
        (root($var0))(cat(v))
        (phr((opt(+))(root(out up))(cat(prep))))
        (directobject((root($var2))(cat(np))))
        (pp-adjunct((opt(+))(root(for to))(cat(prep))
            (obj((root($var3))(cat(np))))))
    ))
    (sem-struc(unfold/give-access/establish
        (agent(value(^$var1)))
        (theme(value(^$var2)))
        (beneficiary(value(^$var3)))
    ))
)
```

For the simplicity purposes, we will consider only one (physical) sense of *door* (physical movable door), only one sense of *man*, and the following, non phrasal, senses of *with*:

1. accompanier (animate or thing) [*went with a friend*]

2. instrument [*cut with a knife*]
3. beneficiary [*left the parcel with Bob*]
4. object-as-part [*door with a handle*]
5. location-of [*door with a mirror*]
6. containment [*bowl with cherries*]
7. manner [*ate with gusto*]

The first six definitions of *with* can be represented in the following format, where PROP is the property from the list above:

```
(with-prep[1-3]
    …
    (syn-struc((vp((root($var1))(cat(vp))))
        (root($var0))(cat(prep))
        (obj((root($var2))(cat(np))))))
    (sem-struc(^$var1(PROP(value(^$var2)))))
)
(with-prep[4-6]
    …
    (syn-struc((np((root($var1))(cat(np))))
        (root($var0))(cat(prep))
        (obj((root($var2))(cat(np))))))
    (sem-struc(^$var1(PROP(value(^$var2)))))
)
```

The last sense is defined as:

```
(with-prep7
    …
    (syn-struc((vp((root($var1))(cat(vp))))
        (root($var0))(cat(prep))
        (obj((root($var2))(cat(np adv))))))
    (sem-struc(^$var1(manner(value(^$var2)))))
)
```

The same variables in the syntactic and semantic structure (syn-struc and sem-struc) are bound together, with '^' standing for the meaning of the variable that follows the symbol, and '$' standing for the value of the variable. In other words, '$' refers to a word that a variable points to, and '^' to its ontological meaning. Because the lexicon senses only point to the conceptual definitions in the ontology, the bulk of work is carried by the ontology.

B. *Ontology*

The ontology is a lattice that contains the knowledge necessary to accept or reject an interpretation of a sentence. Each concept is defined through properties and their fillers. Each filler is accented by the facet which is interpreted as supplying the degree of membership in a set.

An ontological concept has the following format:

concept-name
    (attribute(facets(literal-value^{+}))$^{+}$)*
    (relation(facet(concept-name^{+}))$^{+}$)*
facet[4]
    sem | value | default | relaxable-to | not

In this paper, we are only interested in relations. The following interpretations for ontological definitions containing fuzzy concepts and relations were defined in [24]:

[4]This list of facets is only applicable to concepts

Given a set of objects $\mathcal{D}$ and given its interpretation function $\mathcal{I}$, for every fuzzy concept B, object x is an element of B with some degree $\mathcal{I}[B](x) \rightarrow [0, 1]$; for every relation Rel, $\mathcal{I}[Rel](x, y) \subseteq \mathcal{D} \times \mathcal{D} \rightarrow [0, 1]$; We will assume that $x \in B$ if $\mathcal{I}[B](x) \rightarrow (0, 1]$.

With this in mind, the following is true for C and D, using [15]:

$\mathcal{I}[C\ D](x) = \max\{\mathcal{I}[C](x), \mathcal{I}[D](x)\}$
$\mathcal{I}[\text{and } C\ D](x) = \min\{\mathcal{I}[C](x), \mathcal{I}[D](x)\}$
$\mathcal{I}[(Rel(D))](x) = \max_{y \in D}\{\mathcal{I}[Rel](y, x)\}$
$\mathcal{I}[(Rel(\text{and } C\ D))](x) = \min\{\mathcal{I}[Rel(C)](x), \mathcal{I}[Rel(D)](x)\}$
$\mathcal{I}[Rel(C\ D)](x) = \max\{\mathcal{I}[Rel(C)](x), \mathcal{I}[Rel(D)](x)\}$
$\mathcal{I}[C(Rel(D))](x) = \min\{\mathcal{I}[C](x), \mathcal{I}[Rel(D)](x)\}$
$\mathcal{I}[C(Rel_1(D))(Rel_2(E))](x)$
$= \min\{\mathcal{I}[C(Rel_1(D))](x), \mathcal{I}[C(Rel_2(E))](x)\}$

For the construction of the ontology, subsumption definition of [25] was followed: C subsumes D iff $\forall x \in \mathcal{D}$: $\mathcal{I}[C](x) \geq \mathcal{I}[D](x)$.

Fuzzy values of facets as the degree of membership is assumed to be set by the ontology engineer, with DEFAULT facet always corresponding to 1, NOT facet corresponding to 0, while the other three facets varying depending on the application and the domain. We will use a slightly different notation in the paper, specifying the exact degree of membership instead of using a facet. Thus, we adopt the following format, where membership-degree is any number between 0 and 1:

concept-name
    (relation(membership-degree(concept-name^{+}))$^{+}$)*

We assume that a parent concept has at most the same membership degree value as a child concept (unless inheritance is blocked). Then, given a concept B that is a descendant of a concept A and an ancestor of a concept C, where $\mu_P(A)$ and $\mu_P(C)$ are known:

$$\mu_P(B) = \mu_P(A) + \frac{\mu_P(C) * \text{dist}(A,B)}{\text{dist}(A,C)},$$

where dist(X, Y) is the logarithmic distance between the lattice nodes X and Y and either ancestor(X, Y) or ancestor(Y, X) holds.

The somewhat simplified ontological concepts OPEN, UNFOLD, GIVE-ACCESS, and ESTABLISH for the 4 lexical senses of *open* above and the concept DOOR for *door* are shown below, without their inherited properties, unless access to them is warranted by the analyzed sentence:

```
(open
   (definition(…("to open a container door window etc")))
   (is-a(1(change-position)))
   (theme(1(container door window))(0.75(artifact))
      (0.1(physical-object)))
   (instrument(1(key))(0.75(artifact)))
   (agent(1(human))(0.5(animal)))
   (accompanier(1(human))(0.75(animal)))
)
(unfold
```

```
    (definition(…("to change configuration of parts of an object")))
    (is-a(1(change-configuration)))
    (theme(0.75(artifact(part-of-object(0.5(physical-object)))
    (instrument(0.9(body-part))(0.5(artifact)))
)
(give-access
    (definition(…("to allow public access")))
    (is-a(1(permit)))
    (theme(1(building))(0.5(organization))
        (0.1(geopolitical-entity)))
    (beneficiary(0.75(human))(0.5(organization))(0.1(animal)))
    (precondition(0.75(communicative-act)))
)
(establish
    (definition(…("to establish an institution")))
    (is-a(1(create-social-object)))
    (theme(0.5(group))(0.65(organization))
        (0.1(geopolitical-entity)))
)
(movable-door
    (definition(…("the slab that is open and closed as opposed to
the hole in the wall")))
    (is-a(1(building-fixture)))
    (inside-of(1(door)))
    (contains(0.05(physical-object)))
    (has-object-as-part(1(handle))(0.8(lock)))
    (locale-of(0.5(mirror hook writing-symbol))(0.3(ornament)))
)
(man
    (definition(…("the slab that is open and closed as opposed to
the hole in the wall")))
    (is-a(1(human)))
    (gender(1(male)))
    (age(1(adult))(0.75(teenager)))
    (has-object-as-part(1(male-body-parts)))
    (locale-of(0.75(garment accessory)))
)
```

In a situation when a word is unknown, humans use the linguistic clues from the sentence as well as their knowledge of the world to come up with some approximate interpretation of the unknown word. The linguistic clues consist of tentative morphological, syntactic and semantic information (such as the lexical senses of the known words), while the knowledge of the world for humans can range from purely encyclopedic to common sense. The ontology tries to capture parts of such knowledge, also relying on InfoStore for facts and common sense rules resources for the rest.

Similarly, a computer calculates the same possibilities, with the membership functions reflecting the semantic preferences. Thus, when the phrase *open the door* is processed, all but the open-v1 sense are excluded due to the membership value of 0 of some phrase interpretations:

μ_{AGENT}(OPEN, MAN)=1; μ_{THEME}(OPEN, DOOR)=1;
μ_{THEME}(UNFOLD, DOOR)=0; μ_{THEME}(GIVE-ACCESS, DOOR)=0;
μ_{THEME}(ESTABLISH, DOOR)=0;

In other words, according to the ontology, it is not possible to unfold a door, allow public access to a door, or to establish a door as an institution.

C. *Back to door with, man with or open with… xyz*

Our sentence is *The man opened the door with the xyz*. The last word before xyz is the article, since there is no other word after it, we can conclude that it is a noun. Thus information is relevant when we create the lexical sense of a word, but not in guessing its meaning in a sentence. We thus continue to the next closest word, which is the preposition *with*. Now we have more clues to work with. According to the lexical senses of with, *xyz* can be one of the following:

1. It can accompany an animate being in any event
2. It can be used as an instrument for a physical event that has a theme.
3. It can be a receiver of something from somebody in an exchange possession or communicative event.
4. It can be a part of a physical object
5. It can be physically located on an (physical) object
6. It can be contained within a physical object
7. It can signify a manner of an event

According to the syntactic structures, we know that the above definition have to conform to the following format in its normalized form:

1. The subject, indirect object and the predicate must be present in the sentence. The subject must precede the verb, while the prepositional phrase containing the indirect object can be in any position.
2. The prepositional phrase containing the instrument must be in the initial or final position, thus preceding or following the predicate with the direct object.
3. The prepositional phrase containing the beneficiary (receiver) must follow the direct object, which in turn follows the predicate.
4. The prepositional phrase must follow a noun (phrase).
5. The prepositional phrase must follow a noun (phrase).
6. The prepositional phrase must follow a noun (phrase).
7. The prepositional phrase must be used adverbially, contain no article, and follow the predicate, not necessarily immediately.

Applying these rules to the sentence, we can rule out *with-prep7* on a purely syntactic ground and *with-prep3* since *open* has no sense that corresponds to the exchange possession event or communicative event on a purely semantic ground.

An interesting case is presented by *with-prep6*: while it is possible in principle to fill the inside of a door (or even an a man's body part) with something, their $\mu_{CONTAINS}$ is very low. Thus, while they are possible and the sense is not discarded, they are unlikely to become serious candidates contributing to the sense of *xyz* unless some other information props them up. In the case of *door* as a container filled with *xyz*,

$\mu_{CONTAINS}$(MOVABLE-DOOR, *xyz*)=0.05,

where *xyz* is any PHYSICAL-OBJECT small enough to fit inside a hollow part of a door, if any.

The cases of *with-prep4,5* remain valid. The difference between *with-prep4* and *with-prep5* is that the former realized only when the following noun is a part of something while the latter is realized when the following noun is located on something. The following interpretations are then valid:

$\mu_{LOCALE\text{-}OF}$(MOVABLE-DOOR, *xyz*)=0.5,

where *xyz* is any descendant of MIRROR, HOOK, WRITING-SYMBOL;

$\mu_{\text{LOCALE-OF}}$(MOVABLE-DOOR, *xyz*)=0.3,

where *xyz* is any descendant of ORNAMENT;

$\mu_{\text{HAS-OBJECT-AS-PART}}$(MOVABLE-DOOR, *xyz*)=1,

where *xyz* is any descendant of HANDLE;

$\mu_{\text{HAS-OBJECT-AS-PART}}$(MOVABLE-DOOR, *xyz*)=0.8,

where *xyz* is any descendant of LOCK.

In theory,

$\mu_{\text{LOCALE-OF}}$(MAN, *xyz*)=0.75,

where *xyz* is any descendant of GARMENT or ACCESSORY;

$\mu_{\text{HAS-OBJECT-AS-PART}}$(MAN, *xyz*)=1,

where *xyz* is any descendant of MALE-BODY-PARTS. However, the strongly prescriptive direct word order in English makes it extremely syntactically unlikely that the prepositional phrase at the end of the sentence would modify *man* (μ_{syntax}(*man*, xyz)=0.05), thus, lowering this possibility to practically non-existent. Unlike the case of *with-prep6*, where additional semantic information could prop the sense up, it is considerably less likely for such propping syntactic information to be found.

Also valid are the cases of *with-prep1,2*. The only event that can be considered with these two senses of *with* is OPEN, as UNFOLD, GIVE-ACCESS and ESTABLISH were excluded above due to their incompatibility with *door* (the corresponding concept, MOVEABLE-DOOR).

We will consider with-prep1 first. According to its syntactic and semantic structures, it needs a subject that is an agent of an event that can be accompanied by an animate object that is part of the prepositional phrase. Thus, *man* is an agent of *open* and *xyz* must then be an accompanier of *man* in this event:

$\mu_{\text{ACCOMPANIER}}$(MAN, *xyz*)=1,

where *xyz* is HUMAN, and

$\mu_{\text{ACCOMPANIER}}$(MAN, *xyz*)=0.75,

where *xyz* is ANIMAL.

In the case of *with-prep2*, *xyz* must be an instrument of opening the door. Thus,

$\mu_{\text{INSTRUMENT}}$(OPEN, *xyz*)=1,

where *xyz* is KEY, and

$\mu_{\text{INSTRUMENT}}$(OPEN, *xyz*)=0.75,

where *xyz* is any other ARTIFACT.

Similarly to the case of *with-prep6*, we now have to consider the word order in the resulting interpretations in relation to the prescriptive and preferred English sentence word order. Thus, we have to use yet another membership function, that corresponding to the perceived syntactic appropriateness or smoothness.

μ_{SYNTAX}(The man opened the door with the dog)<< μ_{SYNTAX}(The man with the dog opened the door)

In more general terms,

μ_{SYNTAX}(AGENT EVENT THEME *with* ACCOMPANIER)=0.2<< μ_{SYNTAX}(AGENT *with* ACCOMPANIER EVENT THEME)=1

Thus, we have the following possible interpretations of xyz, all with different degrees of acceptability of the alternative sentences: mirror, hook, writing-symbol; ornament; handle; lock; garment, accessory; male-body-parts; human; animal; key; artifact. The acceptability depends both on the semantics and syntax of the resulting sentences.

VI. Putting it all together: Calculating degrees of acceptability

We define an interpretation as acceptable if and only if it is acceptable both syntactically and semantically. We treat such acceptability as the intersection of the syntactic and semantic sets.

Syntactic acceptability of a sentence is defined as a minimum acceptability of all of its (binarized) phrases; where the acceptability of each phrase is maximized to the most acceptable syntactic analysis in case of syntactic ambiguity:

$$\mu_{\text{SYNTAX}}(\text{sent}) = \min_{phr \in sent} \max_{x,y \in phr} [\mu_{\text{phr}}(x,y)]$$

Semantic acceptability is similarly defined as a minimum of acceptability of all semantic relations on the maximally acceptable interpretation of each relation:

$$\mu_{\text{SEMANTICS}}(\text{sent}) = \min_{R \in sent} \max_{x,y \in R} [\mu_{\text{R}}(x,y)]$$

The overall syntactic/semantic acceptability of a sentence is, then:

$\mu_{\text{ACCEPTABILITY}}$(sentence) = min[μ_{SYNTAX}, $\mu_{\text{SEMANTICS}}$]

In *The man opened the door with the xyz*, we have eleven possible components that vary with different meanings of *xyz*:

$\mu_{\text{ACCEPTABILITY}}$([very small] PHYS-OBJECT [contained in door]) = min{1, 0.05}=0.05

$\mu_{\text{ACCEPTABILITY}}$(MIRROR, HOOK, WRITING-SYMBOL [on door]) = min{1, 0.5}=0.5

$\mu_{\text{ACCEPTABILITY}}$(ORNAMENT [on door])=min{1, 0.3}=0.3

$\mu_{\text{ACCEPTABILITY}}$(HANDLE [part of door])=min{1, 1} = 1

$\mu_{\text{ACCEPTABILITY}}$(LOCK [part of door])=min{1, 0.8} = 0.8

$\mu_{\text{ACCEPTABILITY}}$(GARMENT, ACCESSORY [of man]) = min{0.05,0.75} = 0.05

$\mu_{\text{ACCEPTABILITY}}$(BODY-PART [of man]) = min{0.05, 1} = 0.05

$\mu_{\text{ACCEPTABILITY}}$(HUMAN [accompanies man]) = min{0.2, 1}= 0.2

$\mu_{\text{ACCEPTABILITY}}$(ANIMAL [with man]) = min{0.2, 0.75} = 0.2

$\mu_{\text{ACCEPTABILITY}}$(KEY [as instrument]) = min{1, 1} = 1

$\mu_{\text{ACCEPTABILITY}}$(ARTIFACT [instrument]) = min{1, 0.75} = 0.75

Thus, the two interpretations of the sentence, where xyz results in the highest syntax-semantic acceptability, are:

- *The man opened the door with the handle.*
- *The man opened the door with the key.*

While it appears to be intuitively correct, in neither interpretation is it really necessary to communicate the prepositional phrase. We propose an interesting observation: things that have the membership value of 1 are there by default, as it were, and are likely to be dropped from the sentence. The exception is when these defaults are modified: it is unlikely that

we would hear *he unlocked the door with a key* – what else can he unlock the door with by default? – but it is ok to say *he unlocked the door with a golden key* or *spare key*, or *his friend's key*.

Thus, if we wish to model human communication, we should be more likely to consider concept candidates for the unknown words that are a little less than 1 than those at exactly 1. On the other hand, the grammaticality of a sentence should not be compromised. Thus, if a verb requires a direct object, and the unknown word is this direct object, then preferring the membership value of less than 1 should not play into the decision process–as the unknown word must be in the sentence for it to be grammatically correct. It is plausible that such transitive verbs develop an intransitive variant, in which case the preferred membership of exactly 1 consideration is no longer valid: it is then so preferred that it becomes trivial and must be dropped.

More generally, acceptability, which is typically barely mentioned in linguistics, cannot be explored scientifically without a serious fuzzy logic influx, and the math, tentatively offered here, may have to be developed further to capture the individual dimensions of this phenomenon as well as combining them together. Besides the syntactic and semantic dimensions that we have touched upon here, there are the:

- appropriateness dimension, which renders the sentence, *This is the best night of my life*, with the membership degree of 1 on both the syntactic and semantic dimensions, totally inappropriate (or humorous, metaphoric, or poetic) when uttered in the middle of the day;
- relevance dimension that demands that each sentence in a text be clearly related to the surrounding sentences or see its membership degree sharply decreased;
- saliency dimension, where, again, a sentence with the degree membership of 1 on the other dimensions may have a much lower value if it does not convey new and important information.

And the list is not exhaustive because, for instance, humorous, metaphoric, and poetic are probably also additional dimensions. While the membership functions will be more difficult to define in the current state of scholarship on those dimensions, the principle of calculating the acceptability of a sentence, which in turn helps with determining meanings of unknown words, will—we believe—remain essentially unchanged.

***Abstract*—In an era in which organizations increasingly consider the competencies of their employees as a crucial resource, human management becomes a key activity for improving staff and business performances. Important is also knowing who knows what inside the organization, so that project teams are assembled as the right mix of skill, knowledge and workforce abilities. At the same time, trust, an essential component, related to understanding interpersonal and group behavior, is an indisputable prerequisite for organizational effectiveness, in terms of social-cognitive capital, global competency as well as economic exchange and social and political stability.**

This paper defines an approach to support competency-based management by providing recommendations about the reliability of a worker in terms of trust information and own competencies. The approach lies on an agent-based architecture which supervises the Human Resources Management (HRM). Task-oriented agents monitor the employees' profiles and capabilities by maintaining update the competencies and the trusts in the organizational social network. Particularly an agent endowed by fuzzy reasoning capabilities provides recommendation about workers' competencies in HRM decision-making processes.

***Index Terms*—Competency-Based Management, fuzzy rules, multi-agent systems, trust/distrust**

I. Introduction

In a climate of global competitiveness, organizations can retain their competitive position by providing innovative products, services, and processes. The innovative potential of an organization depends on features such as skills, abilities, knowledge, experience, perspectives, and social network ties that it can draw on [1]. Organizations succeed in leveraging high levels of trust that represent a necessary condition that must be met for reaching the competitiveness potential. Trust has been defined as the "social glue" [2], that correlates positively with high degrees of personnel involvement, commitment, and organizational success. At the same time, it is " a mental state comprising expectancy (the trustor expects a specific behavior from the trustee) and belief" [3]. Computational trust models have recently been drawing the attention of many scientific communities from various disciplines [6], [7] to analyze interpersonal or inter-organizational trust in different domains such as e-commerce [8] and social web applications [9].

In literature [14], several works provide models for the trust management in virtual communities and social networks. Yet, they do not always consider the relationship existing between trust in competencies and the workers employed on specific jobs. A set of organizational processes identified by Competency-Based Management (CBM) guarantees that there is the right worker with the right competency in the right position at the right time in order to pursue high level of organizational productivity and effectiveness. Typically, CBM processes are top-down organizational processes supported by enterprise software that cannot be exploited to support team building operations in not-formal working activities.

It would be desirable to define an approach to enrich CBM with trust information in order to support the Human Resource Management in finding competencies. On the other hand, because trust is subjective measure of human beings, some works have exploited fuzzy logic as a possible best fit approach for manage uncertainties within organizational data. On the other hand, trust can be naturally expressed by linguistics terms rather than numerical values. In [8], trust has been modeled through Fuzzy Logic by defining a model for identify the information that customers expect to find on a vendors to increase their trust. The work described in [12] instead, exploits the theory of Fuzzy Cognitive Time Maps (FCTMs) into modeling and evaluating trust relationships in the virtual enterprises setting. Similarly to our approach, a fuzzy inference system has been exploited [13] to model trust measurement. The approach has been applied to improve knowledge sharing within a community to lead organizations to high level of productivity: the fuzzy system returns the degree of knowledge sharing. The goal of our approach instead is mainly devoted to suggest recommendations through the agents' supervision in HRM decision-making processes: our fuzzy system, embedded in an agent reasoning, suggests for each selected worker, the personal acquired level of competency.

Many researchers have studied the concept of trust in inter-organizational relationships and investigated trust between organizations [5], evidencing the important benefits produced by exploiting trust both individually and collectively. The

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

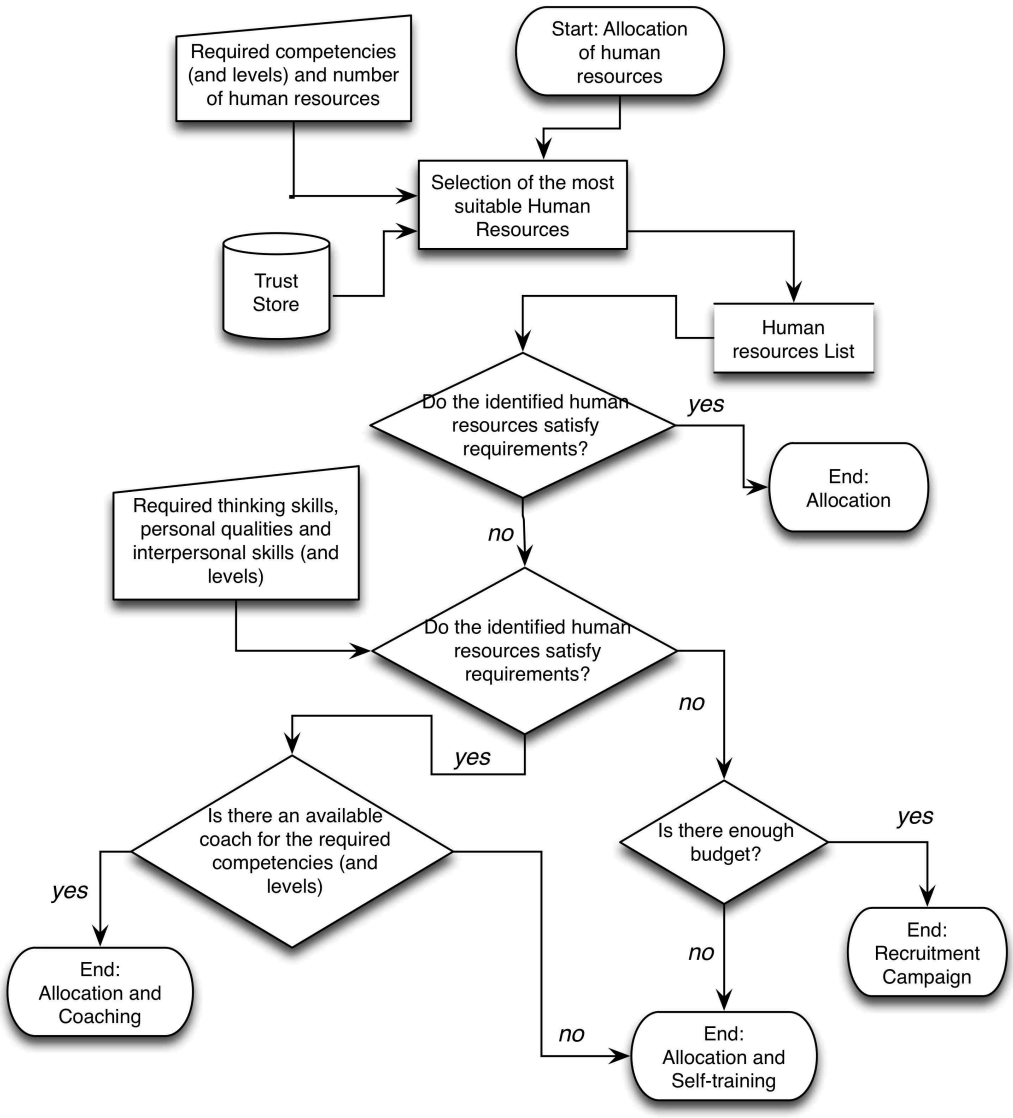

Fig. 1. Activities flow of an organizational strategy

influence of organizational procedures on attributions regarding organization' trustworthiness has been investigated in [5]. These procedures tend to increase trust between worker and supervisor or, in general, the trustworthiness in the organization. Trust might have positive effects on attitudes, perceptions, behaviors, and performance outcomes within organizational settings. In fact, the receipt of positive outcomes constitute evidence that the organization can be counted on to perform behaviors desired by the trustors and is related to employee job satisfaction and overall perceptions of organizational effectiveness.

This work presents an agent-based approach to support competency-based management in an organization. Recommendations address organizational strategies as well as the trustworthiness of a worker in terms of acquired trust degree and own competency levels. Fundamental role to reach this goal is played by the team builder agent which embeds fuzzy reasoning capabilities, in order to provide recommendation about workers' competency in Human Resources Management (HRM) activities.

The remaining of this paper is organized as follows. Section II presents the main step of an enterprise strategy for the human resources management. The role of trust for the human resources allocation is presented in Section III where the concepts of trust and also distrust are formally given. Section IV depicts the logical view of the framework and the role of the agent-based platform. The tasks accomplished by each agent and their interactions are given too. Particularly, Section V provides a closer look on the task accomplished by the team builder agent; it implements a fuzzy inference system to deduce a single overall measure of the worker's competency. Then, Section VI gives an example of applicative scenario. Finally,

conclusion and future works close the paper.

II. Organizational Strategies

In order to refine the human resource allocation process we also need to consider the specific enterprise strategy with respect to human resource management. Figure 1 shows an example of an enterprise strategy aimed at allocating workers whose profiles meet the competency (and level) required by the Decision Support System (briefly, DSS).

In [11], a set of strategic human resource management practices are described. The most relevant, for the purpose of this work, are "Recruitment and Selection" and "Training and Development". During a human resource allocation process, in situations where there is not a perfect match between the required competencies (and levels) and the available competencies (and levels), the awareness of the enterprise strategy could help the decision making. As shown in Figure 1, when there are no workers that match the required competencies and level, the strategy is designed to apply one of two practices. When the company's strategies aim at growing its employees professionally, Training and Development is the favorite practice. It is selected if there are workers in the company that have the required competency, even though with a different (lower) level. In particular, additional skills (e.g. continuous learning, teamwork, etc.) and personal qualities are required for the human resources to be allocated. The strategy foresees a training time (individual or flanked by a coach if available) for them. Otherwise, if the organizational budget allows it, a recruitment campaign (Recruitment and Selection practice) can be activated. The flow of Figure 1 is only one of the plausible practices that an organization could use with respect to the current adopted strategies. A practice can be defined and executed by using a Decision Support System.

In the following sections an approach to refine and improve these practices, by using trust information, will be proposed.

III. Trustor, Trustees and Trust in Competencies

Trust emphasizes how people work together and build effective relationships; it is a critical link to all good relationships, both personal and professional.When workers believe that they are working for trustworthy organization, they are willing to invest their time and talents in making a real contribution in the activities where they are involved. People who trust supervisor will invest more of themselves in their work. Similarly, the trustor evaluates the worker's behavior on the activities, providing a trust degree which be rewarding and incentives him to do better. High trust degrees lead to a great sense of self responsibility, interpersonal insight and collective wishes to reach common goals.

In this work, the trustor is the corporate identified as the community of its employees, the trustees are the employees and we are interested in trust in competencies:

$$trust_c(e, x, k), \tag{1}$$

Category	Sub-category	Examples
Technical Competencies	Knowledge	Java language syntax
		Description logics
		UML notation
	Technical Skills	Java programming
		OWL modeling
		Project management
Behavioural and Cognitive Competencies	Thinking Skills	Problem-solving
		Innovation & creativity
		Continuous learning
	Interpersonal Skills	Teamwork
		Relationship management
		Communication
		Teaching others
	Action Skills	Decision-making
		Results orientations
		Planning & organization
	Personal Qualities	Integrity
		Self-motivation
		Responsibility
		Self-management

Fig. 2. Different types of competencies

The statement 1 indicates that the corporate (trustor) trusts employee e (trustee) regarding the capability of e to apply competency x in context k. Similarly, the distrust is defined as following:

$$distrust_c(e, x, k), \tag{2}$$

The statement 2 indicates that the corporate (trustor) does not trust employee e (trustee) regarding the capability of e to apply competency x in context k.

In the organizations, it seems to be a good choice to divide competencies into behavioral and technical competencies (see Figure 2). *Behavioral competencies* include all those soft skills and attitudes that enable a person to perform well in a specific function, such as *communication*, *problem-solving*, *integrity*, *planning and organization*, etc. *Technical competencies* are specific and depending on the job. These latter could range, for instance, from the knowledge of software development methodologies to skill for Java programming. Authors in [10] propose to calculate trust values in terms of frequencies of positive experiences between the trustor and the trustee. In our proposal, an experience is modeled as a work activity (or task). For each task there are a worker (an employee) and a supervisor. The underlying idea is that the supervisor assigns a rate to the performance of the employee involved in the task. The rate can be interpreted as a value indicating how the required competencies have been applied during the execution of the task. Our goal is to calculate the corporate trust in competencies for each employee. More in details, in the case of **trust in competencies**, formula (3) can be used. In this case the `trustor` is the corporate (intended as the community of

the employees) and the `trustees` are the employees.

$$\alpha = td_c(e, x, k) = n/m, \tag{3}$$

where m is the total number of situations in which e (trustee) has applied competency x in the context k, and n is the number of positive experiences in that set, β (distrust) can be calculated with the same formula (3) of α by replacing n with l and td_c with dtd_c, where l is the number of negative experiences in the same set. Values for n and l can be calculated with the following:

$$n = \sum_{m}^{i=1} e_p(i), l = \sum_{m}^{i=1} e_n(i), \tag{4}$$

where $e_p(i), e_n(i) \in [0, 1]$, representing the degree of the experience i being positive or negative separately, and $e_p(i) + e_n(i) \leq 1$. In the context of this work, a positive (negative) experience is represented by a task, that requires competency x, where any supervisor has provided a positive (negative) review rate $e_p(i)$ ($e_n(i)$) to the worker e for the application of competency x in the context k. Untrust γ can be calculated by using the formula $\alpha + \beta + \gamma = 1$ [10].

IV. Architecture Overview

The proposed approach is based on an agent-based platform aimed at sustaining and exploiting trust-based competency management by improving decision making processes with respect to human resource management activities. The approach also foresees a mechanism to weigh up each decision with organizational strategies and policies. Figure 3 provides a sketched sample enterprise IT environment showing all the components/systems involved in our approach.

- **Human Resource Management (HRM) System** is a typical system used in enterprise context in order to manage employees' profiles, competencies, career plans, payroll, allocations, etc. Typically, HRM systems are not in charge of the trust management.
- **Competency Assessment System** represents a set of tools used to assess employees' competencies and relative competencies levels. These tools can range from questionnaires (electronic form-based, papery, etc.) to Web-based e-Testing System.
- **Collaborative Working Environment (CWE)** is a set of tools used, in the organization, to support employees' tasks. Document Management Systems, Collaborative Workspaces, Wiki, Blog, Instant Messaging and Videoconferencing are examples of these tools.
- **Decision Support System** represents an environment providing human resource managers with suggestions regarding decision making processes. In this work, we focus on decision making about human resource management.
- **Trust Store** is the database in which, for each employee, trust degrees are stored and associated to employees' competencies (and levels). Data used to calculate trust degrees for each employee are also maintained in Trust Store. We assume that for each employee there is a set of tuples <*competency, competency level, context, trust, distrust, untrust*> that states all the competencies owned by the employee. The first three values come from the Human Resource Management System. Trust, distrust and untrust values are calculated by agents exploiting a social approach. Competency is a label representing a specific competency (e.g. Project Management), competency level is a value in the set {*novice*, *advanced beginner*, *competent*, *proficient*, *expert*} (according to Dreyfus model of skill acquisition [4]), context is a label (e.g. R&D Projects) representing the domain in which the competency is applied.

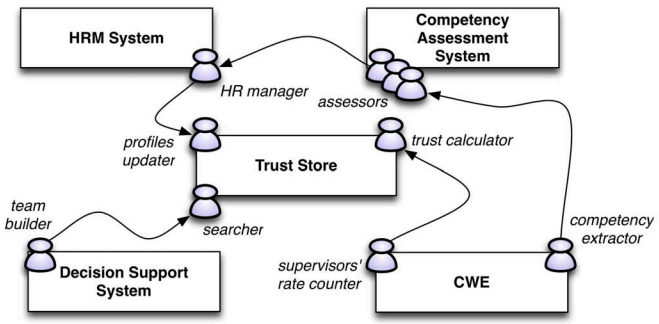

Fig. 3. Logical overview of the architecture

The agent-based paradigm represents the glue to make the several and heterogeneous systems communicating though distributed interactions. In fact, task-oriented agents are designed for each system to guarantee ACL-based communication, monitoring the interaction to each other and support a competency management in human resource processes such as, for instance, effective project team building. Let us introduce the role of each agent, associated to the components of the architecture.

- **HR manager agent**: handles workers' competency profiles inside the HRM system by updating them when new competencies must be added to a specific worker (this information comes from assessors agents) and by communicating last updates to the profiles and network updater agent.
- **Assessors agents**: handle different types (formal and informal) of workers' competency assessment. For instance, this agent is responsible for receive and elaborate the information extracted from collaborative sessions data and content in order to discover unknown competencies from actions and results of workers during their collaborative work activities carried out by using CWE.
- **Competency extractor agent** is responsible for extracting information about employees' competencies from content and data tracked by CWE and for communicating it to the assessor agent.
- **Supervisor's rate counter agent** is responsible for no-

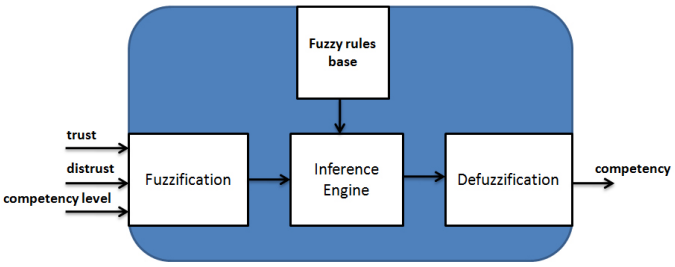

Fig. 4. Fuzzy Inference System

tifying new rates added by a supervisor to judge the performance (applying a specific competency) of a worker (trustee) with respect to a specific task. This agent communicates new posted rates to the trust calculator agent.

- **Trust calculator agent** uses supervisors' rates to produce trust degrees and updates values into the Trust Store.
- **Searcher agent** answers to the queries coming from decision support systems in order, for instance, to find workers owning specific competencies.
- **Team builder agent** provides recommendations about project team composition with respect to a set of needed competencies (and levels). This agent produces recommendations by elaborating information coming from the searcher agent.
- **Profiles updater agent** handles updates into the Trust Store with respect to employees' profiles (modifications to the owned competencies and levels) according to HR manager agent.

V. A CLOSER LOOK AT THE TEAM BUILDER AGENT

The aim of the team builder agent is to support DSS in the competency-based management and suggest recommendations for selecting suitable human resources to recommend to DSS. Precisely, this agent provides a list of workers whose competency matches the DSS request, in terms of competencies and associated levels. The goal of the agent is to provide not only the suitable workers that match the request, but, at the same time, evaluate the "accumulated" trust of the worker (during his previous organizational tasks) on the requested competency. In this way the agent suggests information which represents a kind of trade-off between the two different types of information: on one hand, the trust assigned (and calculated through the above described social approach) by the corporate to the worker on the requested competency, on the other hand, his competency and level in his profile. This balanced evaluation represents an added value that is not directly traceable by the DSS, but it is computed by agent exploiting its embedded reasoning model.

The team builder agent indeed incorporates a fuzzy inference system, which exploits a fuzzy rules base to deduct the overall evaluation of competency of a worker.

Fuzzy inference systems (FIS) are very simple conceptually (see Figure 4). They consist of an input stage, a processing stage, and an output stage. The input maps inputs to the appropriate membership functions and truth values (fuzzification). The processing stage invokes each appropriate fuzzy rule and generates a result for each, then combines the results of the rules (fuzzy reasoning). Finally, the output stage converts the combined result back into a specific control output value (defuzzification). The use of fuzzy inference system makes more intuitive the interpretation of values describing the trust (or the distrust) in a competency of the worker (i.e., trustee). In the real world, when human beings inquire to each other about the competency of an entity, preferably the answers are expressed through a linguistic terms, such as HIGLY COMPETENT, NO COMPETENT, etc., rather than using numerical values. In the light of this consideration, the team builder agent has been designed to simulate the human behavior, then it should provide answers using the same terminology as humans to make it more believable.

The fuzzy inference process exploits Mamdani's fuzzy inference method [15], which takes as input two numerical values representing the number of positive and negative experiences of some trustor for that worker (on a given context) and a competency level (assigned by the organization on the same context). Figure 4 shows information flows from three input variables to a single-output. Let us observe that the organization, by means HRM System, stores competencies (and levels) for each employee. Levels are defined according to the Dreyfus model of skill acquisition [4] which identifies five levels of competencies (detailed in Section IV). The competencies are assigned a priori to each workers through the organizational policy of competency Assessment System, through the assessors agents (see Figure 3), in accordance with their capabilities, certification and past working experiences. Competencies are always associated to a specific context in which they are applied, as said in Section IV.

The output of the fuzzy rules is a "synthetic" value that describes the overall competency of that worker for a specific context. Precisely, the IF-THEN fuzzy rules composing the knowledge based have the following form:

- IF trust is *high* AND distrust is *low* AND comp_level is *expert* THEN competence is *very high*
- IF trust is *high* AND distrust is *low* AND comp_level is *proficient* THEN competence is *high*
- IF trust is *medium* AND distrust is *low* AND comp_level is *proficient* THEN competence is *high*
- ...
- IF trust is *low* AND distrust is *low* AND comp_level is *advanced beginner* THEN competence is *low*
- IF trust is *low* AND distrust is *low* AND comp_level is *novice* THEN competence is *very low*

These rules evaluate a worker regarding to a specific competence by exploiting associated supervisors' trust and

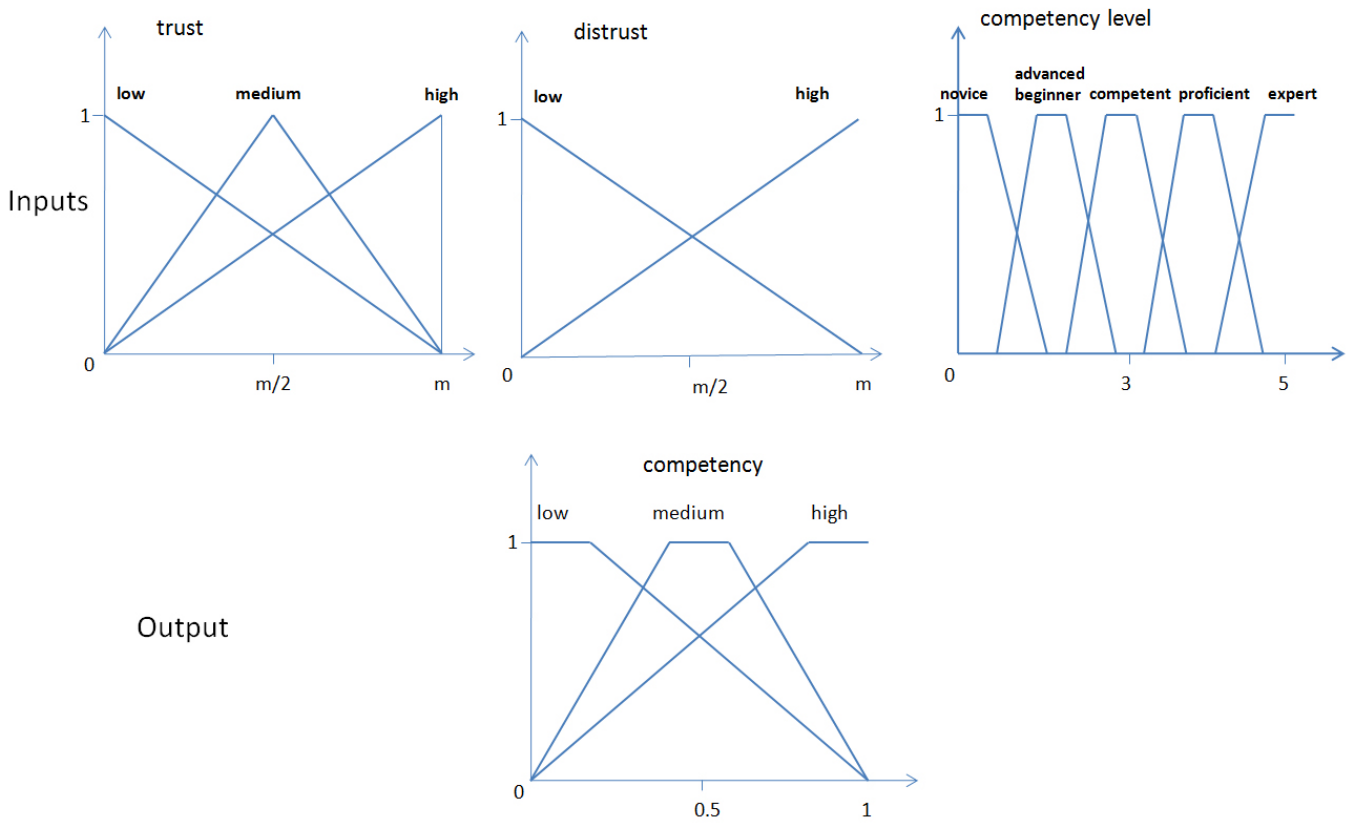

Fig. 5. Inputs and Output fuzzy sets for the reasoning of the team builder agent.

competence level.

Although the specific competency of each worker is related to the trust of the corporate, it is not influential in this stage, because we exploit only the type (positive or negative) of experiences gained during his working activities. Then, the untrust is not considered in this modeling. Figure 5 shows the fuzzy sets associated to the fuzzy reasoning embedded into the team builder agent. The linguistic terms of trust and distrust are modeled as triangular fuzzy sets, while the competence level is described by trapezoidal membership functions; similarly, the output is represented by trapezoidal membership functions. These functions seem good enough to capture the vagueness of those linguistic assessments. Due to many rules associated to knowledge base defined to model our variables, we give just same example of them. Moreover, the output fuzzy variable is defined through its primary terms: *low, medium and high*, the other are derived by applying linguistic modifiers (not shown in Figure 5).

Note the function memberships describing the inputs have the same distribution for all the worker, even though the input fuzzy sets are defined on a domain which depends on a parameter m. The value m represents the total number of situations in which the trustee has exploited his own competency in a certain context, according to the definition of *trust in competencies* (see formula (3)). This value strictly depends on the worker. Specifically, for each worker, the team builder agent loads the relative fuzzy rules based knowledge and applies the inference based on the instanced set of fuzzy rules.

According to the Mamdani-type inference, the output of the fuzzy system is a single value computed by defuzzification of the aggregated output fuzzy sets. Herein, we have exploited the most popular defuzzification method, i.e. the centroid calculation, which returns the center of area under the curve representing the aggregated output. This value represent the "overall" competency of a given worker in a given context.

For each selected worker, the team builder agent returns a synthetic competency value. Then a ranked list of workers is returned. It represents the recommendation to send DSS.

VI. An Example Scenario

Let us suppose a team building request occurs. The DSS requires for some specific competencies with the associated level of assessment about those competencies in some specified context. For instance, one of the desired requirements might be to select a human resource whose competence level is *expert* in Java programming and *proficient* in team working. The searcher agent, which is in charge of complying this request, returns to the team builder agent the set of workers that have both the competencies. For each worker, the agent instantiates the set of fuzzy rules associated to him: his value m of total number of situations (experienced by trustors) and the fuzzy set representing the own competence level as well. In

other words, if the worker *d* has competence level *competent* in Java programming and his number of experiences in this context is 7, the relative fuzzy rules base will be the domain [0, ..., 7] of membership functions for trust and distrust (see Figure 5) and the linguistic term used will be *competent*. Thus, the team builder agent applies the inference model on the knowledge based associated to that worker and deduces how he is "competent" in the specific context. At the end, the ranked list of all the workers is returned.

It is interesting to observe that sometimes an organization prefers to select workers with competencies levels that are slightly lower than the desired ones, for internal policy such as personnel cost, career development, etc. As said in Section II, Figure 1, the organizational strategies/policies could be to apply "Training and Development" practice. In fact, it would be desirable that, when the team builder agent is committed to find human resources with a specific competency level (in a given context), it does not answer with a perfect match, but provides workers whose competency level and trustworthiness together approximate the request.

The agents should select all the workers that have competency in a requested context (for instance, in Java programming), without further filtering on the required competence level. An idea is to use for each worker twice the fuzzy inference system: firstly, compute the overall competency by exploiting his competence level, as described in Section V. We call the final value of inference process the *personal competence* of each worker. Then we would evaluate the expected overall competency of the selected worker, considering instead the required its competence level. The goal is to compare the two output values. Thus, when the team builder agent instantiates the fuzzy inference rules associated to a worker, executes once the inference with is personal rule base. Then it executes a modified version of the worker rules base that substitutes the fuzzy linguistic term describing the competence level of worker with the required one.

After the inference, the agent obtains two values that represent the competency: the *personal* and the *expected* ones. By comparing the two values, it possible to assess how much the personal value of worker's competence approximate the expected one. Thus, the agent will return the worker whose difference between these two values is minimum. Let us note that when the agent selects a worker whose competence level fully matches the the requested one, the two values will be equal. This comparison allows us to get the worker whose competence approximates to desired one. More important, the output values include an evaluation with respect to the trust. In other words, we evaluate the competence of a worker (with respect to the requested one), taking into account also the trustworthiness of the worker. The final ranked list will be a pool of suitable human resources, which could do not fully match the DSS request, but meets the organizational policy.

Modelling the competence level, trust and distrust allows us to get a new measure of competence as a balanced mix of these parameters that could better reflect the organization policy. This result is preferable to a crisp reply for the request "all and just the workers with a given competence level on a context", that can mean an high cost in terms of resources allocation. As said in Section II, the organization can be interested in activity of "Training and Development", to professionally increase the competencies levels of its employees. The fuzzy inference model of the team builder agent can provide this kind of answers.

VII. Conclusion

This paper defines an agent based framework which supports competency-based management. The trustworthiness of a worker is evaluated as combination of his accumulated trust and competency levels for a specific context. A fuzzy inference system, embedded into the team builder agent, accomplishes the combined evaluation which provides an added value to the overall evaluation of a worker, through an adequate balancing of human expertise, competencies and capabilities. The agent returns recommendations to DSS request, providing a ranked list of the workers which matches or just approximates the request competency and level.

In this work, we have exploited Fuzzy Logic to model the trust (and distrust) in competency as well as the competency level. Although the modeling of this framework is still in progress, as future work, we intend to extend the fuzzy modelling to other parameters related to organizational strategies and the human resource management. The approach will be experimented in ARISTOTELE FP7 EU-Project.

***Abstract*—The particle swarm optimization (PSO) is an alternative for global optimization. A standard for PSO (SPSO) was defined which took into the latest developments, and was used as a baseline for performance testing of improvements. In SPSO, however, particles need to search the optimal solution in the constraint space, and the item velocity in PSO makes particles difficult to adjust themselves to meet those complicated constraints. A new PSO without the item velocity based on SPSO is proposed in this article. The new algorithm inherits the capability of SPSO with fast convergence and high accuracy. This research proves that the convergence process of PSO has nothing to do with the velocity and the proposed method modified simple PSO (msPSO) can converge. The experiments show that msPSO is able to achieve a good result.**

Keywords- particle swarm optimization; constraint space; optimal solution

I. INTRODUCTION

Particle swarm optimization (PSO) was first proposed by Eberhart and Kennedy in 1995[1]. For the sake of simplicity, we call the original PSO algorithm traditional particle swarm optimization (TPSO). This method, inspired by simulation of bird flocking or fish schooling, is a stochastic global optimization. In TPSO, each particle adjusts itself in the search space according to the best position it has found so far and the best position of all the particles in the swarm. The iteration will terminate when the particle converges to the global best point. In TPSO, particles represent potential solutions for the optimized problem. In the search process, each particle has its own position and velocity, represented by X and V respectively.

Compared to other evolutionary algorithms, such as genetic algorithms, artificial neural networks, genetic programming and ant colony optimization, PSO has the advantage of easy implementation and fast convergence. It is amenable to solve complex and diverse issues. PSO has been applied in function optimization, artificial neural network, fuzzy system control, machine learning and so on [2].

TPSO is mainly dependent on the experience of the corresponding particle and the particle's companions. Under some extreme conditions, convergence of TPSO will be very slow with low accuracy during the process of iteration; moreover, the particles will always "spiral" around the local extreme value. An inertia coefficient is added to TPSO to increase the probability of jumping out of local minimum [3]. The inertia coefficient can also balance between global and local search. TPSO is non-linear, and until now there still has not been an effective way to mathematically determine the value of parameters in TPSO to simulate the search process. A fuzzy system was proposed to dynamically adapt the inertia coefficient of TPSO, which could adaptively adjust the coefficients [4]. Another modified PSO (MPSO) was proposed to discard the velocity to get rid of restrictions of the range of velocity and the process was only controlled by the particle's position [5]. PSO has developed a lot with many researchers exploring the concepts and application of the algorithm. Because of different kinds of PSO existing, it is hard for researchers to find a reference to improve. A standard for PSO (SPSO) was defined which took into account current developments. SPSO is regarded as the extension of the TPSO, and can improve performance effectively [6]. The algorithm is intended as a baseline of improvements and provides a valuable point of comparison which can be used for researchers to better test new advances. However, SPSO is still limited to velocity. In some situation, the particle still has the problem with divergence and low accuracy. This research proves that the iteration of SPSO has nothing with the velocity, and proposes a new modified simple PSO (msPSO). The new algorithm removes the constraints of velocity and is proved to converge at a fixed position. The experiment illustrates that msPSO can improve its performance for the five benchmark functions.

The paper is organized as follow: In Section Ⅱ, the related background is presented in details. In Section Ⅲ, a new modified particle swarm optimization is proposed. What is more, the research also proves that the convergence process of PSO has nothing to do with the velocity and the proposed method msPSO can converge. Experiments are done on five benchmark functions and results are analyzed in Section Ⅳ. Finally we conclude the paper in Section Ⅴ.

II. RESEARCH BACKGROUND

TSPO is a global optimization algorithm. The search space for a specific problem is represented by a swarm with a great number of particles. During the process of iteration, the position X and velocity V of the corresponding particle are updated according to the particle's individual best position of its experience, denoted by "iBest", and the swarm's best position, represented by "gBest". The criterion of judging the position for a particle is presented by a "fittness" function. TPSO can be formulated as follows:

$$V_{id}(t+1)=\omega V_{id}(t)+c_1r_1(P_{iBest}(t)-X_{id}(t))+c_2r_2(P_{gBest}(t)-X_{id}(t)) \quad (1)$$

$$X_{id}(t+1)=X_{id}(t)+V_{id}(t+1) \quad (2)$$

where $i=1,2...N$, N is the number of particles in the swarm, $d=1,2...D$,D is the dimension of particles. c_1 and c_2 are nonnegative constants, r_1 and r_2 are random number uniformly distributed in[0,1]. $V_{id}\in[-V_{\max},V_{\max}]$, when V_{id} is more than $V_{\max}$, set $V_{id}=V_{\max}$, and on the other hand, when V_{id} is less than $-V_{\max}$, set $V_{id}=-V_{\max}$, $V_{\max}$ is a pre-set parameter. ω is the inertial weight, which is a constant value distributed in[0,1] . `

Clerc et.al [7] add a constraint factor α to control V as:

$$X_{id}(t+1)=\alpha X_{id}(t)+V_{id}(t+1) \quad (3)$$

[5] shows the evolution of TPSO has nothing to do with the particle velocity, and proposes a modified PSO (MPSO). In MPSO, the velocity V is removed so the discussion of V is avoided, which can simplify the process of iteration. The algorithm is presented by:

$$X_{id}(t+1)=\omega X_{id}(t)+c_1r_1(P_{iBest}-X_{id}(t))+c_2r_2(P_{gBest}-X_{id}(t)) \quad (4)$$

In 2007, Daniel Bratton and James Kennedy designed a standard particle swarm optimization (SPSO), which is the extension of TPSO[6]. SPSO combined the latest developments of PSO, and could improve the performance of iteration effectively. SPSO is denoted by:

$$V_{id}(t+1)=\chi(V_{id}(t)+c_1r_1(P_{iBest}(t)-X_{id}(t))+c_2r_2(P_{gBest}(t)-X_{id}(t))) \quad (5)$$

$$X_{id}(t+1)=X_{id}(t)+V_{id}(t+1) \quad (6)$$

subject to:

$$\varphi=c_1+c_2 \quad (7)$$

$$\chi=\frac{2}{|2-\varphi-\sqrt{\varphi^2-4\varphi}|} \quad (8)$$

The research has found that when $\varphi<4$, particles will spiral around the best found solution in the search space with no guarantee of convergence. While $\varphi>4$, SPSO can converged quickly.

SPSO is different from TPSO . The difference is as follows:

1) *Swarm Communication Topology:*

The global topology is used in TPSO, as shown in Fig.1 (a). In this topology, the global extreme is chosen by the comparison of all the particles in the swarm. While in SPSO, a local topology is used, and the global extreme for a specific particle is obtained by comparison of its neighbors, as shown in Fig.1 (b). To distinguish between the two concepts, in this paper, the global extreme obtained by the global topology is called the global optimal solution, while chosen by the local topology is called the local optimal solution.

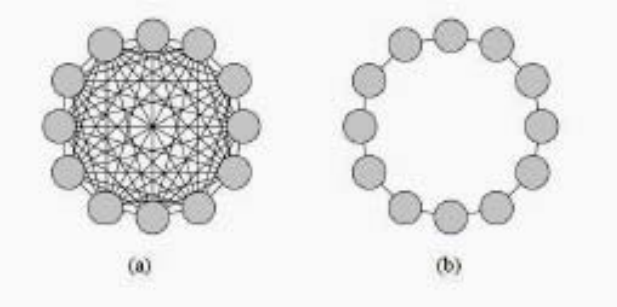

Fig.1. TPSO and SPSO topologies

2) *Inertia weight*

In TPSO, the inertia weight is used to adjust the influence of velocity in the previous step affected on the present step. By adjusting the inertia factor, particles in TPSO can be bound into the region containing the global optimal solution, while not trapped into local optimal solution. A new variable λ is introduced into SPSO which removes the inertia weight. Experiments show that compared with TPSO, SPSO gets better results while maintains the same simplicity with TPSO. Because SPSO is a combination of the latest PSO developments, it can be used as a reference for future work, thus avoid the redundant work of comparison.

III. METHOD

SPSO includes both velocity (V) and position(X). In practice, due to a lot of restrictions with X, the existence of V makes it very difficult to limit X into a designed search space. In this paper, it is found that evolutionary process of SPSO is independent of V.

Theorem A: SPSO has nothing to do with the particle velocity

Proof: let $\omega=c_1r_1\lambda p_0+c_2r_2\lambda p_g$, $\varphi=c_1r_1\lambda+c_2r_2\lambda$. In SPSO, the constraint factor $\alpha=1$. [7] has proved that the constraint of V is equivalent to the constraint factor α , so the scope of V will not be considered. Excluding P_{iBest} and P_{gBest} on the impact of each dimension, each dimension is dependent of each other. In order to simplify the certification process, we can just consider the case of one-dimension, and the subscript d can be omitted. Assuming that the other particles are kept fixed except the i - particle, the subscript i can also be omitted. For SPSO, after one iteration, we can get:

$$V(t+2)=\lambda V(t+1)+\omega-\varphi X(t+1) \quad (9)$$

$$X(t+2)=X(t+1)+V(t+2) \tag{10}$$

From equation (9) and(10), we can get:

$$V(t+1)=\frac{1}{\lambda}(X(t+2)-X(t+1)-\omega+\varphi X(t+1)) \tag{11}$$

Put equation(11) into equation(6):

$$X(t+2)+(\varphi-\lambda-1)X(t+1)+\lambda X(t)-\omega=0 \tag{12}$$

From equation(12), SPSO has no concept of V, which can simplify the process of PSO. Because SPSO is independent of V, so the item V can be removed from SPSO, just as:

$$X_{id}(t+1)=\chi(X_{id}(t)+c_1r_1(P_{iBest}-X_{id}(t))+c_2r_2(P_{gBest}-X_{id}(t))) \tag{13}$$

The research calls this new algorithm modified simple particle swarm optimization (msPSO). In msPSO, the global extreme is obtained through the local topology.

Theorem B: if the average behavior of msPSO is observed through its expected value, msPSO converges

Proof: For ease of exposition, the symbols in theorem A will be used, and the equation(13) can be formatted as:

$$X(t+1)=(\chi-\chi c_1r_1-\chi c_2r_2)X(t)+\chi c_1r_1P_{iBest}+\chi c_2r_2P_{gBest} \tag{14}$$

The equation (14) is a first order differential equation, and we can set:

$$X(t+1)=X(t)+X'(t)(t+1-t) \tag{15}$$

From the equation(15), the equation (14) can be deformed as:

$$X'(t)+(\chi c_1r_1+\chi c_2r_2-\chi-1)X(t)=\chi c_1r_1P_{iBest}+\chi c_2r_2P_{gBest} \tag{16}$$

Solution for the differential equation is:

$$X(t)=\frac{\chi c_1r_1P_{i\mathrm{Best}}+\chi c_2r_2P_{\mathrm{gBest}}}{\chi c_1r_1+\chi c_2r_2-\chi+1}+\mathrm{C}e^{-(\chi c_1r_1+\chi c_2r_2-\chi+1)t} \tag{17}$$

Since the first half items of equation(17) is constant, they can be omitted. If $\lim_{t\to\infty}X(t)$ converges, then:

$$\lim_{t\to\infty}\left|\frac{\mathrm{C}e^{-(\chi c_1r_1+\chi c_2r_2-\chi+1)(t+1)}}{\mathrm{C}e^{-(\chi c_1r_1+\chi c_2r_2-\chi+1)t}}\right|<1 \tag{18}$$

Equation (18) is equivalent to equation(19):

$$\chi c_1r_1+\chi c_2r_2-\chi+1>0 \tag{19}$$

Since r_1 and r_2 are uniformly distributed, the average behavior of msPSO is observed through its expected value.

$$E(r_1)=\int_0^1\frac{x}{1-0}dx=\frac{1}{2} \tag{20}$$

$$E(r_2)=\int_0^1\frac{x}{1-0}dx=\frac{1}{2} \tag{21}$$

From the equation(20) and the equation(21), we can infer that the equation(19) is equivalent to equation(22)

$$\chi(c_1+c_2-2)>-2 \tag{22}$$

Since $\chi>0, c_1+c_2>4$, the equation(22) holds. Equation(13) converges to:

$$\lim_{t\to\infty}X(t)=\frac{\chi c_1r_1P_{iBest}+\chi c_2r_2P_{gBest}}{1-\chi+\chi c_1r_1+\chi c_2r_2}=\frac{2\chi c_1P_{iBest}+2\chi c_2P_{gBest}}{2-2\chi+\chi c_1+\chi c_2} \tag{23}$$

IV. EXPERIMENTS AND RESULTS

To analysis the effect of the proposed algorithm, five benchmark functions are provided for the comparison of particle swarm optimization:

Sphere f1: $f_1(x)=\sum_{i=1}^{n}x_i^2$

Griewank f2: $f_2(x)=\frac{1}{4000}\sum_{i=1}^{n}(x_i)^2-\prod_{i=1}^{n}\cos(\frac{x_i}{\sqrt{i}})+1$

Rastrigin f3: $f_3(x)=\sum_{i=1}^{n}(x_i^2-10\cos(2\pi x_i)+10)$

Duadric f4: $f_4(x)=\sum_{d=1}^{n}\left(\sum_{j=1}^{d}x_j\right)^2$

Shaffer f5: $f5(x)=0.5+\frac{\left(\sin\sqrt{x^2+y^2}\right)-0.5}{\left(1.0+0.001\left(x^2+y^2\right)\right)^2}$

The details about the five benchmake functions described as table 1. In table 1, Dim represents the particle dimension, and Range is the search range of particles. Optimal is the extreme value of the corresponding functions and Goal

represents the accuracy of optimization. Four PSO algorithms (MPSO, msPSO, TPSO, SPSO) will be compared using the five functions. To increase the difficulty of the optimization process, the paper expands the dimension of functions and increases the target precision. With these harsh conditions, it can be more easily for us to compare and highlight performance. In our research, the number of particles is 15, and the maximum number of iterations is 500000. After 500000 iterations, iteration will terminate even the result does not meet the target accuracy. For the other parameters in PSO, the recommended parameters in [5] will be used. In MPSO and msPSO, $c_1 = c_2 = 2.05$, $\omega = 1.0$; in TPSO and SPSO, $c_1 = c_2 = 2.05$, $\omega = 0.8$, $V \in [-2,2]$.

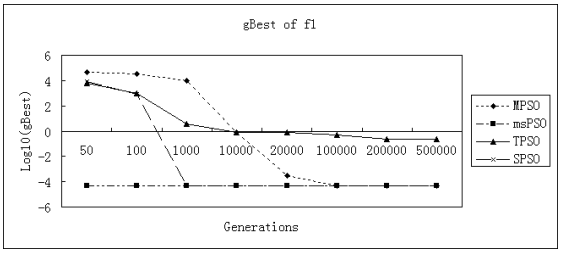
The convergence precision and speed with the fix number of iterations is as shown as fig.2. In Fig.2, X axis represents the iteration number and Y axis represents logarithm of the global optimal solution. When the algorithm reach the required precision after less than 500000 iterations, it will exit and the global optimal.

It can be found in Fig.2 that the five functions can meet the precision requirements with less than 50 iterations. For the function f3, TPSO, SPSO and MSPO always hover around a local minimum, and can not converge; however msPSO can meet the required precision in the number of 50 iterations or less. Compared with other three algorithms, msPSO has a good performance to escape the local minimum. In addition, from the Fig.2, it can be found that for all the objective functions msPSO can achieve the target in less than 500000 iterations, which means that msPSO has good capability of convergence.

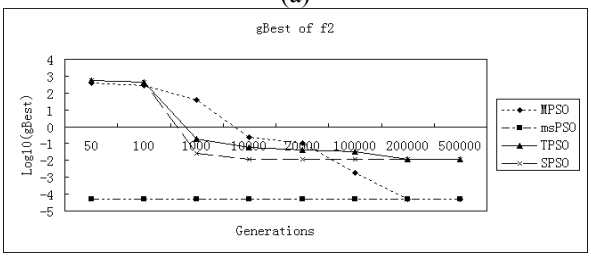
Table 2 shows the number of iterations with the accuracy of 0.00005 for PSO to train the five baseline functions. ">500000" represents that the algorithm is not able to achieve the required precision after 500000 iterations. From Table 2, TPSO, which relates to the selection of too many unknown parameters, is not able to convergence in a fixed number of iterations for f1-f4.

TABLE 1 BENCHMARK FUNCTION

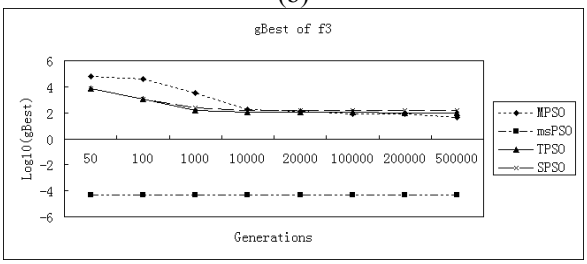
Function name	Dim	Range	Optimal	Goal
Sphere f1	30	$[-100,100]^{30}$	0	0.00005
Griewank f2	30	$[-600,600]^{30}$	0	0.00005
Rastrigin f3	30	$[-100,100]^{30}$	0	0.00005
Duadric f4	30	$[-100,100]^{30}$	0	0.00005
Shaffer f5	2	$[-100,100]^{2}$	0	0.00005



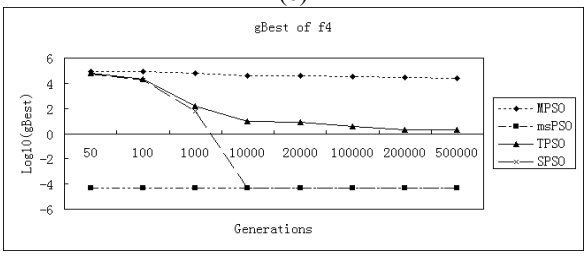
(a)



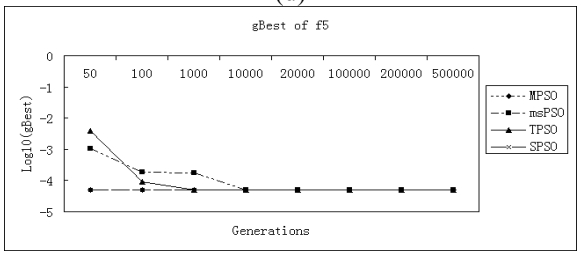
(b)



(c)



(d)



(e)

Fig.2. the evolution curve of the global optimal value for f1-f5

TABLE 2 NUMBERS OF INTERATION UNDER TARGET PRECISION

Function name	Iterations of MSPO	Iterations of msPSO	Iterations of TPSO	Iterations of SPSO
f1	21725	34	>500000	723
f2	123397	35	>500000	>500000
f3	>500000	46	>500000	>500000
f4	>500000	35	>500000	7782
f5	42	3279	105	26

SPSO takes into account the current latest progress of PSO, and its convergence speed has achieved a lot of improvements for f1, f4, f5. Just because of the item V to be considered in SPSO, f2 and f3 still diverge after 500000 iterations. MSPO has been improved a lot to get rid of the constraint of V compared with TPSO, and achieves a good result for f1, f2 and f5. In terms of SPSO msPSO removes the restrictions of V and improve the convergence speed and accuracy.

V. CONCLUSION

In reality, optimization problems face up with many complex and varied constraints. PSO is one of the methods to solve them. However, the velocity V makes X difficult to meet those constraints. The paper proposes msPSO based on SPSO. The new algorithm inherits the capability of SPSO with fast convergence and high accuracy, and gets rid of the item V. This research proves that the convergence process of PSO has nothing to do with V and the proposed method msPSO can converge. The experiments show that msPSO is able to achieve a good result.

***Abstract*—Agent-based artificial immune system (ABAIS) is applied to intrusion detection systems (IDS). A multiagent-based IDS (ABIDS) inspired by the danger theory of human immune system is proposed. The intelligence behind ABIDS is based on the functionality of dendritic cells in human immune systems and the danger theory, while dentritic cells agents (DC agent) are emulated for innate immune subsystem and artificial T-cell agents (TC agent) are for adaptive immune subsystem. Antigens are profiles of system calls while corresponding behaviors are regarded as signals. This ABIDS is based on the dual detections of DC agent for signals and TC agent for antigen, where each agent coordinates with other to calculate danger value (DV). ABAIS is an intelligent system with learning and memory capabilities. According to DVs, immune response for malicious behaviors is activated by either computer host or Security Operating Center (SOC).**

Multiple agents are "embedded" to ABIDS, where agents coordinate one another to calculate mature context antigen value (MCAV) and update activation threshold for security responses. Accordingly, computer hosts met with malicious intrusions can be effectively detected via input signals and temporary output signals such as PAMP, danger and safe signals.

***Index Terms*—intrusion detection, multiagent, artificial immune systems, dendritic cell algorithm**

I. Introduction

The Internet has become a major environment for propagating malicious codes, in particular, through web applications. Internet worms spread through computer networks by searching, attacking and infecting remote computers automatically. Intrusions, in particular, web-based ones, have become increasing threats for information assets. In order to defend against network attacks, one efficient way is to understand various properties of virus, which include the impact of patching, awareness of other human countermeasures and the impact of network traffic, even the ways how these malicious codes reside in a certain hosts, etc.

Forrest et al. [1] proposed an instance of computer immunology to protect the computer systems using the principles of human immune systems. Gu et al. [2] proposed an architecture of combining multiagent systems and dendritic cells. Most AIS researches focus on the development of specialized AIS algorithms inspired by theories such as the negative selection theory or the danger theory. Applying AIS algorithm to IDS can be traced back to [3].

Greensmith et al. [4] employed dendritic cells (DCs) within AIS which coordinate T-cell immune responses. Kim et al. [5] proposed "CARDINAL" which embedded T-cell process within the danger-theory-based AIS. Greensmith et al. [4], [6] proposed the Dendritic Cell Algorithm (DCA) whose purpose is to correlate data in the form of antigens and signals, then to identify groups of antigens as normal or anomalous. DCA achieves such missions through a generation of an anomaly coefficients, namely, *mature context antigen value (MCAV)*. It is believed that a DC is better performed by agent technology while considering its adoption to network environment. This antigen-plus-context information is passed on to a class of responder cells, termed T-cells. DCs are natural intrusion detection agents, which monitor the host tissue for evidence of cell damage. DC agents in our agent-based intrusion detection system (ABIDS) will evaluate antigens and corresponding signals according to DCA to determine whether antigens are malicious nor not.

For information security, one important aspect learned from immunology is the following: a computer security system should protect a host or network of hosts from unauthorized intruders, which is analogous in functionality to the immune system protecting the body from invasions by foreign pathogens. For example, anti-virus software has recently adopted some features analogous to the innate immune system, which can detect malicious patterns. However, most commercial products do not yet have the adaptive immune system's ability to address novel threats.

The motivation of this research is the following. Can agent-based information security systems learn itself to effectively determine whether the abnormality is "actually" incurred by some malicious attacks? This paradigm is very similar to the danger theory proposed in the immunology [7]. The arrangement of this paper is as follows. In section 2, preliminary knowledge such as AIS, danger theory, intelligent agents system and computer security are introduced. For section 3, IDS based on ABAIS model inspired by DT is discussed Simulations of two agent-based algorithms for ABIDS based on different scenarios will be given in section 4.

II. Background

A. Intrusion Detection Systems (IDS)

Intrusion detection systems (IDS) focus on exploiting attacks, or attempted attacks, on networks and systems, in order to take effective measures based on the system security policies, if abnormal patterns or unauthorized access is being suspected. However, there are two potential mistakes by IDS, namely, false positive error (FPE) and false negative error (FNR). For FPE (FNE), a pattern is mistakenly determined as abnormal (normal).

The main goal of IDSs is to detect unauthorized use, misuse and abuse of computer systems by both systems insiders and external intruders. It can be a device or software application that monitors network and/or system activities for malicious activities or policy violations and produces reports to a Management Station. A host-based intrusion detection system (HIDS) consists of an agent on a host that identifies intrusions by analyzing system calls, application logs, file-system modifications (binaries, password files, capability databases, Access control lists, etc.) and other host activities and state. In a HIDS, sensors usually consist of a software agent. Some application-based IDS are also part of this category. It is an crucial issue of establishing principles of designing an IDS. According to [5]. there are three such principles as follows.

1) Types of system response should be determined by attack severity and certainty.
2) For performing adequate magnitudes of responses, both local and peer information needs to be taken into account.
3) Optimize the number of peer hosts polled.

B. Human Immune System (HIS)

The human immune system (HIS) consists of the antibodies and lymphocytes, which include T-cells and B-cells. HIS uses a large number of highly specific B- and T-cells to recognize antigens. Only B-cells secrete antibodies. Clonal selection theory explains the details of antibody secretion specific to an antigen where T-cells help regulating. The binding between antigen and specific lymphocytes trigger proliferation from immature lymphocytes to mature one and the secretion of antibodies.

HIS can be categorized as innate and adaptive immune system. The innate immune system is characterized by three roles, namely, host defense in the early stages of infection, induction of the adaptive immune response and determination of the type of adaptive response through antigen presenting cells (APCs) [8]. On the other hand, the main characteristics of the adaptive immune system are recognitions of pathogens.

1) Dendritic Cells: The dendritic cell (DC) is a vital link between the innate and adaptive immune system and provides the initial detections of pathogenic invaders. DC is an APC which captures antigen protein from the surrounding area and processes it by ingesting and digesting the antigen. DCs are also part of innate immune system; once activated, they migrate to the lymphoid tissues where they interact with T-cells and B-cells to initiate the adaptive immune response. Moreover, adaptive immune response is ”orchestrated” by DCs.

DCs are the first defense line for HISs which will arrive at the locations where antigens intrude and then swallow the latter to the pieces. These pieces will be attached to APCs and presented to the T-cells. DCs can be regarded as the commanders for HISs; they can combine the danger and safe signal information to decide if the tissue environment is in distress or is functioning normally.

2) T-Cell: DCs will influence the differentiation of T-cells by releasing particular cytokines. In other words, DCs drive the T-cell to react to the antigen in an appropriate manner. Naive T-cells are those who have survived the negative and positive selection processes within the thymus, and have migrated to circulation system between the blood and lymphoid organs where they wait antigen presentation by DC's. Naive T-cells reach an activated state when the T-cell receptor (TCR) on their surfaces binds to the antigen-peptide-MHC molecules on the surfaces of DC's, and co-stimulatory molecules are sufficiently upregulated on the surface of the DCs to show the degree of danger signals. The activated T-cells proliferate and their clones will differentiate into other cells such as helper t-cell and cytototoxic T-cells (CTL).

C. Artificial Immune Systems

Artificial Immune Systems (AIS), which is based on HIS, have been applied to anomaly detections [2][3][5][9][10]. AISs have been developed according to negative selection algorithm and clonal selection algorithm which are based on the classical self-nonself theory; nonselfs are entities which are not part of human organisms. This so-called self-nonself classification theory had been challenged while failing to explain several immunological phenomena. Some alternative theories have been proposed, for example, the danger theory (DT). DT postulates that the human immune systems respond to the presence of molecules known as danger signals, which are released as results of unnatural cell deaths.

D. Danger Theory (DT)

Matzinger [7] proposed the Danger Theory, which has become more popular among immunologists in recent years for the development of peripheral tolerance (tolerance to agents outside of the host). DT states that the immune system will only respond when damage is indicated and is actively suppressed otherwise. DT proposes that APCs, (in particular, DCs), have danger signal receptors (DSR) which recognize signals sent out by distressed or damaged cells. These signals inform the immune systems to initiate immune responses. APCs are activated via the danger signals. These activated APCs will be able to provide the necessary signals to the T-cells (more precisely, T-helper cells) which control the adaptive immune response.

Danger signals are generated by ordinary cells of the body that have been injured due to attacks by pathogens. These signals are detected by DCs. There are three modes of operation: immature, semi-mature and mature. In the DC's immature

state, it collects antigens along with safe and danger signals from its local environment. DC is able to integrate these signals to decide whether the environment is safe or dangerous. If it is safe, DC becomes semi-mature. Upon presenting antigens to T-cells, DC will cause T-cells tolerance. If it is dangerous, DC becomes mature and causes the T-cells to become reactive on antigen-presentations.

E. Agent-based Artificial Immune Systems

Agent is an entity that has the ability of consciousness, solving problem, self-learning and adapting to the environment, which is very similar to immune systems in functionalities. Table I summaries such similarities between AIS and multiagent systems (MAS). Accordingly, AIS can be contributed to the learning mechanism of agents: the immune system response attributes of specificity, diversity, memory and self/non-self recognition are needed. It may be used to optimize the agent's responses to intruders. Functionalities of the biological immune system, such as content addressable memory, adaptation, etc., can be utilized in intelligent agents.

TABLE I
COMPARISONS BETWEEN MAS AND AIS

System	MAS	AIS
Diversity Generation	Yes	Yes
Self Tolerance	Yes	No
Learning	Yes	No
SNS Act. Threshold	Yes	Yes
Self Maintenance	Yes	Yes
Short-term Memory	Yes	Yes
Long-term Memory	Yes	No

Adaptiveness is a challenge and also an important feature for MAS to interact with the environment. Three major stages for ABAIS inspired by the clonal selection theory are diversity generation, self-maintenance and memory of nonself. The last two properties define the adaptiveness of the IBMAS. These steps are carried out by agents distributed over the MAS.

- **Diversity Generation**: Continuous diversity generation leads to the "adaptation" of ABAIS. Diverse agents with distinct specificity of the receptor and the effector are generated by way of mutations.
- **Self-Maintenance**: Agents are adjusted to be insensitive to known patterns (self) during the developmental phase. Negative selection theory is a central of this phase.
- **Memory of Nonself**: Agents are adjusted to be more sensitive to unknown patterns (nonself) during the working phase.

III. INTRUSION DETECTION MECHANISM BASED ON ABAIS

According to [10][11][12], we propose improved IDS based on ABAIS, or ABIDS in short. Different from traditional self-nonself paradigm for immune systems, our IDS will first detect danger signals emitted by computer hosts. These danger signals are based on some security threat profile, which defines by system calls generated by running processes. According to [9][11], threat profile may be composed of excessive CPU, memory load at the host, bandwidth saturation, high connection number of the host, etc. In this multi-agent system, several agents are generated which can communicate each other to emulate functionalities extracted from DT-inspired AIS (Fig 1).

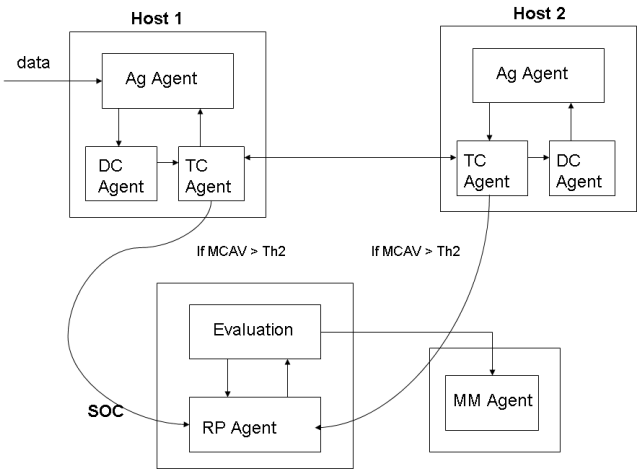

Fig. 1. Architecture of ABIDS.

A. Antigen

For most network detecting systems (for example, those adopting self-nonself paradigm), an antigen is defined as an information vector extracted from network packet. For example, antigens are binary strings extracted from the IP packets, which include IP address, port number, protocol types, etc. However, the antigen defined at Our ABIDS is related to system calls rather than network packets. A system call is the way how a program requests a service from an operating system's kernel. System calls provide the interface between a process and the operating system. Each process invokes some system calls. The more active the process, the more system calls it makes. Each system call is captured and converted into an antigen [13].

B. Intelligent Agents in AIS

We design a MAS with antigen agents, DC agents, T-Cell agents, Responding agents and Memory agents to perform functionalities of ABIDS such as DCAs, antigen memorization, etc.

1) Antigen Agent (Ag Agent): Antigen agents, which are installed at computer hosts, represent data item from the nonself dataset. They extract and record selected attributes from these data items. According to the agent-based DCA (ABDCA) which will be described later, each Ag agent sends corresponding DC agent a picked message when a nonself antigen appears.

2) Dendritic Cell agent (DC agent): In order to determine whether a malicious behavior is taking place, ABIDS needs to analyze antigens. DC agents are the kernel of the ABAIS which are complex compared to other agents; they are installed and distributed at each computer hosts. When an Ag agent issues a picked signal, corresponding DC agent will evaluate the risk

state facing by the host by calculating the danger value (DV). Similar to nature DC, each DC agent has three stages, namely immature, semimature and mature. DC agents are started from immature stages. When a picked signal issued from the Ag agent, DC agent executes data processing function such as the ABDCA. When a DC agent is at either semimature state or nature state, it returns the mature context to corresponding TC agent.

3) T-cell agent (TC Agent): TC agents are also installed at each computer hosts. TC agents are activated by the signals from DC agents when the DVs exceed thresholds. Each TC agent have three numerical values associated with it; these represent the accumulated certainties and severities of attack: *T-cell activation threshold, Th1 activation threshold, Th2 activation threshold*. These TC agents will communicate each other for exchanging these numerical values. There are two perspectives of this agent communications.

- For TC agent issuing malicious act warning for corresponding antigen, it informs TC agents "nearby" by exchanging its numerical values.
- For TC agent not issuing malicious act warning for this antigen, it simply update its numerical values according "nearby" TC agents issuing malicious act warning.

4) Responding Agent (RP agent): Ag agents, DC agents and TC agents are coordinating one another to perform malicious act responses. After DV exceeds threshold value , TC agents will inform RP agent, which is installed at SOC and each computer host. RP agents will activate some control measure to such malicious act. Two measures are considered:

1) Reporting to the SOC or security manager, for example, patches downloaded, activate relevant anti-virus software on this infected host and removes virus.
2) Disruption of intrusion, discards a suspicious packets, kill the related process, cut-off infected sub-network. These can prevent large-scale spreading of computer viruses, in particular internet worms, which have high spreading rate by their natures.

C. Algorithm: Agent-based Dendritic Cell Algorithm (ABDCA)

If an antigen is collected in an environment of danger, the context of this antigen is marked as anomalous and such antigen collected by the DC agent is potentially an intruder. While in the immature state, DC agent performs the following three functions:

1) Antigen Sampling: DC agents collect antigens from some external sources (in this case, from computer hosts) and places these antigens in its own antigen storage.
2) Update input signals: DC agent collect values of all input signals present in the signal storage area.
3) Calculate interim output signals: each DC agent calculates its three temporary output signal values from the received input signals, then derives its final output signal.

We observe that multiple DCs present multiple copies of the same antigen type for invoking an immune response; it leads to an error-tolerance immune system as a single DC is far from stimulating a "false positive" error. The ABDCA is listed as follows.

Algorithm 1 Agent-based DCA (ABDCA)

```
input : Antigens and signals
output: Antigen context (0 for safe/1 for danger)
Initialize DC agents (Immature state);
for each DC_agent_i do
    get antigen (Ag);
    store antigen;
    get input_signal;
    calculate output_signal_i;
    if output_signal_i > Activation_Threshold_i then
        Ag_context is assigned as 0;
        State of DC_agent_i="semi-mature";
    else
        Ag_context is assigned as 1;
        state of DC_agent_i="mature";
    end if
end for
update cumulative output_signals;
```

Three temporary output signals are PAMP signal, danger signal and safe signal. According to Greensmith et al. [13], the system should respond with a very high rate of false positives by switching the PAMP and safe signal. The definitions of PAMP, danger and safe signals, by way of parameters of computer hosts such as CPU usage, memory load, network connection (number) and bandwidth saturation, are as follows.

1) PAMP Signal: Network Connection $>$ th_netconnection AND bandwidth Saturation $>$ th_bandsaturation.
2) Danger Signal: CPU Usage $>$ th_cpuload OR Memory Load $>$ th_memoryload.
3) Safe Signal: All parameters $<$ th_parameter.

Where "th_parameter" represents the threshold value of the parameter. Now the computation of output signals by three temporary output values is the following.

$$output_signal = \frac{W_P \cdot C_P + W_D \cdot C_D + W_S \cdot C_S}{W_P + W_D + W_S} \quad (1)$$

According to empirical experiments [4], the weights for this output signal is $W_P = 2$, $W_D = 1$, $W_S = 1$. C_P, C_D, C_S represent PAMP signal, danger signal and safe signal. The principle for this weights is the following: PAMP signal will decide whether the danger signal will be a "really" harmful one. Whether output signal is harmful or nor is defined by the Table II.

TABLE II
DEFINITIONS OF OUTPUT SIGNAL.

Output Signal	C_P	C_D	C_S
Normality	0	0	1
Harmless Abnormality	0	1	0
Harm Abnormality	1	1	0

D. Algorithm: Agent-based IDS

Now according to ABDCA, we propose an algorithm describing agent-based IDS. This algorithm is also illustrated as Fig. 2. ABDCA can provide information not only a network packet but also a group of network packets is anomalous or not. This is achieved by the generation of an anomaly coefficient value, namely MCAV.

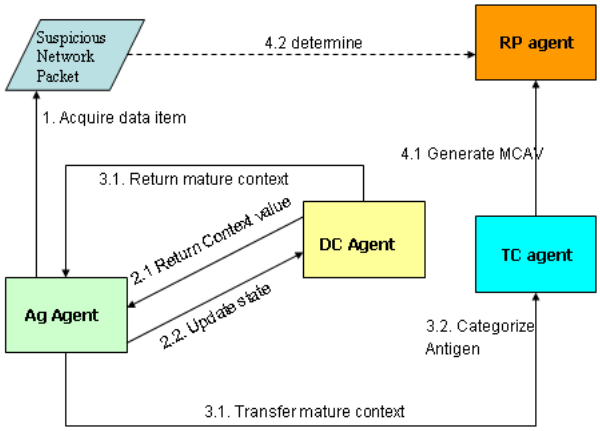

Fig. 2. Diagrammatic Illustration of Agent-based intrusion detection system.

Algorithm 2 Agent-based IDS (ABIDS)

Input: Antigen and Signals
Output: Antigen Types
1. Data Processing:
1.1 Ag agent extracts antigen from network traffic signal according to ag agent attribute.

2. Agent response:
2.1 DC agent returns context value according to threat profile; also according to the policy of the SOC if necessary.
2.2 DC agents will response to such antigen by updating its state according to DCA.

3. Danger Signal processing:
3.1
if this DC agent returns mature values to Ag agent **then**
Ag agent transfers it to the TC agent.
end if
3.2 TC agent categorizes such antigen according to the(updated)threat profile.

4. MCAV generation:
4.1 TC agent generates MCAV, which is sent to the RP agent.
4.2 RP agent determines if the corresponding antigen is malicious or not.
5. Antigen Memory:
5.1 Memory Agent stores necessary MCAV information

For the step 4 of the Algorithm 2, each nonself antigen gets a binary string of mature contexts from every selected DC agent installed at corresponding computer host. MCAV can be calculated through the number of context "1" divided by the number of all contexts. According to [2], it is similar to a voting system, where the antigen is the candidate and the DC agents are the voters. If the context is "1" ("0"), it means the DC agent determines this antigen is malicious (benign). The MCAV is actually the probability of that this antigen is being malicious.

The reactions of RP agents can be multiple according to the SOC's security policies. For example, passive reaction is initiated by sending some alarm signal such as an e-mail to the administrator and a strategy proactive is defined through mobile agents that implement the characteristics of the reaction. According to [11], for example, an applied reaction is defined for each of the following internet protocols such as DNS, FTP, HTTP, POP3 and SMTP. The issue of RP agents is out of the scope of this paper.

E. Agent Communications

One advantage of ABIDS is the communications and coordination between DC agents and TC agents. The basic idea is as follows. TELL and ASK-based communication permit agents share their internal information, enhancing their performances to respond to intruders [10]. On the other hand, useful knowledge obtained by DC agents and TC agents should be stored in some databases. These databases could also be shared by each DC and TC agent to improve their detection efficiencies. Suitable mechanisms of agent communications can contributed to better performance of ABIDS.

On the other hand, if a TC agent determines its host is under malicious attack by analyzing the corresponding MCAV, it will inform other TC agent "nearby". Such communication is direct and does not pass through proxy server or SOC. The activation threshold of this TC will be updated according to the following equation.

$$T(t) = T(t-1)+\alpha E(t-1)(E(t-1)-T(t-1)), t = 1, 2, \ldots, t_b \quad (2)$$

where E_i is the excitation level of TC agent, and t_b is the attacking time by this antigen.

Table III and Table IV illustrate the agent communications [14].

TABLE III
AGENTS AND THEIR COMMUNICATIONS (1).

Communication	Initiator	Receiver
eRaiseWarning	Ag Agent	DC agent
eContextReturned	DC Agent	TC Agent
eMaliciousOrNot	DC agent	TC agent
eEvidenceResponse	TC Agent	RP agent
eMemoryInitiation	RP agent	Memory Agent

TABLE IV
AGENTS AND THEIR COMMUNICATIONS(2).

Communication	Description
eRaiseWarning	Notify of a possible malicious attack
eContextReturned	sending MCAV
eMaliciousOrNot	Identify the malicious antigen
eEvidenceResponse	Implement the system response according to TC agent's information
eMemoryInitiation	Memorize the nonself antigen being encountered; update antigen database of Proxy server

F. Agent Platform

One advantage of this ABIDS is the following: it is feasible to be adapted into large-scale computer networks such as cloud computing environment, as TC agents will collect information from computer hosts to calculate MCAVs, and also update threat profile if necessary. Fig. 3 illustrates the agent interactions between SOC and computer hosts on agent platforms.

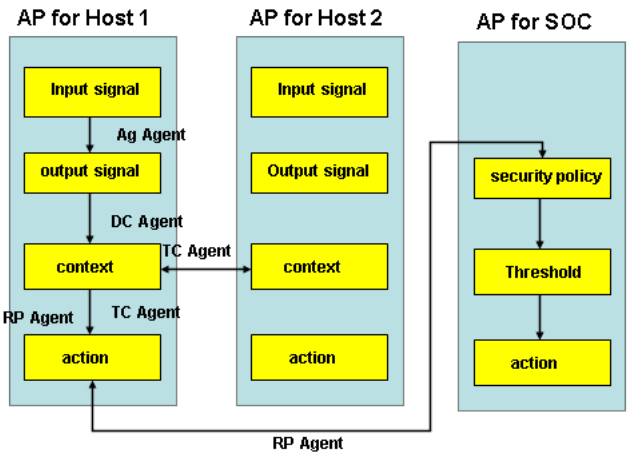

Fig. 3. Agent Interaction for ABIDS.

Table V and Table VI are the comparisons for goals and services fulfilled by these agents.

TABLE V
AGENTS, GOALS AND SERVICES (1).

Agent	Goals
Ag Agent	Data Parsing
DC Agent	Detect malicious codes or network attacks at the input sources
TC Agent	Categorize nonself antigen
RP Agent	Reduce the malicious antigen
Memory Agent	Memorize the nonself antigen

TABLE VI
AGENTS, GOALS AND SERVICES (2).

Agent	Services
Ag Agent	antigen label and signal association
DC Agent	MCAV estimation, update activation threshold
TC Agent	Identify the malicious antigen
RP Agent	Implement the system response
Memory Agent	Update the antigen database of the proxy server

IV. SIMULATION

A. Malicious Behaviors determined by ABDCA

According to essence of the danger theory, the advantage of ABIDS is the following: it can determine some nonself-antigenic behavior which is at the verge of normality and abnormality. For example, for those network behaviors with short attacking time. In this section, we simulate several critical cases for this ABIDS. The threshold of S, C and T are the following $S_{th} = 0.50$, $C_{th} = 0.50$ and $T_{th} = 0.5$. The number of computer hosts within this network is 2000. Each host has its fixed vector of weights. Simulation principle is to determine those critical behaviors, which include one extremely high factor with other low factors, or some factors are closing to the corresponding threshold values.

1) Nonself Antigen with High Severity, Low Certainty and Short Attacking Time: While an antigen intrudes a computer host with behaviors of high severity but low certainty and short attacking time, it is difficult sometimes to determine if this is a malicious attack. In this case, we consider the threat profile TP=$[0.9, 0.01, 0.01]$ for the ABDCA algorithm.

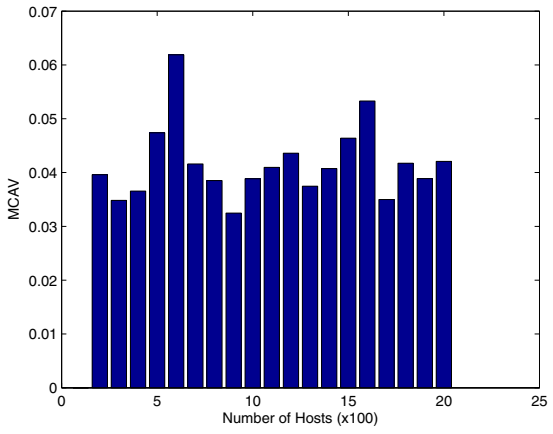

Fig. 4. Average MCAV for an Antigen with High Severity solely.

We expect the simulation should be "stable" for reasonable many hosts as Fig. 4. MCAV is around 0.03 and 0.05, which shows that this nonself antigen is normal.

2) Nonself Antigen with Edge Behavior: While an antigen intrudes a computer host with edge behavior such that severity, certainty and attacking time are all closing to their threshold values, respectively. It is also difficult to determine if this is a malicious attack or not. In this case, we consider TP=$[0.65, 0.65, 0.65]$.

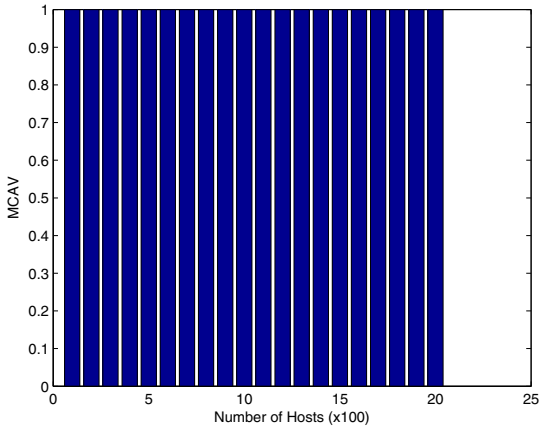

Fig. 5. Average MCAV for an Antigen with Critical Threshold Behavior.

The simulation also show a stable result (see Fig. 5); average MCAV is equal to 1, which indicates that this nonself antigen is harmfully abnormal.

3) Nonself Antigen with Short Time Attack: In this simulation, an antigen causes computer hosts with both high severity and certainty, but relative medium attacking time. It is difficult to determine if this is a malicious attack or not. In this case, we consider TP=$[0.9, 0.9, 0.4]$.

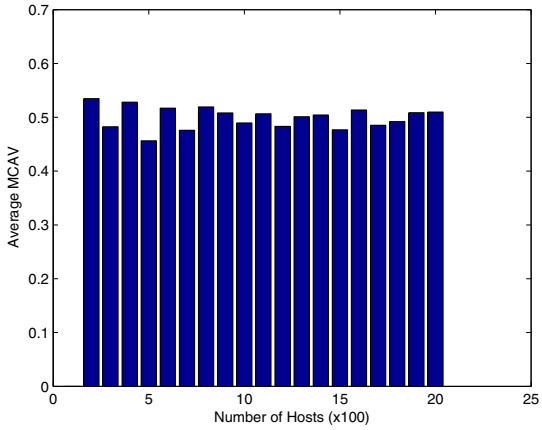

Fig. 6. Average MCAV for an Antigen with High Severity and certainty, but relatively short Attacking Time.

The simulation show a stable result (see Fig. 6); average MCAV is around 0.5, which indicates that this nonself antigen can be harmfully or harmful abnormal depending on the SOC's security profile.

B. Simulation of TC Agents' Coordinations

1) Interactions between Two TC Agents: We consider two computer hosts with TC interactions. TC1 and TC2 are informing each other for confirmed attack from the corresponding antigen.

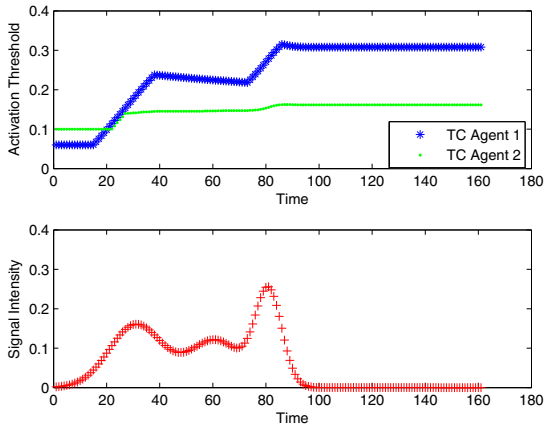

Fig. 7. Activation Thresholds of Two TC agents within the attacking cycle.

According to Fig. 7, even two TC agents will lead to "more" complex threshold behaviors.

2) Interactions among Three TC Agents: We consider three computer hosts with TC agents interactions. TC1, TC2 and TC3 are informing each other for confirmed attack from the corresponding antigen.

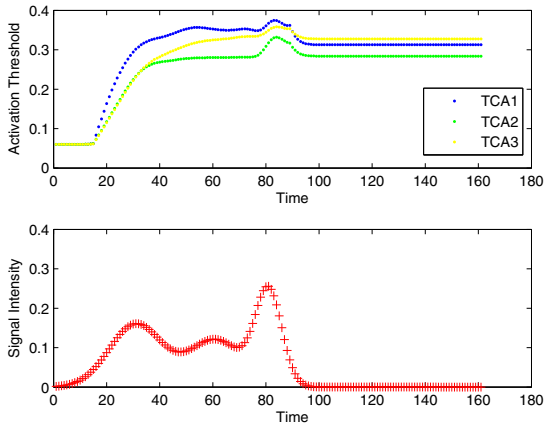

Fig. 8. Activation Thresholds of Three TC agents within the attacking cycle.

V. Conclusion

We propose a multiagent-based intrusion detection system. The intelligence behind such system is based on the danger theory of human immune systems. In particular computations of danger values with dynamic thresholds will reduce the false positive rate of danger signals issued by computer hosts. Three agents, namely, Ag agent, DC agent and TC agents are

coordinated to exchange information of intrusion detections. The evaluations of three factors S, C, and T are pragmatic issues. On the other hand, threshold values have to be defined by SOCs according to security profiles.

***Abstract*—The rapid changes in modern knowledge, due to exponential growth of information sources, are complicating learners' activity. For this reason, novel approaches are necessary to obtain suitable learning solutions able to generate efficient, personalized and flexible learning experiences. From this point of view, the use of different cooperative intelligent agents can be exploited to analyze learner's preferences and generate high quality learning presentations which provide attractive learning solutions. In particular, to achieve this goal this paper exploits an ontological representation of the learning environment and an adaptive memetic algorithm based on a cooperative multi-agent framework. In this framework different agents analyze the e-learning instance and solve it in a parallel way, cooperating among them. This cooperation is performed by jointly exploiting data mining, via fuzzy decision trees, together with a decision making framework exploiting fuzzy methodologies. As will be shown in the experimental results section, this multi-agent strategy is capable of speeding up the convergence to high-quality personalized e-learning experiences.**

***Index Terms*—Adaptive Memetic Algorithms, Multi-Agent Systems, E-learning.**

I. Introduction

Multi-agent systems have been applied to many different fields obtaining outstanding results. By using intelligent agents we are able to solve complex problems, typically difficult to solve individually, but that can be solved by the interaction of different entities. One of this kind of problems are optimization problems, which are those problems in which the best solution has to be found among a set of feasible solutions. In the context of e-learning, the problem of binding subjects and technologies with learning activities and leaner's preferences can be modeled as an optimization problem, in particular the one called *Learning Presentation Problem* (LPP). For this reason, we believe that a multi-agent framework can help us in its resolution.

Regarding e-learning solutions, for many years most of them have been modeled as learning software platforms which constrain learners to learn following a predefined approach without taking into account their preferences. In addition, they tend to ignore several tools provided by Web 2.0, that could improve learners' experience. In order to face these weaknesses, new e-learning solutions should support the whole learning process, and manage new e-learning 2.0 scenarios [1] by incorporating tools like Blogs, Wikis, Podcast, and so on. Moreover, next generation Learning Management Systems (LMSs) should dynamically and intelligently create personalized e-learning experiences adapted in the Web 2.0 environment.

In this scenario, a representation model to describe both educational domains and learners characteristics is required. Ontologies [2] are a good methodology to model the e-learning contexts and enable a convenient way to bind subjects with learning activities in order to fit specific learning objectives, which we defined as LPP. LPP could be viewed as a modified version of the Uncapacited Facility Location Problem (UFLP) [3] and, consequently, solved through a specific deterministic algorithm. However, this approach is not convenient for Web 2.0 environment characterized by distributed repositories and a wide number of learning activities and learning paths made by numerous subjects.

Starting from this consideration, this work proposes an adaptive multi-agent memetic algorithm which decides, depending on the instance being solved, how to combine and configure different optimization agents in order to derive high-quality learning experiences in the e-learning 2.0 scenarios. In detail, a collection of agents analyzes learner preferences and generates high quality learning presentations by executing, in a parallel way, different cooperating optimization strategies. The metaheuristics cooperation is performed by exchanging solutions among optimization methods in precise moments and under certain conditions that are controlled by a set of fuzzy rules. The fuzzy engine uses knowledge obtained by a preliminary machine learning process that analyzes the performances of different optimization methods applied to well-defined problem's instances.

As will be shown in the experimental results section, where a plug-in for an open-source LMS has been designed and tested, the proposed strategy is capable of speeding up the convergence to high-quality personalized e-learning experiences.

II. The Ontological e-Learning Environment

Our e-Learning system is based on 1) a set of models able to represent the main entities involved in the process of teaching/learning and on 2) a set of methodologies, leveraging on such models, for the generation of individualized learning experiences with respect to learning objectives, pre-existing

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

knowledge and learning preferences. The four models adopted by our solution, based on the *Learning Model* [4], are summarized below:

- the *domain model* represents the knowledge domain that is object of teaching by means of concepts, relations among concepts and teaching preferences connected with concepts;
- the *learner model* represents a learner including concepts that he knows as well as his learning preferences;
- the *learning activity model* represents a single learning object or service that may be used as a building block to generate a learning experience;
- the *unit of learning model* represents a whole learning experience personalized for a single learner and composed by a set of target concepts and a sequence of learning activities needed to learn the target concepts.

By exploiting these models, our system generates a personalised *learning path* (sequence of concepts to be taught) for each learner through a *learning path generation algorithm* and introduces placeholders for testing activities.

Once the learning path is available, the system selects a fragment of the learning path and efficiently generates the best *learning presentation* (sequence of learning activities) for each enrolled learner by applying our proposal of Multi-Agent Memetic Algorithm. The learner then undertakes the learning and testing activities of the learning presentation until its end. When the learner ends a presentation fragment, his learner model is updated on the basis of the results of testing activities and a new learning presentation fragment is generated (possibly including recovery activities for concepts that he did not understand).

A. The Domain Model

The domain model describes, in a machine-understandable way, the piece of the educational domain that is relevant for the e-learning experience we want to define, concretize and broadcast. Our approach is design an ontology composed by a set of concepts representing the topics to be taught and a set of relations between concepts representing connections among topics. Such a structure can be formally represented as a $(n+1)$-tuple $G(C, R_1, \ldots, R_n)$ where C is the set of nodes representing domain concepts and each R_i is a set of arcs corresponding to the i^{th} kind of relation. Several kinds of relations are allowed. As an example we can consider a concept graph $G(C, BT, IRB, SO)$ with three relations BT, IRB and SO whose meaning is explained below (where a and b are two concepts of C):

- $BT(a, b)$ means that the concept *a belongs to b*, i.e., b can be understood if every a so that a belongs to b is already learned. (hierarchical relation);
- $IRB(a, b)$ means that the concept *a is required by b*, i.e., a necessary condition to study b is to have understood a (ordering relation);
- $SO(a, b)$ means that the *suggested order* between a and b is that a precedes b, i.e., to favour learning, it is desirable to study a before b (ordering relation).

TABLE I
EXAMPLE OF DIDACTICAL PROPERTIES AND FEASIBLE VALUES.

Properties	**Feasible Values**
didactic method	deductive, inductive, etc.
activity type	text reading, video clip, simulation discussion with a peer, discussion with the teacher, etc.
interactivity level	high, medium, low

A set of *teaching preferences* may be added to the domain model to define feasible teaching strategies that may be applied for each available concept. Such preferences are represented as a function $TP(C \times Props \times PropVals) \rightarrow [0, 10]$ where $Props$ is the set of didactical properties and $PropVals$ is the set of feasible values for such properties. The Table I provides some (non exhaustive) example of didactical property and associated feasible values. It is worth noting that TP is defined only for couples of $Props$ and $PropVals$ elements belonging to the same row in Table I.

B. The Learner Model

The learner is the main actor of the whole learning process and it is represented with a cognitive state and a set of learning preferences. The *cognitive state* represents the knowledge reached by a learner at a given time and it is represented as a function $CS(C) \rightarrow [0, 10]$ where C is the set of concepts of a given domain model. Given a concept c, $CS(c)$ indicates the degree of knowledge (or grade) reached by a given learner for c; the value 0 indicates *no knowledge*, whereas, the value 10 indicates *full knowledge*. If such grade is greater than a given "passing" threshold θ then c is considered as known, otherwise it is considered as unknown.

The *learning preferences* provide an evaluation of learning strategies that may be adopted for a given learner. They are represented as an application $LP(Props \times PropVals) \rightarrow [0, 10]$ where $Props$ and $PropVals$ are the same sets defined in Table I for teaching preferences, whereas, the value 0 and 10, represent, respectively, the lowest and highest level of learning preference. Differently from teaching preferences, learning preferences are not linked to a domain concept but refer to a specific learner. The cognitive state of any learner is initially void (i.e., $CS(c) = 0$ for any c included in a given domain model) and may be initialized on a teaching domain with a pre-test. Learning preferences may be initialized by the teacher or directly by learners through a questionnaire capable of evaluating learners styles and transform them in suitable values for learning preferences. Both parts of the learner model are automatically updated by the system during learning activities.

C. The Learning Activity Model

A *learning activity* must be performed by a learner to acquire one or more domain concepts. Activities may relate to learning objects (e.g., textual lessons, presentations, videoclips, podcasts, simulations, exercises, etc.) or learning services (e.g.,

virtual labs, wikis, folksonomies, forums, etc.). Our system uses learning activities as bricks to generate learning experiences. In order to be used in this way, a learning activity LO is described through the following elements:

- a set of *concepts* C_{LO} related to a given domain model, that are covered by in the learning activity;
- a set of *didactical properties* expressed as an application $DP_{LO}(property) = value$ representing learning strategies applied by the learning activity;
- a set of *cost properties* expressed as an application $CP_{LO}(property) = value$ that must be taken into account in the optimisation process connected with the *learning presentation generation algorithm.*

Didactical properties components have the same meaning with respect to teaching and learning preferences, i.e., property and value may assume values from a closed vocabulary (see table I). Differently from learning and teaching preferences, they are neither linked to a domain concept nor to a specific student but to a learning activity. Cost properties are couples that may be optionally associated to learning activities, whose properties may assume values from the closed vocabulary {price, duration} and whose values are positive real numbers representing, respectively the price of a single learning resource and its average duration in minutes.

D. The Unit of Learning Model

A unit of learning represents a sequence of learning activities needed for a learner in order to understand a set of target concepts in a given domain with respect to a set of defined cost constraints [6]. It is composed by the following elements:

- a set of *target concepts* TC part of a domain model, that have to be mastered by a given learner in order to successfully accomplish the unit of learning;
- a set of *cost constraints* $CC(property) = value$ that must be taken into account in the optimisation process connected with the learning presentation generation algorithm;
- a *learning path* $LPath(c_1, \ldots, c_n)$, i.e., an ordered sequence of concepts that must be taught to a specific learner in order to let him master target concepts;
- a *learning presentation* $LPres(lo_1, \ldots, lo_m)$, i.e., an ordered sequence of learning activities that must be presented to a specific learner in order to let him/her master the target concepts.

While target concepts are defined by the course teacher, the learning path and the learning presentation are created by the generation algorithms described below. Concerning cost constraints, the property may assume values from the closed vocabulary {price, duration}. Feasible values are positive real numbers representing, respectively the maximum total price and the maximum total duration of the unit of learning.

The generation of the learning path is the starting point to completely generate a unit of learning. Starting from a set of *target concepts* TC and from a *domain model*, a feasible learning path must be generated taking into account the concepts graph $G(C, BT, IRB, SO)$ part of the domain model (with $TC \subseteq C$).

The four steps of the learning path generation algorithm are summarized below:

- The *first step* builds the graph $G'(C, BT, IRB', SO')$ by propagating ordering relations downward the hierarchical relation. IRB' and SO' are initially set to IRB and SO respectively and then modified by applying the following rule: for each arc $ab \in IRB' \cup SO'$ substitute it with arcs ac for all $c \in C$ such that there exist a path from c to b on the arcs from BT.
- The *second step* builds the graph $G''(C', R)$ where C' is the subset of C including all concepts that must be taught according to TC, i.e., C' is composed by all nodes of G' from which there is an ordered path in $BT \cup IRB'$ to concepts in TC (including target concepts themselves). R is initially set to $BT \cup IRB' \cup SO'$ but all arcs referring to concepts external to C' are removed.
- The *third step* finds a linear ordering of nodes of G'' by using a depth-first search that visits the graph nodes along a path as deep as possible. The obtained list L will constitute a first approximation of the learning path.
- The fourth step generates the final learning path $LPath$ by deleting from L all non-atomic concepts with respect to the graph G, i.e., $LPath$ will include any concept of L apart concepts b so that $ab \in BT$ for some a. This ensures that only leaf concepts will be part of $LPath$.

Successively it is necessary to generate the learning presentation suitable for a specific learner based on a *learning path* $LPath$ that has to be covered, on a set of teaching preferences TP belonging to a *domain model*, on a cognitive state CS and a set of learning preferences LP both part of the *learner model* associated to the target learner, on a set of optional *cost constraints* CC and on a set of available *learning activities*. The learning presentation is generated by following the steps below:

- The *first step* is to select the sub-list L of $LPath$ that has to be converted in a presentation. L is the sequence of all the concepts of $LPath$ not already known by the learner (i.e., any concept a so that $CS(a) < \theta$). If L is empty then the algorithm ends because the learner already knows all concepts of the learning path.
- The *second step* is to define the best sequence of learning activities P, selected from available learning activities, covering L on the basis of TP, LP and CC. This sequence definition has been given the name of *Learning Presentation Problem (LPP).*

LPP problem represents the core of this work, in fact, its solution defines the learning experiences personalization. Hereafter, LPP problem will be modeled by means of well known UFLP problem and, successively, it will be efficiently solved through an innovative memetic algorithm.

In order to model LPP by means of UFLP problem, first of all a measure of distance $d_{TP}(lo, c)$ between an activity lo and the set of preferences TP has to be defined with respect

to a concept c. In a similar way a measure of distance $d_{LP}(lo)$ based on LP may be defined. A further measure $d(lo, c)$ shall be defined as a weighted sum of the two measures.
Once the measure of distance is defined the problem of selecting the best set of activities P covering concepts of L becomes a UFLP that may be outlined with the bi-partite graph in Fig. 1, where available activities are displayed on the left and concepts to be covered on the right.

There is an arrow between a learning object LO_i (considering the available activities related to learning objects) and a subject C_j only if the metadata instance of LO_i includes a semantic link to the subject C_j

For each couple (LO_i, C_j) linked in the bipartite graph there is an assigned value $d(i, j)$ representing the distance between LO_i and C_j. Short distances define good coverings. Furthermore, to each learning object LO_i, a value $p(i)$ representing the cost of the introduction of the learning object LO_i into the sequence of LOs delivered to the learner is associated . Assume that distances $d(i, j)$ are calculated applying a specific function that evaluates the matching between the metadata values of LO_i covering C_j and the learning preferences of the learner who requests the personalized e-learning experience. Then, P must be built as the smallest set of activities covering all concepts of L with the minimum sum of distances between activities and covered concepts. Now, consider m as the number of learning objects available and n the number of subjects in the Learning Path to be filled. Set y as a binary vector where each element y_i, $(i = 1, \ldots, m)$, assumes value 1 if you decide to use the learning object LO_i, 0 otherwise, and x as binary vector in which each entry x_{ij}, $(i = 1, \ldots, m$ and $j = 1, \ldots, n)$, assumes value 1 if subject C_j is covered by the learning object LO_i, 0 otherwise. Then, the linear programming model which formalizes the whole problem is described as follows:

$$\min \sum_{i=1}^{m} p(i) y_i + \sum_{i=1}^{m} \sum_{j=1}^{n} d(i, j) x_{ij} \tag{1}$$

subject to constraints

$$\begin{array}{lll} \sum_{j=1}^{n} x_{ij} = 1 & i = 1, \ldots, m & \\ x_{ij} \leq y_i & i = 1, \ldots, m & j = 1, \ldots, n \\ x_{ij} \in \{0, 1\} & i = 1, \ldots, m & j = 1, \ldots, n \\ y_i \in \{0, 1\} & i = 1, \ldots, m & \end{array} \tag{2}$$

The optimal solution of the LPP means the identification of the optimal set of learning objects that better match (minimal distance) the learner preferences.

III. A Novel Memetic Approach to Solve Learning Presentation Problem

As any other optimization problem, LPP can be solved by means of a deterministic algorithm. This approach is valid when we consider a repository with a limited number of learning activities and subjects. However in e-Learning 2.0 scenario, the number of learning activities and subjects tends to be very high, and thus we need to look for more flexible

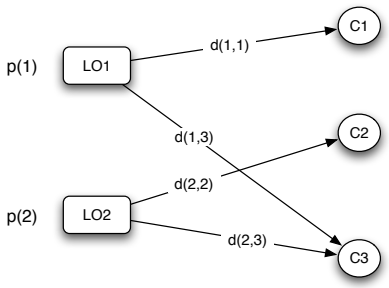

Fig. 1. Formalization of LPP.

approaches. Metaheuristics have been used extensively in the literature obtaining satisfactory results for all kind of problems. Among metaheuristics, Memetic Algorithms (MAs) [8] have become one of the most used approaches due to their ability to combine a high exploration of the search space and a high exploitation of the most promising regions.

Starting from this consideration, our proposal is to design an innovative memetic algorithm capable of efficiently generating learning presentations. In detail, this work introduces a novel parallel cooperative adaptive memetic algorithm aimed to personalize e-learning environment by combining and configuring cooperative evolutionary and local search metaheuristics in order to improve overall performance. The cooperation among the different optimization strategies is performed by intelligently exchanging solutions in precise moments and under certain conditions. The exchange control is supervised by a set of fuzzy rules, which exploits knowledge modeled by a collection of fuzzy decision trees and obtained using a preliminary learning process. With this knowledge the fuzzy engine can predict the behavior of each metaheuristic and adapt it to the presentation being personalized.

Hereafter, this section precisely describes the proposed novel multi-agent memetic algorithm capable of efficiently solving the LPP problem and, consequently, supporting e-learning environments to define high-quality personalized learning experiences.

A. A Novel Multi-agent Based Memetic Algorithm

In this section the proposed Multi-Agent Memetic Algorithm (MAMA) is introduced. MAMA is computed in two steps (see fig. 2), dealing respectively with evolutionary and local methodologies. In the first step, a collection of different evolutionary optimization strategies (Genetic Algorithm, Particle Swarm Optimization, ...) are executed in a *parallel* way in order to locate the best region of problem's search space. Successively a set of local search strategies (Tabu Search, Simulated Annealing, ...) simultaneously exploits this region in order to find a high quality solution. In each step, the optimization strategies, *intelligently choose* their configuration parameters and *cooperate* by exchanging their solutions in *adaptive* way. The adaptability is achieved by means of a fuzzy rule base able to evaluate information extracted by a preliminary machine learning approach [9] that ranks computational

performances related to evolutionary and local metaheuristics applied to a given optimization problem.

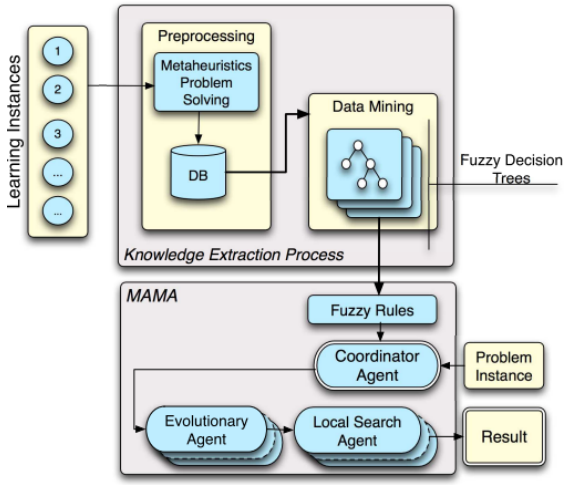

Fig. 2. Adaptive Memetic Architecture.

The parallel and distributed nature of our approach is fully suitable to be modeled using a multi-agent system [7] where a set of so called *optimization agents* computes the cooperating metaheuristics under the supervision of a *coordinator agent* whose intelligence is provided by the aforementioned fuzzy rules and machine learning approach. The coordinator agent is responsible of initiating optimization process by parallel activating optimization agents and, in each phase, it coordinates the cooperation among optimization agents by choosing their configuration parameters and exchanging their solutions in an adaptive way.

The adaptability task of coordinator agent is performed by considering knowledge coming from machine learning (see section III-B) coded by means of a collection of fuzzy decision trees. In particular, trees' analysis supports coordinator agent to 1) choose the best metaheuristic parameters and 2) rank the metaheuristics suitability to solve the instance using numerical weights in the range $[0, 1]$. Through weights analysis, coordinator may realize that a metaheuristic is poorly performing and, consequently, it may update its solutions by adding a set of better solutions computed by other more suitable metaheuristics. This process allows poor metaheuristics to restart their optimization task in a more interesting point of the search space.

The cooperation is performed in the following way, optimization agents evaluate, during a certain period, the objective function then they stop their computation in order to allow the coordinator agent to collect their information and make decisions. After that, each optimization agent continues exploring the search space but executing coordinator agent's orders.

To perform the communication between coordinator and optimization agents, a blackboard architecture [10] will be used. Blackboards are data structures usually used as general communication mechanisms. In our proposal each agent has an assigned space on the blackboard where it periodically *writes* information about the solution it has found. The coordinator *reads* this information and directs the search of each agent.

1) Modeling intelligence of the coordinator agent: A crucial question of proposed memetic architecture is how to model the coordinator agent's intelligence in order to allow it to evaluate metaheuristics performances and control the cooperation among related optimization agents. This goal is achieved by using a set of fuzzy rules able to exploit the knowledge obtained by machine learning. More precisely, the coordinator agent uses fuzzy inference to:

- choose the best metaheuristics' parameters values;
- individuate when poor evolutionary metaheuristics have to receive a collection of individuals from other strategies that are showing a better behavior.
- individuate when local search methods have to reinitiate their search using the solution of another one which is showing a better behavior.

Coordinator agent implements first behavior by using a collection of fuzzy decision trees, as many as metaheuristics, obtained through machine learning. These trees analyze the instance in order to infer the most suitable parameters values for each metaheuristic. Moreover, the coordinator agent realizes the remaining two behaviors by considering two additional trees coming from machine learning. In detail, these trees analyze the instance and respectively rank evolutionary metaheuristics and local search metaheuristics, by returning a weights collection Ω where each $\omega_i \in \Omega$ takes a value in the range $[0, 1]$, the sum of the weights of evolutionary metaheuristics is 1, as the sum of the weights of local search metaheuristics. In short, each weight ω_i is associated with a metaheuristic and represents its suitability to solve the instance under consideration , i.e., the higher the weight of a metaheuristic the more suited it is.

In each phase, the coordinator agent uses a collection of fuzzy rules (one for each metaheuristic) exploiting Ω in order to derive the collection of poor strategies. For the sake of simplicity the rule shown below is related to evolutionary strategies (however rules acting in local phase are equivalent):

> IF [$(\omega_1 \cdot d_1$ OR ... OR $\omega_{|E|} \cdot d_{|E|})$ IS *enough*] THEN change the current solution of m_h.

where:

- m_h is the metaheuristic being evaluated by the rule;
- $d_i = (\xi(m_i) - \xi(m_h))/\max(\xi(m_i), \xi(m_h))$, where ξ is a measure of performance shown by metaheuristics. It is defined by the user;
- $\omega_i \in [0, 1]$ is the weight of m_i;
- $enough$ is a fuzzy set with trapezoidal membership function defined by a quadruplet (a, b, c, d) and whose universe of discourse is the range $[0, 1]$.

The main goal of each rule is to change the position in the search space of a metaheuristic which is showing a bad performance for a position near the solution of another metaheuristic with a better behavior. It should be noted that this rule tries to solve the problem that appears in parallel strategies where the exchange of solutions is unrestricted [11]

and which tend to prematurely converge to local optimums characterized by a low quality.

To perform the firing of the fuzzy rules, $\alpha - cuts$ are used. In other words, only those rules whose activation value exceeds the defined $\alpha - cut$, are fired. In the event that more than one rule is activated then the coordinator applies all of them. In this way, the coordinator agent is capable of simultaneously adapt the behavior of several poor metaheuristics.

The metaheuristics' solution exchange is performed by taking into account two different situations: 1) a single antecedent clause of rule is fired or 2) many clauses are fired during inference process. In detail, let S be the collection of strategies related to fired clauses and let m_h be the poor metaheuristic that have to receive better solutions. If a single clause is fired then $|S| = 1$ otherwise $|S| > 1$.

Then, during the first phase (evolutionary phase), the poor metaheuristics' solutions changing is performed as follows:

1) $|S| = 1$. A proportion of the worst individuals of m_h is substituted by a set of solutions consisting of the best members of the population of strategy $m_k \in S$. The proportion is equals to ω_k.
2) $|S| > 1$. A proportion of the worst individuals of m_h is replaced by a set of solutions where each meta-heuristic chooses its solutions as said before. The proportion is equals to $\sum_{i=1}^{|S|} \omega_i$.

Differently from first phase, during the local optimization phase the changing is performed as follows:

- A solution "near" to the best solution obtained among the meta-heuristics $m_k \in S$ is sent to m_h. Where "near" means that the best solution is changed by applying, $\lceil \frac{1}{(2 \cdot \omega_k)} \rceil$ times, a mutation operator that depends on the problem. This operation is performed in order to introduce some diversification, since the exchange of identical solutions can cause that all metaheuristics perform the search in the same space.

B. MAMA Configuration through Machine Learning

As previously mentioned the adaptability of the proposed MA is provided by the knowledge obtained through an extraction process introduced in this section. The aim of the knowledge extraction process is to evaluate the performances of metaheuristics composing the MA when applied to instances of the problem under consideration. This process returns a set of trees containing: two trees respectively modeling the suitability of the evolutionary and local search strategies by providing the aforementioned weights Ω and, on the other hand, one tree for each metaheuristic which provides the most suitable parameters choice for each metaheuristic.

The Knowledge extraction process is subdivided in two subphases, as can be seen in figure 2, Preprocessing and Data Mining.

1) Preprocessing: In preprocessing phase, metaheuristics that compose the system are applied to a set of training instances in order to build a collection of databases, named *refined databases*, that will be exploited by data mining to compute the trees that guide the coordinator. The obtaining of these databases is carried out in two steps. First, information about the performance of metaheuristics is stored in a set of so called *raw databases*, where each raw database is associated to a different metaheuristic. Successively, data contained in raw databases are processed in order to compute the final refined databases, which contain additional information useful to extract significant knowledge during data mining.

In particular, the obtaining of raw databases is carried out in the following way. For each metaheuristic and each parameter configuring this metaheuristic, a set of parameter values is chosen, after that each metaheuristic is executed k times with each possible combination of parameter values, being k an *iterative factor*, i.e., a predefined value used to obtain more accurate performance estimations. For each one of these executions a row is inserted into the raw database related to the metaheuristic being evaluated. In details, a raw database row contains:

- a description of the specific instance of the problem;
- the values of the parameters used in the execution of each metaheuristic;
- the final solution obtained.

Next step is to analyze raw databases in order to compute the refined databases. Refined databases are smaller than raw databases and contain additional information useful to extract significant knowledge during data mining. In detail, for each metaheuristic a refined database is computed which contains information about its best parameters combinations, i.e., which parameters values obtained a better performance. Besides, two more refined databases are computed which respectively contain information about the weights Ω associated to evolutionary and local search strategies.

In order to build databases concerning parameters for each metaheuristic its raw database is processed as follows:

1) for each instance and for each parameters combination calculate the average fitness value of its k executions.
2) for each instance select the parameter combination computing the best average fitness value;
3) the refined database is updated with a new entry containing the description of instance and the best parameter combination.

The remaining two databases are directly related to evolutionary strategies and local search methods. In detail, the refined database related to evolutionary methods is processed as follows:

1) for each metaheuristic, for each instance and for each parameters combination calculate the average fitness value of its k executions.
2) for each metaheuristic and each instance, select the best average fitness value and compute the *metaheuristic suitability weight* ω_i as:

$$\omega_i = \frac{fit^i_{best}}{\sum_{l=1}^{\#evolutionary_strategies} fit^l_{best}}$$

3) for each metaheuristic and each instance the refined database is updated with a new entry containing the de-

scription of the instance and the metaheuristic suitability weight ω_i.

Database associated to local search methods is analogously built by replacing evolutionary strategies with local search methods. Refined databases represent the output result of Preprocessing phase and they will be used by a data mining technique to complete the Knowledge Extraction Process in computational efficient way.

2) Data Mining: Once gathered performance information and collected it through refined databases, the Data Mining phase extracts the collection of knowledge models through data mining. Our data mining approach exploits a fuzzy decision tree (FDT) technique [12] to extract knowledge from refined databases and build the aforementioned collection of trees. Two main reasons have guided the choice of FDTs. First their interpretability, decision trees stand out on account of their simplicity and readability, which is an important issue in data mining, and enable a full understanding of the knowledge that guides the coordinator. Second, their fuzziness, i.e., the possibility of dealing with fuzzy theory, which can improve inference performance by means of approximate reasoning and provide an easy way to obtain the weights Ω, one of the most important parts of coordinator's knowledge.

Once this phase is finished the collection of fuzzy decision trees that models coordinators's knowledge, is obtained, and it is ready to control the execution of the optimization agents.

IV. Experimental Results

In this section we want to asses the validity of the proposed approach, MAMA. The main purpose of MAMA is to help improving the e-learning process. For this reason we plan to include it as a plug-in of a learning management system. In particular, we plan to include it in Sakai project[1]. Sakai is an open source learning management which enables powerful teaching, learning and research collaboration within a feature-rich, enterprise platform. However, Sakai does not provide the possibility of automatically personalize e-learning experiences in the previously explained way. We consider this an essential feature for modern e-learning solutions, and thus believe that the development of a plug-in that adds this feature can improve learners' experience. In the design of the planned plug-in, a crucial issue has been the choice of the metaheuristics that will made up the system. For the problem being considered we have chosen four strategies, two evolutionary metaheuristics, a Genetic Algorithm (GA) and a Particle Swarm Optimization (PSO), and two local search metaheuristics, a Tabu Search (TS) and a Simulated Annealing (SA). Other metaheuristics could have been chosen or even added, but as a first step we have chosen these four.

Hereafter, the results of some preliminary performance tests and a study with real learners will indicate the positive impact of MAMA in the process of e-learning.

A. Computational experiments

In this subsection, we perform some tests in order to assess the validity of MAMA, comparing its results with those obtained by the different non-adaptive MAs that can be obtained from the combination of the single metaheuristics that compose MAMA in a sequential way, namely:

- Genetic Algorithm + Tabu Search (GA+TS).
- Genetic Algorithm + Simulated Annealing (GA+SA).
- Particle Swarm Optimization + Tabu Search (PSO+TS).
- Particle Swarm Optimization + Simulated Annealing (PSO+SA).

The parameters used by each metaheuristic are shown in Table II.

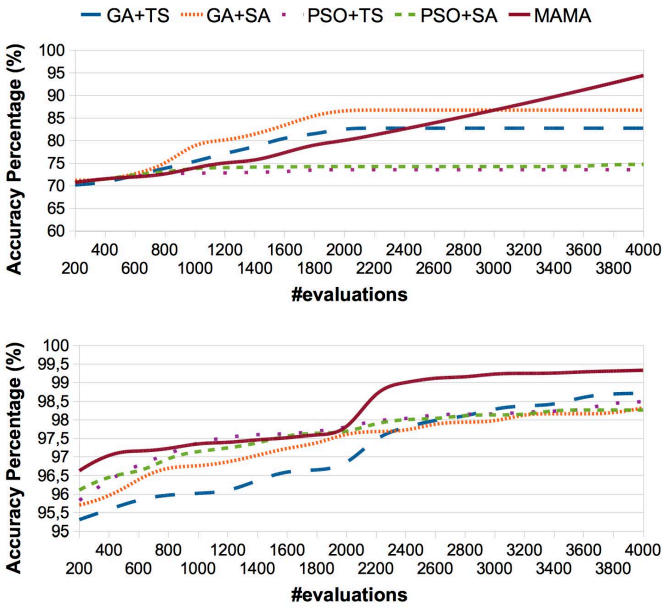

Fig. 3. Evolutions of the different strategies.

1) Performance tests: As a first approach it would be interesting to perform some preliminary tests in order to asses the validity of the proposed strategy. In order to perform these tests we have created an instance generator able to construct artificial instances of the learning presentation problem. We

have identified some instance's features that may influence the behavior and performance of different solving strategies:

- Number of learners.
- Ratio between learning objects and learners.
- Connection percentage between learning objects and learners.

We have carried out two tests with two different instances generated using the aforementioned generator. The purpose of these tests was to graphically interpret the behavior of the different strategies during their search of the optimum. The results are shown in Fig. 3, this figure illustrates the evolution of the 5 strategies. The graphics plot the fitness value obtained by each strategy at each moment of the execution, showing the average of 10 executions of 4000 evaluations. From these graphics we can extract interesting information about the behavior of MAMA. In particular, it can be observed that although MAMA's convergence is not the fastest, it obtains in both instances the best performance. These are promising results which seem to indicate that MAMA solves e-learning LPP problem in a more efficient way than other static memetic approaches and, as will be shown afterwards, it generates very suitable personalized learning experiences.

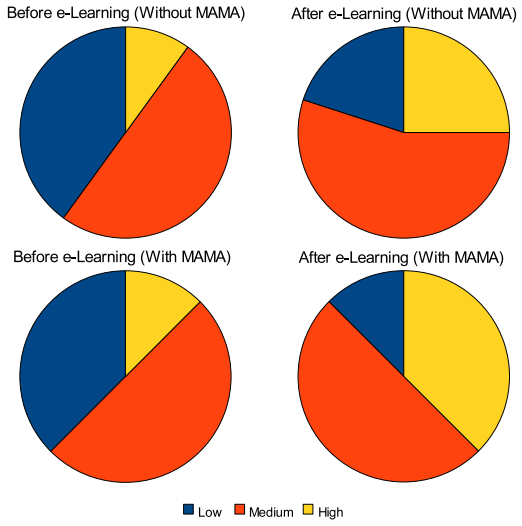

Fig. 4. Experimentation results on a group of 38 learners with and without the proposed memetic Sakai plug-in prototype.

2) Learning Comparative Studies: Once we have demonstrated the effectiveness of MAMA with artificial instances, we perform a real world test, involving real learners that want to train on enterprise management. The control and experimental groups were made up of 20 and 18 learners respectively. Data corresponding to the control group comes from historical data from a previous experiment, and shows the results of learning using Sakai without the help of MAMA. On the other hand, data corresponding to experimental group was obtained from the results achieved by a new group of learners, which were able to use the capabilities of MAMA. All the voluntary learners were tested before and after a training phase on the same topics. In all the tests the learners' skills in the chosen domain were quantified using three ability ranges: low-level (0-3 scores), medium-level (4-7 scores) and high-level (8-10 scores). Figure 4 presents a summary of the results. As can be observed, both e-Learning approaches provide the necessary tools to improve learners' knowledge, in fact the quantifications of the knowledge are statistically better with a significance of the 99.9% after using e-learning. Moreover those learners that have used MAMA have obtained better results than those which not, with an statistical significance of the 95%. These results are very promising and support the creation of a plug-in for Sakai able to include MAMA's capabilities.

V. Conclusions

Recent advances in Web 2.0 have impulsed the development of the so called e-learning 2.0. In this context, Learning Management Systems should promote new e-learning trends by means of suitable models and processes that dynamically and intelligently create personalized e-learning experiences adapted to learner expectations and objectives. Our work proposed an innovative memetic algorithm capable of efficiently generating personalized learning presentations. In detail, we have proposed a parallel cooperative adaptive memetic algorithm aimed to personalize e-learning environment by combining and configuring cooperative evolutionary and local search metaheuristics in order to improve overall performance. The cooperation is supervised by a set of fuzzy rules, which exploits knowledge modeled by a collection of fuzzy decision trees and obtained using a preliminary learning process. As shown by experimental results, our proposal enhances significantly the learning framework in terms of flexibility and efficiency.

Abstract— **In the area of ambient intelligence there is a need to address user needs according with context features. Recently, the synergy between context aware computing and collaborative filtering is leading to enhance recommender systems with capabilities always nearer to user needs. Specifically, in the domain of tourism it is useful to proactively suggest right sets of attractive locations, events and so on. This work defines a context aware recommender system aimed at suggesting pertinent points of interest (POIs) to tourists. In particular, the approach is strongly based on the synergy between soft computing and data mining techniques. The general framework integrates user profiles, history of social networking and POIs data. Then by defining collaborative filtering approach on the history meaningful POIs are extracted. Indeed, soft computing techniques are mainly applied in order to support activity of unsupervised users and POIs classification. On the other hand, data mining techniques are exploited in order to extract rules able to associate user profile and context features with an eligible set of recommendable POIs. Experimental results show performance in terms of recommendations accuracy.**

Keywords-component; context-awareness; fuzzy data analysis; data mining; recommender system; points of interest

I. INTRODUCTION

The tourism sector is one of the biggest in the global market employing 200 million people and serving 700 million tourists worldwide. Furthermore, this trend is intended to grow in the next years. Additionally, Information Technology with its constant progress has decisively affected the way that tourism services are performed and provided. In effect, tourists thanks to advances in Information and Communication Technologies (ICTs) are enabled to access tourist information as well as to reservations and plans in a more reliable, accurate, inexpensive and efficient way. As a result, services related to tourism are increasingly influenced by the Internet and related technologies, so much so that it is possible to find most of them on line without the necessity of relying on travel agency. On the other hand, ICTs and the Internet have increased the number of choices so dramatically that is very difficult for the users to retrieve what they are looking for. The appropriate discovery of tourism services is one of the main drawbacks when people travel [1]. According to [2] research, the reasons of consumers not purchasing travel products online are the lack of personal service, security issues, lack of experience, and time consuming. Furthermore, different users have different preferences and needs. So a remedy for these problems is to develop systems with an ability to adapt their behavior to the profile, context and other features of individual users and groups of them. An interesting solution for reducing Internet researches complexity and overcoming the aforementioned difficulties is provided by so called recommender systems. Recommender systems have already been applied to several application domains such as finding books, movies, tv-programs, news, music, web-pages, etc. One of the main characteristics of a recommender system is that it can personalize its interaction to each individual user according with context. In that case, personalization involves the design of enabling systems to capture or infer the needs of each person and then to satisfy those needs in a known context [3]. Context-awareness computing and recommender systems can enhance and complement each other; they both help users in finding relevant and interesting objects based on their interests and current context.

In the specific of this paper, our intention is to propose a hybrid context-aware recommender system aimed at adaptively and proactively suggesting points of interest (POIs) to tourists according to their profile, but also to their context. In particular, the work defines an integrated environment applying content based and collaborative filtering on historical data through soft computing and data mining techniques in order to predict and suggest POIs to users. In other words, the main goal of the proposed work is related to define context-aware recommender system whose quality of feedback relies on the acquisition of user context and profile by means of a robust theoretical approach. So, the overall framework is composed of two main workflows: knowledge discovery and recommendation. In particular, Knowledge Discovery Process concerns the fuzzy data analysis of users and POIs. Indeed, fuzzy clustering and classifiers enable us to integrate cluster of users and POIs with historical data. Then association rule mining activity points out a correspondence between user, contexts and cluster of POIs. On the other hand, Recommendation Process foresees activities of user classification and rule matching in order to provide some ranked recommendation about pertinent POIs.

The paper is organized as follows: Section II presents some related works available in literature; Section III proposes a theoretical background for supporting workflows description; Section IV and Section V introduce workflows of the framework by focusing on the Knowledge Discovery Process and Recommendation Process, respectively. Then, Section VI describes the system performance in terms of accuracy. Finally, conclusions and future works close the paper.

II. RELATEDWORKS

The aim of this section is to depict the research trend with reference to context aware recommender systems in ambient intelligence for tourist guidance and to point out the benefits of the proposed approach. Among research works regarding personalized and/or location-based recommender systems based on web service, with specific reference to tourist domain, Kakaletris et al. [4] address the design and implementation issues for delivering location-based tourism-related content services. By illustrating an example of generic tourist guide, Scherp and Boll [5] emphasize on supporting the dynamic generation of personalized multimedia content in respect of the tourist's interests and preferences, current location and environment, and mobile device used. Aiming at effectively coordinating and integrating disparate information and service resources anytime and anywhere, Chiu and Leung [6] propose a ubiquitous tourist assistance system that is built upon multi-agent and semantic web technologies for providing personalized assistance and automation to the tourists with different preferences and often changing requirements during their trips. Five agent clusters specified in the system architecture include tourist assistant, ontology maintenance and search, requirement/preference management, package planning, and local tour planning. Ricci and Nguyen [7] present a critique-based mobile recommender system that lets users expressing session-specific preferences in addition to the long-term collected preferences. The objective is to provide on-tour system support to mobile travelers for selecting products or services based on the integration of both types of preferences. The COMPASS system [8] allows easy creation of context-aware personalized applications and the services that are part of such a platform, including a service registry, a context manager and a recommendation engine. Console et al. [9] created a prototype system called MastroCARonte, which provides personalized services that adapt to the user and his context onboard cars. This research focuses on the effects of having such adaptive systems onboard cars.

Among research works regarding more specifically context aware and adaptive recommender systems for tourist guidance, the Intrigue system [10] is an interactive agenda offered by a tourist information server that assists the user in creating a personalized tour along tourist attractions. This research focuses on planning and scheduling a personalized tour taking into account the location of each tourist attraction and the interests of the user. A last example of a tourist guide project is the GUIDE project of the University of Lancaster [11]. This project develops a context sensitive tourist guide for the visitors to the city of Lancaster. Specifically, in this project Users have a portable PC that communicates with a Wireless LAN to retrieve information. The used context information is knowledge of the user and knowledge of the environment (including the physical location of the user). Based on the location and user preferences, visitors can obtain information in two ways. All the required information is broadcasted by cell base-stations to portables either as part of a regular schedule (information relevant for the region the station covers) or in response to user requests. The system determines the location of the user by the cell coverage, or the user can specify in which location he/she is.

The aforementioned works provide the user with tourist recommendations but do not manage uncertainty among user interests. Furthermore, most of them are only content based, omitting collaborative information that is a crucial aspect for user recommendations personalization. In this sense, our approach presents an hybrid system which main aim is related to provide an integrated environment for tourist guidance that combines collaborative and content based filtering. Indeed, the main idea of this work is related to enhanced context awareness by means of data analysis, computational intelligence and rule mining techniques in order to obtain a recommender system able to suggest users in the tourist domain with pertinent POIs. Strictly related approach is described in [12] where a personalization method for tourist Point of Interest (POI) Recommendation is defined by considering both user preferences and collaborative aspects. Indeed, [12] exploits a memory based algorithm to carry out suggestions. In particular, our system define a model based approach that trains itself by performing activities of fuzzy context data analysis in order to support both POIs and user's context identification by means of fuzzy classifiers.

III. THEORETICAL BACKGROUND

The overall system takes into account users data, available POIs and historical data in order to provide proper recommendations (i.e., POIs) according to his/her preferences and context. In particular, algorithms of clustering and classification allow to tackle the huge amount of incoming data (Users and POIs). On the other hand, association rules mining algorithm on historical data allows to extract correspondences with pertinent tourist POI categories.

Since, this work relies on a mathematical model that exploits soft computing and data mining techniques, this section provides some theoretical basis in order to support understanding of the overall framework workflows.

A. Fuzzy clustering

Once data, about users and POIs, are collected and arranged adequately, they are processed by Fuzzy C-Means (briefly FCM) algorithm [15][16]. FCM is an unsupervised clustering algorithm, which considers a prior fixed number of clusters. In order to give more accurate partitions of data, many researchers have studied the cluster validity criteria [17]. In our past studies and experimentations we have achieved good results by the application of Xie and Beni's validity measure [18]; so we have also selected it for the approach proposed in this work. Advanced approaches to (fuzzy) clustering methods could be exploited, according to the nature of the data space and the inherent relationships. As said, we exploit the well-know FCM algorithm, particularly useful for flexible data organizationally. It takes as input a data matrix and it tries to get an "optimal" partitioning of the feature space (composed by the data matrix). FCM aims at maximizing the homogeneity, grouping into the same cluster the patterns which are closer. Herein, each pattern is a row of matrix. FCM recognizes spherical "clouds of points" in a multi dimensional data space (i.e. data matrix) and each cluster is represented by its center point (prototype or centroid). The function minimizes the weighted sum of the

distances between data points *x* and the centroid *v*, according to this formula:

$$V(U)=\sum_{l=1}^{c}\left(\sum_{i=1}^{n}w_{i,l}\sum_{j=1}^{p}(\underline{x}_{i,j}-\underline{v}_{l,j})^2+\gamma\sum_{i=1}^{n}w_{i,l}\sum_{j=p+1}^{m}\partial(\underline{x}_{i,j},\underline{v}_{l,j})\right) \quad (1)$$

where $c \geq 2$ is the number of clusters, $w_{i,l} \in [0,1]$ is the membership degree of $x_{i,j}$ in the l-th cluster and *m* is the features number. In particular, since our feature set is mixed, because of numeric and nominal features, the *m* features are partitioned in two set, namely a numeric feature set composed by the features from *1* to *p* and a nominal feature set composed by the features from *p+1* to *m*. As a result, the first term in (1) is the squared Euclidean distance measure on the numeric attributes and the second term is a semantic distance on the nominal attributes, where ∂ is equal to a linear combination between a semantic distance taxonomy based [13] and Google similarity distance [14]; finally, γ is used to weight features. After the FCM execution, data partitions are returned, in a prior fixed number *c* of clusters. Anyway, with the application of validity measures it is possible to execute clustering without a prior number of clusters specification.

Details about how Fuzzy Clustering has been applied in this framework are given in Section IV and V, where the workflows of the whole proposed system are detailed.

B. Fuzzy Classifier Design

In computational intelligence literature, fuzzy rules have been often exploited in different approaches for decoding the knowledge in a way closer to the human understanding. In neural network [22] approach, if-then fuzzy rules enable the emulation of the decisions or reasoning of a human expert, whereas fuzzy number and compositional rules of inference have been employed for fuzzy decision making in medical diagnosis [23]. The fuzzy if-then rules provide an interpretation of the clusters, closer to the human understanding and easier to evaluate, with respect to the values range of each feature. Outputs of previous phase are prototypes and a partitioning matrix of the data patterns. This matrix contains the memberships of the elements of the given data set in each of the c clusters. Generally, the linear interpolation of memberships is computed; in order to easily assign linguistic label, the membership function is computed by linear interpolation of the projected membership to each axis (according to the n-dimension space), for each cluster. More specifically, exploiting the cylindrical extension technique [15] (a projection-based method of n-dimensional argument vector), the generic i-th fuzzy cluster can be described by a fuzzy rule, where each features is described through a fuzzy set. Each fuzzy cluster K_i with i = 1, . . . , c can be represented through n functions A_{i1} , A_{i2} , . . . , A_{in}, obtained by the projected and interpolated memberships. The generated rules are subject to a proper validation by experts of the specific domain and then exploited for suitable classifications. In our work, the fuzzy rules are exploited to classify new tourist POIs and users. Just to provide an example, a fuzzy rule, supposed to be in the form of Takagi-Sugeno model [19] is described as follows:

R_i : **If** x_1 is A_{i1} AND x_2 is A_{i2} AND … AND x_n is A_{in} **then** $y_i = a_{i1}\, x_1 + a_{i2}\, x_2 + \ldots + a_{in}\, x_n + b_i$,

with weight $[w_i]$ i = 1, … , c

where R_i is the i-th rule, x_1, x_2, . . ., x_n are the input variables, A_{i1},A_{i2}, . . .,A_{in} are the fuzzy sets assigned to corresponding input variables, variable y_i represents the value of the i-th rule output, and $a_i = [a_{i1}, a_{i2}, \ldots, a_{in}]$ and b_i are parameters of the consequent function. As said before, the antecedent fuzzy sets are usually achieved by projecting the membership degrees in the fuzzy partitions matrix U onto the axes of individual antecedent variable x_j to obtain a point-wise defined antecedent fuzzy set A_{ij}. Then we approximate it by a normal bell-shaped membership function [20]; indeed the uniform structure of bell-shaped function is suitable for identification, analysis and optimization. Hence, each fuzzy set A_{ij} is calculated from the sampled input data $x_j = [x_{1j}, \ldots, x_{nj}]^T$ and the fuzzy partition matrix $U = [u_{ij}]$ as follows:

$$A_{ij}(z)=\exp\left\{-\frac{1}{2}\left(\frac{z-\alpha_{iq}}{\beta_{iq}}\right)^2\right\} \quad (2)$$

where

$$\alpha_{iq}=\frac{\sum_{j=1}^{n}u_{ij}x_{qj}}{\sum_{j=1}^{n}u_{ij}} \quad and \quad \beta_{ij}=\sqrt{\frac{\sum_{j=1}^{n}u_{ij}(x_{qj}-\alpha_{iq})^2}{\sum_{j=1}^{n}u_{ij}}} \quad (3)$$

represent the mean and standard deviation of the bell-shaped membership function, respectively.

On the other hand, the computation of parameters $a_i = [a_{i1}, a_{i2}, \ldots, a_{in}]^T$ and b_i in the consequent part requires a deepened study, in order to evaluate the firing strength w_i of the i-th rule and the value of y_i [21].

Goal is to evaluate the final output of the TS fuzzy model y_i for an arbitrary x_j input sample, which is calculated using the following formula [21]:

$$\hat{y}_k=\sum_{i=1}^{c}[\underline{w}_i(\underline{x}_k)(\underline{x}_k\,\underline{a}_i+b_i)] \quad (4)$$

with k = 1, 2, 3, . . .,n and where $\underline{w}_i(\underline{x}_k)$ represent the firing strength of i-th rule for the k-th pattern. Thus, in order to compute the parameters of consequent part of a rule, a regression model of the compact form $\hat{Y} = X'\,[a_i^T, b_i] + \varepsilon$ is evaluated: herein ε is the approximation error, X' assumes the form: $X' = [w_1, x_k^T, 1, w_2\, x_k^T\, 1, \ldots, w_c\, x_k^T, 1]$. Vectors $[a_i^T, b_i]$ are determined using the least-squares method [21].

C. Rule Mining

The proposed approach foresees activities of rule mining on historical data, in order to associate user contexts and tourist POI categories. The problem of mining association rules over was introduced in [24]. An example of an association rule in our case might be that 90% of users arriving in a tourist town in the morning, being scientific researchers and walking, select POI about the nearer science museum. The following is a

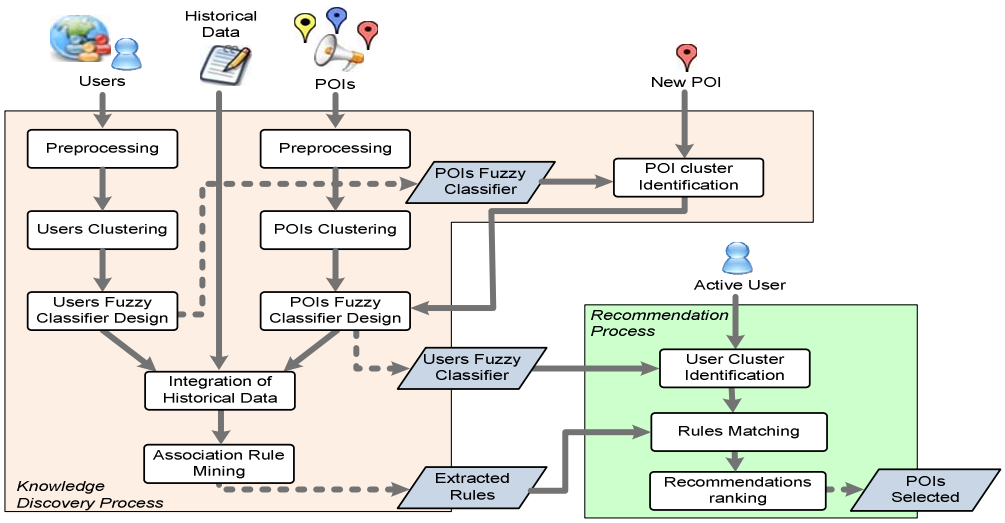

Figure 1. Workflows of the overall framework: Knowledge Discovery Process, Recommendation Process.

formal statement of the problem [24]: given a set of items $I = \{I_1, I_2, \ldots, I_m\}$ and a database of transactions $D = \{t_1, t_2, \ldots, t_n\}$

where $t_i = \{I_{i1}, I_{i2}, \ldots, I_{ik}\}$ and $I_{ij} \in I$, an association rule is an implication of the form $X \Rightarrow Y$ where $X, Y \subset I$ are sets of items called itemsets and $X \cap Y = \emptyset$. X is called the antecedent and Y is called the consequent. We are generally not interested in all implications but only those that are important.

Here, two features called support and confidence are usually used to measure the importance of association rules. The support for an association rule $X \Rightarrow Y$ is the percentage of transactions in the database that contain $X \cup Y$. The confidence for an association rule $X \Rightarrow Y$ is the ratio of the number of transactions that contain $X \cup Y$ to the number of transactions that contain X. Rules that satisfy both the minimum support (MinSup) and confidence (MinConf) thresholds are called strong rules. An algorithm for finding all association rules, henceforth referred to as the AIS algorithm, was presented in [24]. Another algorithm for this task, called the SETM algorithm, has been proposed in [25].

In this work, we use an algorithm, Apriori [26], that differ fundamentally from these algorithms and exhibits better performance. Furthermore, in our future works we would like to experiment a Formal Concept Analysis-based Association Rule Mining Algorithm as proposed in [27].

IV. KNOWLEDGE DISCOVERY PROCESS

As highlighted in Fig.1, the overall framework consists of two main workflows: *Knowledge Discovery Process* and *Recommendation Process*. Following subsections detail the first one.

A. Users and POIs Preprocessing

Preprocessing tasks on Users and POIs data allow to start the process of Knowledge Discovery. In particular, gathering and normalization activities take place in order to prepare data for the next phase, that is, *Users and POIs clustering*. Specifically, preprocessing carries out the user and POIs data sets, as shown in Table I (A) and (B). In the example the user data set includes three features (i.e., age, skill and interest), whereas POIs data set is composed of five features (i.e., type, lat, long, when, period). Furthermore, as highlighted in the Table I features may be numerical or nominal. For instance, in the user data set features space, *age* is a numerical attribute whereas *skill* and *interest* are rather nominal.

B. Users and POIs clustering

Analogously with the previous step, clustering execution takes place on user and POIs data sets. We stress that users and POIs are considered in two off-line separate processes and the subsequent extraction of classification rules enable us to properly add new users and POIs to clusters. So, the execution of these two distinct processes should not be time consuming, because there is no need to execute clustering again whenever a new user or POI must be considered. Specifically, the framework exploits FCM algorithm in order to arrange data according to their similarities. In particular, in order to use mixed features, namely, numeric and nominal, a light variant of FCM is performed.

TABLE I. (A) USER DATA SET AND (B) POIS DATA SETS

…					

TABLE II. (A) USER PROFILE PARTITION MATRIX AND (B) POI PARTITION MATRIX

(A)

ID User	*Clusters*		
	UC1	*UC2*	*UC3*
U1	0,68	0,12	0,2
U2	0,2	0,7	0,1
U3	0,05	0,35	0,6
U4	0,7	0,1	0,2
U5	0,15	0,65	0,2
…			

(B)

ID POI	*Clusters*			
	PC1	*PC2*	*PC3*	*PC4*
P1	0,6	0,05	0,3	0,05
P2	0,07	0,7	0,03	0,2
P3	0,06	0,25	0,04	0,65
P4	0,07	0,7	0,03	0,2
P5	0,2	0,07	0,7	0,03
…				

The input of this algorithm are matrices similar to Table I (A) and (B), and the output consists of partition matrices that synthesize users and POIs in different clusters (see Section III for more details).

Anyway, since we use a fuzzy algorithm for clustering, we obtain that each user or POI belongs to several clusters with different membership degrees. Table II shows part of the aforementioned partition matrices.

C. Users and POIs fuzzy classifier design

In this step, the previously obtained user and POI clusters are used to design fuzzy classifiers that are useful to relate new incoming data, such as POI or active user, with the existing clusters.

This design process extracts lists of if-then rules characterizing clusters obtained in the previous step. By designing classifiers the system trains itself in order to avoid clustering execution every time to position new POIs or new users. Theoretical details about this phase can be found in Section III. Table III (A) and (B) shows part of rules concerning users and POI classifiers.

D. Integration of historical data

One of the main aim of the proposed approach is to apply collaborative filtering on historical data, in order to recommend POIs to users that meet their context and preferences. Each record in such historical data asserts interest of a certain user that is identified in a specific context for a proper tourist POI. In this step, an integration between historical data and clusters obtained in the previous steps is achieved by exploiting fuzzy classifiers. Specifically, for each row of the historical data, if the user data in a historical transition are:

- age = 20
- skill = student
- interest = science

then these data can be replace with UC1 (User Cluster 1) according to classifier in Table III (A). Similarly, if the POI attribute values in a transition are the following:

- type = museum
- lat = 42.20
- long = 19.46
- when = from 9 a. m.
- period = always

then, data can be replaced with PC3 (POI Cluster 3) according to classifier in Table III (B). In Fig. 2, are highlighted the substitutions described above, but it is important to point out that a historical transition is also characterized by context data, that is, the context where the user was when he/she selected the specific POI. This further information will be exploit in the next step and it will be of use to provide context aware recommendations to users.

E. Association rules mining

As said before (see Section III) a Apriori algorithm have been selected to carry out association rule on historical data. In particular, in this step, extracted rules synthesize the relation between cluster of users, context and POIs clusters. These rules are useful to recommend eligible POIs to the tourists according with context and user features. Extracted rules are in the following form:

{lat=40/42, long=13/15, time=morning, date=saturday, walk/drive=walk, User Cluster=UC1} ⇒{Poi Cluster=PC3}.

Furthermore, to each rule is associated an importance degree by two features, namely, support and confidence. These features allow to set thresholds (i.e. MinSup, MinConf), in order to trigger only the so called strong rules (see Section III).

V. RECOMMENDATION PROCESS

The results obtained from *Knowledge Discovery Process*, are exploited to recommend POIs to users according to their context and preferences. In particular, the recommendation process, described in this section, consists of three steps detailed below.

TABLE III. (A) USER CLASSIFIER AND (B) POI CLASSIFIER

(A)

TABLE IV. ACTIVE USER CLASSIFICATION

ID User	*Clusters*		
	UC1	*UC2*	*UC3*
U1	0,1	0,2	0,7
U2	0,65	0,2	0,15
U_{Active}	0,1	0,7	0,2
...			

A. User cluster identification

The aim of this step is to identify the cluster of the active user that have "checked-in" to the application system. Thanks to the user classifier, it is not needed to run clustering again in order to determine the belonging of the active user to a specific cluster. When there is a new active user or already registered user changes him preferences the classification take place. In that cases, through the execution of classification rules (see Table III) a new row is added to the user partition matrix as shown in the Table IV. More specifically, Table IV highlights that the considered active user belongs to User Cluster 2 (UC2) with a membership degree higher than the other clusters; therefore, the active user is considered belonging to UC2.

B. Rules matching

In this step, the triggering of a specific rule is achieved according to higher degree of matching between the active user and extracted rules. In particular, a matching degree is calculated by considering a matching matrix M where the rows are represented by the extracted rules ranked according to their support and confidence features, whereas the columns are represented by active user context features and user cluster. Let be *M* the matching matrix, the maximum matching degree M_{max} is given by the following formula:

$$M_{max} = \max_{k} \left(\frac{\sum_{j=1}^{m} \mu_{ij}}{m} \right) \quad i = 1,\ldots, n \quad k = 1,\ldots, n \tag{5}$$

$$\mu_{ij} = S(u_j, a_{ij}) \quad i = 1,\ldots,n \quad j = 1,\ldots,m \tag{6}$$

$$S(u_j, a_{ij}) = 1 - \partial(u_j, a_{ij}) \quad i = 1,\ldots,n \quad j = 1,\ldots,m \tag{7}$$

where u_i represents the context and profile features of the active user, a_{ij} represents the antecedent clause of each extracted rule in the knowledge discovery process and ∂ is defined as described in Section III. So, Table V shows an example of maximum matching degree between the active user and the extracted rules according to (5), (6) and (7).

TABLE V. MAXIMUM MATCHING BETWEEN ACTIVE USER AND RULES

Matching User/Rule	*Context*					*User Cluster*	*POI Cluster*
	lat	*long*	*time*	*date*	*walk/drive*		
$User_{Active}$	41.50	13.88	evening	monday	drive	UC2	???
$Rule_{Active}$	40/42	13/15	evening	monday	drive	UC2	PC2
$S(User_{Active}, Rule_{Active})$	0,75	0,68	1	1	1	0,7	
M_{max}	(0,75 + 0,68 + 1 + 1 + 1 + 0,7)/6 = **0,855**						

C. Recommendations ranking

In the last step of this process, we determine the ranked list of POIs that may be suggested to the user.

In particular, the previous step determines the maximum matching between a new user that starts a transaction and the extracted rules. Rules matching evaluation, defines the highest match of the active user respect with extracted rules. Since, the consequent of a rule is represented by a POI Cluster, this match points out that POIs belonging to a specific cluster can be recommended as relevant for the active user. For instance, user is in a certain context and with a determinate profile if the active rule is the following:

{lat=40/42, long=13/15, time=evening, date=monday, walk/drive=drive, User Cluster=UC2} ⇒ {Poi Cluster=PC2}

then, the ranked list of POIs consists of those belonging to the cluster PC2, as shown in Table V.

TABLE VI. POIs RECOMMENDATION RANKING

ID POI	*Features*					*Cluster*	*Recommendation Ranking*
	type	*lat*	*long*	*when*	*period*	*PC2*	$\rho_i = b_{ic} \times M_{\max}$
P8	restaurant	40.33	14.14	all day	ever, except thuersday	0,8	0,684
P2	restaurant	42.23	12.34	all day	ever, except Tuesday	0,7	0,6
…	…	…	…	…	…	…	…
P5	restaurant	40.20	14.02	all day	ever, except monday	0,55	0,47
P3	hotel	42.90	15.30	all day	always	0,47	0,4
P1	zoo	41.24	14.06	all day	always	0,34	0,3
…							

In order to carry out the ranked list of POIs the framework assigns a ranking value to each POI corresponding to b_{ic} , that is the belonging degree of the i-th POI to the cluster c (i.e., PC2) in the consequent of rule with maximum matching in the antecedent and n is the number of POIs. Table VI shows an example of POIs recommendation ranking.

I. EXPERIMENTAL RESULTS

This section presents the performance results of our proposed recommender system. In particular, Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) are used in order to evaluate the accuracy of the system. Specifically, by considering different set of features the system has been evaluated in the following variants:

- LS - System considering Location
- LUC - System considering Location and User Context
- LUP - System considering Location and User Profile
- HRS - Hybrid Recommender System considering Location, User Context and User Profile

The system has been evaluated with 20 users and 200 POIs. Obviously, little by little the history data grow the system retrieve more meaningful results (the history considered contains about 1000 records). As previously said, MAE and RMSE are used for performance evaluation of the proposed recommender system. MAE is a quantity used to measure how close forecasts or predictions are to the eventual outcomes. On the other hand, RMSE measures the average magnitude of the error, that is, the difference between forecast and corresponding observed values, where each of these differences is squared and then averaged over the sample; so, a relatively high weight is given to large errors. MAE and RMSE can be used together to diagnose the variation in the forecasting errors.

Since the lower the MAE, the more accurately the recommendation engine predicts user ratings [28], the obtained results, shown in Fig. 3, highlight a clear superiority of the overall proposed recommender system among the other variants. Furthermore, since the greater difference between MAE and RMSE, the greater the variance in the individual errors in the sample, Table VII points out that all the errors are of the same magnitude.

II. CONCLUSIONS AND FUTURE WORKS

As a result of demands continuously growing in ambient intelligence for systems able to exploit context for satisfaction of user preferences, a context aware recommender system for tourist guidance is proposed in this paper.

The proposed system presents several improvements. Firstly, user context and profile are considered in order to effectively identify his preferences. Uncertainty among user interests is an important issue which is clearly considered in this approach in order to establish an effective recommendation strategy. Additionally, this approach provides dynamic user clustering for active users and supports them with a personalized and adaptive environment. Moreover, any POIs change can be simply notified to all interested users. Anyway, there are some limitations in this research area that we consider as future research directions. FCM alternative clustering algorithms that work better with mixed data can be experimented as well as alternative rule mining algorithms using fuzziness and based on lattice. However, the proposed framework confirms the useful of considering context factor in recommender systems and provides us with reasonable results in terms of recommendation accuracy as evidenced by the experimental results.

TABLE VII. RECOMMENDER SYSTEMS MAE COMPARISON

Recommender System	LS	LUC	LUP	Hybrid Recommender System
MAE	0,932	0,869	0,851	0,811
RMSE	0,932	0,869	0,851	0,811

***Abstract*—Estimating the number of people in a scene is a very relevant issue due to the possibility of using it in a large number of contexts where it is necessary to automatically monitor an area for security/safety reasons, for economic purposes, etc. The large number of people counting approaches available in the literature can be roughly abscribed to two categories: direct approaches and indirect ones. In the first category there are methods that first detect people and then count them; differently, the indirect methods face the counting problem by establishing a relation between some scene features and the estimated number of people. Some recent comparative evaluations carried out in the framework of the PETS initiative have demonstrated that the indirect methods tends to be more robust than direct ones, above all when they are used in very crowded conditions. In this paper, we analyze the behavior of an indirect approach that is based on a trainable estimator that does not require an explicit formulation of a priori knowledge about the perspective and density effects present in the scene at hand. In particular, we investigate on the way the counting accuracy in different crowding conditions is affected by the choice of the trainable estimator.**

***Index Terms*—Indirect People Counting, Trainable Estimators, ANFIS, ϵ-SVR.**

I. Introduction

Knowing the number of people present in an area is a so important issue in the framework of video surveillance applications, that an increasing number of papers on this topic have been proposed in the recent past.

Despite of the fact that recently some pioneering systems have been made available, further improvements are still necessary, especially concerning their generality and flexibility. Many aspects make the problem really challenging: systems are required to work in real time on general purpose computers, possibly in parallel on different video streams coming from megapixel cameras, so as to supply up to date information on crowd density. Of course, the computational charge is a crucial but a less important issue with respect to the expected accuracy: as the output is mainly used for safety issues, the estimation accuracy of the number of people must be sufficiently high, even in presence of dense crowds. To this concern, it is worth pointing out that in these situations only parts of people's body appear in the image; the occluded parts generally cause significant underestimation in the counting process; it means that the partial occlusions must be forecasted and suitably taken into account starting from the information about the crowd density. Another crucial point is the unavoidable presence of perspective distortions: the optical equipment of the cameras, especially those with wide angle views, cause that people far from the camera appear small while the close ones significantly bigger. So, methods must deal with this perspective issue, so as to obtain an estimation independent from the local scale of the image. Moreover, it is convenient that the system works with uncalibrated cameras, as calibration is generally time consuming and demands for suitable technical skills, not owned by the end user. Consequently, the availability of simple training procedures, not requiring knowledge about the internal organization of the computational model, but possibly depending on simple geometric properties derivable from the scene, is an extremely desirable feature.

The literature on people counting presents two conceptually different ways to face this task. In the *direct approach* (also called *detection-based*), each person in the scene is individually detected, using some form of segmentation and object detection; the number of people is then trivially obtainable. In the *indirect approach* (also called *map-based* or *measurement-based*), instead, counting is performed using the measurement of some features that do not require the separate detection of each person in the scene; these features then have to be put somehow in relation to the number of people.

The direct approach has the advantage that people detection is often already performed on a scene for other purposes (e.g. detecting events based on a person's position or trajectory), and as long as people are correctly segmented, the count is not affected by perspective, different people densities and, to some extent, partial occlusions. On the other hand, correct segmentation of people is a complex task by itself, and its output is often unreliable, especially in crowded conditions (which are of primary interest for people counting). Recent examples of the direct approach can be found in [1], [2] and [3].

The indirect approach, instead, is more robust, since it is based on features that are simpler to detect, but it is often not easy to find an accurate correspondence between these features and the number of people, especially if people may appear in the scene at different distances from the camera, and in groups

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

with diverse densities. For the indirect approach, methods such as the use of measurements such as the amount of moving pixels [4], blob size [5], fractal dimension [6] or other texture features [7] have been proposed.

However, one of the most recent indirect approaches has been presented in [8] where the estimation of the count is obtained through a trainable estimator that takes into account perspective effects and the influence of people density on the detection of corner points, and consequently, can be easily adapted to the characteristics of a new scene. This paper is devoted to analyze the behavior of the mentioned approach when it is used with two different estimators: ANFIS and ϵ-SVR.

As will be shown in the experimental results, even though the two approaches yield similar global performance, the neuro-fuzzy based estimator is more efficient when the scenes are characterized by a high density crowd, whereas, the approach based on ϵ-SVR works in a better way when the scenes are characterized by a low density crowd. This comparative analysis opens new scenarios for the development of novel indirect approaches for people counting able to adaptively select the most suitable estimator that reduces the output error measure under particular scene conditions.

II. An Indirect People Counting Approach based on a Trainable Estimator

In this section, a description of an indirect approach based on a trainable estimator is provided in order to evaluate its performance when different regression methods are used to estimate the number of people. The approach uses as its features the moving interest points, where the interest points are first detected using a feature detector from the state of the art, and then the static ones are filtered out on the basis of a motion vector estimation.

An outline of the considered method is described by the following steps: Moving SURF points detection, SURF point Clustering and Feature extraction and regression. More in details, in the first step, SURF algorithm proposed by H. Bay et al. in 2006 [9] is adopted in order to detect interest points; in the second step, the detected points are partitioned into clusters corresponding to separated groups of persons, as to be able to compute for each group its distance from the camera and its density; in the last step, a trainable function estimator is exploited to estimate the number of people in a scene.

This paper focuses on the last step. Precisely, the aim of this work is to compare two different regression methods, ANFIS and ϵ-SVR, when they are used to implement the trainable function estimator of an indirect people counting approach.

However, before presenting the description of the explored methods, in the following subsections, a description of the architecture (see Fig. 1) of the considered approach is given.

A. Moving SURF points detection

In order to detect interest points associated to people, two basic assumptions are made: persons within the scene are not static and there are no other moving elements in the scene. Thus, if we compute the interest points of the image and the associated motion information, the above assumptions guarantee that only the interest points with a non null motion vector must be associated to people. As proposed in [10], the interest points associated to people are extracted in two steps. First, we determine all the interest points within the frame under analyzis. Then, we prune the points not associated to persons by taking into account their motion information. In this approach, interest points are determined by using the SURF algorithm.

In order to remove the static interest points (that are not associated to people), for each point detected by the SURF algorithm we estimate the motion vector with respect to the previous frame by using a block-matching technique. Then the algorithm distinguishes between static and moving interest points on the basis of the following rule:

$$p(x,y) = \begin{cases} \text{moving point} & \text{if } |\vec{v}(x,y)| > \beta \\ \text{static point} & \text{if } |\vec{v}(x,y)| \leq \beta \end{cases} \quad (1)$$

where $p(x,y)$ is the interest point at the x,y coordinates, $|\vec{v}(x,y)|$ is the magnitude of the motion vector calculated in x,y with respect to the previous frame; β is a bias value (in our experiments we set $\beta = 0.0$).

B. SURF point Clustering

In order to compensate for changes in the number of points due to perspective and to partial occlusions, the algorithm needs to partition the detected points into clusters corresponding to separated groups of persons, so as to be able to compute for each group its distance from the camera and its density.

The faced clustering problem is characterized by the fact that there is no priori knowledge about the number and the

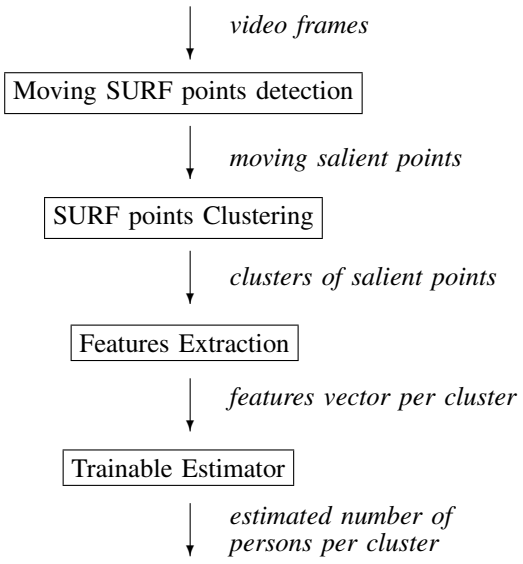

Fig. 1. System architecture.

shape of the clusters to be found. As observed in [11], the clustering algorithms based on graph theory are well suited to face clustering problems where no assumptions can be made about the clusters. In particular, the considered algorithm adopts the technique presented in [12], since (differently from other algorithms in the graph-based clustering family) it requires no parameters to be tuned or adapted to the particular application.

This algorithm represents the set of points as a graph in which each point corresponds to a node and each edge is labeled with the distance between its endpoints. The minimum spanning tree (MST) of the graph is computed; this tree will contain some edges that are between nodes in the same cluster (intra-cluster edges) and other edges between nodes of different clusters (inter-cluster edges). Assuming that the clusters are well separated, it can be expected that the intra-cluster edges are shorter than the inter-cluster edges. So the algorithm uses a thresholding to divide the edges in two sets (the ones below the threshold, say it λ, and the ones above the threshold λ). The edges in the second set are deleted, and the remaining connected components are the clusters output by the algorithm.

The use of a fixed value for the threshold λ would be problematic, since the threshold would need to be adjusted depending on the resolution, the distance from the camera and so on. Instead, this approach used a threshold proportional to the average edge length, computed as:

$$\lambda = \gamma \cdot \frac{1}{N} \sum_{i=1}^{N} x_i \tag{2}$$

where γ is the proportionality factor, N is the number of edges of the spanning tree, while x_i is the weight of the i-th edge of the tree. We have experimentally found that the choice $\gamma = 2.0$ works adequately for all the considered scenes.

C. Feature extraction and regression

In this stage of the algorithm, a feature vector is computed from each cluster detected in the previous step, and is fed into a regressor. The output of the regressor is the estimated number of persons in the group represented by the cluster.

The considered approach reasonably assumes that when the density of people increase,the detected points get closer to each other. So, the density of the points as related to people density is considered, and indirectly it is possible to take into account people density by establishing a relation between the average number of points per person and the point density.

The relation between the number of interest points and the number of people appears more complex than a direct proportionality, because it is possible to take into account also the distance of the people from the camera and the point density. This relation can be formulate as:

$$n_{people} = f(n_{points}, \rho, d) \tag{3}$$

where:

- n_{people} is the estimated number of people;
- n_{points} is the number of interest points within the cluster;
- ρ is the average density of the points in the cluster: the value is obtained as the ratio between the number of points into the cluster and the area of the bounding box. Note that the area of the bounding box is computed with respect to real world coordinates. This allows us to normalize the average density of the points to the value it would have if the cluster were moved to a predefined distance from the camera;
- d is the distance of the cluster from the camera: assuming that the bottom points of the bounding box lie on the ground plane, the calculation is done by applying an Inverse Perspective Mapping and is referred to the center of the bottom edge of the cluster's bounding box.

Since the analytical form of f is not known a priori, the considered approach choices to learn this function from a set of labeled examples by using a regression method.

In particular, this paper aims to compare two different techniques to implement the aforementioned function estimator: the ϵ-SVR regressor and ANFIS. Both explored methods are able to learn a non linear relation and show a good generalization ability. In details, they receive as inputs the number of points of a cluster, the distance from the camera and the point density of the cluster, and are trained (using a set of training frames) to output the estimated number of people in the cluster. However, as will be shown in section IV, ANFIS obtains better results when the people counting is applied to high density crowd, whereas the ϵ-SVR regressor provides more benefits when the indirect people counting method is used to estimate the number people in low density crowd.

III. Trainable Estimators: ANFIS and ϵ-SVR

In this section, a description of the two methods useful to implement the trainable function estimator for indirect people counting is provided. In particular, a brief description about ANFIS and ϵ-SVR is given.

A. Adaptive Neuro Fuzzy Inference System

Adaptive Neuro-Fuzzy Inference Systems (ANFIS) [13] is a class of adaptive networks that are functionally equivalent to conventional fuzzy inference systems. An adaptive network is a multilayer feed forward network in which each node performs a particular function (node function) on incoming signals using a set of parameters specific to this node [14]. The form of node functions may vary from node to node, and the choice of each node function depends on the overall function, which the adaptive network is designed to implement. Adaptive networks are composed by two different classes of nodes: *adaptive nodes* and *fixed nodes*. Adaptive nodes are characterized by a collection of modifiable parameters, named *parameter set*, whereas, the fixed nodes only deal with unmodifiable parameters. Adaptive networks work in order to achieve a desired input-output relationships by updating the parameter sets according to given training data and a gradient-based update procedure. ANFIS exploits this updating feature to learn and adapt the parameters of a given Takagi-Sugeno-Kang (TSK) fuzzy inference system.

As an example, Fig. 2 shows an adaptive network that models a first-order TSK fuzzy inference system composed by two rules:

1) If x is A_1 and y is B_1 Then $f_1 = p_1 \cdot x + q_1 \cdot y + r_1$
2) If x is A_2 and y is B_2 Then $f_2 = p_2 \cdot x + q_2 \cdot y + r_2$

where the symbols $x$and y are the system's inputs, A_1, A_2, B_1 and B_2 are linguistic labels determined by fuzzy sets defined on the universe of discourse related to the variables x and y whereas, the f_1 and f_2 are linear functions computing the output value of the TSK inference system.

To reflect the ANFIS adaptive capabilities, in Fig. 2 the square nodes represent the adaptive nodes, whereas the circle nodes represent the fixed nodes.

Each ANFIS layer implements a particular fuzzy inference subtask. In detail:

Layer 1 Every node i in this layer implements the node function:

$$O_i^1 = \mu_{A_i}(x) \tag{4}$$

where x is the input to node i , and A_i is a linguistic label. From a fuzzy inference point of view, O_i^1 is the membership function related to the fuzzy set A_i, and it specifies the degree to which the input x satisfies A_i. Typically, A_i is a bell-shaped function characterized by a set of three parameters $\{a, b, c\}$ corresponding to the parameter set of the node i.

Layer 2 The nodes labeled with Π multiply their input signals:

$$w_i = \mu_{A_i}(x) \times \mu_{B_i}(y) \text{ with } i = 1, 2; \tag{5}$$

where w_i represents the firing strength of a rule.

Layer 3 The node in this layer calculate the ratio of the i^{th} rules firing strength to the sum of all rules firing strengths:

$$\overline{w_i} = \frac{w_i}{w_1 + w_2} \text{ with } i = 1, 2. \tag{6}$$

The value w_i represents the *normalized firing strenght*.

Layer 4 The adaptive node i in this layer computes the following function:

$$O_i^4 = \overline{w_i} f_i = \overline{w_i}(p_i x + q_i y + r_i) \tag{7}$$

where the collection $\{p_i, q_i, r_i\}$ is the parameter set of the node i and corresponds to the TSK consequent parameters.

Layer 5 The single and fixed node in this layer, labeled Σ, computes the overall network output as the summation of all incoming signals:

$$O_i^5 = \sum_i \overline{w_i} f_i = \frac{\sum_i w_i f_i}{w_i} \tag{8}$$

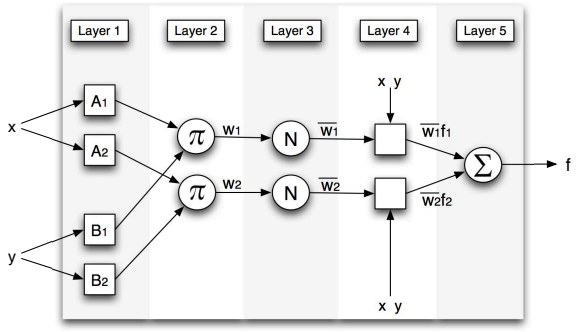

Fig. 2. The Adaptive Neuro Fuzzy Inference System.

B. ϵ-Support Vector Regression

The ϵ-SVR is a variant of the Support Vector Machines(SVM) designed to face the regression estimation task.

SVM is a class of learning algorithms originally developed for classification task, where in order to find a decision rule with good generalization ability one selects some (small) subset of the trained data called *Support Vectors*. Optimal separation of the Support Vectors is equivalent to optimal separation the entire data. In order to deal with the SV Regression, Vapnik [15] devised the so-called ϵ-insensitive loss function which does not penalize errors below some $\epsilon > 0$, chosen a priori [16]. Hereafter, a formal description of ϵ-SVR method is given.

As described in [17], let $G(x)$ be the unknown function where the vector $\mathbf{x} = [x_1, x_2, \ldots, x_d]$ is the *input space* characterized by a dimensionality equal to d. Let $F = (\mathbf{x}, \mathbf{w})$ be a family of functions parameterized by $\mathbf{w}$ and $\hat{\mathbf{w}}$ be the value of $\mathbf{w}$ which minimizes the error between $G(\mathbf{x})$ and $F = (\mathbf{x}, \hat{\mathbf{w}})$. The objective is to estimate $\mathbf{w}$ with $\hat{\mathbf{w}}$ by observing N training instances $\mathbf{v}_j$, $j = 1, \ldots, N$.

In order to achieve this aim, the approximation function F, employed by the SVR method, is defined:

$$F(\mathbf{x}, \hat{\mathbf{w}}) = \sum_{i=1}^{N} (\alpha_i^* - \alpha_i)(\mathbf{v}_i \cdot \mathbf{x} + 1)^p + b)$$

This function represents an expansion which explicitly uses the N training vectors. Indeed, different from other approximation functions, F depends on $2N+1$ coefficients α_i^*, α_i and b that must be determined from the training examples. Now, let $\boldsymbol{\alpha}$ represent the $2N$ values of α_i^* and α_i, the optimum values for the components of $\hat{\mathbf{w}}$ or $\boldsymbol{\alpha}$ depends on the definition of the objective function. Formally, the objective function is defined as:

$$||\mathbf{w}||^2 + C \sum_{j=1}^{N} L[y_j - F(\mathbf{v}_j, \hat{\mathbf{w}})]$$

where L is a general loss function, F is the approximation function, y_j is the observation of $G(\mathbf{x})$ in the presence of noise, and the first term, i.e, the 2-norm of the weight vector $\hat{\mathbf{w}}$, is a regularizer. Finally, the constant C represents a further regularization.

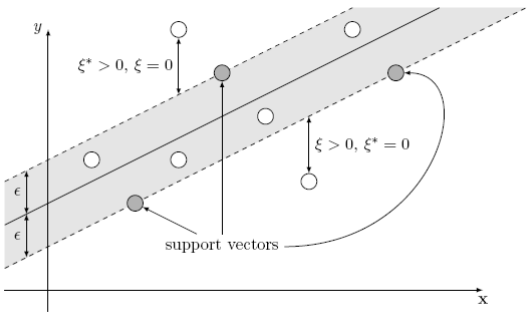

Fig. 3. The ϵ-SVR representation

In particular, the ϵ-SVR exploits as loss function the so-called ϵ-insensitive loss function defined as:

$$L = \begin{cases} 0 & \text{if } |y_j - F(\mathbf{x}_i, \hat{\mathbf{w}})| < \epsilon \\ |y_j - F(\mathbf{x}_i, \hat{\mathbf{w}})| - \epsilon & \text{otherwise} \end{cases} \quad (9)$$

This function defines an ϵ tube [18] (see Figure 3) so that if the predicted value is within the tube the loss is zero, while if the predicted point is outside the tube, the loss is the magnitude of the difference between the predicted value and the radius ϵ of the tube.

In this way, the objective function becomes to minimize this specific function:

$$\frac{1}{2} \cdot \mathbf{w}^2 + C(\sum_{i=1}^{N} \xi_i + \xi_i^*)$$

where ξ_i and ξ_i^* represents the so-called *slack variables* for each input point x_i. Precisely, ξ_i measures positive deviation of more than ϵ, while ξ_i^* indicates negative deviations. So, if a data point is is situated within the tube, both slack variables are 0. However, since no point can be on both sides simultaneously, at least one of the two slack variables is always 0. This is mathematically expressed by means of the ϵ-insensitive loss function defined in the equation 9.

Finally, in order to complete the description of the ϵ-SVR method, the constraints on the objective function are described:

$$\begin{aligned} & y_i - (\mathbf{w} \cdot \mathbf{v}_i) - b \leq \epsilon + \xi_i \\ & (\mathbf{w} \cdot \mathbf{v}_i) + b - y_i \leq \epsilon + \xi_i^* \\ & \xi_i \geq 0 \\ & \xi_i^* \geq 0 \end{aligned} \quad (10)$$

IV. Experimental Results

In this section, the performances of the indirect people counting approach are evaluated on a specific dataset by using two different estimators, ANFIS and ϵ-SVR, in order to compare the results provided by these regression methods.

In particular, the performance of the proposed methods has been assessed using the PETS2009 dataset [1]. The dataset is organized in four sections, but our attention is primarily focused on the section named S1 that was used to benchmark algorithms for the "'Person Count and Density Estimation"' PETS2009 contest. The main characteristics of the subset of video sequences of the PETS 2009 dataset used for assessing the performance of the proposed method are summarized in the Table I in terms of their length, number of people in the scene (minimum, maximum and average number) and other elements as density of the crowd, illumination conditions, etc.

For our experimentations, four videos of the view 2, namely S1.L1.13-57, S1.L2.14-06, S1.L2.14-31 and S3.MF.12-43, are used. For all the sequences the number of people in the whole frame is computed.

(a)

(b)

Fig. 4. Examples of the frames of the video sequences (a) S1.L2.14-06 and (b) S3.MF.12-43 used for the test

In order to exploit the proposed function estimators for people counting, a phase of training is necessary. The training set was built by manually collecting some samples of people groups from a subset of the test frames. For each selected box, the feature vector and the associated ground truth, i.e. the true number of persons that are inside the box, are calculated. Samples were carefully selected in order to guarantee that all the possible combinations in terms of number of persons in

TABLE III
PERFORMANCE OF THE ANFIS AND ϵ-SVR. IN EACH CELL THERE ARE REPORTED THE VALUES OF THE MAE AND OF THE MRE (IN PARENTHESIS).

Video (view)	ϵ-SVR	Anfis
medium density crowd	11.76 (30.0%)	11.02 (28.32%)
high density crowd	11.84 (30.9%)	9.3 (25.27%)
low density crowd	0.63 (18.8%)	1.79 (41.67%)

the group, points density and distance from the camera were adequately represented in the training set. In our tests, about 30-40 training frames, which correspond to about 5% of the frames within the whole dataset, have been taken into account.

Testing has been carried out by comparing the actual number of people in the video sequences and the number of people calculated by the two considered function estimators, ANFIS and ϵ-SVR. The indices used to report the performance are the Mean Absolute Error (MAE) and the Mean Relative Error (MRE) defined as:

$$MAE = \frac{1}{N} \cdot \sum_{i=1}^{N} |G(i) - T(i)| \tag{11}$$

$$MRE = \frac{1}{N} \cdot \sum_{i=1}^{N} \frac{|G(i) - T(i)|}{T(i)} \tag{12}$$

where N is the number of frames of the test sequence and $G(i)$ and $T(i)$ are the guessed and the true number of persons in the i-th frame, respectively.

This index is very useful to exactly quantify the error in the estimation of the number of person which are in the focus of the camera, but it does not relate this error to number of people; in fact, the same absolute error can be considered negligible if the number of persons in the scene is high while it becomes significant if the number of person is of the same order of magnitude. For this reason, we introduced also the MRE index which takes into account the estimation error related to the true people number.

The performances of the ANFIS and ϵ-SVR algorithms applied on the adopted dataset are reported in Table II.

Starting from the Table II, it is possible to summarize that the two tested function estimators show a different behavior depending on the scene features. In particular, ANFIS method is more suitable to estimate number of people in scenes characterized by a high density crowd, instead, the ϵ-SVR is more adequate for scene with a low density crowd. The results are summarized in the table III.

V. CONCLUSIONS

In this paper, we have analyzed and evaluated the performance of an indirect method for counting moving people in video-surveillance scenes by considering two different trainable estimators, ANFIS and ϵ-SVR. As highlighted in experiments both methods achieve good performances when applied to two different kinds of scenes. Precisely, the neuro-fuzzy based estimator obtains good performance when scenes are characterized by a high density crowd, whereas, the approach based on ϵ-SVR works in a better way when the scenes are characterized by a low density crowd. As a future work, we may use these different estimation behaviors to design an adaptive people counting method capable of identifying the scene features and dynamically selecting the most suitable estimator to deal with these features.

***Abstract*—This paper introduces a new type of TSK-based neuro-fuzzy approach and its application to modeling highly dynamic systems. In details, our proposal performs an adaptive supervised learning on a collection of time series in order to create a so-called Timed Automata Based Fuzzy Controller, i.e. an evolvable fuzzy controller whose dynamic features yield high performances in variable structure systems representation. The adaptive learning is accomplished by merging together theories from the area of times series analysis such as the Adaptive Piecewise Constant Approximation method, with a well-known neuro-fuzzy framework, the Adaptive Neuro Fuzzy Inference System. As will be shown in our experiments, where our proposal has been tested on a Fuzz-IEEE 2011 Fuzzy Competition dataset, this approach reduces the output error measure and achieves a better performance than a standard application of the ANFIS algorithm when applied to highly dynamic systems.**

***Index Terms*—Dynamic Systems Modeling, Neuro-Fuzzy Systems, Time Series Approximation, Variable Structure Systems, Timed Automata based Fuzzy Controllers.**

I. Introduction

Traditional systems modeling exploits conventional mathematical methods, such as differential equations, that are not able to deal with complex systems characterized by high levels of imprecision and uncertainty. By contrast, the *fuzzy control theory* [1][2] uses collections of linguistic *if...then* rules in order to model the above mentioned systems by considering qualitative aspects of human knowledge and reasoning processes without employing a precise quantitative analysis[3]. Thanks to their versatility, fuzzy systems have found a great variety of applications ranging from control engineering, qualitative modeling, pattern recognition, signal processing, information processing, machine intelligence, decision making, management, finance, medicine, motor industry, robotics, and so on [4].

However, in spite of their wide applicability, fuzzy systems suffer from some design weaknesses:

1) there are no recognized techniques for capturing human knowledge or experience through a fuzzy rule base;
2) some effective methods for learning and/or tuning the membership functions are necessary to minimize the output error measure or maximize performance index;
3) fuzzy control paradigm does not allow the modeling of systems characterized by a discontinuous nonlinear behavior or, in other words, it cannot directly represent highly dynamic systems and Variable-Structure Systems (VSSs)[5].

In order to solve these drawbacks, this paper introduces an adaptive supervised learning algorithm, based on a neuro-fuzzy approach, able to infer the different behaviors that a system exhibits during its life-cycle, and return a so-called *Timed Automata based Fuzzy Controller (TAFC)*, i.e. a novel kind of evolvable fuzzy inference engine whose dynamic features yield high performances in dynamic systems representation. The main idea underlying the learning algorithm is to identify the time ranges where the system shows a behavior characterized by soft oscillations and, for each range, to compute the most appropriate TSK fuzzy controller [6] modeling the system behavior in that range.

More in detail, the proposed neuro-fuzzy approach learns a suitable TAFC for modeling a given system by performing two sequential subtasks. The first subtask, that is based on the *Adaptive Piecewise Constant Approximation (APCA)* method [7], analyzes a collection of time series representing the temporal evolution of the system variables and identifies a set of disjointed temporal ranges where such variables are simultaneously characterized by soft oscillations or, in other words, by a low variance. This choice will allow the following subtask to work on a more reliable data collection. The second subtask takes as inputs the temporal ranges computed by the first subtask and, for each range, uses the *Adaptive Neuro-Fuzzy Inference Engine (ANFIS)* in order to compute the most suitable TSK controller that models the system behavior in that range. Finally, the computed temporal ranges and TSK controllers will be used to determine the main components of a TAFC modeling the whole system life-cycle.

As will be shown in experiments, where our proposal has been tested on a Fuzz-IEEE 2011 Fuzzy Competition dataset, the TAFC obtained by means of the proposed neuro-fuzzy approach reduces the output error measure error and achieves performances better than a conventional application of the ANFIS algorithm, when applied to highly dynamic systems.

II. Basic Concepts and Background

The following subsections will be devoted to present the main methodologies used by our approach: TAFC, APCA and ANFIS. Successively, the section III will formally introduce the proposed supervised learning algorithm.

A. Timed Automata based Fuzzy Controllers

A complete and theoretical discussion about the TAFC definition can be found in [8]. However, in this section a brief description about the most important features characterizing this evolvable inference engine is presented.

TAFCs are evolvable fuzzy systems mainly useful for modeling variable structure systems. In particular, they extend standard fuzzy controllers (Mamdani or TSK) by using three additional concepts: *control eras*, *control configurations* and *control time*. By means of these concepts, the life-cycle of a given system can be considered as composed of a sequence of disjointed time intervals (the control eras) where each era is characterized by a well-defined fuzzy controller (the control configuration) suitable for controlling the system during that era; the control time is the mechanism that allows the system to switch between adjacent control eras; in other words, the control time set the current control configuration of the system and the duration of the control eras.

In order to extend the fuzzy control vision with above said concepts, a modified version of Timed Automata has been used. A timed automaton is a standard finite-state automaton extended with a finite collection of real-valued clocks providing a straightforward way to represent time related events. Conventional automata-based approaches cannot offer this feature. The clocks can be reset to 0 (independently of each other) with the transitions of the automaton, and keep track of the time elapsed since the last reset. The transitions of a timed automaton are labeled with a *guard* (a condition on clocks), an *action* or *symbol* on alphabet Σ, and a *clock reset* (a subset of clocks to be reset). Intuitively, a timed automaton starts execution with all clocks set to zero. Clocks increase uniformly with time while the automaton is within a node. A transition may be taken only if the current values of the clocks satisfy the associated constraints. By taking the transition, all clocks in the clock reset will be set to zero, while the remaining keep their values.

In our vision, TAFCs use the nodes of a timed automaton to implement control era and control configuration, whereas the clocks and transitions realize the control time idea. In particular, when a TAFC transits from a state S_1 to a state S_2 through a transition T_1, an opportune control configuration (or fuzzy controller) C is activated to manage the system until a successive transition T_2 will be taken. The time that elapses between the two transitions is the duration of the control era related to the control configuration C. The control configuration C is obtained by transforming a previous control configuration related to the state S_1 by means of particular transformation operators that are related to the transition T_1. In details, transformation operators change a TAFC's control configuration by means of the following operations: adding ($\oplus$) or deleting ($\ominus$) a variable; adding ($\boxplus^k$), removing ($\boxminus^k$) or changing ($\boxdot^k$) k rules in the rule base; changing implication method of the rule base ($\sim$); adding ($\circledast$), deleting ($\oslash$) or changing ($\circledcirc$) a term to a variable; changing defuzzify method ($\propto$), aggregation method ($\bowtie$) or default value ($\divideontimes$) of an output variable; changing lower bound ($\ltimes$) or upper bound ($\rtimes$) of

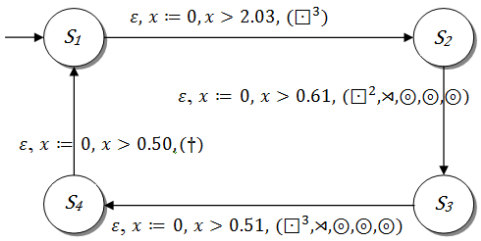

Fig. 1. A Sample of Timed Automata based Fuzzy Controller: an evolution scheme for the Matlab^{TM}Tipper

the universe of discourse of a variable. This process is iterated for each transition taken. A sample of TAFC is shown in Fig. 1. This TAFC evolves the classical tipper controller used as sample of fuzzy system in Mathworks Matlab^{TM}. The Tipper system manages the following issue: what is the right amount to tip your waitperson working in a restaurant placed in a sea village? The system determines the amount of tip by analyzing two data: the quality of service and the quality of served food. Although, it may seem a very simple system, the Tipper can be considered as a dynamic system since it changes its structure and behaviour over the time. Indeed, usually, the tip amount is higher in high season than low season and, as consequence, the fuzzy variable modeling this value should be gradually modified among the four year seasons. In details, it is possible to individuate four periods where the Tipper can show different behavior: from october 10^{th} to april 30^{th}, from may 1^{th} to june 30^{th}, from july 1^{th} to august 20^{th} and from august 21^{th} to october 9^{th}.

As proved in [9], where a comparison between a standard TSK controller and a TAFC has been accomplished, a TAFC results more efficient when it is devoted to control a dynamic system such as the Tipper.

In following sections, an introduction to APCA and ANFIS will be provided in order to define a supervised learning algorithm capable of analyzing a collection of time series related a given system and learning the control eras, the control configurations and the control time of the TAFC most suitable to model a system.

B. Adaptive Piecewise Constant Approximation

The APCA is a method for time series approximation originally designed for solving the problem of similarity search in large time series databases. In particular, APCA is a method for approximating a time series by dividing it into M varying-length segments and recording the mean value of the datapoints that fall within the segment. In our context, this approach is used to identify the collection of temporal ranges where a system shows a soft oscillation behavior. Hereafter, an introduction to APCA is provided starting from the time series definition.

A time series is a sequence of data points, measured at successive times spaced at uniform time intervals. A sample of time series is shown in Fig. 2. A common formal notation

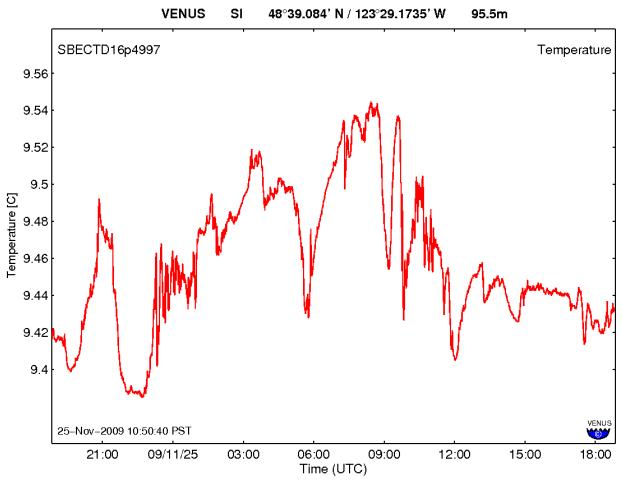

Fig. 2. A Sample of Time Serie for Representing Temperature Variations.

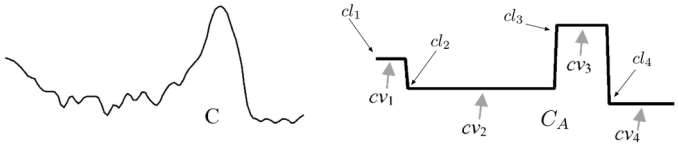

Fig. 3. A time series C and its APCA representation C_A, with $M = 4$.

specifying a time series C is:

$$C = \{c_1, c_2, c_3, \ldots, c_n\} \tag{1}$$

where c_i is the i^{th} datapoint in time series C sampled at the times $\{t_i, i = 1, \ldots, n\}$, with $t_i - t_{i-1} = \delta$ and $\delta \in \mathbb{R}$ (δ is the fixed sampling step).

Given a time series $C = \{c_1, \ldots, c_n\}$, an APCA approximation is represented as:

$$C_A = \{\langle cv_1, cl_1\rangle, \ldots, \langle cv_M, cl_M\rangle\} \tag{2}$$

where cv_i is the mean value of datapoints in the i^{th} segment (i.e., $cv_i = mean(c_{cl_i}, \ldots, c_{cl_{i+1}-1})$) and cl_i the left endpoint of the i^{th} segment. The length of the i^{th} segment can be calculated as $(cl_{i+1} - cl_i)$. Fig. 3 illustrates this notation.

In our neuro-fuzzy context, the APCA is used to analyze the temporal behavior of the variables related to a given system and compute a collection of temporal ranges enabling the proposed learning algorithm to learn the set of desired TAFC control eras.

C. Adaptive Neuro Fuzzy Inference System

Adaptive Neuro-Fuzzy Inference Systems (ANFIS) is a class of adaptive networks that are functionally equivalent to conventional fuzzy inference systems. An adaptive network is a multilayer feed forward network in which each node performs a particular function (node function) on incoming signals using a set of parameters specific to this node [3]. The form of node functions may vary from node to node, and the choice of each node function depends on the overall function, which the adaptive network is designed to implement. Adaptive networks are composed by two different classes of nodes: *adaptive nodes* and *fixed nodes*. Adaptive nodes are characterized by a collection of modifiable parameters, named *parameter set*, whereas, the fixed nodes only deal with an unmodifiable parameters. Adaptive networks work in order to achieve a desired input-output by updating the parameter sets according to given training data and a gradient-based update procedure [10]. ANFIS exploit this updating feature to learn and adapt the parameters of a given TSK fuzzy inference system.

As example, Fig. 4 shows an adaptive network that models a first-order TSK fuzzy inference systems composed by two rules:

1) If x is A_1 and y is B_1 Then $f_1 = p_1 \cdot x + q_1 \cdot y + r_1$
2) If x is A_2 and y is B_2 Then $f_2 = p_2 \cdot x + q_2 \cdot y + r_2$

To reflect the ANFIS adaptive capabilities, in Fig. 4 the square nodes represent the adaptive nodes, whereas the circle nodes represent the fixed nodes.

Each ANFIS layer implements a particular fuzzy inference subtask. In detail:

Layer 1 Every node i in this layer implements the node function:

$$O_i^1 = \mu_{A_i}(x) \tag{3}$$

where x is the input to node i , and A_i is a linguistic label. From a fuzzy inference point of view, O_i^1 is the membership function related to the fuzzy set A_i, and it specifies the degree to which the input x satisfies A_i. Typically, A_i is a bell-shaped function characterized by a set of three parameters $\{a, b, c\}$ corresponding to the parameter set of the node i.

Layer 2 The nodes labeled with Π multiply their input signals:

$$w_i = \mu_{A_i}(x) \times \mu_{B_i}(y) \text{ with } i = 1, 2; \tag{4}$$

where w_i represents the firing strength of a rule.

Layer 3 The node in this layer calculate the ratio of the i^{th} rules firing strength to the sum of all rules firing strengths:

$$\overline{w_i} = \frac{w_i}{w_1 + w_2} \text{ with } i = 1, 2. \tag{5}$$

The value w_i represents the *normalized firing strenght*.

Layer 4 The adaptive node i in this layer computes the following function:

$$O_i^4 = \overline{w_i} f_i = \overline{w_i}(p_i x + q_i y + r_i) \tag{6}$$

where the collection $\{p_i, q_i, r_i\}$ is the parameter set of the node i and corresponds to the TSK consequent parameters.

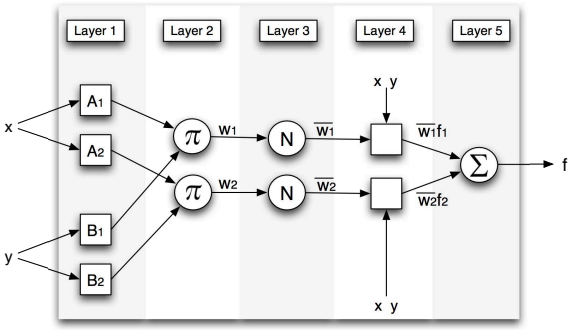

Fig. 4. The Adaptive Neuro Fuzzy Inference System.

Layer 5 The single and fixed node in this layer, labeled Σ, computes the overall network output as the summation of all incoming signals:

$$O_i^5 = \sum_i \overline{w_i} f_i = \frac{\sum_i w_i f_i}{w_i} \tag{7}$$

In our learning context, ANFIS is used to compute a collection of TSK controllers, each one useful to control a given system during a particular control era previously computed by the APCA approach.

III. A Supervised Learning Algorithm for Modeling Highly Dynamic Systems through TAFCs

This section formally introduces our proposal of a neuro-fuzzy approach for learning the TAFC most suitable to modeling the behavior of a given system. The proposed algorithm achieves this goal by taking as input a collection of time series representing the temporal evolution of the different variables of the system. The main idea underlying the learning algorithm is to identify the time ranges where the system shows a behavior characterized by soft oscillations and, for each range, to compute the most appropriate TSK controller modeling the system behavior in that range. Starting from the time ranges and TSK controllers the algorithm returns the control eras, the control configurations and the control time of the TAFC that better models the system under modeling.

The algorithm is essentially based on two steps, the *temporal learning step* and *qualitative learning step* (see Fig. 5). The first step uses the APCA in order examine the time series and computes the sequence of aforementioned time intervals; the second step, taking as input the sequence of time intervals, returns the appropriate (one for each time interval) TSK controller, computed by means of ANFIS.

A. Temporal Learning Step

Let S be a system characterized by n_i input variables and n_o output variables belonging, respectively, to the following sets:

$$\begin{aligned} V_i &= \{v_j, j = 1, \ldots, n_i\} \\ V_o &= \{v_j, j = n_i + 1, \ldots, n_i + n_o\} \end{aligned} \tag{8}$$

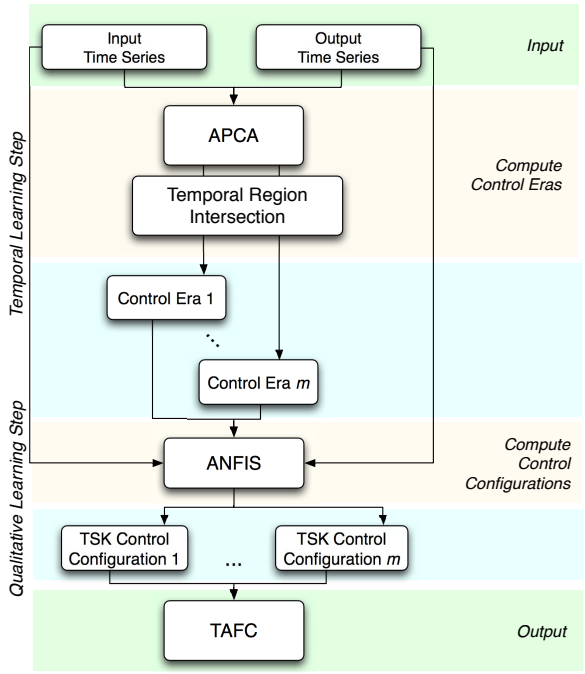

Fig. 5. The Supervised Learning Algorithm for modeling Highly Dynamic Systems: a Flow Chart

For each variable $v_j \in V_i \cup V_o$, let $C^j = \{c_1^j, c_2^j, \ldots, c_n^j\}$ be a time series containing the values of the variable v_j sampled at the time t_i with $i = 1, \ldots, n$ by a fixed sampling step δ.

The main aim of the temporal learning step is to analyze, for each output variable $v' \in V_o$, the time series C^j in order to identify the temporal ranges where the variables $v_j \in V_i \cup \{v'\}$ are simultaneously characterized by soft oscillations. In order to achieve this goal, the APCA method is applied. More in detail, the APCA method is executed on each time series C^j in order to compute the following time series approximation:

$$C_A^j = \{\langle cv_1^j, cl_2^j \rangle, \ldots, \langle cv_{M_j}^j, cl_{M_j}^j \rangle\}$$

where cv_i^j is the mean value of variable v_j in the i^{th} segment and $cl_i^j \in \{t_1, t_2, \ldots, t_n\}$ is the left endpoint of the i^{th} segment. Successively, the algorithm extracts from C_A^j a collection of M_j time instants, $T^j = \{cl_1^j, cl_2^j, \ldots, cl_{M_j}^j\}$, corresponding to the left endpoints of the time ranges where the variable v_j is characterized by soft oscillations. A sample of this process, with $M = 9$, is shown in Fig. 6.

Once APCA has computed the collection T^j for each variable $v_j \in V_i \cup V_o$, it is necessary to identify a further collection of time instants, $\mathbf{T} = \{\tau_1, \tau_2, \ldots, \tau_p\}$, corresponding to the left endpoints of the time ranges where the system variables are 'simultaneously' characterized by soft oscillations. This operation is performed by a *temporal intersection operator*. We give an algorithmic representation of this operator (see Algorithm 1) and an example of temporal intersection applied to two sequences $T^1 = \{0, 27, 289, 437, 595, 759\}$ and $T^2 = \{0, 27, 389, 547\}$ whose temporal intersection returns $\mathbf{T} = \{0, 27, 289, 389, 437, 547, 595, 759\}$ (see Fig. 8).

Starting from $\mathbf{T} = \{\tau_1, \tau_2, \ldots, \tau_p\}$, the algorithm computes the collection of control eras as follows:

$$E = \{\langle \tau_1, \tau_2 - \delta \rangle, \langle \tau_2, \tau_3 - \delta \rangle, \ldots, \}$$

We remind that δ is the fixed sampling step related to time series C^j. In order to compute the TAFC control configurations, the qualitative learning step prepares a collection of datasets, each one of the related to a given control era in E, and successively uses ANFIS to complete the learning process.

Algorithm 1 T-INTERSECTION$(T^1, \ldots, M^1, \ldots)$

Require: The collections $T^1, T^2, \ldots, T^{n_i+n_o}$
Ensure: The collection $\mathbf{T} = \{\tau_1, \tau_2, \ldots, \tau_p\}$.

```
T ← ∅
k ← 1
for i = 1 to |T^1| + |T^2| + ... + |T^{n_i+n_o}| do
    for j = 1 to (n_i + n_o) do
        if |T^j| > 0 then
            m_j ← min(T^j)
        else
            m_j ← +∞
        end if
        {m_j is the minimum value of T^j}
    end for
    τ ← min({m_j, j = 1, ..., n_i + n_o})
    if (τ ∉ T) then
        τ_k ← τ
        T ← T ∪ {τ_k}
        k ← k + 1
    end if
end for
return T
```

B. Qualitative Learning Step

The qualitative learning step applies the ANFIS system to a collection of dataset $D = \{D_i, i = 1, \ldots, |E|\}$ where D_i is the dataset related to the control era $\langle \tau_i, \tau_{i+1} - \delta \rangle$. Precisely, D_i is a matrix with n_i+1 rows and $\frac{(\tau_{i+1}-\delta)-\tau_i}{\delta}$ columns where the j^{th} row corresponds to the values taken by variable v_j at time instants:

$$\tau_i, \tau_i + \delta, \tau_i + 2 \cdot \delta, \ldots, \tau_i + \frac{(\tau_{i+1} - \delta) - \tau_i}{\delta} \cdot \delta$$

These values are extracted from the time series C^j related to the variable v_j.

Once each dataset D_i has filled, the qualitative learning step uses ANFIS in order to learn the best suitable TSK controller modeling the system S in the i^{th} control era: $\phi_i = \text{ANFIS}(D_i)$. The set $\Phi = \{\phi_i, i = 1, \ldots, |E|\}$ is the collection of control configurations related to the TAFC modeling the system S and the time instants $\tau_i + \frac{(\tau_{i+1}-\delta)-\tau_i}{\delta} \cdot \delta$ $(i = 1, \ldots, |E| - 1)$ are used by the control time to move the TAFC from the state corresponding to the controller ϕ_i to the next state corresponding to the controller ϕ_{i+1}.

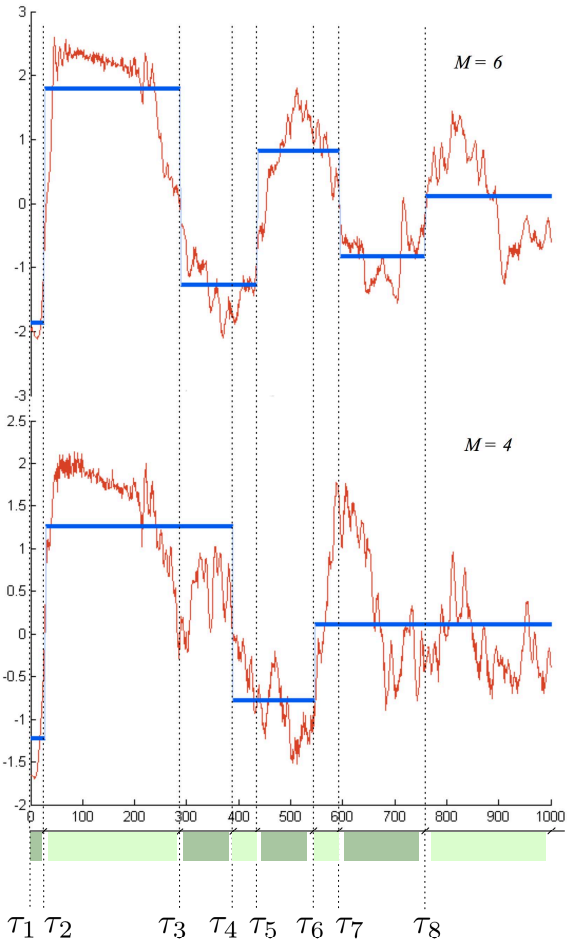

Fig. 7. The time ranges computed by the temporal intersection operator.

IV. Experimental Results

In order to verify and validate the benefits provided by our neuro-fuzzy approach, a dataset from FUZZ-IEEE 2011

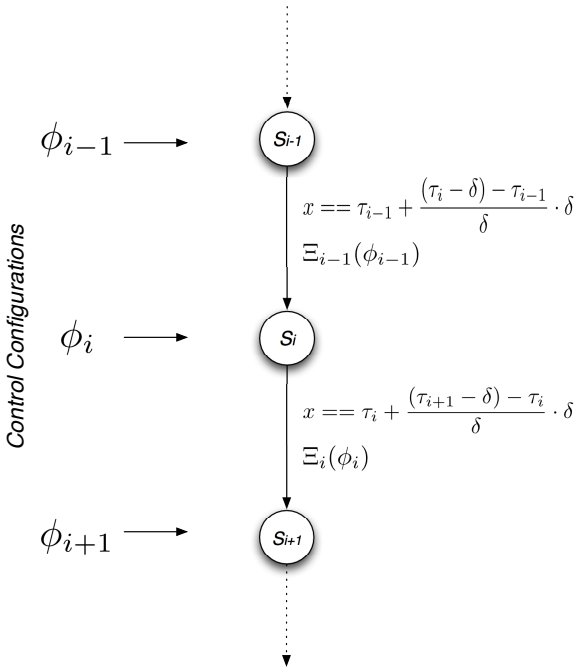

Fig. 8. A portion of TAFC returned by the learning algorithm.

Competition has been used. This dataset is related to a Multi-Input Multi-Output system with output couplings. An important feature of such a system is that each of the system's output variables may depend on all the input variables.

In particular, this competition dataset involves a nonlinear coupling system with four inputs and four outputs. Through data acquisition, 1000 input-output data points (namely, $u_1(n)$, $u_2(n)$, $u_3(n)$, $u_4(n)$, $y_1(n)$, $y_2(n)$, $y_3(n)$, $y_4(n)$, $n = 1, 2, ..., 1000$) were collected from the system with the sampling period $Ts = 0.0005s$. This data acquisition is used to create eight different time series $C_1, C_2, \ldots, C_8$, where the series $C_1, \ldots, C_4$ correspond to the four input variables, whereas the time series C_5 and C_8 correspond to the output variables.

The proposed neuro-fuzzy modeling system approach applies the APCA method to the time series C_i with $i = 1, \ldots, 8$ in order to obtain $M_1 = 4$ temporal segments for the variable u_1, $M_2 = 4$ temporal segments for the variable u_2, $M_3 = 5$ temporal segments for the variable u_3, $M_4 = 4$ temporal segments for the variable u_4, $M_5 = 8$ temporal segments for the variable y_1, $M_6 = 8$ temporal segments for the variable y_2, $M_7 = 6$ temporal segments for the variable u_3 and $M_8 = 6$ temporal segments for the variable y_4. In particular, for each output variable, the approach uses APCA method in order to compute the time instants corresponding to the left endpoints where the variables shows a soft oscillation. For example, considering the output variable y_4, the following collections are obtained:

$$
\begin{aligned}
T^1 &= \{0, 0.126, 0, 0.225, 0.297\} \\
T^2 &= \{0, 0.159, 0.283, 0.379\} \\
T^3 &= \{0, 0.056, 0.192, 0.291, 0.381\} \\
T^4 &= \{0, 0.176, 0.268, 0.334\} \\
T^8 &= \{0, 0.014, 0.17, 0.215, 0.268, 0.335\}
\end{aligned}
$$

The temporal intersection operator 'merges' together the collection T^1, T^2, T^3, T^4, $T^8$and obtains the time instants collection $\mathbf{T}$:

$$
\begin{aligned}
\mathbf{T} = \{&0, 0.0140, 0.056, 0.126, 0.159, 0.170, 0.176, \\
&0.192, 0.215, 0.225, 0.268, 0.283, 0.291, 0.297, \\
&0.335, 0.379, 0.381\}
\end{aligned}
$$

The collection $\mathbf{T}$ is used to learn 17 TAFC control eras:

$$
\begin{aligned}
E = \{&\langle 0, 0.0135\rangle \langle 0.0140, 0.0555\rangle, \langle 0.056, 0.1255\rangle, \\
&\langle 0.126, 0.1585\rangle \langle 0.159, 0.1695\rangle, \\
&\langle 0.170, 0.1755\rangle \langle 0.176, 0.1915\rangle, \\
&\langle 0.192, 0.2145\rangle, \langle 0.115, 0.2245\rangle, \\
&\langle 0.225, 0.2675\rangle \langle 0.268, 0.2825\rangle, \\
&\langle 0.283, 0.2905\rangle \langle 0.291, 0.2965\rangle, \\
&\langle 0.297, 0.3345\rangle \langle 0.335, 0.3785\rangle \\
&\langle 0.379, 0.3805\rangle \langle 0.381, 0.5\rangle\}
\end{aligned}
$$

Starting from E, the collection of ANFIS dataset $D = \{D_i, i = 1, \ldots, 17\}$ is computed in order to learn the control configurations $\Phi = \{\phi_i, i = 1, \ldots, 17\}$ and the control time of the TAFC modeling the behavior of the output variable y_4. The TAFC modeling the behavior of the systems regarding the output variable y_4 is shown in Fig. 9.

By iterating the learning process for each output variables, the performance of our neuro-fuzzy approach can be evaluated. In particular, this performance has been assessed according to the following error measure:

$$
\begin{aligned}
&\hat{e}_{total} = \hat{e_1} + \hat{e_2} + \hat{e_3} + \hat{e_4} = \\
&= \sum_{i=1}^{1000} (y_1(n) - \hat{y_1}(n))^2 + \\
&+ \sum_{i=1}^{1000} (y_2(n) - \hat{y_2}(n))^2 + \\
&+ \sum_{i=1}^{1000} (y_3(n) - \hat{y_3}(n))^2 + \\
&+ \sum_{i=1}^{1000} (y_4(n) - \hat{y_4}(n))^2
\end{aligned}
$$

where $\hat{y}_i$ with $i = 1, \ldots, 4$, are the output value computed by the TAFC model. We used Matlab to the learn the TAFCs related to the FUZZ-IEEE 2011 Competition and we obtained

the following error measures:

$$\begin{aligned}
&\sum_{i=1}^{1000}(y_1(n)-\hat{y_1}(n))^2 = 0.0645\\
&\sum_{i=1}^{1000}(y_2(n)-\hat{y_2}(n))^2 = 0.0474\\
&\sum_{i=1}^{1000}(y_3(n)-\hat{y_3}(n))^2 = 0.5906\\
&\sum_{i=1}^{1000}(y_4(n)-\hat{y_4}(n))^2 = 0.6512
\end{aligned} \tag{9}$$

and, as a consequence:

$$\hat{e}_{total} = 0.0645 + 0.0474 + 0.5906 + 0.6512 = 1.3536 \tag{10}$$

In order to validate the benefit provided by the proposed approach, a comparison between the total error shown in equation 10 and the error $\dot{e}_{total}$ returned by a conventional ANFIS application is given. Indeed, by using the conventional ANFIS approach, the following errors are measured:

$$\begin{aligned}
&\dot{e}_{total} = 455.2466 + 377.2482 + 315.9917 + 300.0843 =\\
&= 1.4486 \times 10^3
\end{aligned} \tag{11}$$

with a percentage improvement:

$$\Delta_E = \frac{(1.4486 \times 10^3 - 1.3536)}{1.4486 \times 10^3} \times 100 = 99.9066\%$$

The values $\hat{e}_{total}$ and Δ_E strongly depend upon the number of control eras returned by the temporal intersection operator. In turn, the number of control eras is related to M_j with $j = 1, \ldots, 8$ i.e, the number of segments used by APCA to approximate the time series C_j related to the variable v_j. In this experiment, we have chosen the M_j values in an empirical way in order to minimize the value of the total error $\hat{e}_{total}$ and try to avoid the overfitting issue. In the future works, a more accurate study about overfitting question will be done by validating the learned TAFCs by means of opportune testing datasets.

V. Conclusion

This paper introduced a novel of TSK-based neuro-fuzzy approach and its application to dynamic system modeling. This approach used the ANFIS system together with a time series approximation method, the APCA, in order to identify the time ranges where the system shows a behavior characterized by soft oscillations and, for each range, to compute the most appropriate TSK controller modeling the system behavior in that range. Successively, the time ranges and TSK controllers have been used in order to define the control eras, the control configurations and the control time of a TAFC, an innovative evolvable fuzzy inference engine. As show in experimental results section, our approach reduces the output error measure and achieves a better performance than a standard application of the ANFIS algorithm when applied to a highly dynamic system. In the future, we will test our neuro-fuzzy system on real-world scenarios in order to further validate the provided benefits.

***Abstract*--This paper introduces a solution to Dynamic Economic Dispatch (DED) problem using a hybrid optimization methodology bacterial foraging and PSO-DE (BPSO-DE) by integrating Bacterial foraging optimization Algorithm (BFOA), Particle Swarm Optimization (PSO) and Differential Evolution (DE). In the proposed method BFOA performs local search and global search for entire search space is accomplished through PSO-DE operators in this way they move to reach the global optimization. The BFOA also takes care of the constraints such as ramp-rate limits, valve-point loading effects, system load demand, prohibited operating zones, power losses and spinning reserve capacity. A ten unit test system is considered to show the effectiveness of the proposed method over other existing methods.**

***Index Terms* -- Bacterial Foraging, Particle Swarm Optimization, Differential Evolution**

I. NOMENCLATURE

D : Dimension of search space.

N_b : The number of bacteria in the population.

N_C : The number of chemo-tactic steps.

N_{re} : The number of reproduction steps.

N_{ed} : The number of elimination-dispersal events.

N_S : Swimming length N_S is the maximum number of steps taken by each bacterium when it moves from low nutrient area to high nutrient area.

P_{ed} : Probability of elimination and dispersal

CS : The size of the step taken in the random direction specified by the tumble.

w : The inertia weight.

$P(t,j,k,l,m)$: Position vector of j^{th} unit in t^{th} hour, k^{th} bacterial population, l^{th} reproduction and m^{th} elimination-dispersal, where $k=1,2,.....,N_b$, $l=1,2,....,N_{re}$ and $m=1,2,....,N_{ed}$.

$V(t,j,k)$: Velocity vector of the j^{th} unit in t^{th} hour and k^{th} bacterial population.

$pbest$: The best previous position of k^{th} particles.

$gbest$: The index of the best particle among all particles in the group.

sf : The scale factor

CR : The Cross over probability

C_1, C_2 : Acceleration constants

rand, Rand : Random value in the range [0,1]

$J(k,l,m)$: Cost value of k^{th} bacterial population, l^{th} reproduction and m^{th} elimination-dispersal

$JF(k,l,m)$: Fitness value of k^{th} bacterial population, l^{th} reproduction and m^{th} elimination-dispersal

r_2, r_3 : Parameter vectors chosen randomly from the current population.

II. INTRODUCTION

DED problem determines the optimal generation schedule of on-line generators, so as to meet the predicted load demand over a time horizon satisfying dynamic constraint such as ramp-rate limits. The goal of DED problem is to minimize operating cost under various system and operational constraints. The ramp-rate limits must be properly modeled in production simulation as the operational decision at an hour t may affect the operational decision at a later hour. So DED is a most difficult dynamic optimization problem.

The literature addresses DED problem with convex cost functions [1]–[4], though in reality, large steam turbines generally have a number of fuel admission valves which are opened sequentially in order to increase the production. When the valve is opened, the throttling losses increases rapidly as a

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

result of which, the incremental heat rate rises suddenly. The valve-point effects and prohibited operating regions contribute non-convexity in the fuel cost function of the generating units [5]-[9]. The generators operating in prohibited operating region experience amplification of vibrations in their shaft bearing [10], [11] due to physical operation limits such as faults in the machines themselves or the associated auxiliaries, such as boiler, feed pumps, etc. Traditional methods like gradient projection method [1], Lagrangian relaxation [12], and dynamic programming when used to solve DED problem often use more approximations to limit the complexity of the problem and take longer solution time. Hence these methods suffer from solution stagnation problem leading them to a less desirable performance. Genetic Algorithm (GA) [5], [13], evolutionary programming (EP) [6], [14]-[16], simulated annealing (SA) [17], [18], particle swarm optimization (PSO) [7] and differential evolution (DE) [19], [20] may prove to be very effective in solving nonlinear ED problems without any restriction on the shape of the cost curves. They often provide fast and reasonable solutions. EP seems to be a good method to solve optimization problems, when applied to problems consisting of more number of local optima the solutions obtained from EP method when combined with sequential quadratic programming (SQP) is just near global optimum[21]-[24]. Recently, a variable scaling hybrid differential evolution (VSHDE) and hybrid differential evolution (HDE) [25] methods are used to solve the DED problem.

The Bacterial Foraging Optimization Algorithm (BFOA) is currently gaining popularity in the community of researchers, for its effectiveness in solving certain difficult real-world optimization problems. BFOA is based on the foraging strategies of Ecoli bacterium cells and was proposed by Prof. K. M. Passino in 2001 [26]. PSO and DE are excellent heuristics like other evolutionary algorithms [29]. Practical experiences suggest that they reach stagnation after certain number of generations as the population is not converged locally, so they will stop proceeding towards global optimal solutions. The stochastic search methods are proven in reaching global solutions for certain difficult real world optimization problems [30]-[36]. Hence this article comes up with a hybrid approach involving PSO-DE and BFOA algorithm for solving non-convex DED problem considering valve-point loading effects, ramp-rate limits, prohibited operating regions and spinning reserve capacity. The new method is shown to be statistically significantly better on a test systems consisting of ten generating units. The results obtained through the proposed method are compared with those reported in the literature.

III. Dynamic Economic Dispatch Problem Formulation

The classic DED problem minimizes the following incremental cost function associated to dispatchable units

$$Min \quad F = \sum_{t=1}^{T}\sum_{i=1}^{N} F_{it}(P_{it}) \qquad (\$) \qquad (1)$$

where F is the total generating cost over the whole dispatch period, T is the number of intervals in the scheduled horizon, N is the number of generating units, and $F_{it}(P_{it})$ is the fuel cost in terms of its real power output P_{it} at time t. Taking into account of the valve-point effects, the fuel cost function of i^{th} thermal generating unit is expressed as the sum of a quadratic and a sinusoidal function in the following form

$$F_{it}(P_{it}) = a_i P_{it}^2 + b_i P_{it} + c_i + \left| e_i \sin(f_i(P_{i\min} - P_{it})) \right| \qquad (2)$$

$$J = F_{it}(P_{it}) \qquad (3)$$

$$JF = 1/J \qquad (4)$$

where a_i, b_i and c_i are cost coefficients, e_i and f_i are constants from the valve point effect of the i^{th} generating unit, and P_i is the power output of the i^{th} unit in megawatts. The minimization of the generation cost is subjected to the following equality and inequality constraints

1) Real power balance constraint

$$\sum_{i=1}^{N} P_{it} - P_{Dt} - P_{Lt} = 0 \qquad (5)$$

where t = 1, 2, …, T. P_{Dt} is the total power demand at time t in megawatts and P_{Lt} is the transmission power loss at time t in megawatts. P_{Lt} is calculated using the B-Matrix loss coefficients and the general form of the loss formula using B-coefficients is

$$P_{Lt} = \sum_{i=1}^{N} B_{ii} P_{it}^2 \qquad (6)$$

2) Real power generation limit

$$P_{i\min} \le P_{it} \le P_{i\max} \qquad (7)$$

where $P_{i\min}$ is the minimum limit, and $P_{i\max}$ is the maximum limit of real power of the i^{th} unit in megawatts.

3) Generating unit ramp rate limits

$$\begin{aligned} P_{it} - P_{i(t-1)} &\le UR_i, \qquad i = 1,2,3,.....,N \\ P_{i(t-1)} - P_{it} &\le DR_i, \qquad i = 1,2,3,.....,N \end{aligned} \qquad (8)$$

where UR_i and DR_i are the ramp-up and ramp-down limits of i^{th} unit in megawatts. Thus the constraint of (8) due to the ramp rate constraints is modified as

$$\max(P_{i\min}, P_{i(t-1)} - DR_i) \le P_{it} \le \min(P_{i\max}, P_{i(t-1)} + UR_i) \qquad (9)$$

such that

$$\begin{aligned} P_{it,\min} &= \max(P_{i\min}, P_{i(t-1)} - DR_i) \\ &\text{and} \\ P_{it,\max} &= \min(P_{i\max}, P_{i(t-1)} + UR_i) \end{aligned} \qquad (10)$$

4) Prohibited operating zones

$$\begin{aligned} P_{it,\min} &\le P_i \le P_{i,1}^L \\ P_{i,q-1}^U &\le P_i \le P_{i,q}^L \\ P_{i,ni}^U &\le P_i \le P_{it,\max}, \; q = 2,3,.....,n_i \end{aligned} \qquad (11)$$

where

i = unit index

n_i = the number of prohibited zones for unit i.

q = the index of prohibited zones for unit i.

$P_{i,q}^{L}$ = the lower boundary of q^{th} prohibited zone for unit i.

$P_{i,q}^{U}$ = the upper boundary of q^{th} prohibited zone for unit i.

5) System spinning reserve constraint

$$\sum_{i=1}^{N} S_{it} \geq S_{Rt}$$
$$S_{it} = \min\{(P_{it\max} - P_{it}), S_{i\max}\} \quad (12)$$

where S_{it} = reserve contribution of the i^{th} unit at t^{th} interval

S_{Rt} = spinning reserve demand at t^{th} interval in megawatts

$S_{i\max}$ = maximum reserve contribution of i^{th} unit

IV. An Overview of Integrated Techniques

The Particle Swarm Optimization was introduced by James Kennedy and Russell C. Eberhart in 1995 [26]. PSO is motivated from the simulation of the behavior of social systems such as fish schooling and birds flocking. It is similar to other evolutionary computation techniques like Genetic Algorithm (GA) and Evolutionary Programming (EP) in that PSO also initializes a population of individuals randomly. These individuals are known as particles and have positions and velocities. Each particle adjusts its velocity dynamically corresponding to its flying experiences and its neighbors. The three main components that affect the changing of the velocity are internal, cognitive and social components. Internal component represents the particles behavior for moving in the previous direction. The cognitive component represents the memory of the particle for attracting to its best position ($pbest$) based on its own thinking. The social component represents the memory of the particle for attracting its previous best position among the group ($gbest$), here the particle changes its velocity based on the social-psychological adaptation of knowledge. So the velocity of the particle is updated to new position according to its modified velocity. The best evaluation function (fitness) is evaluated for the entire run and is stored in $gbest$. The velocity of i^{th} particle is represented as $V_i = (V_{i1}, V_{i2}, ...V_{ij})$. Hence the modified velocity of each particle can be calculated using the information.

a) The current velocity
b) The distance between the current position and $pbest$.
c) The distance between the current position and $gbest$.

$$V_{ij}(it+1) = w * V_{ij}(it) + C_1 * rand_1 * (pbest_{ij} - x_{ij}(it)) + C_2 * rand_2 * (gbest_i - x_{ij}(it)) \quad (13)$$

where

$x_{ij}(it)$ = current position of the i^{th} particle in j^{th} dimension at iteration it.

$V_{ij}(it)$ = velocity of the i^{th} particle in j^{th} dimension at iteration it.

The i^{th} particle position can be represented as $x_i = (x_{i1}, x_{i2}, x_{i3}, ..., x_{iN})$ in the N-dimensional space. The best previous position of the i^{th} particle is stored and represented as $x_{besti} = (x_{best,i1}, x_{best,i2}, ..., x_{best,ij})$. The updated position of each particle is expressed as

$$x_{ij}(it+1) = x_{ij}(it) + V_{ij}(it+1) \quad (14)$$

The new positions are calculated repeatedly till a pre-specified maximum number of iterations are reached.

Differential Evolution is one of the excellent evolutionary algorithms for global optimization developed by Price and Storn in 1995 [27]. It is a simple population based, stochastic parallel search evolutionary algorithm developed for nonlinear and non-differentiable continuous space functions in order to attain global optimization. DE is a robust statistical method for cost function minimization, which does not make use of a single parameter vector but instead uses a population of equally important vectors. To generate a new generation the evolutionary operator's mutation, recombination, and selection are applied to every population member. In each generation to change each population member X_i, a donor vector v_i is created. Three parameter vectors *r*1, *r*2, and *r*3 are chosen in a random fashion from the current population. A scalar number sf scales the difference of any two of the three vectors and the scaled difference is added to the third one. Donor vector for j^{th} component of k^{th} population at G generation is expressed as

$$v_{i,j}(G+1) = X_{r1,j}(G) + sf * (X_{r2,j}(G) - X_{r3,j}(G)) \quad (15)$$
where $j = 1,2,...,D$

The mutation factor sf is a control parameter which scales the difference of any two of the three vectors and the scaled difference is added to the third one. This step is known as differential variation and the result is known as the mutant vector. DE is sensitive to the choice of mutation factor and to avoid search stagnation it is usually taken in the range 0.1 to 1. In recombination a trial vector is generated by replacing certain parameters of the target with the corresponding parameters of a randomly selected donor vector. The crossover constant CR is taken in the range [0, 1].

$$u_{i,j}(G+1) = v_{i,j}(G+1) \ \ if \ \ rand(0,1) < CR$$
$$u_{i,j}(G+1) = X_{i,j}(G) \quad otherwise \quad (16)$$

The evaluated fitness value of population vector and the

trial vector are compared and the best is selected as in equation (16). Hence the fitness of each trial vector $u_{ij}(G+1)$ is compared with that of its parent target vector $X_{ij}(G)$ and the maximum fitness or minimum cost one is allowed to proceed to the next generation.

Bacterial foraging algorithm was proposed by Passino in 2002 [28], the BFO approach was based upon the fact of survival of bacteria especially Escherichia coli, in the natural changing environment. The process depends upon their fitness criteria which depend upon their food searching and motile behavior. The law of evolution supports the bacteria with good foraging strategies and eliminates or reshapes those with poor strategies. The genes of bacteria with good foraging strategies are propagated in evaluation chain since they posses ability to reproduce even better bacteria in future generations. The foraging strategy of Escherichia coli bacteria is explained by three steps chemo-tactic, reproduction and elimination–dispersal with the help of which global searching capability of this algorithm is executed. Chemo-tactic process of bacterial foraging describes the movement of an E.coli cell through swimming and tumbling via flagella. It can move in two different ways, it can swim for a definite period of time or it can tumble and it alternates between these two modes of operation for the entire lifetime. For example if θ_k denotes the k^{th} bacterium and CS_k is the size of the step taken in the random direction specified by the tumble.

$$\theta_k = \theta_k + CS_k * Delta_k$$

$$Delta_k = \frac{\Delta_k}{\sqrt{\Delta_k^T \cdot \Delta_k}} \tag{17}$$

where Δ is a unit length vector in the random direction

In this article we come up with a hybrid optimization technique, which synergistically couples the BFOA with the PSO and DE. The proposed algorithm performs local search through the chemo-tactic movement operation of BFOA whereas the global search over the entire search space is accomplished by a PSO-DE operator. In this way it balances between exploration and exploitation enjoying best of both the worlds.

V. Bacterial Foraging PSO-DE Algorithm for DED Problem

The steps for implementation of the Bacterial Foraging and PSO-DE optimization are given below.

Step1: Initializing parameters

1a) Randomly initialize positions $P(t,j,k,l,m)$ and velocities $V(t,j,k)$ in t^{th} hour for j^{th} unit, k^{th} bacterial population, l^{th} reproduction $(l=1)$ and m^{th} elimination-dispersal $(m=1)$.

1b) Define each particle best as $pbest$ and the best position of all particles as $gbest$.

Step2: Starting of the elimination-dispersal loop $(m=m+1)$.

Step3: Starting of the reproduction loop $(l=l+1)$.

Step4: Starting of the chemo-tactic loop $(iter=iter+1)$.

Step5: For each bacteria $(k=k+1)$.

Step6: Compute fitness function $JF(k,l,m)$ and cost function $J(k,l,m)$, let

$$JFlast = JF(k,l,m) \tag{18}$$

$$JF = \frac{1}{J + penality\ function} \tag{19}$$

$$penality\ function(k) = \begin{cases} k_c \left| (P_k - P_{k,\lim}) \right| & if\ violated \\ 0 & otherwise \end{cases} \tag{20}$$

where k_c is a constant value and $P_{k,\lim}$ is the specified boundary limits

Step7: Move to new position

7a) Compute $CS(k) = rand * k_d$ (21)

7b) $P(t,j,k,l,m) = P(t,j,k,l,m) + CS(k) * Delta(t,j,k)$ (22)

$where\ Delta(t,j,k) = V(t,j,k)$ for k=1, 2, 3……, N_b

7c) Handle constraints

- generation limit
- ramp rate limit
- prohibited operating zones
- system spinning reserve

7d) Compute fit and cost- JF and J

Step8: swimming

8a) $swim-count = 0$

8b) while ($swim-count < N_s$) and $JF(k,l,m) > JFlast$

I. $swim-count = swim-count+1$

II. $JFlast = JF(k,l,m)$

III. $P(t,j,k,l,m) = P(t,j,k,l,m) + CS(k) * Delta(t,j,k)$

IV. Handle constraints

- generation limit
- ramp rate limit
- prohibited operating zones
- system spinning reserve

V. Compute JF and J

Step9: Differential Evolution

9a) $while(rand < CR)$

$$P_{def}(t,j,k,l,m) = P(t,j,k,l,m) + sf * (P(t,j,r_2,l,m) - P(t,j,r_3,l,m) \tag{23}$$

9b) Handle constraints

- generation limit
- ramp rate limit
- prohibited operating zones
- system spinning reserve

9c) Compute cost and fit- J_{def}, JF_{def}

Step10:

$if\,(JF_{def} > JF)\quad then$

$JF = JF_{def}, P = P_{def}, J = J_{def}$

Step11: Update best location $pbest$ and $gbest$ for JF, J and P.

Step12: 12a) Compute new velocity

$$V(t,j,k) = w * V(t,j,k) + C_1 * rand * (pbest(t,j,k) - P(t,j,k,l,m)) + C_2 * rand * (gbest(t,j) - P(t,j,k,l,m)) \quad (24)$$

12b) $Delta = V$

Step13: If $k < S$ then go to step5

Step14: If $iter < N_c$ then go to step4

Step15: Reproduction operations

15a) $JFhealth$ is the measure of particles with good fitness (good fitness means higher fitness and lower cost)

$$JFhealth(k) = pbestJF(k,l,m) \quad (25)$$

where $pbestJF$ is the population of best fitness of the current generation

15b) Sort bacteria in the order of ascending fit. The weaker $N_{br} = N_b / 2$ bacteria die and the rest N_{br} best bacteria each split into two bacteria which are placed at the same location.

15b) If $l < N_{re}$ then go to step3 to start the next generation in the chemo-tactic loop else go to step16.

Step16: Elimination-dispersal operation

16a) For k=1, 2, 3……, N_b a random number is generated and if it is less than or equal to P_{ed} than that bacterium is dispersed to a new random location else it remains at its original location.

16b) If $m < N_{ed}$ then go to step2 otherwise stop.

In the original bacterial foraging algorithm CS_k indicate a basic chemo-tactic step size (chemo-tactic step size is the lengths of steps taken during runs). This value should be greater than zero. It is taken in the tumble and swimming operations so that it moves in a direction specified by them and helps in reduction of cost. The normal choice for this step size is 0.1. The chemo-tactic step size in this paper is proposed to vary in the range (approximately 0.1 to 4.5) by using the relation

$$CS(k) = rand(0,1) * k_d \quad (26)$$

Usually the k_d value is a number between 1 and 5; rand (0, 1) is a uniformly distributed random number within the range [0, 1]. For every chemo-tactic step in the tumble and swimming operation the step size value taken in this paper lead to fine reduction in cost.

VI. Results and Discussions

The feasibility of the method BPSO-DE is demonstrated on a test system (ten-unit) for scheduled time duration one day divided into 24 intervals. The spinning reserve is required to be greater than or equal to 5% of the load demand at every dispatch interval. The proposed method satisfies the constraint load demand in each interval, prohibited operating zones, system spinning reserve and also dynamic constraint ramp-rate constraint. An experimentation is done for different values of control parameters such as C_1, C_2, CR, sf and k_d. It is observed that for C_1=0.1, C_2=0.1, CR=0.8 and sf =0.1 and k_d =5 the convergence leads to better cost.

Example: ten-unit system

Ten-unit system data such as cost coefficients, generation limits, ramp-rate limits, spinning reserve maximum limit for each unit and load demand in each interval is taken from [25]. The parameters chosen for this system are $N_c = 500$, N_{ed} =2, N_{re} =2, N_s =4, N_b =120 and P_{ed} =0.2. The convergence characteristic are plotted for number of evaluation (number of evaluation= $N_c * N_{ed} * N_{re}$) and total generation cost is as in Figure 1, Figure 2 represents the cost for each hour and Figure 3 compares the spinning reserve per hour with 5% load demand.

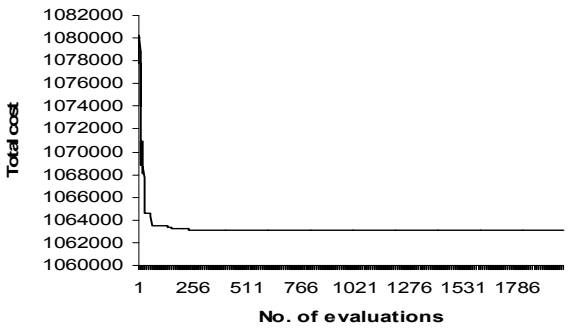

Fig. 1. Cost convergence characteristics for ten-unit system

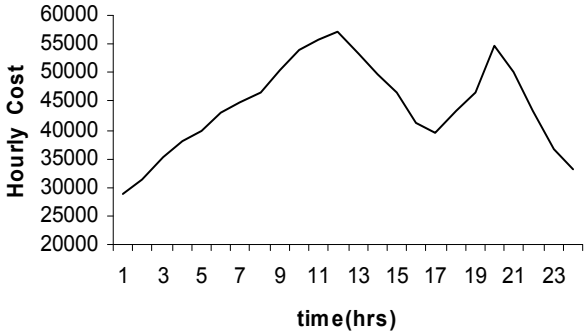

Fig. 2. Hourly cost curve for ten-unit system

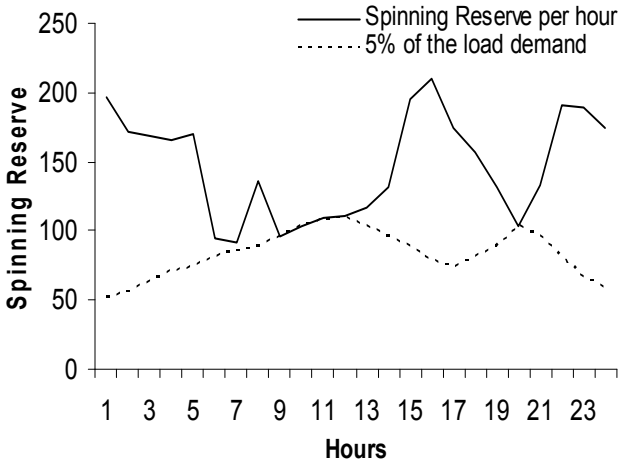

Fig. 3. Comparison of spinning reserve with 5% of the load demand for each hour

From simulation it is observed that the proposed method reduces the total generation cost when compared with other heuristic methods like HDE and VSHDE as shown on Table I. The optimum scheduling of generating units for 24 hours using the proposed method is tabulated in Table II. Computation time of the proposed method per a chemo-tactic step is 7.065seconds.

TABLE I
COMPARISON OF RESULTS FOR TEN-UNIT SYSTEM

Method	HDE [25]	VSHDE [25]	BPSO-DE
Fuel Cost ($)	1343243.2	1100666.4	1063048

VII. CONCLUSION

In this article a new heuristic technique is developed by integrating BFOA, PSO and DE techniques for solving DED problem. PSO-DE operators work effectively when combined with BFOA and leads to reach global solutions. The efficiency of the proposed BPSO-DE method for solving non-convex DED problem considering prohibited operating zones, valve-point loading effect and spinning reserve is observed from its solutions and compared with the results obtained from heuristic methods like HDE and VSHDE. The comparative study reveals the superiority and feasibility of BPSO-DE technique to solve the DED problem. Due to its superiority in reaching good quality solution this method in future work can be extended to solve for security constraints.

***Abstract*—Analysis of noisy data gathered from measurement devices is challenging in the power grid. In this study, an effective noisy data regression approach based on general regression neural networks (GRNN) is employed to deal with the problem for remote terminal units (RTU) in power SCADA systems. Experimental results show the proposed model is able to handle noisy data for practical applications, and has good performance in removing the unintended changes to the original data.**

Keywords- general regression neural networks; genetic algorithms; remote terminal units; power SCADA systems

I. INTRODUCTION

Supervisory control and data acquisition (SCADA) systems are indispensable in the operation of modern power systems. A SCADA system is a centralized control and monitoring system that typically consists of a master station, communication networks, and remote terminal units (RTUs). In power SCADA systems, all the field data are collected by RTUs, and transmit to the host computer in the control center based on some protocol through communication networks. Data acquisition at the RTU includes meter readings and equipment status reports. In the data transmission process, there will be a chance that parts of the collected data are corrupted due to noise interference. Past research indicated the processing of the noisy data at RTU is necessary in SCADA systems [1]-[2].

In the data transmission process, there are different data processing stages between field sites and the control center, including raw data acquisition, transformation, conversion, and transmission in various devices. Spikes or power surges can cause data corruption in the data transmission process, which makes the acquired data become unreliable. For data integrity, it is essential to process the raw data in the substation level before transmitting them to the host computer in the control center. How to handle the corrupted data for improving information accuracy becomes essential as it can have an impact on the system operation and can influence dispatchers during the decision-making process.

To take the data corruption issue into consideration, the converted data in the RTU needs to be processed using data processing techniques before converting back to practical engineering values in the host computer. For improving the data accuracy, in [2], the authors applied fuzzy logic theory to deal with the problem of data uncertainty. In the application of fuzzy logic theory, the selection of membership functions is a key issue, and is time-consuming by try-and-error process. As inappropriate membership functions can cause bad results. The authors in [3] applied genetic algorithms to adjust the required parameters of the membership function to improve the estimation results. However, it is not easy to obtain the optimal membership function using few sample data.

In this study, a computational approach based on general regression neural networks (GRNN) was proposed to construct a systematic fitting model for RTU noisy data processing. The proposed approach is employed to examine the analogue data collected by RTUs as a data preprocessing step to reduce errors existing in the conversion process before running the required data analysis.

The rest of the paper is organized as follows. Section II introduces the proposed GRNN model for dealing with the noisy data. Section III provides an example to verify the effectiveness of the proposed GRNN model. Conclusions are finally drawn in section IV.

II. METHODOLOGY

A. GRNN Architecture

The GRNN is a powerful regression tool proposed in [4] as an alternative neural network based learning paradigm. The network training speed of GRNN is extremely fast as it adopts a one-pass learning algorithm with a highly parallel structure. In addition, the parameter that needs to be determined in GRNN is much fewer than the widely used back-propagation neural networks (BPNN). Due to the simplicity of network structure and ease of implementation, GRNN has been applied to a variety of applications including noisy data removal [5], function approximation [6], active vibration control [7], and fault diagnosis [8].

In GRNN, each training sample is operated as a kernel during the training process. The regression surface is established by using Parzen window estimator. The estimation of GRNN is based on non-parametric regression analysis to make the best fit of the observed data. As such, GRNN does not require prior knowledge of the regression function. These

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

features are useful for obtaining a better estimation of noisy data in the problem of RTU data processing.

Assume that the underlying scalar function to be approximated is denoted as $y=f(\boldsymbol{x})$ where $\boldsymbol{x}\in R^{m}$ is an independent variable and $y\in R^{1}$ is a dependent variable. Regression in the GRNN is carried out by calculating the expected conditional mean of y given $\boldsymbol{x}$ as shown in (1). The Parzen probability density estimator $g(\boldsymbol{x},y)$ with Gaussian function defined in (2) is based on sample values $\boldsymbol{x}_i$ and y_i of the random variable $\boldsymbol{x}$ and y, where n is the number of training samples and m is the dimension of $\boldsymbol{x}$.

$$E[y \mid \boldsymbol{x}] = \frac{\int_{-\infty}^{\infty} y g(\boldsymbol{x}, y)dy}{\int_{-\infty}^{\infty} g(\boldsymbol{x}, y)dy} \tag{1}$$

$$\begin{aligned} g(\boldsymbol{x}, y) = & \frac{1}{(2\pi)^{(m+1)/2}\sigma^{(m+1)}} \\ & \cdot \frac{1}{n}\sum_{i=1}^{n} \exp[-\frac{(\boldsymbol{x}-\boldsymbol{x}_i)^T(\boldsymbol{x}-\boldsymbol{x}_i)}{2\sigma^2}] \\ & \cdot \exp[-\frac{(y-y_i)^2}{2\sigma^2}] \end{aligned} \tag{2}$$

The probability estimator $g(\boldsymbol{x},y)$ assigns the sample probability of width σ for each sample $\boldsymbol{x}_i$ and y_i, and the probability estimate is the sum of those sample probabilities. The non-negative constant σ called smoothing parameter or spread constant is the only parameter that needs to be determined in the GRNN-based approach, and is related to how much the neural network will generalize. Therefore, the performance of the GRNN is affected by the adjustment of spread constants.

When the spread constant is made large, the estimation is forced to be smooth but it does not represent the training samples very precisely. On the other hand, a small value of spread constant allows the estimation that represents the training samples very well but it has many wiggles in the fitting curve. Therefore, a tradeoff between smoothness and minimal error has to be made between precision and smoothness.

Substituting the joint probability estimator in (2) into the conditional mean in (1) yields the desired estimated value as follows,

$$\hat{y}(\boldsymbol{x}) = \frac{\sum_{i=1}^{n} y_i \exp(-\frac{D_i^2}{2\sigma^2})}{\sum_{i=1}^{n} \exp(-\frac{D_i^2}{2\sigma^2})} \tag{3}$$

where D_i is defined as

$$D_i^2 = (\boldsymbol{x}-\boldsymbol{x}_i)^T(\boldsymbol{x}-\boldsymbol{x}_i) \tag{4}$$

The distance, D_i, between the training sample and the point of estimation is used as a measure of how well each training sample can represent the position of estimation. With (3) it is possible to estimate values of the fitting function based on training samples.

B. Noisy Data Regression Using GRNNs

The use of GRNN to build a regression model for noisy data from RTUs is described in this subsection. A feed-forward neural network, as shown in Fig. 1, is used to estimate the regression variable y from a measurement vector $\boldsymbol{x}$.

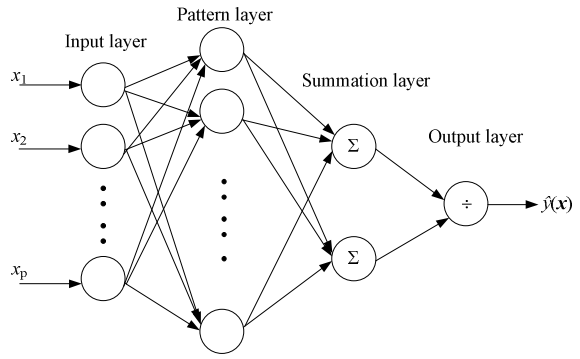

Fig. 1 Schematic diagram of the GRNN architecture.

There are four different types of layers in the structure of the GRNN model: input layer, pattern layer, summation layer, and the output layer. The input neurons in the input layer are merely distribution units, which provide all of the measurement variables to the second layer, the pattern layer. The pattern layer is a latent regression layer. Each neuron in the pattern layer is corresponding to a training sample or one cluster center. The calculations performed in each pattern neuron are the normal distribution centered at each training sample.

The summation layer performs a dot product between a weight vector and a vector composed of the signals from the pattern layer. It includes two units. One is the denominator summation unit, and the other is the numerator summation unit. The first unit adds up the weight values coming from each of the hidden neurons. The numerator summation unit adds up the weight values multiplied by the actual target value for each hidden neuron.

The output layer generates the desired estimation of y, denoted by $\hat{y}$. It divides the value accumulated in the numerator summation unit by the value in the denominator summation unit, and uses the result as the estimated value. This estimated value is an exponentially weighted average of all observed values y_i.

The training of GRNN does not need to determine the connection weights between the neurons in different layers but to adjust the spread constant to make the estimation model best fit the sample data. In other words, the generalization ability of GRNN is controlled by this spread constant. Traditionally, the value of spread constant of GRNN is usually selected by a try-and-error process. In the GRNN-GA model,

the genetic algorithm is used to optimize the spread constant of GRNN.

Genetic algorithms (GA) are population-based search algorithms based on the mechanics of natural selection and genetics. GA is able to globally exploring a solution space searching for potential solutions, and has been applied to solve many optimization problems [9]-[11].

The process of GA begins with a randomly selected population of chromosomes. Each chromosome string contains possible solution to the spread constant of GRNN. GA is used for searching an appropriate spread constant that can minimize the mean square errors between the target values and training samples. The fitness function f is defined as follows,

$$f \equiv \frac{\sum_{i=1}^{n}[y_i - \hat{y}(\boldsymbol{x}_i)]^2}{n} \tag{5}$$

where n is the number of samples.

The optimum solution can be obtained by minimizing the fitness function defined in (5). The fitness function is used to evaluate the quality of each chromosome. The lower fitness value chromosome at each searching step will be chosen to be the parent of the next generation, while the higher fitness one will be discarded. In creating the new offspring, the selected parent chromosomes will get through the reproduction process by performing GA operations, such as crossover and mutation as described in [12]. The process continues updating newer and more suitable chromosome until a predefined stopping condition is satisfied.

III. Experimental Results

The performance of the proposed GRNN model was evaluated by a set of RTU data and is described in this section. The optimal spread constant of the GRNN model is determined according to the mean square error (MSE) criterion using GA searching technique.

The program codes in this experiment are written in MATLAB language for all the simulations. The performance evaluation used in this study is the mean absolute percentage error (MAPE) in accuracy. This value is calculated by first taking the absolute deviation between the actual value y_i and the estimated value $\hat{y}_i$. Then the total ratio of deviation with its actual value is calculated. The percentage of the average of this ratio is the mean absolute percentage error. The process of calculating the MAPE is shown in (6).

$$\text{MAPE} = \frac{\sum_{i=1}^{n}(|y_i - \hat{y}_i|/y_i)}{n} \times 100\% \tag{6}$$

where n is the total number of test data.

To examine the performance of the proposed GRNN model, a comparison with an existing method was given. The test data was adopted from [3]. Suppose that a bus voltage recorded from a substation varies from 180 kV to 260 kV (nominal 220 kV with 18% variations). The voltage values are converted to the value in pulse counts, ranging from 19800 to 28600 (110 counts per kV). Table I lists the test examples and their corresponding calibrated values. In Table I, the measurands in the second column are measurements that contain errors, which are transformed to the pulse output via A/D converters in terms of counts. Actual values in the fourth column are calibrated quantities without errors.

TABLE I
Test Examples and Their Corresponding Calibrated Values

No. of samples	Measurand (kV)	Counts	Actual values (kV)
1	180	19800	180.911
2	190	20900	190.0015
3	200	22000	200.00
4	210	23100	210.0005
5	220	24200	220.00
6	230	25300	230.0005
7	240	26400	240.2563
8	250	27500	250.00
9	260	28600	259.6281

In this experiment, the parameters of GA are initialized with a population of 40 chromosomes, and the crossover probability and mutation probability are taken as 0.85 and 0.01, respectively. Fig. 2 depicts the relation between the number of iterations and the corresponding spread constants. The MSE is plotted versus the number of iterations in Fig. 3. The optimal spread constant was set at 0.6647 to leverage the smooth of fitting function and the mean square error.

The performance evaluation of the Fuzzy-GA (FGA) model proposed in [3] and the proposed GRNN model is listed in Table II. From the results, it can be seen that the performance of the proposed model outperforms that of the FGA model. These results justify the proposed approach is able to approximate the fitting function more accurate than that in [3].

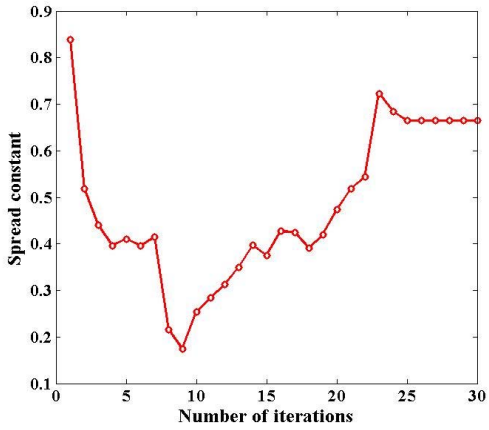

Fig. 2 The iteration-spread constant graph.

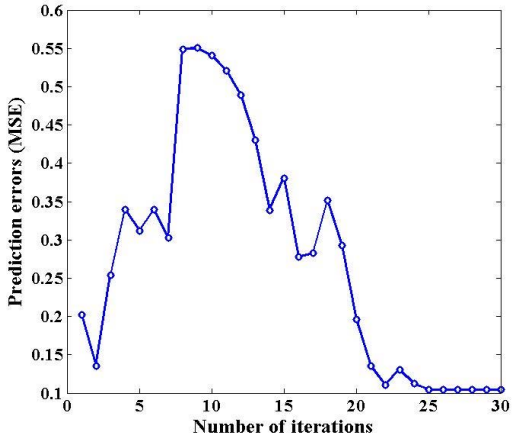

Fig. 3 The MSE-spread constant graph.

TABLE II
PERFORMANCE EVALUATION BETWEEN GRNN AND FGA MODELS

Counts	Actual value (kV)	FGA model (kV)	The proposed GRNN model (kV)
19800	180.911	181.822	182.5051
20900	190.0015	190.003	190.1614
22000	200.00	200.000	200.0015
23100	210.0005	210.001	210.0004
24200	220.00	220.000	220.0005
25300	230.0005	230.001	230.0379
26400	240.2563	240.512	240.1800
27500	250.00	250.00	249.9565
28600	259.6281	249.243	257.9410
	MAPE	0.5124	0.1868

IV. CONCLUSION

This paper has presented an efficient noisy data regression model for the RTU application using GRNN approach. The main merits of the proposed method include its simple computational framework, precision in nonlinear approximation, and fast learning speed. Although we only provide the voltage parameter for demonstration, the proposed approach can also be applied to other analogue quantities in the measurement of remote terminal units.

***Abstract*— Load modeling is a very important aspect of voltage stability analysis as load characteristics governs voltage behavior. In this paper a compact solution to extract parameters of a load model is presented, which includes estimation of power components based on Improved Recursive Newton Type Algorithm and estimation of parameters of a dynamic Load Model using Genetic Algorithms. The paper demonstrates the influence of the preprocessing of the instantaneous values on the final estimation of load parameters. All tests were carried out using 9-buses P.M.Anderson system built in DIgSILENT.**

Keywords—load modeling, parameter estimation, genetic algorithm, power components

I. INTRODUCTION

Power system loads have a significant impact on system stability. It is known that load dynamic response is one of the key elements driving the system to voltage instability or even to voltage collapse [1], so it is crucial to use appropriate load models within Voltage Stability Assessment applications. Additional difficulty related to power system loads is caused by the constantly changing demand, which means that the characteristics of loads vary in time on daily, weekly, monthly and seasonal basis. It is thus essential not only to estimate load parameters once but also to update them when unacceptable difference between model output and power system response is detected. One of two possible approaches to load modelling is the Measurement-based approach [2-5] which enables updating of load parameters whenever it is necessary by taking new measurements at substation. The method consists in comparing measured post disturbance system response versus load model output and based on that, the model's parameters are adjusted. The second method, Component-based approach [6], consists in modelling different types of loads separately, thus requires specific information about contribution of particular devices (e.g. induction motors, heating devices, lighting devices) and classes of loads (e.g. industrial, commercial, residential). Generally, it is difficult to gather all these information precisely enough to create a reliable load model, hence the Measurement-based approach was adopted in this paper.

Currently, the results of estimation of load parameters presented in the literature are mostly based on the assumption of the availability of the measurements of active and reactive power as well as voltage *RMS* value. It is well known that these values are not directly available from the measurements, but they are a product of Digital Signal Processing based on a variety of existing algorithms capable of extracting signal parameters from instantaneous values of voltage and current. It has been proven that sensitivity of different methods may influence the final result, especially when the signal's frequency deviates from its nominal value [7].

In this paper the estimation of active power, reactive power and voltage *RMS* value has been obtained by using a recursive estimation method – Improved Recursive Newton Type Algorithm (IRNTA) [8]. Then the result of this signal processing has been sent to the input of the algorithm estimating the parameters of the load model, which in this case is a widely used Artificial Intelligence (AI) method called Genetic Algorithms (GA) [2], [4] and [5]. The final result will be compared against an estimation performed on the *RMS* values obtained directly from the simulation software (the estimation of *RMS* values is not applied).

The rest of the paper is organized as follows: first the load model and the signal models are described in Section II, then both estimation methods are presented in Section III, after which the simulation results are presented in Section IV, finally conclusions are given in Section V.

II. MODELS

The first part of this Section contains a description of a dynamic load model, parameters of which are being estimated in the experiment. The second part presents an instantaneous power model developed in [7] which is used to obtain active power P and reactive power Q. This part also includes a description of a traditional sine signal model, which has been used to obtain the *RMS* voltage from the instantaneous signal.

A. Exponential Recovery Load Model

Exponential Recovery Load Model (ERLM) is a general load model and it is formulated as a mathematical description of the relationship between voltage and active/reactive power (dynamic, voltage dependent load model). Equations (1)-(4) present the model for both, active and reactive power [1], [9].

$$T_P \dot{z}_P = \left(\frac{V}{V_0}\right)^{\alpha_s} - z_P \left(\frac{V}{V_0}\right)^{\alpha_t} \tag{1}$$

$$P_d = z_P P_0 \left(\frac{V}{V_0} \right)^{\alpha_t} \tag{2}$$

$$T_Q \dot{z}_Q = \left(\frac{V}{V_0} \right)^{\beta_s} - z_Q \left(\frac{V}{V_0} \right)^{\beta_t} \tag{3}$$

$$Q_d = z_Q Q_0 \left(\frac{V}{V_0} \right)^{\beta_t} \tag{4}$$

where z_P and z_Q are the state variables, T_P and T_Q are the recovery time constants, whereas V_0, P_0 and Q_0 are the pre-disturbance voltage, active and reactive power, respectively. P_d and Q_d are the load power demands, α_s and β_s are the static exponents and α_t and β_t are the transient exponents. Vectors of unknown parameters to be estimated are as follows (5-6):

$$\theta_P = [\alpha_s, \alpha_t, T_P] \tag{5}$$

$$\theta_Q = [\beta_s, \beta_t, T_Q] \tag{6}$$

Since the load model for active power is not mathematically related to the reactive power, the unknown parameters can be grouped into two vectors and the estimation process can be performed separately (or in parallel). Maintaining the Integrity of the Specifications

B. Signal Model

Extraction of the *RMS* values (*P*, *Q* and *V*) required by the load model is crucial since its quality will directly influence the final accuracy of the estimated load model. In this paper it is not assumed that the *RMS* values are readily available, instead the instantaneous signals of voltage and current are used (7-8):

$$v(t) = V_{\mathrm{m}} \cos\left(\omega t + \varphi_v\right) \tag{7}$$

$$i(t) = I_{\mathrm{m}} \cos\left(\omega t + \varphi_i\right) \tag{8}$$

where V_m and I_m are the voltage and current magnitudes, respectively, φ_v and φ_i are voltage and current phase angles, respectively and ω is the system angular frequency.

Based on [7] the instantaneous power model is described as follows (9):

$$p(t) = v(t) \cdot i(t) = V_{\mathrm{m}} I_{\mathrm{m}} \cos\left(\omega t + \varphi_v\right) \cos\left(\omega t + \varphi_i\right) \tag{9}$$

which after some mathematical manipulations yields (10):

$$p(t) = \frac{1}{2} V_m I_m \cos\varphi + \frac{1}{2} V_m I_m \cos\left(2\omega t + \varphi\right) = \\ = P + S\cos\left(2\omega t + \varphi\right) \tag{10}$$

where P is the active power, S is the apparent power and φ is the power angle (phase difference between voltage and current).

Now IRNTA can be applied to (10) and both P and S can be directly extracted from the instantaneous power signal. Q can be simply obtained by applying the following formula (11):

$$Q = \sqrt{S^2 - P^2} \tag{11}$$

The vector of unknown parameters for the instantaneous power model consists of (12):

$$\theta_{IP} = [P, S, \omega, \varphi] \tag{12}$$

By treating ω as an unknown parameter, the model becomes insensitive to system frequency deviations, which is increasing the overall quality of the estimation [7].

Similarly, V_{RMS} can be easily obtained by applying IRNTA directly to (7) to extract V_m, which is related to V_{RMS} in the following way (13):

$$V_{RMS} = \frac{V_m}{\sqrt{2}} \tag{13}$$

and the vector of unknown parameters is defined as (14):

$$\theta_V = [V_m, \omega, \varphi_v] \tag{14}$$

Here also ω is estimated together with the amplitude, which makes this signal model insensitive to possible deviations of system frequency.

The next Section presents the estimation methods (IRNTA and GA) and explains in detail how the load model and the signal models are related in this experiment.

III. Parameter Estimation Methods

There are two optimization tasks in this experiment. The first one is related to extraction of the *RMS* values of *P*, *Q* and *V* from the instantaneous signals *v(t)* and *i(t)* and the second one is the estimation of load model parameters based on the previously extracted *RMS* values. An overall picture of this process is shown in fig. 1.

Both stages of the whole procedure can be defined as a curve fitting problem where the task is to minimize the difference between the output of the model and the 'measured' value with respect to the vector of unknown parameters, which in general can be expressed by (15).

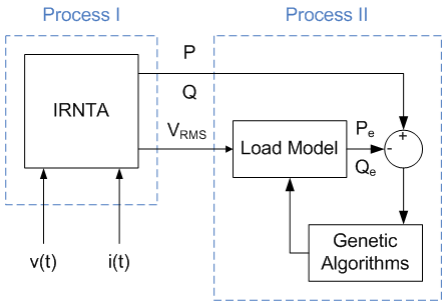

Figure 1. Block diagram of the optimization procedure

$$\min \varepsilon(\theta) = \min \frac{1}{n} \sum_{k=1}^{n} \left(y(k) - M(\theta, k) \right)^2 \tag{15}$$

where *y(k)* is the 'measurement' and $M(\theta, k)$ is the model output, θ is the vector of unknown parameters, and n is the number of samples in the data set.

In this paper IRNTA has been incorporated to extract the *RMS* values of the required signals (find optimal θ_{IP} and θ_V) and GA are used to obtain the parameters of the assumed load model (find optimal θ_P and θ_Q). Both methods are described in the following subsections.

A. *Genetic Algorithms*

GA have become popular in the estimation of load model parameters because of their ability to find a global solution. The method is based on the evolution theory and it is imitating such mechanisms as natural selection, mating of individuals in a population and mutation of genes [4]. The algorithm starts by producing an initial population of individuals, where each individual is vector of unknown parameters θ with randomly selected values. Then, so called fitness is calculated for each individual in the following way (16):

$$f = \frac{1}{\varepsilon(\theta)} \tag{16}$$

which means that fitness is simply a reciprocal of the model error formulated by (15) and this indicates the accuracy of the optimization represented by each individual in the population (the smaller the error the higher the fitness). After identifying the strongest individuals (with the highest fitness) the next generation is bred by applying one of the genetic operators called crossover. In this process the information carried by two selected individuals is exchanged to create two new individuals. The selection of individuals for the crossover is such that the individual with higher fitness have better chance to take part in the process (imitation of mating). The last stage in producing of the next generation is application of the second genetic operator – mutation. This is accomplished by introducing small random changes to randomly selected parameters contained in an individual undergoing a mutation.

The process is repeated until the maximum number of generations is reached or a satisfactory accuracy is achieved. The whole procedure is illustrated in fig. 2.

To improve the overall performance of GA the mutation level is adjusted according to achieved accuracy. At the start of the algorithm, mutations make significant changes to selected parameters contained in an individual, but when the procedure gets closer to the solution, the level of the changes is smaller. This improves the exploration of the searching space at the beginning as well as the fine tuning of the final solution.

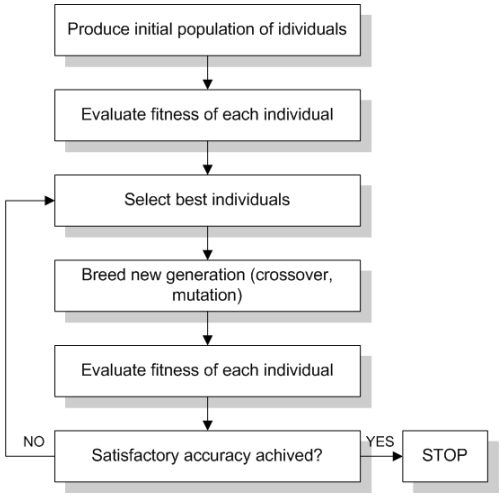

Figure 2. Block diagram of GA procedure

B. *Improved Recursive Newton Type Algorithm*

IRNTA is a recursive variation of the traditional Newton-type algorithm proposed in [8]. The method has several advantages over the classical algorithm because it can be easily applied in real-time applications and it does not require inversion of the Jacobian matrix. The method is formulated in the following way (17-18):

$$\theta_{k+1} = \theta_k + \mathbf{P}_{k+1} \mathbf{j}_{k+1} \left(y(k+1) - M\left(\theta_k, k\right) \right) \tag{17}$$

$$\mathbf{P}_{k+1} = \frac{1}{\lambda_{k+1}} \left(\mathbf{P}_k - \frac{\mathbf{P}_k \mathbf{j}_{k+1} \mathbf{j}_{k+1}^T \mathbf{P}_k}{\lambda_{k+1} + \mathbf{j}_{k+1}^T \mathbf{P}_k \mathbf{j}_{k+1}} \right) \tag{18}$$

where $\mathbf{j}_k = [j_1, j_2, \ldots, j_m]$ is the k-th row of the Jacobian matrix, λ is the forgetting factor and $\mathbf{P}$ is a matrix through which the inversion of the Jacobian matrix is carried out in a recursive way. The forgetting factor λ is a nonlinear function defined as follows (19):

$$\lambda_{k+1} = g\left(\lambda_{\min}, \lambda_{\max}, R_0, R_{k+1}\right) = \lambda_{\min} + \left(\lambda_{\max} - \lambda_{\min}\right) e^{-R_{k+1}/R_0} \tag{20}$$

where $\lambda_{\min}$, $\lambda_{1\max}$, ($\lambda_{\min} \le \lambda_{\max}$) and R_0 are the tuning parameters and R_{k+1} is the sum of absolute values of residual errors (21-22):

$$R_{k+1} = \sum_{p=k+1-L}^{k+1} |r_p| \tag{21}$$

$$r_{k+1} = y(k) - M(\theta_k) \tag{22}$$

where L is the size of the data window.

As it can be seen from (17) that at each discrete time step k the method is giving a new estimation of the unknown parameters defined in vector θ. This means that the algorithm has to start from an initial guess θ_0 provided by the user at the start of the procedure.

IV. Simulation Results

This section is divided into two parts: first the result of the estimation of the RMS values is presented, then in the second part this result is used to obtain parameters of the assumed load model. The simulation data was obtain from DIgSILENT software, where the well known 9-buses P.M.Anderson network [10] was built, and the mathematical analysis of the results were carried out in MATLAB. The simulated event was a loss of a line (causing a sudden voltage drop across the system) and the measurements (v(t) and i(t)) were taken at a bus, where a dynamic load was connected.

A. Signal Processing

Figs. 3 and 4 present the measurements of *v(t)* and *p(t)* (according to (9)), respectively. These signals were used directly to estimate P, Q and V by applying IRNTA. This result is compared against the same signals obtained directly for the simulation software (figs. 5-7).

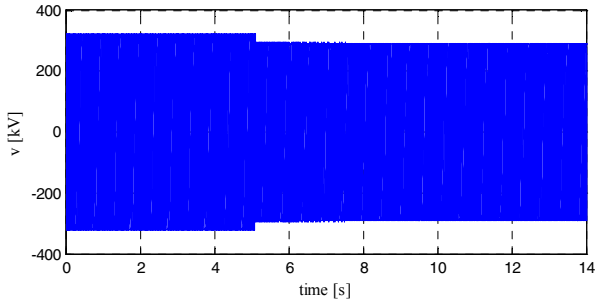

Figure 3. Instantaneous voltage

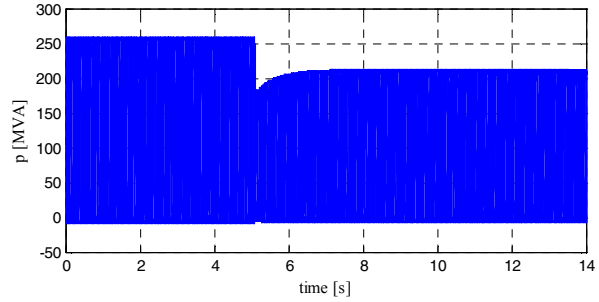

Figure 4. Instantaneous power

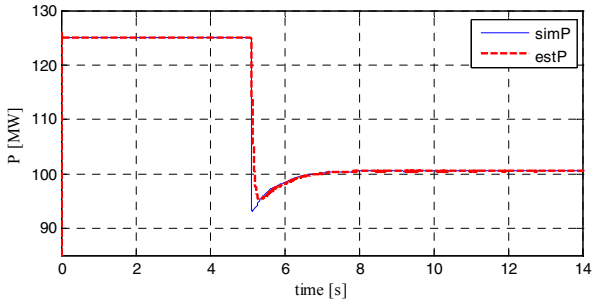

Figure 5. Simulated P versus estimated P

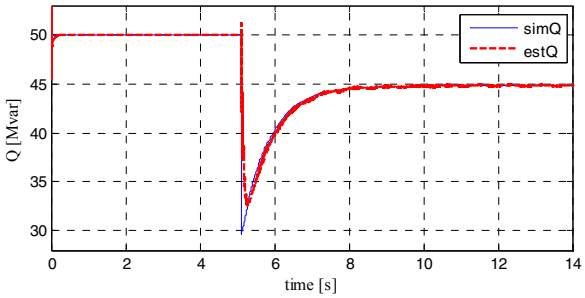

Figure 6. Simulated Q versus estimated Q

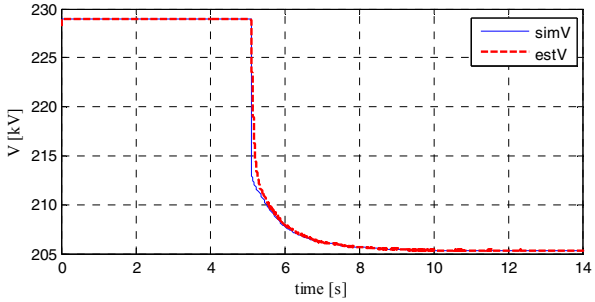

Figure 7. Simulated V versus estimated V

From figs. 5-7 it is clear IRNTA gives a very good estimation of the electrical quantities despite the frequency deviation, which occurs right after the loss of a line at t = 5s. As expected, in the steady state the method gives an error practically equal to zero and during the dynamic state the algorithm produces an error related to the convergence properties of the method, which are considerably good.

In the following subsection these results will be used to obtain parameters of the load model to investigate the influence of the dynamic error introduced during the estimation of the *RMS* values of *P*, *Q* and *V*.

B. Estimation of Load Model Parameters

In this part of the experiment the estimation has been carried out by GA. To ensure that the accuracy of the result is optimal, in each case the algorithm has been apply 10 times to obtain mean value and standard deviation of each estimated parameter.

In the first case original simulated *P*, *Q* and *V* (*simP*, *simQ* and *simV* in fig. 5, 6 and 7, respectively) has been used to

perform the estimation of unknown parameters defined in (5) and (6). The results are presented in tab. I and II and the corresponding plots are shown in fig. 8 and 9.

TABLE I. ESTIMATED PARAMETERS RELATED TO ACTIVE POWER

	α_s	α_t	T_P
mean	1.9991	4.2302	0.3426
std dev	0.0004	0.0282	0.0048

TABLE II. ESTIMATED PARAMETERS RELATED TO REACTIVE POWER

	β_s	β_t	T_Q
mean	0.9848	7.8145	0.2453
std dev	0.0019	0.0226	0.0017

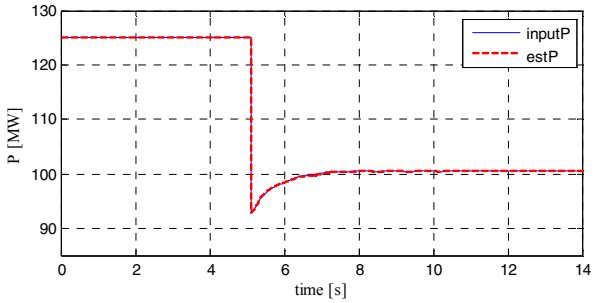

Figure 8. Load model response (active power)

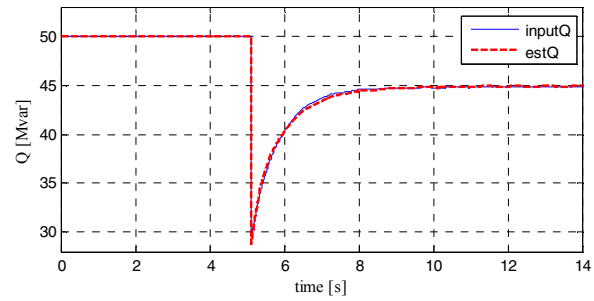

Figure 9. Load model response (reactive power)

From figs. 8 and 9 it can be noted that the quality of estimation is considerably high, which confirms that the algorithm is suitable for this task.

In the second case the parameters of the load model are obtained from the estimated *P*, *Q* and *V* (*estP*, *estQ* and *estV* in fig. 5, 6 and 7, respectively). The results are presented in tab. III and IV and in fig. 10 and 11.

TABLE III. ESTIMATED PARAMETERS RELATED TO ACTIVE POWER

	α_s	α_t	T_P
mean	1.9987	4.1774	0.3518
std dev	0.0031	0.0169	0.0041

TABLE IV. ESTIMATED PARAMETERS RELATED TO REACTIVE POWER

	β_s	β_t	T_Q
mean	0.9845	7.6615	0.2547
std dev	0.0068	0.0909	0.0051

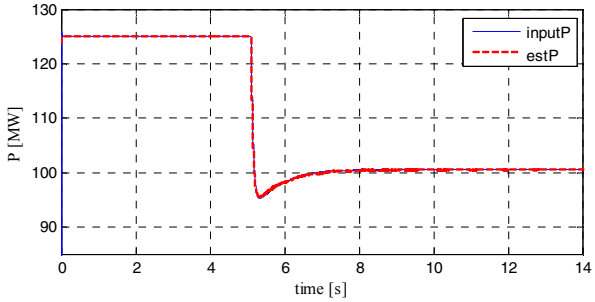

Figure 10. Load model response (active power)

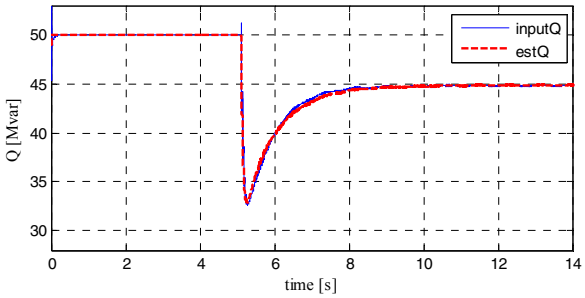

Figure 11. Load model response (reactive power)

In this case GA again confirmed its good performance in this task. By comparing the mean values of the parameters obtained in tab. I and II against the results presented in tab. III and IV, respectively, it is clear that the result is not the same in both cases. Tab. V is summarizing the differences (between mean values) expressed in percents with respect to the original results (mean values in tab. I and II).

TABLE V. DIFFERENCES BETWEEN THE ESTIMATED PARAMETERS

	α_s	α_t	T_P
diff [%]	negligible	1.2482	2.6853
	β_s	β_t	T_Q
diff [%]	negligible	1.9579	3.8320

As expected most affected are parameters governing the dynamic behavior of the model (transient exponents α_t and β_t and recovery time constants T_P and T_Q) whereas the parameters characterizing steady state behavior of the model are practically the same. This result proves that the estimation technique used to obtain the *RMS* values will introduce additional error to the final values of extracted parameters of load model. In this experiment the differences are acceptable, which means that this combination of methods can be efficient and accurate enough to be used in Measurement-based approach to load modeling.

V. CONCLUSIONS

A compact procedure for obtaining parameters of a load model based on instantaneous measurements has been proposed in this paper. The method has been tested in two stages using 9-buses P.M.Anderson test system. Firstly the quality of extracted RMS values has been presented (IRNTA), followed by the estimation of parameters of a dynamic load model performed by GA. The procedure returned considerably good results proving that the combination of both methods is suitable for this task. In the next step the algorithm should undergo extensive testing using more simulated cases and finally its performance should be tested on real data captured by recording equipment in the power system.

***Abstract*—Choquet Integral (CI), which is known as a fuzzy measure-based technique, has been a general aggregation tool for multi-criteria decision making problem. In this paper, we apply Choquet Integral to unit selection problem in Real Time Strategy (RTS) game. In addition, three new fuzzy integrals named Mean-based Fuzzy Integral (Me-based FI), Max-based Fuzzy Integral (Ma-based FI), and Order-based Fuzzy Integral (Or-based FI) are developed, which relax the monotonicity requirement of the traditional fuzzy measures and consider different properties of game play. We compare the performance of Choquet Integral and the new proposed ones on this practical application with highly non-monotonic data. Experiments show that the proposed new fuzzy integrals achieved better learning performance and testing result.**

Keywords-Real time strategy game; feature interacton; fuzzy integral; fuzzy measure; Warcraft III

I. INTRODUCTION

Sugeno [1] (1974) proposed the concepts of fuzzy measure and fuzzy integral which are working by finding the disordered means among cases. Suppose we have a dataset X, and A is a subset of it. As an extension of the probability measure, the fuzzy measure of A, expressed as $\mu(A)$, demonstrates the degree of belief or confidence of its elements. Fuzzy integrals cover a wide range of aggregation criteria and able to represent the interactions among variables. In addition, Choquet Integral is a powerful nonlinear aggregation tool. By considering non-additive set function, it has been widely used in information fusion [2] and data mining [3]. Mostly, the adopted non-additive set function is referred to as the class of fuzzy measures which are constrained by the monotonic property. Although Murofushi [4] has proved that the Choquet Integral is meaningful in the case of non-monotonic situation, there are few literatures in real application.

Real time strategy (RTS) game is a genre of computer war-games which does not process incrementally in turn. Players need to control the use of limited resource, create units and buildings, and lead their armies to attack their opponents. This kind of interactive game provides a rich environment for incremental research on human-level Artificial Intelligence (AI), especially real-time planning [6] and decision making under uncertainty [7]. The core of strategy planning is to build up the army with appropriate unit types which can gain massive destroy power against enemy's army in a short time. On the other hand, the army is taking great risk of being easily defeated by other kinds of units [16]. Thus, understand the effect of unit combination in this complicated game play design is a different problem and it already becomes one of the major challenges to game players. Furthermore, there are feature interactions existing among different unit types ranging from redundancy to synergy [17]. In this situation, the effectiveness of unit combinations cannot be simply computed by weighted average. This leads to a more difficult task of dealing with non-additive properties in game. In this paper, we try to apply fuzzy integrals in unit selection problem of RTS game.

The rest of the paper is organized as follows. In section II, we review the fuzzy measure and Choquet Integral. Section III explains our methodology of fuzzy measure learning with different integrals. Section IV compares the performance of Choquet Integral and our new developed fuzzy integrals on game problem. Finally, conclusions are drawn in Section V.

II. FUZZY MEASURE FND CHOQUET INTEGRAL

To increase the modeling ability, the original non-additive fuzzy measure is preferred. Some experiments are performed by using Sugeno-λ and K-additive fuzzy measure, but unfortunately, both of them achieved poor results with high error. One possible reason is the sense of monotonic assumption. Building a balanced army with many kinds of unit types is improper in game environment.

In this section we review the concepts of fuzzy measure and Choquet Integral. The concept of non-monotonicity and some related properties of the Choquet Integral will also be given.

A. Fuzzy Measure

Additive property is the main characteristic of classical measures. This is an effective and convenient nature, but is often too rigid in many practical applications. Fuzzy Measure extends the application area by replacing the additive property with weaker condition as monotonicity.

Definition 1: A fuzzy measure on a measurable space (X, F) is a real-valued set function $\mu : F \to (-\infty, +\infty)$ satisfying:

(MM1) $\mu(\phi) = 0$,

(MM2) $\mu(A) \geq \mu(B)$ whenever $A \in F$, $B \in F$, $A \subseteq B$.

In case of emphasizing the monotonicity, we can also call it a monotonic fuzzy measure [4].

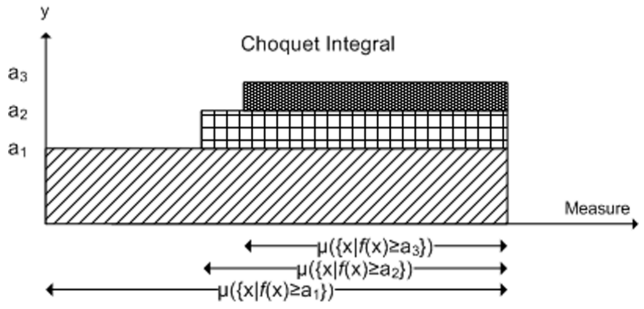

Figure 1. Choquet integral. μ is the fuzzy measure of function *f(x)*

Definition 2: A non-monotonic fuzzy measure on (X, F) is a real-valued set function $\mu : F \to (-\infty, +\infty)$ satisfying $\mu(\phi) = 0$.

B. Choquet Integral

Choquet Integral (Figure 1), as a classical fuzzy measure and an expansion of Lebesgue Integral, is defined by *Definition3*. Over decades, it has gained considerable attention and success in multi-criteria decision making and data mining.

Definition 3: Suppose a fuzzy measure μ on X. The discrete Choquet integral of a function $f : X \to \mathbb{R}^+$ can be written as:

$$(c)\int f(x) \circ \mu(X) = \sum_{i=1}^{n} [f(x_i) - f(x_{i-1})] \cdot \mu\{[x \mid f(x) \geq f(x_i)]\} \qquad (1)$$

Where x_i is permutation on X and $f(x_0) = 0$.

Choquet Integral has the following 3 basic properties:

1) $(c)\int 1_A d\mu = \mu(A)$

2) If $f < g$ then $(c)\int f d\mu \leq (c)\int g d\mu$

3) If a is non-negative real number and b is a real number, then

$$(c)\int (af + b) d\mu = a(c)\int f d\mu + b\mu(X)$$

As Murofushi introduced in [4], non-monotonic measure occurs when resources are limited. The basic properties of the Choquet integral are still useful for a non-monotonic fuzzy measure. RTS game provides a very similar environment with limited time and resource. If player wastes his resource in developing overmuch types of unit, the enemy will get opportunities to destroy his resources.

III. Proposed Methodology

RTS game provides a complicated environment which consists hundreds of buildings and units with different properties [5]. The various characters lead to various combinations. Even the most expensive and powerful units can be easily defeated by cheap units. In this setting, pro-gamer prefers to develop an unbalanced army with only several unit types [15]. Different combination performs different destroy power to certain kinds of unit types and buildings. Furthermore, the combinations are usually affected by a third dependent variable. By tracing the players' historical action, we find that there are substantial feature interactions among units. For example, melee unit often cooperates with magic and rang unit. With this positive interaction, the model is considered as super additive, i.e., $f(x+y) \geq f(x)+f(y)$. When the interaction is negative, the model is considered as sub additive, i.e., $f(x+y) \leq f(x)+f(y)$.

Quantitative interactions among groups of data can be detected by Analysis of Variance (ANOVA) test [8]. If the calculated p-value is smaller than a certain level (usually 5%), we can acquire a strong confidence to confirm that there are interactions among these testing variables. In this section, we describe how to learning fuzzy measure with different integrals for RTS game.

A. Strategy Definition in RTS Games

Strategy is defined as arranging the army with appropriate unit selection which can gain massive destroy power against enemy's unit. The knowledge was extracted from replay file which is provided by game system of Warcraft III. Each replay file consists of sequential records of players' actions which are designed for reviewing the game battle. We develop a C# program to decrypt and extract the features from replay file. Each battle represents a strategy case and has been divided into three parts as goal, situation, and scores.

Strategy Case = {Goal, Situation, Scores}

"Goal" is the creation of a suitable army mixed with certain proportion, e.g., 10% peasants, 50% footman and 40% rifleman.

"Situation" is used to describe what circumstances the player is dealing with. In this paper we define it as enemy's unit combination. Cases will be clustered into different groups with different races and unit combinations.

"Score" is the point obtained from each battle. It can be regarded as the outcome evaluation for each in-game player. Higher performance will represent better unit combination. We use these scores in learning the fuzzy measure.

B. Learning Fuzzy Measure by GA

Genetic Algorithm (GA) is a stochastic search technique with a parallel random search mechanism which aims to achieve a global minimum on error space. We use it to learn the non-additive fuzzy measure in our application problem [9][10]. The flowchart is shown as in Figure 2.

In Warcraft III, each player will get several scores in each battle as the performance evaluation. The higher score denotes the higher chance of winning. We define our score, i.e., *Score* as the differences between player and enemy.

$$Score(x) = Score_{WarcrafIII,\,player} - Score_{WarcrafIII,\,enemy} \qquad (2)$$

Fuzzy integrals are used to calculate the estimated scores which combine unit production statistic (i.e, *f(x)*) and non-monotonic fuzzy measure. Each fuzzy measure *μ(x)* describes

an interaction of the corresponding unit combination. The *Score(x)* wil be normalized between 0 to 1 and compare with the estimated score.

$$Score_{Different}(x) = \left| Score_{Estimate}[f(x)] - Score(x) \right| \qquad (3)$$

Our fitness function is designed to obtain the average differences between real scores and estimated scores in all the training replays. We apply Wang's fitness function as shown in (5).

$$\text{Fitness value} = -\frac{1}{1+e} \text{ where } e = \left(\frac{1}{N}\sum_{i=1}^{N} score_{Different}^{2}(i)\right)^{\frac{1}{2}} \qquad (4)$$

In our GA algorithm, each chromosome consists 2^{n-1} fuzzy measures of $\mu(X)$ including the entire unit combinations i.e.: $\mu(x_1)$, $\mu(x_2)$, ..., $\mu(x_1, x_2)$, ..., $\mu(x_1, x_2, ..., x_n)$. x_1, x_2, ..., x_n represent n kinds of unit types. Each fuzzy measure is first corrected to seven decimal places and then converted into binary form. A number of chromosomes will be initialized randomly at first. The learning process is repeated until the fitness value is stable or exceeds the maximum generation. After that, a reasonable fuzzy measure $\mu(X)$ for training replays is obtained. Population is set as 50, maximum generation is set as 100 and mutation rate is set as 0.01.The detail of the learning process are introduced in [11] [12].

C. Different Fuzzy Integrals

As seen from Figure 2, we define the function $f(x)$ which represents a player unit statistic of one replay:

$$f(x) = f(\text{Unit Statistic}_{\text{Replay i, Player}}).$$

All the unit statistics are normalized and presented by proportion. E.g.: 4 footmen, 6 riflemen and 10 priests will be normalized into $f(x_1)=0.2$, $f(x_2)=0.3$ and $f(x_3)=0.5$ respectively. This definition is useful in all the fuzzy integrals proposed in this paper.

We use Choquet Integral to calculate the estimated score as an example. Suppose there are 7 unit types, i.e.: n=7 and the unit statistic of a replay is $f(X)=\{x_1=0.2, x_2=0.4, x_3=0, x_4=0.3, x_5=0, x_6=0.1, x_7=0\}$. Then, ascending order sorting is performed with respect to the proportion, i.e.: $a_1= x_3=0$, $a_2= x_5=0$, $a_3= x_7=0$, $a_4= x_6=0.1$, $a_5= x_1=0.2$, $a_6= x_4=0.3$, $a_7= x_2=0.4$ where $a_1 \le a_2 \le ... \le a_7$. Given a fuzzy measure as $\mu(X)=\{ ..., \mu(x_6)=0.4, \mu(x_4, x_6)=0.7, \mu(x_1, x_4, x_6)=0.8, \mu(x_1, x_2, x_4, x_6)=0.2, ...\}$, the estimated score is computed by:

$$(c)\int f(x) \circ \mu(X)$$

$$= \sum_{i=1}^{7} (a_i - a_{i-1}) \cdot \mu(\{x \mid f(x) \ge a_i\})$$

$$= ((a_1 - a_0) \cdot \mu(x \mid f(x) \ge a_1)) + ((a_2 - a_1) \cdot \mu(x \mid f(x) \ge a_2)) + ...$$

$$= 0 + ((a_4 - a_3) \cdot \mu(x \mid f(x) \ge a_4)) + ((a_5 - a_4) \cdot \mu(x \mid f(x) \ge a_5)) + ...$$

$$= 0.1 \cdot \mu(x_1, x_2, x_4, x_6) + 0.1 \cdot \mu(x_1, x_4, x_6) + 0.1 \cdot \mu(x_4, x_6) + 0.1 \cdot \mu(x_6)$$

$$= 0.1 \times 0.2 + 0.1 \times 0.8 + 0.1 \times 0.7 + 0.1 \times 0.4$$

$$= 0.21$$

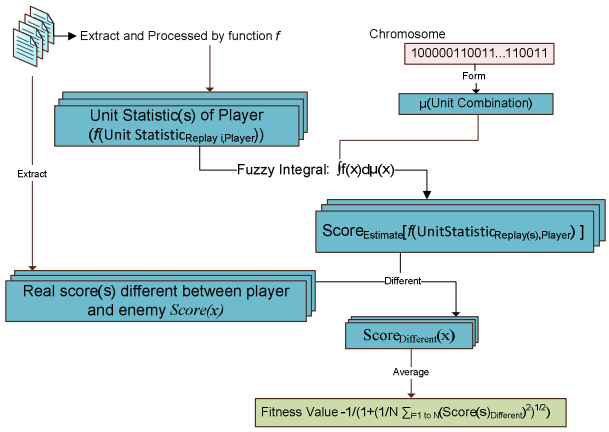

Figure 2. Fitness calculation of one chrommosom

Choquet integral is proved to work in our non-monotonic situation. Unfortunately, according to its fuzzy measure selection, the unit with least production has interaction with all the other units (i.e., basic unit) and the units with most production (i.e., powerful unit) have no interaction with others. This selection cannot well support the Warcraft III game play design. Thus, we develop three new fuzzy integrals based on different considerations. They are named as Max-based Fuzzy Integral (Ma-based FI), Mean-based Fuzzy Integral (Me-based FI) and Order-based Fuzzy Integral (Or-based FI).

1) Max-based Fuzzy Integral

Definition 4: Suppose a fuzzy measure μ on X. The Max-based Fuzzy Integral of a function $f: X \to \mathbb{R}^+$ can be written as:

$$(M)\int f(x) \circ \mu(X) = \sum_{i=1}^{n} x_i \times \max(\mu(S_i)) \qquad (5)$$

Where $x_i \in S_i$ and $\forall x \in S_i, x \neq 0$

Ma-based FI is developed with the thinking of winner takes all. We just consider the most powerful unit combinations which involve the current unit. This setting may lead the fuzzy measure learning process focuses on the important options.

2) Mean-based Fuzzy Integral

Definition 5: Suppose a fuzzy measure μ on X. The Max-based Fuzzy Integral of a function $f: X \to \mathbb{R}^+$ can be written as:

$$(m)\int f(x) \circ \mu(X) = \sum_{i=1}^{n} x_i \times \left(\frac{1}{m_i}\sum_{j=1}^{m_i} \mu(S_{ij})\right) \qquad (6)$$

Where $x_i \in S_{ij}$ and $\forall x \in S_{ij}, x \neq 0$, n is number of unit type, m is the number of set which include x_i

Me-based FI is developed to release the problem of interactions selection. All the fuzzy measures which involve the current unit type will be selected and an average is computed.

3) Order-based Fuzzy Integral

Players may need to develop technology and buildings to unlock advanced unit where the resource weighting in advanced unit is higher and more powerful. According to some data analysis, we found that advanced unit usually dominates the proportion of unit statistic. We infer that most players focus on building their army with advanced units. The advanced units should be considered as having more cooperation with other units. Thus, the largest *f(x)* is combined with the fuzzy measure with most of the units, and the unit type with least production is considered as having no interaction with others.

As Figure.3 shows, players will create labor at the very beginning to exploit resource. Then some basic units will be created for attack or defense. Through some development on building and technology, different kinds of advanced unit are unlocked. Constrained by resource, player will concentrate on certain unit types to build up his army. Proportion of unit combination will also be dominated by the selected unit types in order to maximize the destroy power.

Or-based FI is developed by consider the unit production sequence. Each unit type calculates the interaction with the one who has less production than it. The definition of Or-based FI is shown as follows.

Definition 6: Suppose a fuzzy measure μ on X. The Or-based Fuzzy Integral of a function $f: X \to \mathbb{R}^+$ can be written as

$$(o)\int f(x) \circ \mu(X) = \sum_{i=1}^{n} a_i \cdot \mu(x \mid 0 < f(x) \le a_i) \qquad (7)$$

Where $a_1 \ge \ldots \ge a_{n-1} \ge a_n > 0$

Different from CI, descending order sorting is performed among unit types in Or-based FI. Adopting the same example used in CI, the estimated score is computed as follows.

$$(\mathrm{r})\int f(x) \circ \mu(X)$$

$$= \sum_{i=1}^{4} (a_i) \cdot \mu(\{x \mid 0 < f(x) \le a_i\})$$

$$= a_1(\mu(a_1, a_2, a_3, \ldots, a_7)) + a_2(\mu(a_2, a_3, \ldots, a_7)) + \ldots + a_4(\mu(a_7))$$

$$= x_2(\mu(x_1, x_2, x_4, x_6)) + x_4(\mu(x_1, x_4, x_6)) + x_1(\mu(x_1, x_6)) + x_6(\mu(x_6))$$

$$= 0.4 \times 0.2 + 0.3 \times 0.8 + 0.2 \times 0.7 + 0.1 \times 0.4$$

$$= 0.5$$

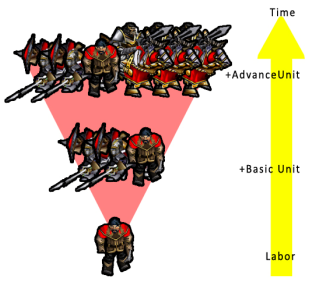

Figure 3. Unit production sequence in Warcraft III

4) Set Selection for Different Fuzzy Integrals

The main difference of these four fuzzy integrals is the set selection. Each *f(x)* will select different fuzzy sets for different fuzzy integrals. According to Wang's [13], the fuzzy measure selection function could be generated by the following equations.

$$K_i = \left\{ k : \frac{i}{2^k} - \left\lfloor \frac{i}{2^k} \right\rfloor \ge 0.5, 1 \le k \le n \right\}$$

$$\overline{K_i} = \{1, 2, \cdots, n\} - K_i$$

where i=1,2,…,2^n-1 and k=1,2,…,n, n is the number of feature $\lfloor a \rfloor$ denotes the integer part for a non-negative number a.

Let δ_i be the set selection operator as defined in (8). Equation (9)-(12) expresses the fuzzy measure selection for different fuzzy integrals: Choquet Integral (10), Or-based- FI (11), Me-based FI (12), and Ma-based FI (13).

$$\delta_i = \max(\min_{k \in K_i} f_k - \max_{k \in \overline{K_i}} f_k, 0) \qquad (8)$$

$$\delta_i = \begin{cases} \min_{k \in K_i} f_k - \max_{k \in \overline{K_i}} f_k, & \min_{k \in K_i} f_k > \max_{k \in \overline{K_i}} f_k \\ 0, & \min_{k \in K_i} f_k \le \max_{k \in \overline{K_i}} f_k \end{cases} \qquad (9)$$

Assume $\min_{k \in \phi} f_k = \max_{k \in \phi} f_k = 0$

$$\delta_i = \begin{cases} \max_{k \in K_i} f_k, & \max_{k \in K_i} f_k < \min_{k \in \overline{K_i}} f_k \\ 0, & \max_{k \in K_i} f_k \ge \min_{k \in \overline{K_i}} f_k \end{cases} \qquad (10)$$

$$\delta_i = \operatorname{avg}_{k \in K_i} f_k \qquad (11)$$

$$\delta_i = \max_{k \in K_i} f_k \qquad (12)$$

The sorting order makes Choquet Integral cannot directly calculate the maximum value. But this mechanism can be applied into Or-based FI. The selected maximum value is then combined with the corresponding unit statistic to calculate the estimated score. The set selection will not involve the assumption of $\min_{k \in \phi} f_k = \max_{k \in \phi} f_k = 0$, while empty set property of $\min_{k \in \phi} f_k = \infty$ is available.

IV. EXPERIMENT

A. Data Collection and Preprocessing

We selected Warcraft III as our research platform. It is a famous RTS game released in 2003 with the award of "Game of the Year" from more than six game publications. It has been sold over 7 million copies and there are concurrently over 200,000 players playing 6,000 battles online.

2,649 replay files of professional one-versus-one competitions from the internet are collected. They consist of two parts of data as shown in TABLE I. The header contains

some demographic data and the other part is composed of different action blocks. Each block is encrypted and stored players' actions in every 250 milliseconds' interval. A detailed example of replay file is shown in TABLE II.

The C# program exacts three kinds of data from these replays: (i) player unit production statistics, (ii) enemy unit type, and (iii) performance scores. Five data sets, as described in TABLE III, with largest amount of cases are prepared for our research. Each data set consist the cases of one race encountering its enemies which have a certain unit combination. Beside two less attended unit types, Figure 4 shows that the unit production follows a normal distribution.

TABLE I. DATA IN WARCRAFT III PEPLAY

	Element
Header	Player Record, Game Name, Map Settings, Map Record, Map & Creator Name, Player Count, Game Type, Language ID, Player List, Game Start Record, Slot Record, Random Seed,
Actions Block	Player ID, Action ID, Action Arguments

TABLE II. SAMPLE OF WARCRAFT III REPLAY

Time	Action
00:00:02:002	Player 1 train 1 Peasant
00:00:02:253	Player 1 select 5 [Peasant]
00:00:02:503	Player 1 Right Click with 0x58a8 at(7296,2432)
00:00:15:241	Player 2 build Altar of Darkness at(-1376,6240)

Player 1 produces 1 Peasants, then select 5 Peasants and move to (X: 7296, Y: 2432). Player 2 builds Altar of Darkness at(X: -1376, Y: 6240)

TABLE III. NATURE OF TESTING DATA SET

Data Set	1	2	3	4	5
Player race Enemy unit	Undead Fm, P	Undead Dr, Fm, P	Orc Pr, So, Sb, P	Orc Fm, P	Elf Fm, P

B. *Experimental Comparison of Different Fuzzy Integrals*

In this part, we compare the performance of the four related fuzzy integrals. All the simulations are performed in MATLAB. The machine used is an Intel premium 4 2. 3GHZ with 2GB Ram PC. 70% cases in each dataset are used for training and the rest 30% are for testing.

Classical weight average (WA) method is also considered since we want to survey whether considering interaction can attain better result in our Warcraft III game data. The setting is similar as Yeung's [14] approach. Each unit type is given a weighting w and the unit combination power is calculated as the summation of the corresponding unit type's weighting. The learning process applies genetic algorithm with the same parameters settings as described in section 4.

$$f(X) = \frac{1}{n}\sum_{i=1}^{n} w_i x_i \tag{13}$$

Error is computed as the absolute difference between the estimated score (calculated by fuzzy integrals) and the real

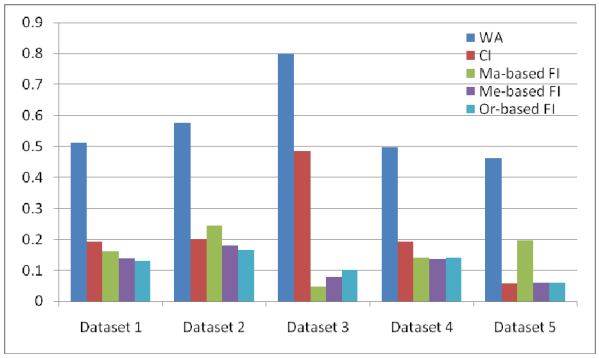

Figure 5. Training error in different Fuzzy Integral

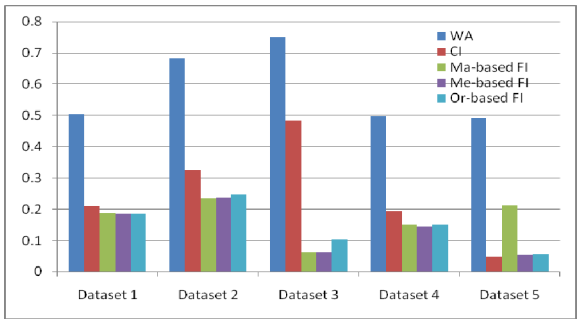

Figure 6. Testing error in different Fuzzy Integral

score from the game system. Training error, testing error and training time of our new fuzzy integrals compared with CI are summarized in TABLE IV-VI, figure 5, and figure 6.

From the experiment result, we provide the following conclusion:

1) Compared with weighted average, fuzzy integrals show an improvement in all the five datasets. Therefore, we believe that non-additive set function has a better representation than weighted average in predicting the power of unit combination.

2) Compared with Choquet Integral, all three new developed fuzzy integrals present better result in both training and testing. Me-based FI has a best performance with the average error of 0.128. Demonstrated by the result of dataset 3, the new fuzzy integrals are more effective if the dataset consists of various combinations. While Choquet Integral has a poor performance in this case.

3) The main weakness of Me-based FI and Ma-based FI is time consuming. Each time for set selection, they need to search for the whole fuzzy set. According table VI, we can observe that both of their training time is about 40 to 180 times more that Choquet Integral.

4) Jointly considering the training time and testing error, Or-based FI shows a best performance among these four methods. It has the similar training time with Choquet Integral with directly addressing the required set. Its training and testing error are similar with Me-based FI, and only 0.005 higher in average. We deem that Or-based FI is more appropriate in interaction detecting on Wacraft III data.

C. *Usage Count of Set in Different Fuzzy Integrals*

We tried to examine the difference of set selection in these four fuzzy integrals. All the selected fuzzy measures in the training process are being recorded and clustered with different amount of elements. As shown in table VIII, the selection of Or-based FI concentrates on the fuzzy measure with two to four elements. The count of selected set with more than five elements is dropped sharply. This phenomenon can be explained as: professional players seldom develop a balance army with many unit types. They usually focus on two to four unit types' cooperation. And this behavior make insufficient or even no data contribute to train up the fuzzy measures with big number of elements.

Or-based FI selects the same amount of fuzzy measures with Choquet Integral, but different selecting result. As show in TABLE II, figure 7 and figure 8, we investigated that Or-based FI concentrates on fewer sets than Choquet Integral. Some fuzzy measures which represent the frequently used unit combination will have a higher chance to be selected by Or-based FI.

We analyze the set selection condition containing different number of elements. According to table VIII， the value of fuzzy sets with less than two elements is concentrating on two unit types which are necessary for each player to create primary. Then the fuzzy measure value concentrates on {1,2,3}, {1,2,4}, {1,2,6} with three elements and {1,2,3,6}, {1,2,6,7} with four elements. Obviously, it shows several different unit production sequences with different advanced units selection. Moreover, because the selection is based on unit production sequence, the battle with longer time which creates more unit types will not be affected by the shorter battle with less unit types. This also avoids the effect of unsuccessful strategy like player being defeated in the early stage and fails to produce the advanced units.

The table also shows that the advanced unit cannot produce alone in a battle. This is because every advanced unit requires additional resource and technology support. In another word, creating the advanced unit requires the contribution of basic unit. The advanced unit should dominate the army and cooperate with other units.

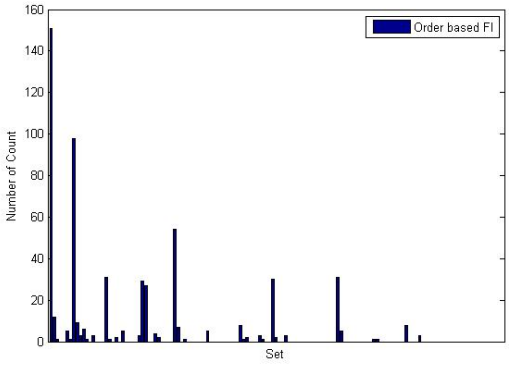

Figure 7. Count of Set selection for Order-based FI in Data cluster 1. X-axis is the set. Statring from the left, they are the set which only contains one element, i.e. , $\{x_2\}$, $\{x_3\}$…etc. Then they are the sets which contain more elements, i.e., $\{x_1, x_2\}$, $\{x_1, x_3\}$,…, $\{x_1, x_2, x_3\}$, etc. The last one on the right is the set which involves the whole set of elements. i.e., $\{x_1, x_{2,\ldots,} x_n\}$

V. CONCLUSION

In this paper, we apply different fuzzy integrals in predicting the power of unit combination in Warcraft III data. We found that weighted average cannot achieve an acceptable predicting accuracy. Since feature interaction exists in game data, non-additive method achieves better result. Furthermore, three new fuzzy integrals are developed with different directions to explain the game play. All of them attain a better result than the traditional Choquet Integral. Through the analysis of set selection, we have the evidence of why our methods got a better performance. We deem that for our data, Or-based FI has a better explanation of feature interaction in unit combination by considering the unit production sequence. Our future work regarding this topic includes new fuzzy application in micro-management. We attempt to generate corresponding unit movement to perform the selected strategy and finally lead the AI bots achieve the winning.

Abstract— **Unit formation planning and target of attack is the core of micro management in real time strategy (RTS) game. It is more complicated than macro management, such as building and unit production sequence. It consists of a great quantity of possibility. Multiple targets and the non-additive property of unit formation leads the micro-management remains a problem. Traditional tree searching or A* searching is unable to handle these two properties. They are time consuming in runtime and difficult to manage in the AI programming development as there are too many weightings and each of them will interact with the others. In this paper, we applied potential field, fuzzy measure and integral to solve the micro-management. Potential field is suitable for complicated and various environment with multiple targets. However, it does not consider non-additive property. We integrated it with fuzzy measure and integral to extend simple additive property to non-additive property and provide the ability to handle interaction among different targets.**

Keywords-component; Fuzzy Measure, Fuzzy Integral, Potential Field, Real time Strategy Game, unit formation planning, Micro-management, Warcraft III

I. INTRODUCTION

Nowadays, RTS game consists of complicated game rule, hundreds of unit type, various battlefields and decision making under the time pressure. More and more researchers such as Buro [1], Lucas [2], Alexander [3] are interested in it and have recently generated much important outputs in both macro and micro management for the RTS game AI community. RTS game provides a fruitful environment for AI research.

The fundamental game play of a typical RTS game is allocating resources to build an army, design units' combination and defeat the enemy by killing the opponent units. Control of RTS game can be classified into two types. The first type is macro management which is also named game strategy. It involves resource gathering, base building and technology upgrade. The second type is micro management, i.e., tactics, involves planning of the unit movement and control. For the marco-management, many researchers have applied case based reasoning CBR to solve it. CBR is potentially a very useful approach in game AI strategy planning and design. Usually, cases can be collected, learned from real game data or constructed using simulation [4], such as ORTS, MadRTS, Wargus, etc. These cases can be reused according to some similarity and effectiveness measures. However, if cases are continuously accumulated, the time to retrieve solutions will be too long in RTS games. Fast indexing methods is needed such as Peter [5] and Puo [6] approaches. In our previous research [7][8], we also applied CBR concept and combined with fuzzy measure and integral to solve macro management, i.e., the unit production planning problem by considering the non-additive property of different unit combination. In this research, we extended the usage of trained fuzzy measure and applied to the micro management. We combined the potential field and fuzzy integral to solve the unit formation and target of attack planning. The methodology extended the normal additive property of potential field to non-additive property and provided the ability to handle the interaction among different targets. We simulated our experiment in Warcraft III. Details step and experimental result are shown in this paper.

II. LITERATURE REVIEW

A. Fuzzy Measure and Integral

Unit formation planning involves unit combinations selection. The unit combination are enormous in RTS game and the combined power of different units is usually "non-linear", i.e., the sum is not simply the total of the individuals [9] and is not additive. Let $X = \{x_1, x_2 ... x_n\}$ be the unit combination where n is the total number of unit types and f be the combined power. We believe that there exists non-additive property, i.e., $f(X) \neq \sum_{i=1}^{n} f(x_i)$. Formally speaking, when the interaction is positive, $f(X)$ is considered as super additive, i.e., $f(X) \geq \sum_{i=1}^{n} f(x_i)$, for all x in the domain of f. This could be easily found in many RTS game designs, such as the melee unit should be supported by magic or range unit. When the interaction is negative, the model is considered as sub additive, i.e., $f(X) \leq \sum_{i=1}^{n} f(x_i)$. If the interaction is

zero, then it will be considered as normal additive model, i.e., $f(X) = \sum_{i=1}^{n} f(x_i)$.

As the non additive properties in unit combination, weighted average and weighted A* searching cannot give a good result in our experiment, we need to find a solution to indicate the interaction. Therefore, the combined power of units can be evaluated. We applied fuzzy measure and integral and the basic idea is illustrated in Fig. 1. All the units, and their possible combinations are assigned with (i.e., learnt from data) some fuzzy measures, μ , and an overall assessment is computed using fuzzy integral. Then, the case's assessment can be computed by referring to known fuzzy measures, and the fuzzy integral. The final strategy selected can be based on these assessments.

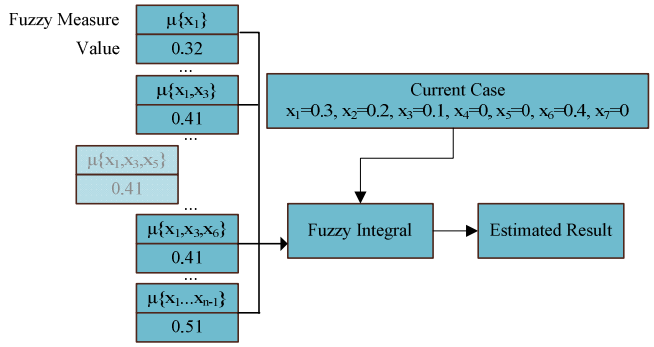

Fig.1. Apply Fuzzy Measure and Integral on Regression

Non additive fuzzy measure is used in our experiment. Non additive fuzzy measure is the original one and can be considered as the basic form of fuzzy measure [10]. It can be regarded as generalization of the classical probability measure. A value is assigned to each combination of variables, i.e., for n variables, there are $2^n - 1$ measures.

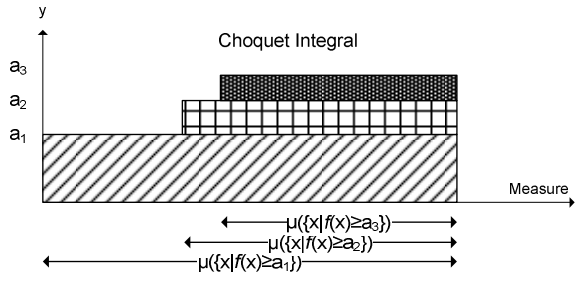

Fig.2. Choquet Integral. μ is the fuzzy measure of a function $f(x)$

$$(c)\int f(x) \circ \mu(X) = \sum_{i=1}^{n} (a_i - a_{i-1}) \cdot \mu(x \mid f(x) \geq a_i) \quad (1)$$

where $a_0 = 0$ and $a_0 \leq a_1 \leq a_2 \leq \ldots a_n$

Choquet Integral (CI) is a kind of fuzzy integral. It has been a general tool for dealing with multiple criteria decision making and is able to model the interactions among different criteria. Sugeno [11] [12] has applied it to the problem of prediction of wooden strength and plant operator. Both of them show a better result than a linear regression. Peter [13] has applied CI in software cost estimation with multiple attribute. Suppose a fuzzy measure $\mu : P(X \rightarrow [0,1])$ and $\mu(\phi) = 0$, definition of CI, see Fig. 2, is shown as follows and a_i is the sorted sequence of x_i

B. *Potential Field*

Potential Field is designed for searching the next movement location in multiple goals and various environments under the time pressure. The classic potential field consists of two virtual forces. One is attractive potential force, $U_{att}(q) = \frac{1}{2}\xi p_g^2$, where ξ is a positive constant scaling factor and $p_g = \|q - q_g\|$ is the Euclidean between the object and the goal. Another force is repulsive potential force, $U_{rep}(q) = \frac{1}{2}\eta(\frac{1}{p(q)} - \frac{1}{p_0})^2$ where η is a positive constant scaling factor, $p(q)$ is the minimum distance from the object to the obstacle and p_0 is a positive constant that presents the influence distance of the obstacles.

Multi-agents Potential Fields of Hagelback [14] [15] and Johan [16] showed the importance to micro management and tactics development. Their experiment result had been proven in events such as Open Real Time Strategy (ORTS) AI competitions which have been held for many years provide a good platform for players to test out their control tactics. They showed a possible solution on micro management in RTS game. Potential field is normal additive. Therefore, it may not have the ability to handle interaction among different goals, especially the sub additive problem, i.e., $f(X) \leq \sum_{i=1}^{n} f(x_i)$.

III. METHODOLOGY

A. *Obtain the Fuzzy Measure from real game data*

Case = {Unit Combination, Situation, Scores}

In our previous research, we try to create a method to evaluate the power of unit combination for macro-management planning, i.e., building sequence and unit production planning [7][8]. A set of fuzzy measure is learnt from real game data. We will briefly explain the flow in this session. A set of game logs which is the replay data of Warcraft III is collected. We converted each replay data, i.e.,

each battle into one case as shown above and divided it into three parts. They are unit combination, situation and scores.

We define the "Unit Combination" of a case as the creation of player and enemy unit production, e.g., player created 10% peasants, 50% footman, 40% rifleman and the enemy created 30% peasants, 70% footman.

"Situation" is used to describe some common circumstances the player is dealing with. For example, if a player faces similar conditions, races, enemy units, etc, we can still think that the player is dealing with similar "situation" or he is under certain typical circumstances. The purpose is to help cluster cases into several similar groups. Depending on the number of training data and game play design, other information, such as map or starting location, could also be selected as the cluster criterion.

Finally, "Score" is the points obtained after the game. It is used for evaluating the outcome of the Warcraft III battle, and is used to guide the training of fuzzy measure, i.e., we can interpret as the higher the scores the more powerful unit combination.

Ontanon [17] [18] and Sharma [19] applied similar approach to index the player action. They used building or architectures as an index to organize the game actions. In our study, we try to use the possible unit that can be produced by player as an index. Game actions are much simplified for the purpose of reducing the complexity of each case description.

After the preprocessing of the game data, we use Genetic Algorithm (GA) to obtain the non additive fuzzy measure [20] [21], i.e., $\mu(X)$ or $\mu(\text{Unit Combination})$, for calculating unit combinations and its' interactions as Fig. 3.

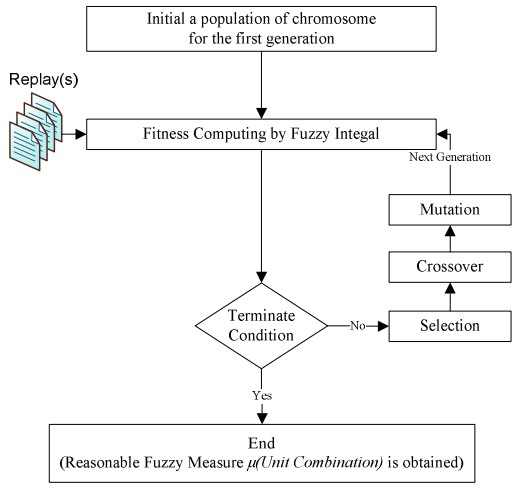

Fig.3. Overview of GA to obtain the Fuzzy Measure

First, a number of chromosomes are generated randomly. Each chromosome represents a fuzzy measure. It is combined by $2^n - 1$ fuzzy measure of $\mu(X)$, where $X = \{x_1, x_2 \ldots x_n\}$ is the unit combination and n is total number of unit type. $\mu(X)$ involves $\mu(x_1)$, $\mu(x_2)$, ..., $\mu(x_1, x_2)$, ..., $\mu(x_1, x_2, ..., x_n)$, each of them represents the fuzzy measure of the unit type sub-set. They are corrected to seven decimal places. Then they are converted into binary form and combined into one chromosome. Population of each generation is set to 50 in our experiment. To simplify the fuzzy measure, the unit types that are not produced in all the replays within the same cluster are not considered.

Each chromosome represents a fuzzy measure. Unit combination in each replay will be extracted and processed by function f. $f(x)$ presents the power of unit combination where x represents a unit combination of a replay, i.e., $f(x) = f(\text{Unit Combination}_{\text{Replay i, Player}})$. Throughout the function f, all the unit productions of player and enemy in the battle (i.e., unit(s) of unit type 1… unit(s) of unit type n) are normalized separately and presented in proportion. We used Choquet Integral (CI) in our experiment to calculate the estimated scores from unit combination, i.e., $f(x)$ and the fuzzy measure chromosome, i.e., $\mu(X)$. The equation is shown in (1).

All the differences between the real scores and the estimation using fuzzy integral in all replays will be summed up and the average is calculated. Then it will become the fitness value of chromosome as shown in (2) where N is the total number of case. We apply Wang's fitness value [22] to calculate the fitness of each chromosome. Finally, after GA operation (100 generations), a reasonable fuzzy measure is learnt.

$$\text{Fitness value} = -\frac{1}{1+e}$$
$$\text{where } e = \frac{1}{N}\sum_{i=1}^{N}\left|(c)\int f(x_i) \circ \mu(X) - score(i)\right| \quad (2)$$

B. *Apply Fuzzy Integral in Unit Formation Planning*

The fuzzy measure has shown improvement on macro-management. We want to extend the usage of trained fuzzy measure to micro-management during the battle, i.e., unit formation planning and target of attack. First, we will discuss about applying fuzzy integral in unit formation planning as shown in Fig.4. When the player decided to fight against the enemy unit in the Warcraft III, the player will divide their army into subgroup and attack the enemy. This is known as formation. We applied fuzzy integral to perform this task.

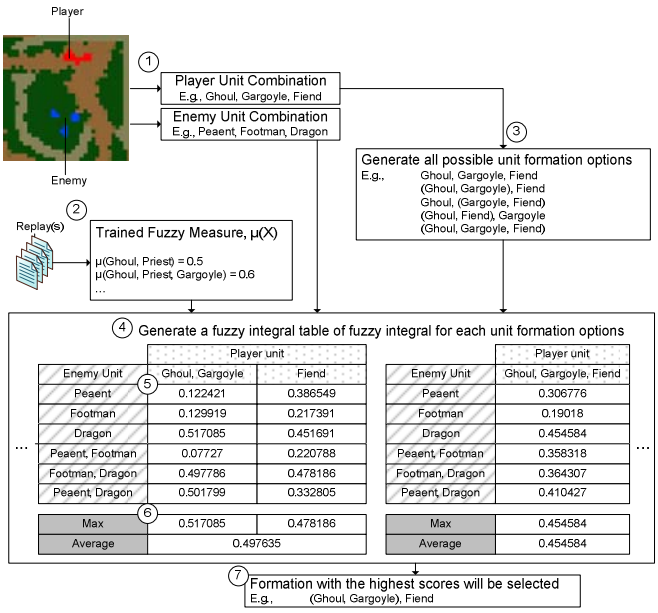

Fig.4. Overview of applying Fuzzy Integral on unit formation planning

1. Fuzzy measure is trained by the replay data.
2. Player and enemy unit proportion is extracted during the battle.
3. When the player decides to fight against the enemy, AI bot will generate all the possible unit formation according player unit type.
4. For each formation, a fuzzy integral table will be generated. Each cell in the table represents the power of the player subgroup to fight against certain the enemy subgroup as shown in Fig. 4
5. The value of each cell is calculated by Choquet integral as shown in (1) by using trained fuzzy measure and unit proportion of the selected player and enemy unit. We can interpret as the higher value the higher chance to win.
6. The maximum fuzzy integral of each player subgroup will be selected and the average will be taken as the score of this unit formation.
7. The unit formation with the highest scores will be selected.

C. *Potential Field with the Fuzzy Integral value*

After AI bot decided unit formation, it needed to decide the target of attack for each subgroup. We applied potential field to perform this task. Player army will be divided into different subgroups according to unit formation planning that described in part B. Then a potential field will be generated for each subgroup of player army as shown in Fig. 5. The centre of the potential field was the middle point of enemy army. The size of potential field was set as 50 x 50 in our experiment. The initial potential field was an empty two dimension array. Each cell of the two dimension array will store the attractive force, , for one coordinate, (x,y) .

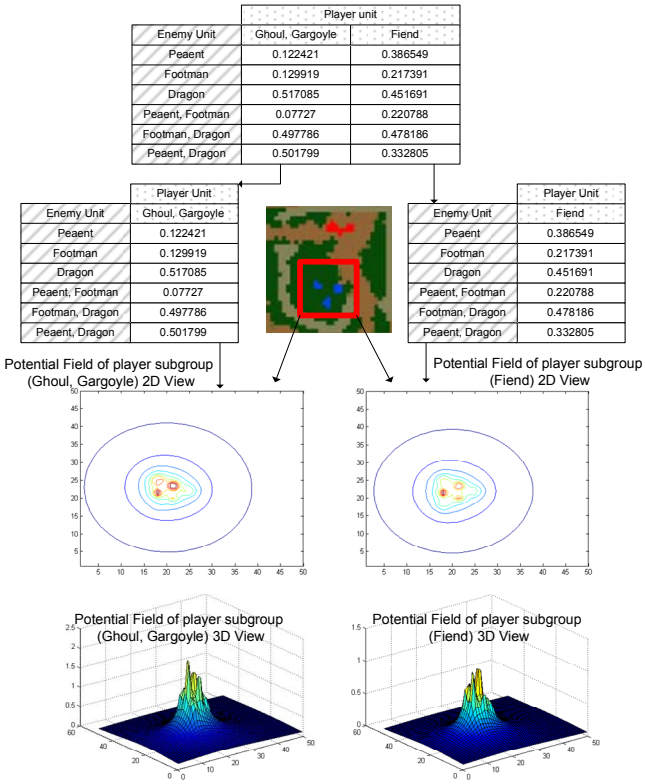

Fig.5. Overview of generating Potential Field by Fuzzy Integral value

$$U(x,y) = \sum_{i=1}^{j} (c)\int f(x) \circ \mu(X) \times d(P_i, P(x,y))^{-1} \qquad (3)$$

We modified the attractive force of potential field, $U(x,y)$ as shown in (3) by applying the idea of opponent force from Johan [14][15]. Each value in the fuzzy integral table will be a point of interest, P_i . Each P_i will generate symmetric surrounding field with the highest attractive force, i.e., fuzzy integral value, $(c)\int f(x) \circ \mu(X)$, in the centre. We used the value that is learnt from real game data instead of expert knowledge. The force will be weakened when it moved away from the center, d where $d(P_i, P(x,y))^{-1} \leq 1$, is used to perform this task.

Fuzzy measure is able to handle the interaction between different units type. To extend this property to potential field, P_i will also consider the outer defense line, i.e., the interaction between different enemy subgroup as shown in the fuzzy integral table. The center of the interaction was set as the middle point of enemy subgroup. Fig. 6 is an example to illustrate our work. The fuzzy integral value of interaction between different enemy subgroup may be negative. Therefore, it changes the simple normal additive property of potential field to non-additive property, especial the sub additive.

	Player Unit
Enemy Unit	Ghoul, Gargoyle
Peaent	0.122421
Footman	0.129919
Dragon	0.517085
Peaent, Footman	0.07727
Footman, Dragon	0.497786
Peaent, Dragon	0.501799

Fig.6. Example of generating Potential Field by Fuzzy Integral value for one subgroup of player army

D. Apply multi-agent Potential Field in Micro-Management

The advantage of applying potential field in micro management of RTS game is the result can be easily multiplied by complicate RTS terrain properties. In RTS game, some unit type can pass through the blocked area or gain extra attack bonus in some special area. All kind of these information could be stored in another two dimensional array as shown in Fig. 8, e.g., zero is set to the blocked area. Once the potential field has been computed by Part C, it can be multiplied by terrain properties array and the resultant potential field could be computed as shown in Fig. 9. The area with the highest attractive force will be the target of attack for certain player subgroup.

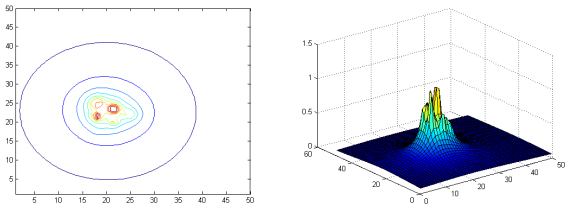

Fig.7. Potential Field by Fuzzy Integral value of one player subgroup

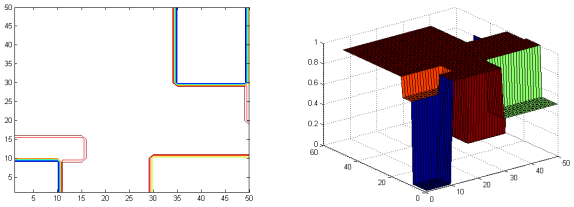

Fig.8. Terrain properties of one player subgroup

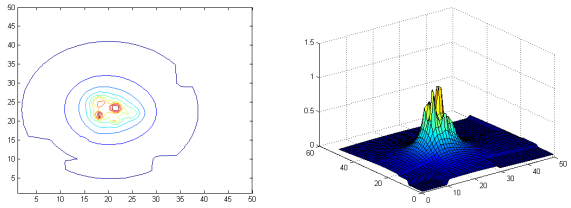

Fig.9. Resultant Potential Field

IV. EXPERIMENTAL RESULT

A. Data Collection

We selected Warcraft III expansion, The Frozen Throne (WIII: TFT) which is a well known and popular RTS game. It is regarded as the best RTS game on the market because of its' interesting, attractive and yet complicated game plays. The purpose of this experiment is to prove our methodology can provide a unit formation and target of attack planning. Hence, the result should be better than Warcraft III AI bot, i.e., the enemy unit scores should be lower.

In this research, 65 replay data are collected to train the fuzzy measure. The player race is Undead and the enemy race is Human. The enemy unit type is peasant, footman and dragon. 5 cases are randomly selected to extract the player and enemy unit combination for simulation.

B. Experimental Setup

For each selected case, player and enemy unit combination is extracted and passed to Matlab for computing the potential field. Then the result will be sent to Warcraft III for simulation.

In Warcraft III, player and enemy units are generated in an official competition field as shown in Fig. 10. Unit formation and the target of attack are set before the battle. After the battle, scores of player and enemy are accorded. For each selected case, 3 additional simulations are performed by using Warcraft III AI bot (Instance) as a comparison of our methodology.

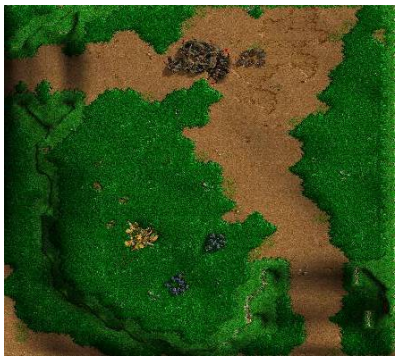

Fig.10. Simulation in Warcraft III

C. Result

As the player won all the selected cases, the scores of players in different simulation are the same. We cannot use it for comparison. We can only compare the scores of enemy. Better micro-management can avoid the enemy to obtain higher scores. Table I shows the enemy scores of using Warcraft III AI bot, while the Table II shows the enemy scores of using potential field and fuzzy integral. Potential field and fuzzy integral obtain a better result in 80% of simulation. The enemy score is lower than the Warcraft III AI bot. Fig. 11 shows the comparison of our methodology and average enemy score that obtained by Warcraft III AI bot. It shows an improvement in 4 selected cases.

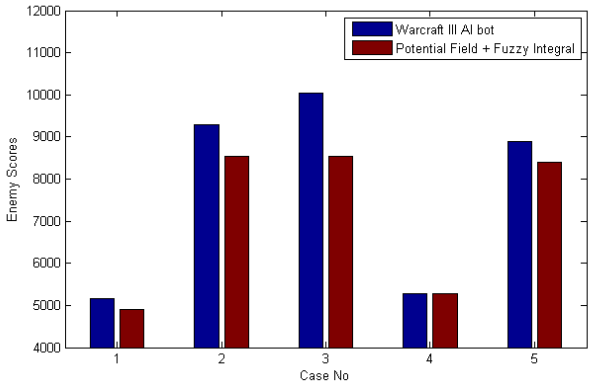

Fig.11. Comparison of our methodology and Warcraft III bot

TABLE I
ENEMY SCORE OF USING WARCRAFT III AI BOT

Case	1	2	3	4	5
Experiment 1	4970	9040	10285	5405	8780
Experiment 2	5350	9295	10160	5165	8950
Experiment 3	5150	9550	9695	5280	8965
Average	**5156**	**9295**	**10046**	**5283**	**8898**

TABLE II
ENEMY SCORE OF USING POTENTIAL FIELD AND FUZZY INTEGRAL

Case	1	2	3	4	5
P.F. + F.I.	**4990**	**8530**	**8540**	**5285**	**8410**

V. CONCLUSION

In this paper, we applied potential field, fuzzy measure and integral to perform a solution on micro management in RTS game. Therefore, the AI bot is able to divide the army into subgroup and perform the unit formation planning. After that the AI bot is also able to consider the interaction among different enemy unit type and decide the target of attack for each player subgroup. Simulation on Warcraft III has been done to test our idea and it shows an improvement.

By integrating the potential field with fuzzy measure and integral, it provides a machine learning approach to obtain the constant scaling factor instead of expert suggestion. It also extends the non-additive property from fuzzy measure and integral to potential field.

Our research is very preliminary. There are still many research problems remain, such as updating and maintaining the fuzzy measure and considering different unit types in player subgroup. We believe that this approach can generate a reasonable solution for AI development in RTS game.

Elimination Search for puzzle games : An Application for Hashi Solver

Shi-Jim Yen, Shih-Yuan Chiu, Cheng-Wei Chou and Tsan-Cheng Su

National Dong Hwa University Dept. of CSIE Taiwan, R.O.C

sjyen@mail.ndhu.edu.tw

***Abstract*—This paper proposes an efficient method to solve Hashi, a logical-type puzzle game with N by M grid. By using two methods, intersection method and elimination search, we can solve Hashi quickly and efficiency. The solver is authenticated by solving problems taken from Internet.**

Keywords- Hashi, Elimination search, Puzzle game

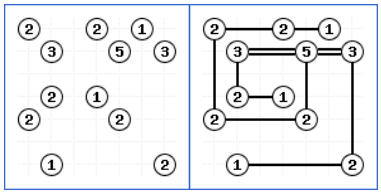
I. INTRODUCTION

Recently, many puzzle games become more and more popular. Rules of these puzzle games are usually very simple, but solving them needs excellent logic concept. With contemplation, it is possible to finish these games, such as Sudoku, Nurikabe, Number Link, and so on.

Because of the popularity of puzzle games, many related studies become very popular. There are some directions for these studies. Some put focus on the generation of questions, trying to use the least implied numbers to generate a question with only one answer [1]; some try to demonstrate some puzzle games are NP-Complete problems [2][3]; besides, studying how to use programs to rapidly solve these puzzle games is an important direction. Previous researchers tried to use pattern matching and DFS to solve Nonogram puzzle games [4][5], and had breakthrough in the speed of solving them. However, DFS may step into a wrong track, stuck in it, and cause great deal of resource waste. To avoid this situation, this research tries to use intersection method and elimination search. Elimination search is a useful method for solving puzzle games, we also use it to solve other puzzle games and get good results[6][7][8]. By making use of the feature of elimination search which won't get stuck into a wrong track, Hashi solver in this research is able to solve questions of Hashi.

In this section, we will introduce rules of Hashi in details and the major method used in this research in the second section, including intersection method and elimination search, Experimental results will be presented in the third section, and the fourth section is conclusion.

The initial board of Hashi is shown in Fig. 1(a). In the figure, the circled numbers are "islands;" in addition, the lines connect islands are "bridges." The goal of the game is to connect all the islands with bridges. Correct solutions of the game must follow rules below:



(a) (b)

Figure 1. An example of a Hashi problem (a) and its solution (b)

1. Every bridge can only connect two islands vertically or horizontally, without any other islands between the two islands.
2. The numbers of all the bridges connecting islands must be equal to the numbers on the islands.
3. The number of every island will be between 1~8, and 2 bridges at most are allowed in every direction of an island, up, down, left, and right.
4. A bridge cannot cross another nor has branches.
5. Every island can reach to any other through bridges.

Figure 1 (b) shows the way the game is completed.

II. PROPOSED METHOD

A. Overall Process

The way we use to solve Hashi is intersection method and elimination search. Before using these two methods, we need to do some basic information calculation. The whole process is shown in Fig. 2.

The following three sections will illustrate the methods we use. Section II.B explains basic information calculation. Section II.C explains intersection method, and Section II.D illustrates elimination search method.

B. Basic information calculation

Before using intersection method and elimination search, some preparation has to be done, this is basic information calculation. This step mainly records possible ways for every island to connect. Taking Fig. 3(a) for example, the island with number 2 on the upper left corner has three ways to connect, listed in Fig. 3(b)(c)(d).

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

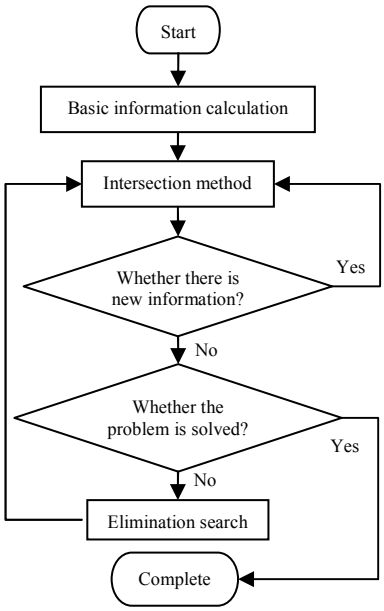


Figure 2. Flow chart of Hashi Solver

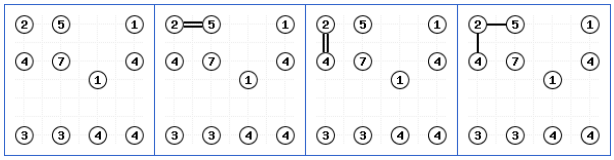
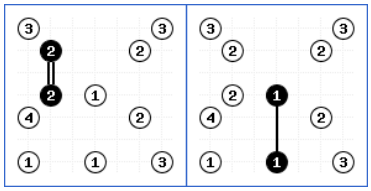


(a) (b) (c) (d)

Figure 3. Possible ways for a island to connect

In addition to the ways of connection, we do some simple judgments to decrease possible ways of connection, increasing the possibility of finding out solutions of intersection method, and decrease the use of elimination search. The way to judge is to delete impossible connection. For example, in Fig. 4(a), if two islands with number 2 connect each other with two bridges, they are impossible to connect other islands, which is against rule 5. Thus, in this step, this possible will be deleted; likewise, in Fig. 4(b), two islands with number 1 connecting together will be against rule 5.



(a) (b)

Figure 4. Connections against rules will be deleted.

Table I lists how the possible connections of two highlighted islands with number 2 will change after the judgment above. Here, we use U(Up), D(Down), L(Left), and R(Right) to represent the connecting directions around a island, and add numbers after directions to show the numbers of bridges. For example, U2 means the island has two bridges connecting the island in the up direction.

TABLE I. HOW THE POSSIBLE CONNECTIONS OF THE TWO HIGHLIGHTED ISLANDS WITH NUMBER 2 IN FIG.4 WILL CHANGE

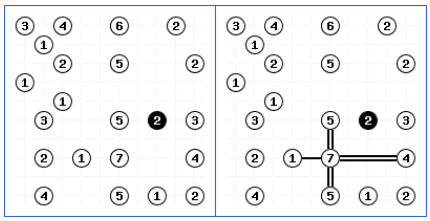
	Original Possible Connections	Impossible Connections	Actual Possible Connections
Up Islands	R2 D1 R1 D2	R2 D2	D1 R1
Down Islands	U1 R1 U2	U2	U1 R1

C. *Intersection method*

We can use an example to illustrate the main concept of intersection method. Assume an island only has two connecting ways, D1 L1 R2 and D2 L1 R1. Because both of the two possibilities include D1 L1 R1, we can believe that the three bridges, D1, L1, and R1, must exist. In other words, finding possible points in common among lots of possibilities to get information is the concept of intersection method.

Before using intersection method, according to present board, we can use more advanced way of sieving to decrease the possibility of matching so that the intersection method can probably get more information. We use three major ways of sieving here.

Because bridges cannot have branches or cross each other, if island a and island b are separated by bridges not connecting them, there will be no possibility for the two islands to connect. The first kind of sieving is used to exclude these impossible matches. For example, like Fig. 5(a), there are five possible connections for the highlighted island, but through some information calculation, the board situation will change into Fig. 5(b). The highlighted island's connection downward is blocked, so all the connections including down are excluded for its impossibility. Table II shows the specific information.



(a) (b)

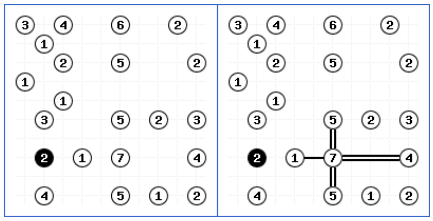
Figure 5. An example of first kind of sieving

TABLE II. HOW THE POSSIBLE CONNECTIONS OF THE HIGHLIGHTED ISLANDS WITH NUMBER 2 IN FIG.5 WILL CHANGE

Original Possible Connections	Impossible Connections	Actual Possible Connections
R2 L2 R1 L1 D1 L1 D1 R1	 D1 L1 D1 R1	R2 L2 R1 L1

When some islands construct bridges, their ability of containing new bridges will decline; therefore, we can make use of this information to exclude some impossible connections. Like Fig. 6(a), there are five possible connections for the

highlighted island, but, after some basic information calculation, the board changes into Fig. 6(b). The island with number 1 on the right of the highlighted island has one bridge, so its capability of containing new bridges is 0. Thus, all the possibility of connecting islands on its right side will disappear, and all the matches that include connections with islands on the right will be excluded. Specific information is in Table III.



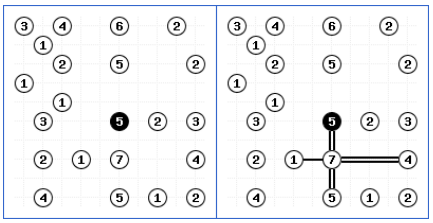
(a) (b)

Figure 6. The second kind of sieving

TABLE III. HOW THE POSSIBLE CONNECTIONS OF THE HIGHLIGHTED ISLANDS WITH NUMBER 2 IN FIG.6 WILL CHANGE

Original Possible Connections	Impossible Connections	Actual Possible Connections
U2		U2
D2		D2
U1 D1		U1 D1
U1 R1	U1 R1	
D1 R1	D1 R1	

At last, considering the original connections of an island itself can effectively exclude some impossibility. Like Fig. 7(b), because the highlighted island already has two bridges downward, all the connections excluding the two can be excluded. Specific information is in Table IV.



(a) (b)

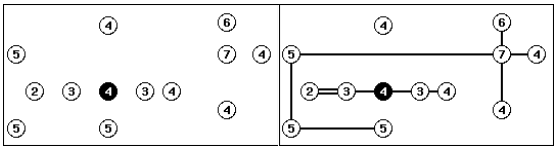
Figure 7. The third kind of sieving

TABLE IV. HOW THE POSSIBLE CONNECTIONS OF THE HIGHLIGHTED ISLANDS WITH NUMBER 5 IN FIG.7 WILL CHANGE

Original Possible Connections	Impossible Connections	Actual Possible Connections
U1 R2 L2	U1 R2 L2	
U2 D2 L1		U2 D2 L1
U2 R1 L2	U2 R1 L2	
U2 D1 L2	U2 D1 L2	
U2 R2 L1	U2 R2 L1	
U1 D2 L2		U1 D2 L2
D2 R1 L2		D2 R1 L2
U1 D2 R2		U1 D2 R2
D1 R2 L2	D1 R2 L2	
U2 D1 R2	U2 D1 R2	
D2 R2 L1		D2 R2 L1
U2 D2 R1		U2 D2 R1

Before using intersection method to find information, using three kinds of sieving above can greatly decrease possible connections for the benefit of using intersection method. For example, if the present board is like Fig. 8(b), use the three kinds of sieving method to delete impossible connection matches. The result is listed in Table V. The italic marks are impossible connections after using every kind of sieving. Once a connection match is considered to be impossible, it will be deleted as Invalid.

After sieving, there are two possibilities. After intersecting the two possibilities, we can get the conclusion that there is at least one bridge downward, and can condense original 19 possible connections into 2.



(a) (b)

D. limination search

Like Fig. 9, when intersection method cannot find any new information anymore, elimination search should be used. By testing every kind of possibility to delete wrong connection match, we can increase the possibility of finding new information.

Elimination search's process is divided into three steps: assumption, extending ratiocination and mistake testing.

STEP1. Assumption: It means to assume some possibility is true for some island, and keep intersecting to change the board situation.

STEP2. Extending ratiocination: Use intersection method to ratiocinate to find more information.

STEP3. Mistake testing: Judge if there is mistake for the situation after extending ratiocination.

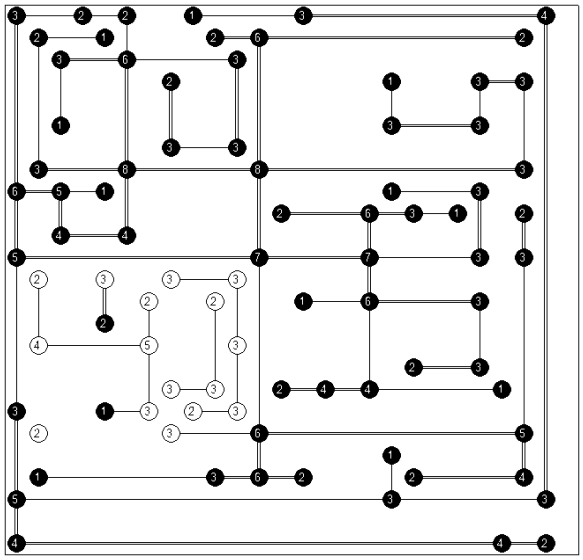

Figure 9. A board that should use elimination search

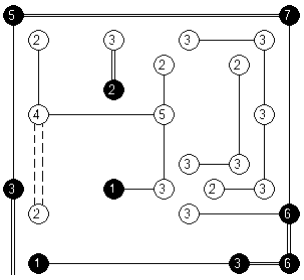

Figure 10. "Assumption" step in a elimination search

We use an example below to illustrate the three steps. Assume the present board is like Fig. 9. Highlighted islands represent those solved, and other islands unsolved. Meanwhile, because intersection method cannot find any information, we will select an unsolved island, and assume some connection is true. For example, possible connections for the unsolved island with number 2 on the left button are R2, U2, and R1U1. Assume the island's connection is U2, and the board will become Fig. 10. The dotted lines are assumed connections.

Next, use extending ratiocination for the new board, and use mistake testing for the board with extending ratiocination to make sure whether it is against rules. Fig. 11 is the board after using extending ratiocination for Fig. 10. The dotted lines are results after using extending assumption. After using mistake testing, we find that because the nine islands in the circle on the left in Fig. 11 cannot connect any direction, they are against rule 5. Besides, the island with number 3 in the center on the up direction can only connect the right direction which is against rule 2 because the capability to contain new bridges of islands on its left, right, and down is 0.

If it is against rules, it is proved that the assumption is not true. In other words, one possibility is excluded, which means we get new information. Because elimination search is slower than intersection method, as long as elimination search has new

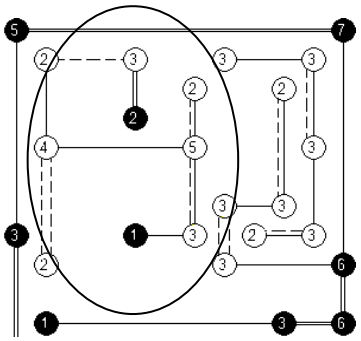

Figure 11. The board after using intersection method

information, we will use intersection method to test if more new information can be found. If it is not against rules after mistake testing, keep using elimination search. In the example above, if the assumption is not true, possible connections for the island with number 2 in the center on the left are U1R1 and R2. After using intersection method, it is found that there must be a bridge connecting the island on the right.

The worst situation is that after using elimination search for all the islands' possibilities, the problem still cannot be solved. However, when we test questions of large size (25X25), we haven't found questions that intersection method and elimination search method cannot solve. Thus, we believe merely using intersection method and elimination search method is enough to deal with the need of solving Hashi.

III. Experiment Results

We use the method in the second section to actually solve questions of Hashi, and list the result here. We use MATLAB 2009 to implement Hashi Solver, and randomly select one thousand questions of 25X25 to the tested objectives from Internet [9]. Our experimental environment is formed by using Intel E8400 CPU, 8G RAM, and the operation system is VISTA64. Testing the one thousand questions, the average time took to solve every question is 0.0342 seconds. Among them, we need only intersection method to solve 76.6% questions without using elimination search, and these questions are those which can be solved without using the rule that "all the islands must connect together." About the comparison between intersection method and elimination search, we list it in Table VI. From the experimental results, intersection method is four times faster than elimination search, which proves that it is a correct way to use intersection method right after finding new information by using elimination search.

TABLE VI. The Comparison Between Intersection Method and Elimination Search

Method	Average Solving Proportion	Average Time Cost	Average Time Cost per 1% Proportion
Intersection	98.9%	0.0327s	3.3064×10^{-4}s
Elimination search	1.1%	0.0015s	13.6364×10^{-4}s

IV. CONCLUSION

This research studies how to quickly solve Hashi. This research tries to use intersection method and elimination search to solve Hashi, and proves that this method can quickly and effectively solve it. According to the experiment results, we can find that over three fourths questions need only intersection method to be completely solved, and the rest of questions can be solved by using elimination search. For every question, 99% information is found by intersection method in average, and only 1% information is provided by elimination search. This proves that the two ways have great performance in solving Hashi. At the same time, because the two methods do not need much domain knowledge basically, we can also try to apply them to other puzzle games and expect there will be great results.

***Abstract*—Fillomino is a logical puzzle game invented by Nikoli Company in Japan. Fillomino is played on a rectangular cell with no standard size; the internal cell lines are often dotted. Some cells of the cell start containing numbers, referred to as "givens". In this paper, we propose a puzzle solving algorithm to treat these problems. Based on the fact the Fillomino are compact and contiguous, some logical rules are deduced to paint some cells. Experimental results show that our algorithm can solve Fillominos successfully and efficient, and the processing speed is significantly faster than that of depth first search algorithm.**

Keywords- Fillomino, Puzzle Game, CSP.

I. INTRODUCTION

Recently, many puzzle games popular in world. These puzzle games of Rules are usually simple, but solving them needs excellent logic concept. With contemplation, it is possible to finish these games, such as Sudoku, Nurikabe, Number Link, and some puzzle games.

Because of the popularity of puzzle games, many related studies become very popular. There are some directions for these studies. Some put focus on the generation of questions, trying to use the least implied numbers to generate a question with only one answer. Some try to demonstrate some puzzle games are NP-Complete problems [2][8]; besides, studying how to use programs to rapidly solve these puzzle games is an important direction. Previous researchers tried to use pattern match and DFS to solve Nonograms puzzle games [2][5], and had breakthrough in the speed of solving them. However, DFS may step into a wrong track, stuck in it, and cause great deal of resource waste.

In the second section, we will introduce others to the methods to solve puzzle game and introduce rules of fillomino in details in third section. The major method used in this research in the fourth section, including intersection method and logic rules. Experimental results will be presented in the fifth section, and the sixth section is conclusions.

II. PREVIOUS WORKS

Yen[6][7] they used Logical Reasoning and Heuristic to solve Nurikabe and Lights-up, and they can quite efficiency to solve puzzle. Their experimental results show that they can solve successfully and high-speed.

Wiggers [10] proposed a genetic algorithm (GA) and a depth first search (DFS) algorithm to solve Japanese puzzles. In 2004, he compared the performance of these two algorithms. For a small puzzle, the DFS algorithm is faster than the GA; otherwise, GA is faster. However, both methods are slow. In this study, some logical rules will be applied to determine the state filled of as many cells in a Japanese puzzle, then the DFS algorithm with "branch and bound" is used to determine the state of the remaining cells.

Jing and Yu [2][5] proposed a method based on logical rules (LR) and chronological backtracking with an LR filter to solve Japanese puzzles. Their rules exploited with a new concept of "the range of a black run." These rules have three main parts. The first part is used to determine which cells should be colored or left empty; the second part is used to refine the ranges of black runs, and that is used to determine which cells should be colored or left empty and to refine the ranges of black runs. One thing should be mentioned at first, we use row information to build a DFS tree, and the column information is used immediately to verify when a row is used to create a layer. It means that every layer of the DFS tree is composed of row information, and all nodes in each layer are possible solutions (PS) for the corresponding row.

Batenburg [3] described an evolutionary algorithm for Discrete Tomography (DT) then Batenburg and Kosters [4] provided a method to solve Nonogram puzzle. By modifying the fitness function in [3], the evolutionary algorithm can be used to solve Japanese puzzle. Since the evolutionary algorithm in [3] will converge to a local optimum, the obtained solution maybe incorrect.

III. GAME RULES

This Puzzle Game rule below:

A. Clues i said, suggesting that the number of i, the number of cell connected.

The rules need to be shown to satisfy the number of questions on a puzzle, if the clues is "i", that suggest you must have the same number i of connected cell. Like figure 8.

*B. In the game have N * M digits to fill all N * M cells.*

This rule needs to N * M of digits, all cells filled with digits in the N * M of Cells. Like figure 8.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

C. All of the cells must meet to be number of block.

This rule is necessary to have filled digits all the cells and the number of connection cells must meet the clues number.

D. The same number of blocks can not be connected.

This prompted rule is the same clues number of cells block can not be connected. However, the different clues number of cells block can be connected.

IV. PROPOSED METHOD

The algorithm of our solver contains three phases. The first phase and second phase are logic rule. The third phase is Intersection. The first phase checked point which has only one way to connection with the other cell. If we determine the first one is true, we can link it with the cell which one way to connection. The next phase inspection one cell which only one cell link to other cell, that we must link it. The last phase intersection all the possible answer matches of every cell. If sure one cell belong which one cell, We immediately fill this cell that should belong to the number of cell. Figure 1 that is our algorithm of flow chart.

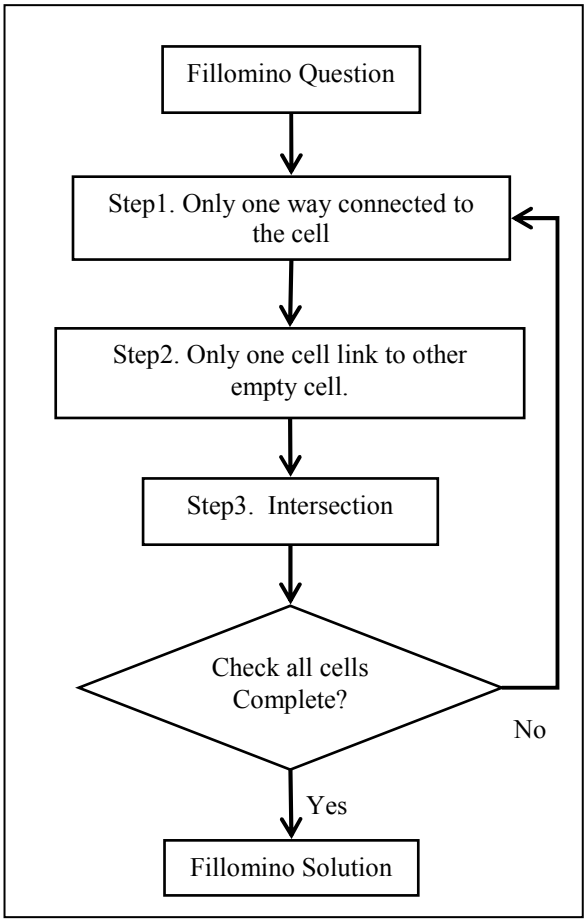

Figure 1. Flow chart of Fillomino.

A. Step1:Only one way connection

One cell that only has one way to connection other cell, that cell must be fill the only other cell numeral. Like figure 2,we marked the cell to fill 「4」.

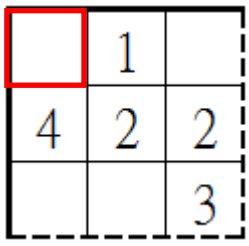

Figure 2. A simple step1.

B. Step2:Only one cell link to other empty cell

We used solid lines mark the cell, which is only one cell link to other cell. If we don't link it we will violation of the rules, and the cell no any numeral to fill it. Like figure 3, we used solid line mark the cell and dotted line mark the cells, these cells must to fill 「6」.

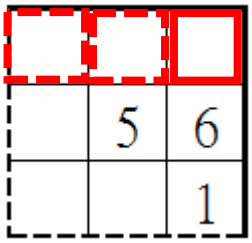

Figure 3. A simple step2.

C. Step3: Intersection

We used Intersection in one cycle of last. Figure 4 is a simple in corner. We do first and second phase, we create all of numeral possibilities pattern for the intersection. Like figure 5.

We intersection again to find intersect of cell. We find Intersect of cell to fill the numeral. Like figure 6. The cell marked that we can fill 「4」.

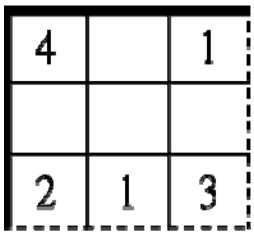

Figure 4. A simple puzzle Part of the corner.

We used three phases repeat continuously until the end of this puzzle. We can efficiently and successfully to solve the puzzle game. Figure 7 and Figure 8 are a simple question and solution.

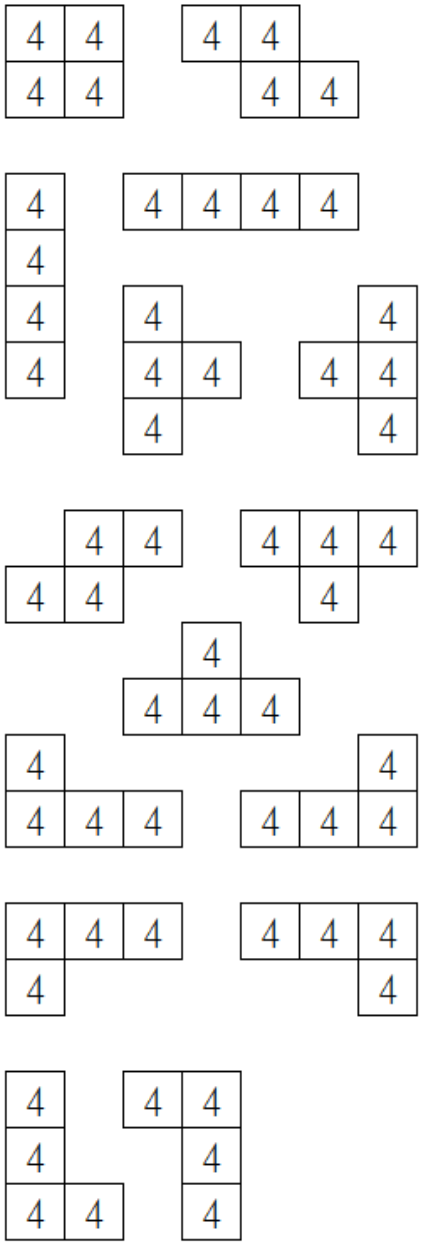

Figure 5. All of numeral possibilities pattern of Fig 4.

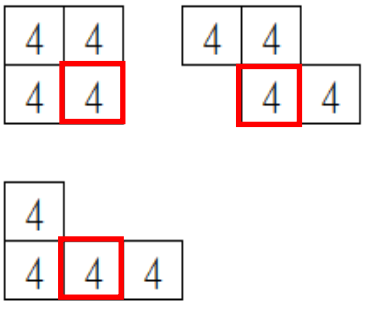

Figure 6. The pattern Intersect of cell.

VI. EXPERIMENTAL

This research studies how to quickly solve Fillomino. This research tries to use intersection method to solve this question, and proves that this method can quickly and effectively solve Fillomino. According to the experiment results, we proved our algorithm than the method using the GA or the CSP more quickly and efficiently. Our algorithm we use is still a drawback to be improved. In Step3 to create all possible patterns, requires a lot of memory resources. This needs to be improved. At the same time, because the three phases do not need much domain knowledge basically, we can also try to apply them to other puzzle games and expect there will be great results.

***Abstract*—This paper introduces a symbiotic neuron evolution algorithm (SNEA) to determine the topology of a neural-network-aided grey model (NNAGM) for time series prediction problem. The SNEA uses an evolutionary approach to evolve partially connected neural networks (NNs) and determine the number of hidden neurons. To achieve symbiotic evolution, SNEA first establishes a neuron population where each neuron is randomly created, and evaluates the neurons by constructing NNs with different numbers of neurons. Each neuron shares fitness from participating NNs. This algorithm then performs evolution on the neuron population by crossover and mutation based on neuron fitness. An NNAGM designed by SNEA is applied to the prediction problems and compared with other methods. The experimental results show that SNEA can produce an NNAGM with appropriate topology and higher prediction performance than other methods.**

Keywords-grey model; symbiotic evolution; neural network; prediction.

I. INTRODUCTION

In time series prediction, a small subset of recent time series information is usually used for prediction. The prediction assumes that the trends of the previous time series will be maintained in the future [1]. This approach is called lagged variables, shift registers, or tapped delay line. This means that accurate predictions can be obtained by using only a finite segment of previous data up to the prediction point [2]-[4]. Many researchers have developed variant systems to address the forecast problem in time series prediction, such as grey theory [5], [6] and neural networks (NNs) [7], [8].

Grey theory, a numerical method, is used to cope with systems with partial information or system dynamic model. The first-order single variable grey model (GM(1,1)) was developed for prediction [9]-[11] based on the gray theory. The GM(1,1) first transforms an amount of historical data into a more exponential-like and smooth signal. The grey differential equation, modified from the first-order ordinary differential equation, is then adopted to calculate the predictive value. Therefore, GM(1,1) can achieve high accuracy in prediction of exponential-type signals, offer the advantages of simplicity, and reduce computation time. However, the precision of this method of prediction is not sufficient for other types of signals.

In addition to GM(1,1), have been developed as a forecasting method based on soft-computing [12], [13]. Cybenko [14] and Hornik et al. [15] suggested that a single hidden layer is sufficient for NNs to approximate any complex nonlinear function and predict time series. Therefore, most researchers use only one hidden layer for prediction purposes. In general, NNs with fewer hidden neurons usually have better generalization ability and present a less severe overfitting problem. However, NNs with too few hidden neurons may not be able to accurately model and learn the data due to limited information processing capability [16], [17]. Thus, determining the number of hidden neurons can be difficult.

Based on the complementary advantages of GM(1,1) and NN, our previous work [18], [19] integrated GM(1,1) and NN into a fusion scheme, neural-network-aided grey model (NNAGM). The NNAGM employed GM(1,1) to predict signals and adopted NN to learn the prediction error of GM(1,1). The NN used in NNAGM has a fully connected topology and the number of hidden neurons is determined by trial-and-error. However, it is possible to have networks that are not fully connected in prediction problems [20]. Thus, automatic design of the topology of NNs is necessary to enable efficient solution of various prediction problems.

Symbiotic evolution is an implicit fitness-sharing algorithm used in an immune system model [21], [22]. In symbiotic evolution, each individual in the population represents a partial solution to a given problem, and complete solutions are constructed from several individuals. The partial solutions can be considered specializations that ensure diversity and prevent a population from converging into suboptimal solutions. The work of [22] proposed symbiotic adaptive neuron evolution to develop NNs according to a population of neurons. The performance of a neuron is determined by how well it cooperates with the other neurons which it combines. This process shows that a neuron that cooperates well with one set of neurons may cooperate poorly with other sets of neurons. However, the number of hidden neurons must be assigned prior to the evolution process. Previous studies have applied symbiotic evolution to design fuzzy controller and neuro-fuzzy systems [23]-[27]. The results of these studies have demonstrated the efficiency and feasibility of symbiotic evolution in reinforcement learning.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

This paper presents a symbiotic neuron evolution algorithm (SNEA) to design an NNAGM. This algorithm determines the topology of NNAGM, including the number of hidden neurons and connected topology. Section II introduces the concept of NNAGM. Section III indicates that the proposed SNEA does not develop NNs with a fixed number of hidden neurons but rather constructs NNs of different size by selecting the neurons from the neuron population. The neurons are evolved through the crossover and mutation operations, according to the shared fitness from the participating NNs. Section IV demonstrates the ability of the proposed SNEA to create an NNAGM for two prediction problems. Finally, Section V presents the conclusion of this study.

II. Neural-Network-Aided Grey Model

An NNAGM combines a GM(1,1) and an NN where GM(1,1) mainly predicts signals and NN learns the prediction error of GM(1,1) [18]. The structure of an NNAGM is depicted in Fig. 1.

Consider a discrete data sequence of length $n \geq 4$ formed as the following column vector

$$\boldsymbol{x}^{(0)} = \left[x^{(0)}[1] \quad x^{(0)}[2] \quad \cdots \quad x^{(0)}[n] \right]^T \tag{1}$$

where each element has the same numeric sign. In general, the GM(1,1) adopts three fundamental operations, given as

Accumulate Generating Operation (AGO):

$$x^{(1)}[k] = \sum_{l=1}^{k} x^{(0)}[l], \quad k = 1,2,...,n \tag{2}$$

Mean Generating Operation (MGO):

$$z^{(1)}[k] = \alpha x^{(1)}[k] + (1-\alpha) x^{(1)}[k-1], \quad k = 2,3,...,n \tag{3}$$

Inverse Accumulate Generating Operation (IAGO):

$$x^{(0)}[k] = x^{(1)}[k] - x^{(1)}[k-1], \quad k = 2,3,...,n \tag{4}$$

where α is often set as 0.5. According to the GM(1,1) [10], its grey differential equation is presented as

$$x^{(0)}[k] + a z^{(1)}[k] = b, \quad k = 1,2,\cdots,n \tag{5}$$

where a is the development coefficient and b is the grey input. Both a and b are unknown and have to be determined first by rearranging (5) into the following matrix form

$$\boldsymbol{x}^{(0)} = \boldsymbol{X}^{(1)} \begin{bmatrix} a \\ b \end{bmatrix} \tag{6}$$

where

$$\boldsymbol{X}^{(1)} = \begin{bmatrix} -\dfrac{x^{(1)}[1]}{2} & -\dfrac{x^{(1)}[1] - x^{(1)}[1]}{2} \\ 1 & 1 \\ \cdots & -\dfrac{x^{(1)}[n] - x^{(1)}[n-1]}{2} \\ \cdots & 1 \end{bmatrix}^T \tag{7}$$

Then a and b could be solved by the least square method as below

$$\begin{bmatrix} a \\ b \end{bmatrix} = \left(\boldsymbol{X}^{(1)T} \boldsymbol{X}^{(1)} \right)^{-1} \boldsymbol{X}^{(1)T} \boldsymbol{x}^{(0)} \tag{8}$$

Based on the GM(1,1), the solution of the grey first-order differential equation (5) is estimated as [10]

$$\hat{x}^{(1)}[n+j] = \left(x^{(0)}[1] - b/a \right) e^{-a(n+j-1)} + b/a, \quad j \geq 1 \tag{9}$$

Further applying the IAGO in (4) to (9) yields

$$\hat{x}^{(0)}[n+j] = \left(x^{(0)}[1] - b/a \right) e^{-a(n+j-1)} \left(1 - e^{a} \right) \tag{10}$$

which is the so-called predictive data. The one-step-ahead predictive value is then calculated by setting $j = 1$, which is the first predictive value after the original data sequence.

Since the GM(1,1) performs the prediction via the data sequence with the same numeric sign, the preprocess is employed to transform the raw data in (1) into

$$x'^{(0)}[l] = x^{(0)}[l] - \min\left(\boldsymbol{x}^{(0)} \right) + \gamma, \quad l = 1,2,\cdots,n \tag{11}$$

where γ is a constant bias to avoid the output to be zero. Then the transformed value is used to estimate $\hat{x}'^{(0)}[n+j]$ from (2)–(11). As a result, the one-step-ahead predictive value is determined as

$$\hat{x}^{(0)}[n+j] = \hat{x}'^{(0)}[n+j] + \min\left(\boldsymbol{x}^{(0)} \right) - \gamma. \tag{12}$$

Therefore, the GM(1,1) can process the data sequence with different numeric signs.

The NNAGM receives the input data $\boldsymbol{x}^{(0)}[k] = [x^{(0)}[k-n+1]\ x^{(0)}[k-n+2] ... x^{(0)}[k]]^T$ at time step k corresponding to $\boldsymbol{x}^{(0)} = [x^{(0)}[1]\ x^{(0)}[2] ... x^{(0)}[n]]^T$ in (1). Based on (12), the one-step-ahead predictive value is $\hat{x}^{(0)}[k+1]$ whose corresponding prediction error is $e_{\mathrm{GM}}[k]$. To improve the prediction accuracy, NNAGM adopts NN to estimate the prediction error $\hat{e}_{\mathrm{GM}}[k+1]$ by $[e_{\mathrm{GM}}[k-m] \ \cdots \ e_{\mathrm{GM}}[k-1]\ e_{\mathrm{GM}}[k]]$. The weight vector of NN is adjusted by the backpropagation algorithm.

With the fusion scheme, NNAGM integrates the outputs of both GM(1,1) and NN. The NNAGM possesses not only the capacity to predict data using GM(1,1), but also the intelligence to learn to estimate the prediction error using NN. The

remaining problem involves determining the topology of NN, i.e., the number of neurons and connections. The next section introduces the proposed SNEA employed to design the topology of an NN.

III. Symbiotic Neuron Evolution Algorithm

This section presents the proposed SNEA in detail. In its current implementation, SNEA is used to determine the structure of an NNAGM, i.e., the number of neurons and connections. The prior work [18] provided a constraint such that the topology of NN used in an NNAGM should be fully connected. Furthermore, the number of neurons is determined through a trial-and-error method. This paper uses SNEA to design NN in an evolutionary way.

The structure of an NN consists of input neurons, hidden neurons, output neurons, and connections between each layer. The number of neurons in the input and output layer is problem-dependent. For the prediction problem in Section IV, four input neurons and one output neuron are employed. Therefore, SNEA mainly determines the number of hidden neurons and the connected topology between input and hidden neurons.

To evolve the neurons, each neuron is encoded as *bj*, where *b* indicates the connection of bias and *j* indicates the topology related to the input neurons. The value of *j* is a bitwise representation and determines which input neuron is connected to the neuron *bj*. For a four-input-one-output prediction problem, each neuron has 2^4-1 types of topology, i.e., j = 1, 2,…, 9, A,…, F. Note that one input neuron should at least be connected to the hidden neuron. Fig. 2 shows two examples of the coding of two neurons and the topology of an NN constructed from the two neurons.

The main steps of SNEA are summarized in Fig. 3 and further explained as follows.

Step 1) Create a neuron population. The neuron population consists of randomly generated N_{pop} neurons.

Step 2) Randomly select p neurons to construct an NN in the pth group, p = 1,2,…,P. As shown in Fig. 4, each group consists of d NNs where each NN of the pth group includes p neurons.

Step 3) Train each NN using the backpropagation algorithm and then calculate the fitness of each NN where the fitness f_{NN} is the inverse of the root mean square error (RMSE).

Step 4) Share the fitness of NN with each participating neuron. For NN in the pth group, each participating neuron can share fitness as f_{NN}/p.

Step 5) Determine the participating time and fitness of each neuron. The neuron participating T NNs has its fitness f_n as

$$f_n = \frac{1}{T}\sum_{t=1}^{T} f_n^t \tag{13}$$

where f_n^t is the shared fitness in tth NN.

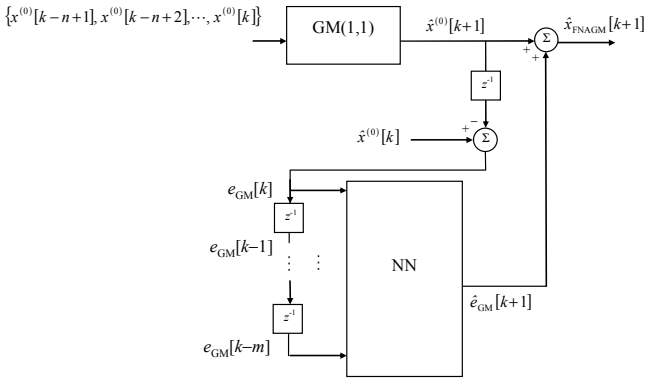

Fig. 1. Neural-network-aided grey model (NNAGM).

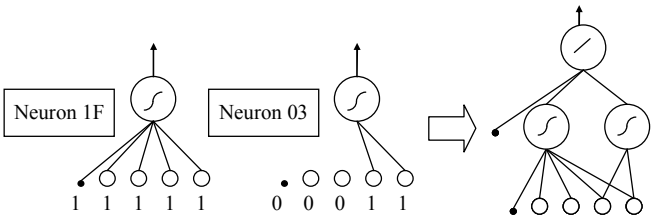

Fig. 2. Coding of two neurons and an NN constructed via two neurons.

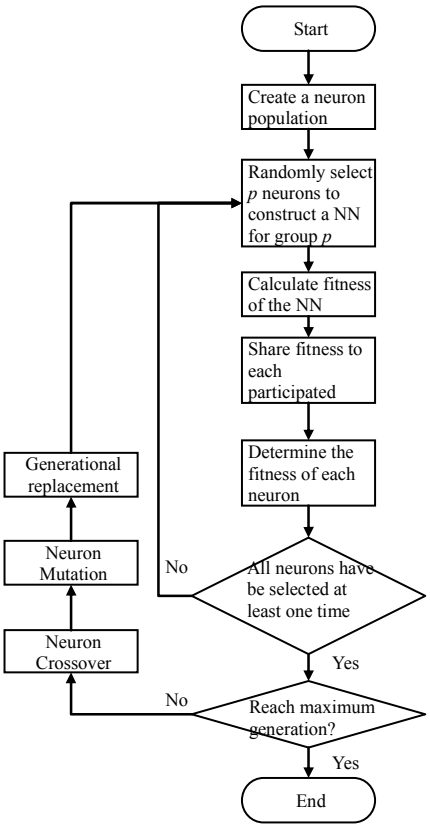

Fig. 3. Flowchart of SNEA.

Step 6) If one of the neurons in the neuron population has not be selected at least one time, then go to Step 2); otherwise, go to Step 7).

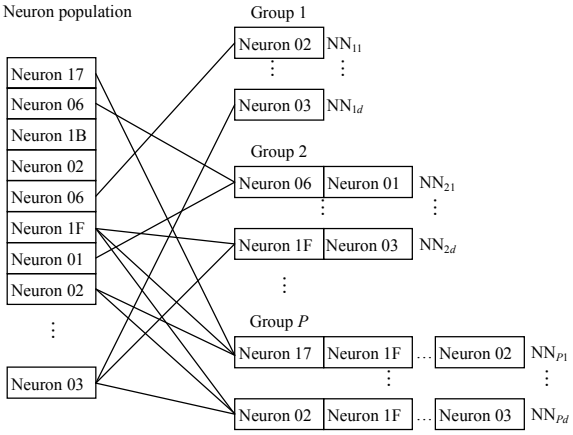

Fig. 4. Construct of NNs of each group from the neuron population.

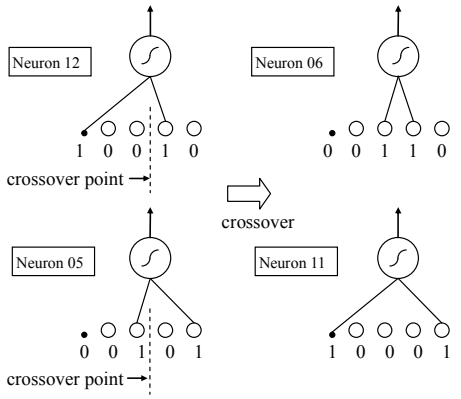

Fig. 5. Neuron crossover.

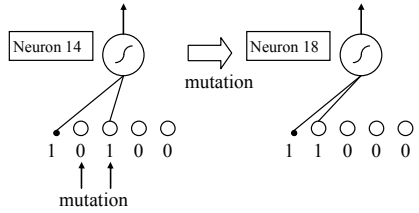

Fig. 6. Neuron mutation.

Step 7) Check the stopping criterion. If the maximum generation is achieved, then stop the algorithm; otherwise, go to Step 8).

Step 8) Perform the neuron crossover to the neuron population. First, the neuron crossover adopts the tournament selection to choose two parents according to their fitness f_n. The crossover point is then randomly assigned, as shown in Fig. 5. Finally, the two parents produce two children by exchanging the connections.

Step 9) Perform neuron mutation on the children. Each connection to either the input or bias might change according to the probability of mutation p_m. For the example shown in Fig. 6, two positions of Neuron 14 are selected to be mutated and then the corresponding connections are disconnected (1→0) or connected (0→1). As a result, Neuron 18 is generated.

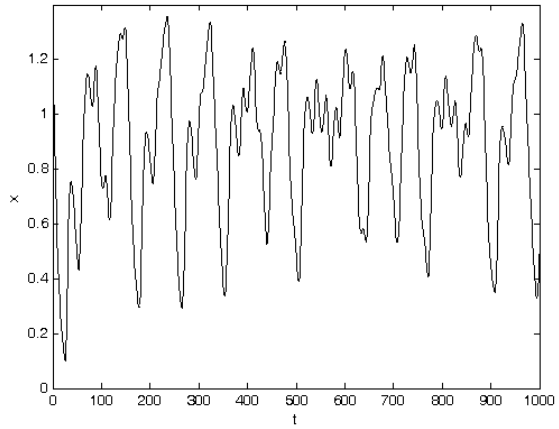

Fig. 7. Mackey-Glass time series.

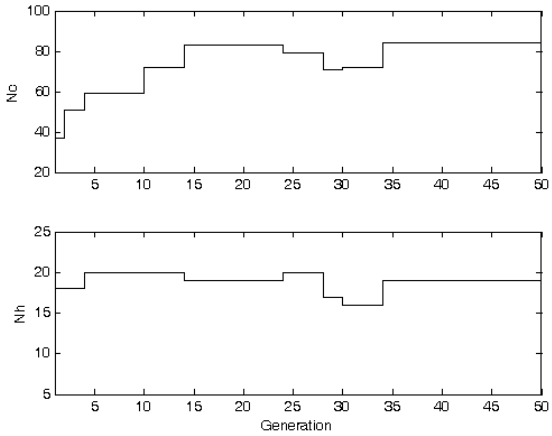

Fig. 8. Evolution progress of neurons and connections for example 1.

Step 10) Perform generational replacement, meaning that all children replace the parents and become parents in the next generation.

IV. Experimental Results

This section provides two examples to verify the performance of the proposed SNEA-NNAGM. The numerical simulations were executed by MATLAB software in an Intel Pentium CPU at 1.5 GHz with 512 MBytes RAM.

Example 1: Chaotic Time Series Prediction

The Mackey-Glass time series shown in Fig. 7 is generated from the following delay differential equation

$$\frac{dx(t)}{dt} = \frac{0.2\,x(t-\tau)}{1+x^{10}(t-\tau)} - 0.1\,x(t) \tag{14}$$

where $\tau = 25$ and $x(0) = 1.2$ in the simulation. The objective involves using $[x(t-3)\ x(t-2)\ x(t-1)\ x(t)]$ to predict $x(t+1)$.

TABLE I. COMPARISON OF PREDICTION RESULTS FOR MACKEY-GLASS TIME SERIES.

	GM(1,1)	Advanced GM(1,1)	NN	NNAGM	SNEA-NNAGM
Training RMSE	---	---	3.27×10^{-4}	2.47×10^{-4}	2.52×10^{-4}
Testing RMSE	1.09×10^{-2}	1.10×10^{-3}	3.58×10^{-4}	2.93×10^{-4}	2.66×10^{-4}
N_h	---	---	34	27	19
N_c	---	---	205	163	84

TABLE II. COMPARISON OF THE PERFORMANCE IN EXAMPLE 2 SUNSPOTS PREDICTION.

	GM(1,1)	Advanced GM(1,1)	NN	NNAGM	SNEA-NNAGM
Training RMSE	---	---	8.24	11.74	12.81
Testing RMSE	30.49	137.52	34.32	65.85	22.01
N_h	---	---	16	14	9
N_c	---	---	97	85	37

Thus, the input of NN of NNAGM is $[e_{GM}(t-3)\ e_{GM}(t-2)\ e_{GM}(t-1)\ e_{GM}(t)]$ and the output is $e_{GM}(t+1)$. The first 500 pairs are used as the training data and the next 500 pairs are the testing data. The parameter of NNAGM is set as $\gamma = 2$ in (12). The parameters of SNEA are set as follows: probability of crossover p_c = 0.8, probability of mutation p_m = 0.5, neuron population size N_{pop} = 40, number of groups N_g = 20, number of group members N_m = 5, and maximum number of generations $G_{\max}$ = 50.

The top side of Fig. 8 shows the number of connections of the evolved NNAGM with the best fitness, N_c, in each generation. The NN has few connections in the first generations and N_c does not always increase. The N_c drops from 83 to 79 in the 24th generation and from 79 to 71 in the 28th generation, implying that more connections do not necessarily result in superior fitness. In other words, appropriate connected topology is the key to improving fitness, not the number of connections. The evolution of NNs almost converges and no further improvement of NN is observed after the 35th generation. The highest quality structure with well-trained weights of NNAGM is then determined.

The bottom side of Fig. 8 shows the number of the hidden neurons, N_h, in the evolved NNAGM. It can be observed that N_h increases to 20 in the 4th generation and decreases to 16 in the 30th generation. As a result, the highest quality structure with well-trained weights of NNAGM has 19 hidden neurons and 84 connections. Clearly, NN of NNAGM is a partially connected network.

Table I shows the prediction results of SNEA-NNAGM compared with other methods including GM(1,1) [9], Advanced GM(1,1) [28], NN [7], and NNAGM [18]. The number of neurons of NNAGM is chosen according to the experimental tests where several NNAGMs with different numbers of neurons, from 1 to 50, were constructed. As a result, a NNAGM with 27 neurons demonstrates the highest performance. The number of neurons of NN is chosen by the same procedure. Consequently, an NN with 34 neurons has the best performance. The neurons of both NN and NNAGM are fully connected. It can be seen that NNAGM has a better RMSE 2.93×10^{-4} than GM(1,1), Advanced GM(1,1), or NN, while SNEA-NNAGM improves the RMSE in advanced 2.66 $\times10^{-4}$ using the evolutionary design of neural networks. It is clear that the evolved NNAGM via SNEA consists of a partially connected NN with 19 neurons and 84 connections. The SNEA-NNAGM obtained a compact structure with fewer neurons and connections, and is superior to NN and NNAGM according to the prediction error.

Example 2: Forecasting the Number of Sunspots

In this example, the sunspots varying nonlinearly from 1709 to 2008 were adopted. The input-output data pair is given as follows:

$$[x[k-3], x[k-2], \cdots, x[k]; x[k+1]] \tag{15}$$

where the four most recent data points are the input data and one step ahead value is the output data. The sunspots of the first 150 years, from 1709 to 1858, were used as the training data and those of the next 150 years, from 1859 to 2008, were the testing data. The input of NN of NNAGM is $[e_{GM}[k-3]\ e_{GM}[k-2]\ e_{GM}[k-1]\ e_{GM}[k]]$ and the output is $e_{GM}[k+1]$. Furthermore, the training data were normalized to the range [0, 1].

Fig. 9 shows the prediction results of the five methods including GM(1,1) [9], Advanced GM(1,1) [28], NNAGM [18], NN [7], and SNEA-NNAGM. The number of neurons of NNAGM is determined by the experimental tests where numerous NNAGMs with different numbers of neurons, from 1 to 50, were constructed. As a result, a NNAGM with 14 neurons has the best performance. The number of neurons of an NN was determined by the same procedure. Consequently, an NN with 16 neurons has the best performance. Note that all neurons in both NNAGM and NN were fully connected. It can be observed that the performance of GM(1,1) was better than the Advanced GM(1,1) in this example, while the performance of NNAGM was better than GM(1,1) due to the use of error prediction via NN. The SNEA-NNAGM further improved the performance by selecting the appropriate structure of NN through SNEA. Table II presents the performance comparison of the five methods. Although SNEA-NNAGM obtained a larger training RMSE than both NN and NNAGM, the testing RMSE is smaller than both of them. Furthermore, the evolved structure of NNAGM via SNEA has 9 neurons and 37 connections. Clearly, the evolved NNAGM is partially connected and is more compact than both NN and NNAGM.

To summarize, through the use of SNEA that designs the structure of NNAGM via symbiotic evolution, SNEA-NNAGM can obtain an appropriate NN structure and outperform NN and NNAGM with a smaller prediction error.

V. CONCLUSION

This paper proposes SNEA to construct automatically NN of an NNAGM. The SNEA determines not only the number of hidden neurons, but also the connected topology between input and hidden layers. The idea behind SNEA is to develop

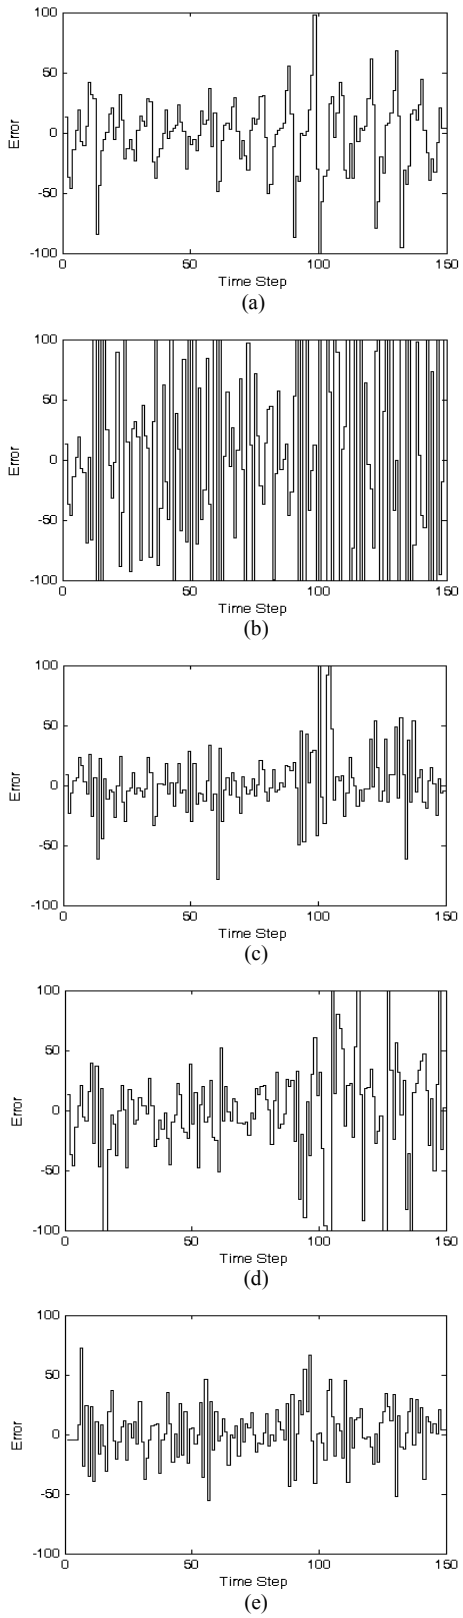

Fig. 9. Prediction errors of (a) GM(1,1) [9], (b) Advanced GM(1,1) [28], (c) NNAGM [18], (d) NN [7], and (e) SNEA-NNAGM.

neurons through symbiotic evolution. This approach facilitates structure learning of NNAGM by evolving neuron population. Each neuron can participate with NNs of different groups and is evaluated through sharing the fitness of the participating NNs. Through symbiotic evolution, NN with appropriate neurons is constructed and the corresponding topology is concurrently established. The experiments in this paper were conducted to evaluate how well SNEA-NNAGM performed in prediction problems. The SNEA can evolve a partially connected NN of an NNAGM with less neurons and connections than a fully connected NN and NNAGM. Furthermore, the prediction performance of SNEA-NNAGM is better than other methods and demonstrates feasibility. Further work should be done to evaluate the performance of this methodology operating in different problems. Thus, future works attempt to analyze the characteristics of this method regarding to the effect of the parameters and apply this method to different numerical experiment and real-world problem.

ACKNOWLEDGMENT

***Abstract*—The use of computers in the production of artifacts has drawn the attention of both artists and computer scientists. Among the different art disciplines, music is one of the arts that most benefited from the use of computers. There are many works which demonstrate the great synergy between these two fields. In this paper we will focus on a specific music composition problem: the figured bass problem, in which we have to automatically generate a 4 voice piece of music, starting from an input the bass line. To solve this problem we use a hybrid strategy, in which different metaheuristics cooperate to find high quality solutions. The cooperation is controlled by means of the combination of fuzzy control and knowledge obtained through Data Mining. As will be shown in the experimental results section, this hybrid strategy is capable of finding musical solutions with an acceptable quality and never discordant which, according to experts, are sound and adhere to scholastic rule.**

***Index Terms*—Computer Music, Evolutionary Computation, Adaptive Memetic Algorithms.**

I. Introduction

The use of computers as means to produce artifacts has been subject of study since the beginning of the computer era. Both artists and computer scientists have been interested in this particular use of the computer. Among the art disciplines, music is one of those that have most benefited from computers. Automatic composition by means of a computer program is almost as old as the computer itself: the ILLIAC suite [1], [2] is a musical piece composed by a computer program and dates back to 1957 just a few years after the introduction of the first computer.

The use of computers in the field of music encompasses many aspects, such as notation programs, sound synthesis, real-time performances, digital instruments, and much more. In this paper we are interested in the aspect of *algorithmic (or automatic) music composition*, that is in the development of computer programs able to automatically generate music, without human intervention.

Algorithmic music composition has fascinated both computer scientists and musicians. We can find works dating back to well before the computer era, which can be considered algorithms for automatic composition (e.g. Mozart's dice game). More recent works include those developed by E.R. Miranda [3] and D. Cope [4], [5], [6].

The tools used to obtain algorithmic composers include many techniques, such as random numbers, formal grammars, cellular automata, fractals, evolutionary algorithms [7][8]. An interesting review of the field can be found in the book by Miranda [9].

Music has a long and interesting history. Music practices have varied during the course of human history developing in various directions also depending on the local culture. This resulted in several formal frameworks for the development of music. The most used one is the so called tempered music system. This system is based on several formal rules that are well suited to be handled by computer programs.

In this paper we are concerned with a very specific tempered music composition problem, known as the *figured bass problem*. A figured bass is a written melody for the bass voice, with indications (numbers or symbols) about the chords to be used. In order to play a figured bass the performer becomes a composer because it is necessary to improvise the other voices in order to obtain a full 4-voice piece of music with the constraints given by the chords indications. The figured bass appeared in the XVI century and was very popular in baroque music. Nowadays it is used (figured or also unfigured) as an exercise for aspiring composers.

So the goal of our automatic composer is that of producing 4-voice piece of music starting from a figured bass line. Formidable examples of 4-voice compositions are Bach's chorales.

Algorithms are frequently used to find optimal or good solutions, where optimal and good are defined according to a precisely defined measure. However, for musical compositions this precise measure does not exist. This is a serious problem, because there is no easy way to decide if a solution is "better" than other. The quality of a musical composition (as the quality of any artistic artifact) is subjective. For the specific problem that we consider in this paper, well known harmony rules can help, although they do not constitute a precise measure. The existence of such a metric would reduce the problem of

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

automatic music composition to an optimization problem with a very large search space. Indeed the figured bass problem, and any other music problem, can be seen as a combinatorial problem where one has to place a finite number of notes on a finite grid (the stave).

In order to "compare" solutions we can exploit harmony rules.

As previously said, there is a broad variety of tools and techniques that can be used to design an algorithmic composer. In this paper we propose the use of a hybrid intelligent tool based on a multi-agent framework and metaheuristics. In this framework different agents analyze a figured bass problem instance and solve it in a parallel way, cooperating between them. This cooperation is performed by jointly exploiting data mining, together with a decision making framework exploiting fuzzy methodologies.

In order to solve the problem each agent implements a metaheuristic. Metaheuristics [10] are intelligent strategies used to design and improve very general heuristic procedures with a high performance. Within metaheuristics, different works [11] have underlined that they can benefit from its combination with fuzzy technologies and data mining improving their results. In this paper we present an adaptive cooperative metaheuristic able to solve figured bass problem. This strategy is able to adapt its behavior depending of the instance being solved. To do that it exploits a set of knowledge models able to code the knowledge obtained from previous executions of the individual metaheuristics. Metaheuristics have already been used for several other problem; to the best of our knowledge, this is the first attempt to use them for a musical problem.

The remainder of the paper is organized as follows. In Section II we introduce some musical concepts necessary to understand the figured bass problem. After that, in Section III the proposed composer is presented. Next, in Section IV we show some results obtained using the composer, and finally in Section V we present some conclusions.

II. Music Background

In this paper we consider the tempered music system, used in western music. This system start from a reference sound (a given frequency, normally 440Hz) and defines *ocatves* as the ranges of frequencies between those sounds obtained by doubling/halving the reference sound. Each octave is divided in 12 equally spaced notes, denoted by the letters A, A♯ or B♭, C, C# or D♭, D, D# or E♭, E, F, F# or G♭, G and G# or A♭. More precisely, if a note has frequency f the "next" note has frequency $f \cdot 2^{\frac{1}{12}}$.

Tempered music is based on the notion of tonality. Roughly speaking, a tonality is a group of notes which form a scale. Using each one of the 12 notes of a scale as starting point we can obtain different tonalities (there are different kinds of tonality for each note, like major, minor, ...). For example, C major scale is C, D, E, F, G, A, B, while D major scale is D, E, F#, G, A, B, C#.

The notes of a scale are often denoted as I, II, III, IV, V, VI, VII, specially when the emphasis is given to the degree of the scale and not to the particular note, which depends on the tonality. Such a notation is possible because all notes are equally spaced.

The interested reader should refer to [12] to get a deeper insight of tempered music.

Usually a tonality is considered the main tonality for a piece, and thus, the notes belonging to the corresponding scale are considered more important than those not belonging to it. Western music, starting from the common practice period, is based on well established harmonic and melodic rules for the tempered music system. We refer the interested reader to any good harmony book as [13] for a discussion about such rules.

In our problem a musical composition is made up of 4 independent voices, called *bass*, *tenor*, *alto*, *soprano*. The bass line is given as input together with numbers, one for each note, that determine the chords to be used.

A musical piece is composed of a sequence of *measures*, each one divided into a given number of *beats*. In each beat the 4 voices play a note (this is a simplification of what really happens, since a composition may also have passing notes, which are not part of the harmony). The vertical set of notes in a beat is a *chord*. The notion of chord is fundamental for this work. There are many types of chords.

In this paper we consider 3- and 4-note chords. Chords are built upon each degree of the scale, that is, I, II, III, IV, V, VI, VII. The note upon which the chord is built, called *root note*, is often given to the bass; however the bass can play any other note which is called chord inversion. Chord inversions usually denoted by a superscript which indicates the inversion (e.g., III^6, V^{46}, I^{357}).

The chords considered on this work are described in Table I (for each one of them we give an example in the tonality of C).

TABLE I
CHORDS CONSIDERED - WITH EXAMPLES IN THE TONALITY OF C

Chord	Root note	Set of notes
Major triad	C	C, E, G
Minor triad	E	E, G, B
Major seventh	C	C, E, G, B
Minor seventh	D	D, F, A, C
Dominant seventh	G	G, B, D, F
Half-diminished seventh	B	B, D, F, A

One of the main rules of tempered music system is that the vertical set of notes has to belong to any of the allowed chords. Other rules may affect sequences of chords. Some sequences are "better" than others, where better is difficult to define, as it is a subjective evaluation. In any case it is largely accepted that particular sequences of chords work better than others. Some chords are "more important" than others because they suggest, prepare, device or enforce tonal centers. The art of tonal music consists precisely in arranging chords in such a way that their interplay is pleasant and significant.

In practice, this is translated into simple rules as the following [13]:

I is followed by IV o V, sometimes VI, less often II o III.
...
...
II is followed by V, sometimes VI, less often I,III o IV.

Besides the rules concerning sequences of chords, we can also find rules about melodic lines. A melodic line is the sequence of notes played by each voice. Rules about melodic lines can refer to the movement of a single voice (for example, a jump bigger than an octave is normally not allowed) or also to the movements of two voices (for example, two voices that proceed by parallel fifth are not allowed). Again, we refer the interested reader to a standard textbook, like [13] for a better and more detailed explanation.

An example of a figured bass problem is provided in Figure 1. Part a of the figure provides the input: only a bass line with indications about the chord; part b provides a solution.

Fig. 1. Chromosome representation

III. An Automatic Music Composer

We propose the use of an adaptive cooperative metaheuristic to solve the figured bass problem. In order to describe the metaheuristic it is necessary to introduce three main aspects: the architecture of the strategy, the cooperation scheme which allows to create a synergy among the different metaheuristics, and the intelligent knowledge extraction process that obtains the data mining models which give adaptability to the strategy.

The development of cooperative metaheuristics lies in the combination of existing metaheuristics to obtain hybrids, in which the different metaheuristics cooperate in a parallel way. Due to their capacity of cooperating in a parallel way, cooperative metaheuristics are closely related to parallel metaheuristics. Many studies have demonstrated [11], [14], [15] that parallel metaheuristics can obtain better results than their sequential components, even when they are allowed to use less time. These studies have shown that the combination of different threads, each one using a different metaheuristic, increments the robustness of the global search independently of the instance being solved.

The proposed strategy combines different metaheuristics which are executed in a parallel way while they exchange information. Information exchange is controlled using previous knowledge about the performance of the individual metaheuristics.

A. Architecture

The strategy is modeled using a multiagent system where we can distinguish two types of agents: *optimization agents* and a *coordinator agent*. Each optimization agent is in charge of executing a metaheuristic, and the coordinator agent is responsible of three tasks: to configure the parameters of the optimization agents depending on the instance being solved, to initiate their parallel execution, and to control their cooperation by deciding how and when they have to exchange information.

Figure 2 shows the architecture of the proposed strategy.

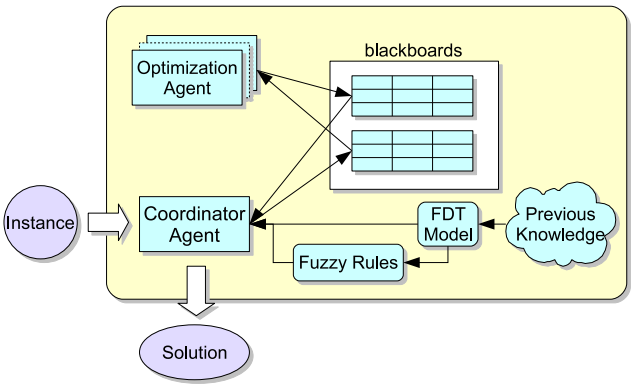

Fig. 2. Architecture of the cooperative metaheuristic strategy

The adaptability of the coordinator is achieved using the knowledge obtained by means of computational learning and coded using a set of trees. In particular, the trees help the coordinator to:

1) choose the best parameters values for each metaheuristic, and
2) sort the suitability of each metaheuristic to solve the instance under consideration, using a set of weights in the range $[0, 1]$.

By analyzing the weights, the coordinator can find out if a metaheuristic is obtaining a poor behavior (according to some measure of performance, e.g. the value of the objective function). As a consequence it can decide to send some solutions to the "bad" metaheuristic from a metaheuristic with a better behavior.

Optimization agents execute in an asynchronous way their associated metaheuristics while send and receive information. The exchange of information is carried out using a blackboard. In detail, two blackboards are used, the first is used by optimization agents to publish the solutions they have found, the second is used by the coordinator in order to indicate the instructions for each agent. Specifically, after a specified period of time, each optimization agent stops and publishes its current solution/population (depending on its type, trajectory or population based). Then the coordinator agent analyzes the behavior of each metaheuristic, using its previous knowledge, and decides if any strategy needs to improve its performance. In this case, the coordinator writes in the second blackboard the new solution/population that the metaheuristic has to use.

B. Cooperation Scheme

The cooperation scheme used by the strategy is mainly defined by the control rules used by the coordinator and the

trees that guide its adaptivity mechanism. These components have to help the coordinator agent to:

- choose the best parameters values for each metaheuristic.
- find out when a metaheuristic is obtaining poor behavior and has to receive new solutions from other metaheuristics with a better behavior.

The first task is carried out using a set of trees obtained through a supervised learning process. Each one of the trees is related to a parameter of a metaheuristic.

The coordinator is able to perform the other task using the information contained in the rest of trees. These trees analyze the instance at hand and sort the different cooperating metaheuristics according to their suitability to solve it. In particular the trees obtain a set of weights $\Omega = \{\omega_i, i = 1, \ldots, n\}$ where n is the number of metaheuristics, $\omega_i \in [0, 1]$ and $\sum_{i=1}^{n} w_i = 1$. Each weight ω_i is associated to a metaheuristic m_i and represents its suitability to solve the instance at hand.

In order to control the exchange of solutions, the coordinator uses the following set of fuzzy rules (this set of rules is replicated once for each metaheuristic):

if $(\omega_1 \cdot \delta_1)$ is *enough* **then**
send solutions from m_1 to m_h

$\ldots$ $\ldots$

if $(\omega_n \cdot \delta_n)$ is *enough* **then**
send solutions from m_n to m_h

where:

- n is the number of metaheuristics.
- m_h is the metaheuristic being evaluated.
- $\delta_i = (\xi_{m_i} - \xi_{m_h})/maximum(\xi_{m_i}, \xi_{m_h})$, where ξ is a measure of performance.
- $\omega_{m_i} \in [0, 1]$ where $\sum_{i=1}^{n} \omega_{m_i} = 1$ and represents the weight of metaheuristic m_i.
- $enough$ is a fuzzy set with trapezodial membership function (with support $\in [0, 1]$) defined by:

$$\mu(x, a, b, c, d) = \begin{cases} 0 & x \leq a \text{ or } x \geq d \\ \frac{x-a}{b-a} & x \in (a, b] \\ \frac{d-x}{d-c} & x \in [c, d) \\ 1 & x \in [b, c] \end{cases}$$

with $(a, b, c, d) = (0, 0.1, 1, 1)$.

Using this set of rules the coordinator is able to know when it has to send new solutions to a given metaheuristic. In detail, it changes the position in the search space of a metaheuristic which is showing a bad performance for a position near the position of another metaheuristic with a better behavior. The firing of the rules is controlled using an α-*cut* defined by the user. In the event that more than a rule is fired, the coordinator applies all of them.

To decide which solutions are sent to a metaheuristic, we consider the following situations:

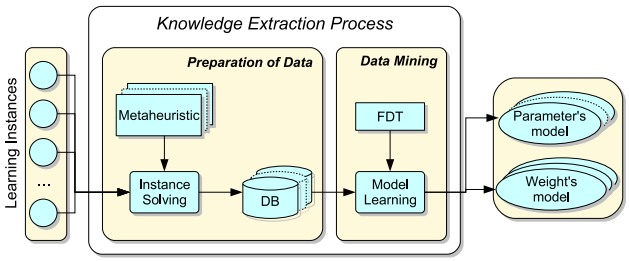

Fig. 3. Obtaining models: Knowledge extraction process

- $m_{receiver}$ is based on trajectories. A solution "near" the best solution obtained by the metaheuristics that have fired the rule is sent. Where "near" means that we apply $\frac{1}{2\omega_{sender}}$ times a mutation operator.
- $m_{receiver}$ is population based:
  - m_{sender} is trajectory based. A proportion of the worst individuals of $m_{receiver}$'s population is substituted by a set of solutions near m_{sender}'s best solution.
  - m_{sender} is population based. A proportion of the worst individuals of $m_{receiver}$'s population is substituted by a set of the best members of m_{sender}.
  - Different metaheuristics have to send solutions. A proportion of the worst individuals of $m_{receiver}$'s population equals to sum of $m'_{sender}s$ ω_i is substituted by a set of solutions where each m_{sender} chooses its solutions as described before.

C. Tree Construction

In order to obtain the models related to weights and parameters we use an intelligent knowledge extraction process, as the one shown in Figure 3.

This process is divided in two different phases, data preparation and data mining. In addition, the process is supervised and previous to strategy's operation.

1) Data Preparation Phase: In this phase the different metaheuristics that compose the strategy are executed several times to solve diverse training instances.

In particular, each metaheuristic is executed using different values for each one of its parameters. Using the information generated in these executions we obtain a dataset which describes the behavior of each metaheuristic.

In detail, we obtain two types of datasets. The first type is related to metaheuristics' parameters and we need one dataset for each parameter of each metaheuristic. The second type is related to metaheuristics' weights and we need one dataset for each metaheuristic.

Focusing on parameters' datasets, each one of them stores for each training instance: a description of the instance and the parameter value that obtained the best performance after solving it. On the other hand, each weights' dataset stores for each training instance: a description of the instance and a weight obtained as

$$\omega_{m_i} = \frac{fit_{best}^{q,i}}{\sum_{l=1}^{n} fit_{best}^{q,l}}$$

where $fit_{best}^{q,i}$ is the best value of the objective function obtained by metaheuristic i for instance q.

2) Data Mining Phase: Once we have obtained the datasets, the data mining phase extracts a collection of fuzzy decision trees which model the information contained in them. Once again we can distinguish two types of models, *parameter models* and *weight models*. The first type is related to the choice of parameters values carried out by the coordinator, and there is one model for each parameter of each metaheuristic. On the other hand, the second type of models is related to the weights Ω, and there is one model for each metaheuristic.

After completing this phase we obtain a set of trees that guide the adaptation of the coordinator. That way it is available to control optimization agents cooperation.

IV. Experimental Analysis

In this section we perform tests in order to asses the validity of the proposed strategy. Each strategy takes as input a figured bass line and produces a complete 4-voice harmonization of the bass line. Some examples of MIDI files generated during the experimental sessions can be listened at http://music.dia.unisa.it/Musimatica/Download.html.

A. Chromosome and gene representation

Figure 4, shows the MIDI-code representation of a chromosome. The time signature $\binom{n_b}{b_\ell}$ is part of the input; we consider as basic time unit the length of the beats. We allow notes of the input to have a length greater than (actually, a multiple of) the beat length. However, if an input note is shorter than the beat length then we consider it only if the note is placed on the beat (otherwise it is only a passage note).

Let n_m denote the number of measures in the input bass line. We can represent a chromosome as an array C of dimension $4 \times n$, where $n \leq n_b \times n_m$. Element $C(i,j)$ contains the j^{th} note for voice i. We place the bass voice in the lower row and the soprano voice in the upper row. Notes are represented using MIDI codes; this allows us to easily play the chromosomes. In the previous example (Figure 4) we have $n_b = 4$, $b_\ell = 1/4$, $n_m = 2$ thus $n = 2 \times 4 = 8$. Notice that this representation doesn't contain information about the notes' length; indeed we do not use such information for the metheuristic. Obviously, we keep the information about the length of the notes in a separate data structure.

For each bass note b_i our goal is to select 3 notes to be played along with the bass note b_i. We will denote such notes with t_i, c_i, s_i. The set of notes $\{b_i, t_i, c_i, s_i\}$ is the chord at position i. We can also think of a (candidate) solution to our problem as an array of $4 \times n$ cells, where each column i contains the four notes b_i, t_i, c_i, s_i. The set of these 4 notes must be one of the allowed chords (see Table I) and must match the indication given in the input.

Since the bass is figured choosing the chord is the easy step, since the input provides already an indication. After choosing the chord we have a huge number of possibilities to place the notes of the chord. Only the bass note is already fixed; notice that the bass not does not necessarily correspond to the root note of the chord.

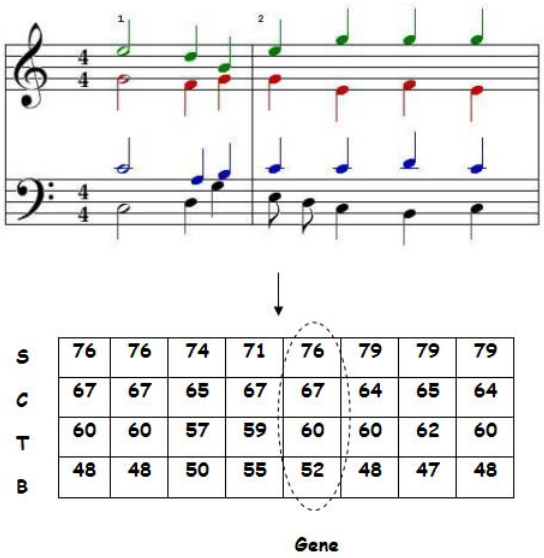

Fig. 4. Chromosome and MIDI representation

B. Fitness function

Our evaluation function takes into account musical composition rules from the common practice period. We consider a simple set of rules, which are detailed in Table II.

To assign a value to a chromosome we start from a reference value which depends on the sequence of chords and thus, depends only on the input, i.e., it is fixed and is based upon harmonic considerations (appropriate sequences of chords);

Given a chromosome x, we assign a reference value by giving a weight for each pair of genes. For each two consecutive bass notes we look at the sequence of the two chords C_1 and C_2 given in x to those two notes and we give the following weights:

- C_1 and C_2 are chords in the same major tonality. The weights are given in Table III.
- C_1 and C_2 are chords in the same minor tonality. The weights are given in Table IV.
- C_1 and C_2 modulate from a major to a major tonality or from a minor to a minor tonality. The weights are given in Table V.
- C_1 and C_2 modulate from a major to a minor tonality or from a minor to a major tonality. The weights are given in Table VI.

The reference value is given by the sum of the weights for pair of genes of x. The weights have been chosen so that good harmonic pattern have heavier weights.

Then to obtain the fitness value of a particular solution we subtract a given cost for each rule violation present in the solution from the reference value. The relations between two consecutive genes (chords) allows us to decide whether the chromosome is good or not. For example, if a voice makes an augmented fourth jump we subtract 40 from the initial value; if two voices make a hidden fifth we subtract 60. If two notes within a chord are at distance greater than an

TABLE IV
WEIGHTS FOR STEPPING BETWEEN CHORDS IN THE SAME MINOR TONALITY. THE CHORDS ARE DENOTED $2^*, 3^*$ ETC. BECAUSE IN A MINOR TONALITY ON THESE DEGREES WE CAN HAVE SEVERAL TYPE OF CHORDS (E.G. ON THE SECOND DEGREE WE CAN HAVE ii OR ii°).

	i	2*	3*	4*	5*	6*	7*
i	250	200	50	200	250	50	10
2*	100	100	100	150	2000	150	10
3*	100	100	100	200	100	250	10
4*	250	150	100	200	1500	100	10
5*	2000	100	100	100	250	150	10
6*	100	200	150	150	200	200	10
7*	1000	50	150	50	50	100	200

octave we subtract 30 (except for the couple bass-tenor). For some violations (which we call critical errors) we have bigger penalties. For example for a voice jump bigger than an octave or for two voices that create exposed parallel fifths we have a penalty of 100. Table II provides also the cost that we used for each rule. We construct the possible chords always putting voices in the order bass, tenor, alto and soprano; hence no voice crossing is allowed.

Let's consider an example and again take the one presented in Figure 1. The reference value is the sum of the weights of the chords sequence I - ii - V - I - I - V - I, that is $200 + 2000 + 2000 + 250 + 250 + 2000$, the total is 6700.

To obtain the fitness value of a particular solution, we start from the base value and subtract all the costs listed in Table II.

In this particular case the overall single voices cost is 48, the cost for errors within a chord is 90, the cost of single voices errors 0 and also the cost of two voices errors is 0. Total cost is 138. The fitness value is 6562.

C. Configuration of the Strategy

We will build a strategy using four different individual metaheuristics:

- Genetic Algorithm,
- Tabu Search,
- Simulated Annealing, and
- Particle Swarm Optimization.

After deciding the composition of the metaheuristic, we have to apply the intelligent knowledge extraction process. We will give a brief description of the decisions taken to apply it to a real problem.

- As a first step we have decided to use 36 training instances, in particular this instances have been chosen among J.S. Bach's chorales.
- Each one of them has been solved using each metaheuristic configured with different combination of parameters values. In particular, for each parameter of each metaheuristic we have chosen 4 different values on average. To choose these values we have used previous knowledge about their behavior, however, if there is no previous knowledge we recommend to use, at least, 10 different values.
- After choosing parameters values, we solve each instance 10 times with each possible combination of parameters values, to obtain more precise values.
- Next we obtain parameters and weights datasets.
- Finally we use a fuzzy decision tree construction technique in order to obtain parameters and weights models.

D. Configuration of the Experiments

In order to test the validity of the approach we compare the proposed strategy with the individual metaheuristics that comprise it. To do so, we perform tests with 4 different instances chosen among J.S. Bach's chorales, in particular chorales 26, 112, 266, 606.

Each strategy was executed during 100000 evaluations of the objective function and each instance was solved 10 times. The results show the averages. For the cooperative strategies one can resort to parallel schemes if time is important, or one can simulate the parallelism in a one-processor computer. This is the strategy taken here and the procedure is extremely simple.

We construct an array of solvers and we run them using a round-robin schema. This implementation uses an asynchronous communication mode that is simulated in this way: solvers are executed during a certain number of evaluations of the objective function. This amount of evaluations is a random number in the interval $[5000, 5500]$ and after this period of time, information exchanges are performed. These steps are repeated until the stop condition, given in terms of objective function evaluations, is fulfilled.

The use of the number of objective function evaluations to control the execution of the strategies is broadly extended as a way to perform fairer comparisons with existing techniques. Because in that way we can compare the results independently of the programming language used, the architecture of the computer utilized or the ability of the programmer to optimize his code.

However, we consider that the time can be considered as an important measure of performance, and in that sense we have to point out that the overhead derived from the execution of the coordinator is negligible and that the execution time of the cooperative strategies is always smaller than that of the slower individual metaheuristic for the same number of evaluations of the objective function.

All tests were executed on an Intel Pentium 4 3.20Ghz with 1GB of Memory.

E. Results

The results obtained are shown in Table VII. For each strategy and each instance we present the average percentage of error obtained with respect to the best solution obtained.

From these results we can observe that the proposed strategy (CS) is the one which obtains the lowest error. In order to demonstrate this conclusion we have carried out a statistical analysis [16] of the results. First, we have applied Friedman test to ascertain if there are any differences among the results obtained by all strategies, concluding with a confidence level of 99% that differences do exist. After that we have applied a post-hoc test (Benjamini-Hochberg test together with Wilcoxon test) to study if the error obtained by the proposed strategy is less than that obtained by the rest.

TABLE VII
RESULTS OBTAINED WITH 4 DIFFERENT INSTANCES CHOSEN AMONG J.S. BACH'S CHORALES.

Instance	GA	PSO	SA	TS	CS
Bach's chorale 70	32,03%	26,71%	0,20%	1,41%	0,04%
Bach's chorale 215	39,70%	35,47%	0,88%	5,15%	0,04%
Bach's chorale 266	43,79%	39,38%	12,82%	5,86%	0,02%
Bach's chorale 3604	21,95%	25,66%	4,26%	11,21%	0,02%

The results of these statistical tests indicated with a confidence level of 99% that the results obtained by the cooperative strategy are better.

From these results we can observe the utility of the cooperation between metaheuristics and the adaptive selection of parameters by means of data mining models.

F. Musical analysis

After performing a performance study with respect to the value of the objective function and checking the superiority of the proposed strategy we want to analyze its results from a musical point of view.

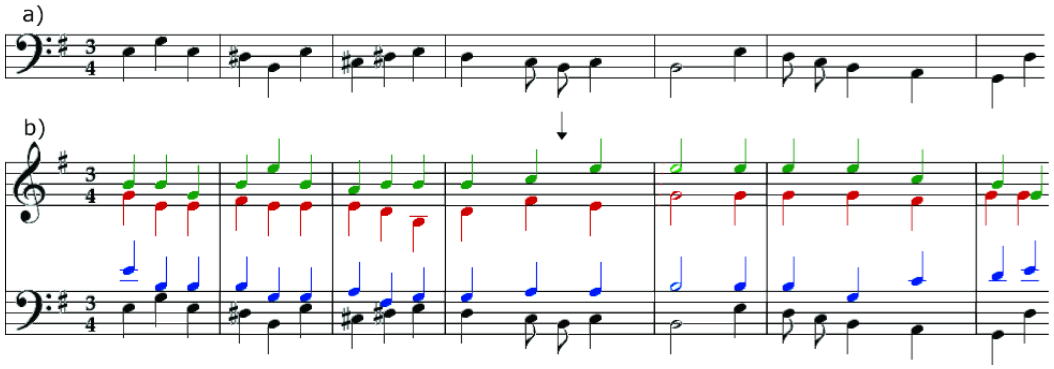

Fig. 5. An example of input - Bach's chorale 266 - (part a) and final solution (part b)

As we have pointed out in the introduction, the quality of a musical composition is a subjective judgment. However the solutions provided do not have any of the errors that guided the search performed by the cooperative metaheuristic.

We have also performed listening tests where we had people, with a music background, listen to the pieces composed by our automatic composer. The avarage response that we had is that the compositions are sound and adhere to scholastic rule. A human composer would probably do better in terms of originality, but most people were surprised that a computer could actually produce such outputs.

V. Conclusions

Figure 5 shows an example of the results obtained by the strategy with Bach's chorale 266. Part a of the figure shows bass line (input) and part b the final solution obtained.

The results obtained fulfill our expectations, returning solutions with an acceptable quality and never discordant. Such results are possible because the cooperative metaheuristic is able to eliminate all critical errors and many of the errors allowed by the used harmonic rules.

In this paper we have presented an automatic composer based on an adaptive cooperative metaheuristic strategy. This composer is able to generate a musical composition without human intervention.

The specific problem under consideration is figured bass problem, in which the objective is the generation of a 4 voice piece starting from bass line. We have tackled the problem using an adaptive cooperative metaheuristic strategy. In this strategy a set of different metaheuristics cooperate under the supervision of a coordinator. This coordinator is modeled using the knowledge extracted by means of a supervised learning process, which is applied to historical data of the execution of individual metaheuristics.

To test the validity of the strategy we have performed different tests obtaining interesting results.

As future work we want to study the similar (but harder) problem called unfigured bass where no indications about the chords is provided in the input. Another interesting direction for future work is the use of an extended set of harmony rules.

***Abstract*—Stock selection has long been a challenging and important task in finance. Recent advances in machine learning and data mining are leading to significant opportunities to solve these problems more effectively. In this study, we aim at developing a methodology for effective stock selection using fuzzy models as well as genetic algorithms (GA). We first devise a stock scoring mechanism using fundamental variables and apply fuzzy membership functions to re-scale the scores properly. The scores are then used to obtain the relative rankings of stocks. Top-ranked stocks can thus be selected to form a portfolio. Furthermore, we employ GA for optimization of model parameters and feature selection for input variables to the stock scoring model. We will show that the investment returns provided by our proposed methodology significantly outperform the benchmark return. Based upon the promising results obtained, we expect this hybrid fuzzy-GA methodology to advance the research in soft computing for finance and provide an effective solution to stock selection in practice.**

Keywords- Stock selection; fuzzy models; genetic algorithms; model validation

I. INTRODUCTION

Stock selection has long been identified as a challenging and important research area in finance. The success of this task is highly contingent upon reliable selection of stocks that provide above-average return on investment in the future. Recent advances in computational intelligence and data mining are leading to significant opportunities to solve these problems more effectively. Feasible quantitative models include methodologies stemming from soft computing [1] for prediction of financial time series, multi-objective optimization of expected investment return and risk reduction, and portfolio management – selection of investment instruments based on asset ranking using a variety of input variables and historical data, etc. [2-3]. All these research efforts were in an attempt to facilitate the task of decision-making for investment.

In the research area of stock selection and portfolio optimization, several machine learning methodologies have been developed, including artificial neural networks (ANNs), support vector machines (SVMs), evolutionary algorithms (EAs) as well as fuzzy inference models. Quah and Srinivasan [4] studied an ANN stock selection system to choose stocks that are top-ranked performers. They showed their proposed model outperformed the benchmark model in terms of compounded actual returns overtime. Chapados and Bengio [5] also trained neural networks for estimation and prediction of asset behavior in order to facilitate decision-making in asset allocation. Although these models worked in some applications, they often suffer from the overfitting problem and may tend to fall into a local optimum.

For portfolio optimization, Kim and Han [6] proposed a genetic algorithm (GA) approach to feature discretization and the determination of connection weights for ANNs to predict the stock price index. They suggested that their approach was able to reduce the numbers of attributes and the prediction performance was enhanced. In addition, Caplan and Becker [7] employed genetic programming (GP) to develop a stock ranking model for the high technology manufacturing industry in the U.S. More recently, Becker, Fei and Lester [8] explored various single-objective fitness functions for GP to construct stock selection models for particular investment specifics with respect to risk. In a nutshell, these GP-based models rank stocks from high to low according to a pre-defined objective function.

In the area of fuzzy applications in finance, earlier work includes, for instance, Chu *et al.*'s fuzzy multiple attribute decision analysis to select stocks for portfolio construction [9]. Analogously, Zargham and Sayeh [10] employed a fuzzy rule-based system to evaluate a set of stocks for the same purpose. Although these fuzzy approaches denote early efforts in employing computational intelligence for financial applications, they usually lack sufficient learning ability. However, more recently, Chang [11-12] studied a hybrid neuro-fuzzy inference system for the forecast of financial time series. Chang showed that this hybrid model is able to improve the predictive accuracy of irregular non-periodic short-term time series forecast.

Despite the promising performance of the aforementioned approaches in finance, their success is highly contingent upon the input variables (features) to the model. Yang and Honavar [13] indicated that several classification issues are determined by the choice of features that describe given patterns presented

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

to a classifier, such as the classification accuracy of the learned classifier, the computational overhead required for learning a classification function, the number of training examples needed for learning, and the cost associated with the features. Therefore, the goal of feature selection aims to identify useful, non-redundant subsets of features for a given data mining or machine learning task.

In addition, since the variables relevant to the machine learning models usually consist of not only the features but also the models parameters, it is expected that a successful model along this line of research shall take into consideration these two issues simultaneously. Therefore, in this study, we devise a hybrid fuzzy-GA stock selection model for this task, where the GA is used for feature selection and optimization of parameters, simultaneously. Furthermore, in our proposed scheme, feature selection depends on the output of the stock selection model. As a result, our hybrid model can be categorized as a wrapper approach [14-15], as opposed to the filter approach. The wrapper approach for feature selection is employed in this study because of its improved performance over the filter approach [14-18].

In a nutshell, we will conduct the stock scoring mechanism using fuzzy membership functions with the GA-optimized model parameters and subsets of features. Based on the scores calculated, top-ranked stocks are then chosen for portfolio construction. We will report the portfolios constructed by our proposed scheme substantially outperform the benchmark over the long period of time.

This paper is organized into five sections. Section 2 outlines the methods employed in our study. In Section 3 we describe the research data used in this study. In Section 4, we present the experimental design and empirical results are reported and discussed. Section 5 concludes this paper with future research directions.

II. METHODOLOGY

This section first describes our proposed scheme to score stocks using fundamental variables and fuzzy membership functions. Afterwards, model optimization, i.e., parameter optimization and feature selection, by the GA will be discussed.

A. Stock scoring via fundamental variables

In this study, we are concerned with the relative quality of stocks described by the fundamental variables, including firms' share price rationality, growth, profitability, liquidity, efficiency, and leverage attributes. In general, these fundamental variables can be used to determine the value of a stock, defined by the score assigned by our proposed model. Our objective of this scoring model is to imply stocks of higher scores to possess higher potential in future price advancement. Based on these scores one can then rank various stocks and top-ranked stocks are picked to construct the portfolio.

In this study, we first propose a straightforward linear model using these fundamental variables to score stocks. Let $X_{i,j,t}$ denote the score of stock i assigned by variable j at time t, where $X_{i,j,t}$ depends on the value of variable j, $v_{i,j,t}$, for stock i at time t. For instance, in the area of value investing, if the variable is the price-to-book value (P/B ratio), a smaller P/B value tends to imply the stock's higher potential of price increase in the future [19]. On the contrary, if the variable is return-on-asset (ROA), a larger value of ROA usually implies the stock's higher potential of price increase in the future.

Therefore, we propose to sort the stocks according to their values of variable j and the individual score assigned to stock i at time t is:

$$X_{i,j,t} = \rho_{i,j,t},$$

where $\rho_{i,j,t} \in N$ is the ranking of stock i with respect to variable j at time t. Here we denote a stock sorting indicator I_j for variable j and consider two cases for the stock sorting scheme:

$$(1)\ I_j = 0:\ \rho_{i,j,t} \geq \rho_{k,j,t} \ \text{ iff } \ v_{i,j,t} \geq v_{k,j,t} \text{ for } i \neq k.$$

$$(2)\ I_j = 1:\ \rho_{i,j,t} \geq \rho_{k,j,t} \ \text{ iff } \ v_{i,j,t} \leq v_{k,j,t} \text{ for } i \neq k.$$

In addition, let W_j denote the weight of the j-th variable. Then the total score of stock i at time t, $S_{i,t}$, can be defined as

$$S_{i,t} = \sum_j W_j X_{i,j,t}. \tag{1}$$

In this study, to allow more flexibility for our model, we introduce a fuzzy scheme as an extension of the scoring mechanism, which will be discussed next.

B. Fuzzy model for stock scoring

To improve the accuracy of the stock scoring model, the fuzzy membership function is applied. This treatment is to increase the flexibility of the model so that the stock scores calculated by the GA may be adjusted properly to reflect the actual potential of stock price increase in the future. This adjusted score, denoted by $y_{i,t}$, is determined by the score calculated by Eq. (1), $S_{i,t}$, and the fuzzy membership function, $\mu(x)$.

More specifically, in the fuzzy stock scoring model, the score for stock i at time t, $y_{i,t}(\boldsymbol{W}, \boldsymbol{\theta}) \in R$, is defined as

$$y_{i\,t}(\boldsymbol{W}, \boldsymbol{\theta}) = S_{i,t}(\boldsymbol{W}, \boldsymbol{\theta}) * \mu(S_{i,t}(\boldsymbol{W}, \boldsymbol{\theta})),$$

where $\boldsymbol{W}$ denotes the vector of the weights of the input features (i.e., the fundamental variables) used by the stock scoring model and $\boldsymbol{\theta}$ denotes the set of the parameters used by the fuzzy membership function.

In this study, we compare three commonly used fuzzy membership function — the triangle, trapezoid and Gaussian functions. As an illustration, Fig. 1 displays the triangular membership function as shown below, where the shape of the fuzzy model is determined by parameters a, b, and c. In this study, these parameters will be optimized by the GA based on the given fitness function.

$$\mu_A(x) = \begin{cases} 0, & x \le a \\ \dfrac{x-a}{b-a}, & a < x \le b \\ \dfrac{c-x}{c-b}, & b < x \le c \\ 0, & c < x \end{cases}$$

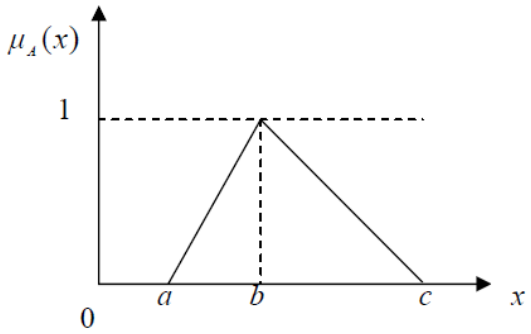

Figure 1. Triangular fuzzy membership function

Our experimental results so far show that the triangle and trapezoid functions exhibited similar, better performance than the Gaussian function. The reason is that the tip and the width of the triangle and trapezoid functions are adjustable, whereas in the Gaussian function, only the width can be adjusted. Therefore, in this paper, we will only demonstrate the experimental results using the triangular membership function.

It is worthwhile to mention that the scores calculated for the stocks may not necessarily represent the precise values of various stocks. Rather, they can serve as surrogates for the actual quality to imply the relative rankings of the stocks. Thus given the scores for all stocks, the ranking of a stock can be defined as:

$$\alpha_{i,t}(\boldsymbol{W}, \boldsymbol{\theta}) = \rho(y_{i,t}(\boldsymbol{W}, \boldsymbol{\theta})), \tag{2}$$

where $\rho(\cdot)$ is a ranking function so that $\alpha_{i,t} \in N$ is the ranking of stock i at time t, and $\alpha_{i,t} \ge \alpha_{j,t}$ iff $y_{i,t} \ge y_{j,t}$.

The task of stock selection can be achieved using these rankings whereby top-ranked m stocks (stocks corresponding to the top m α's) are selected as components of a portfolio. The performance of a portfolio can be evaluated by averaging the actual returns of the stocks in the portfolio, which is defined as:

$$\overline{R_t} = \frac{1}{m}\sum_{i=1}^{m} R_t(s_{i,t}), \tag{3}$$

where $s_{i,t}$ is the i-th ranked stock at time t; $R_t(\cdot)$ is the actual return for a stock at time t and $\overline{R_t}$ is the average return over all the m stocks in the portfolio at time t.

In this study we will use the cumulative total (compounded) return, R_c, to evaluate the performance of a stock selection model, where R_c is defined as the product of the average yearly return, $\overline{R_t}$, of the stocks in a portfolio over n consecutive years as:

$$R_c = \prod_{t=1}^{n} \overline{R_t}. \tag{4}$$

C. Model optimization

The performance of the stock selection model is determined by the set of input features $\boldsymbol{F}$, the set of stock sorting indicators $\boldsymbol{I}$, the weights of the fundamental variables $\boldsymbol{W}$, and the set of parameters $\boldsymbol{\theta}$ to the fuzzy membership function. Therefore, we expect that the selection of optimal subsets of features $\boldsymbol{F}$, and the optimization of $\boldsymbol{I}$, $\boldsymbol{W}$ and $\boldsymbol{\theta}$ will be critical to the effectiveness of the stock selection model. In this study, we propose to use Genetic Algorithms for simultaneous optimization with respect to these tasks. In the next subsections we describe the basics of the GA and the relevant optimization scheme for our stock selection model.

C.1 Genetic algorithms

Genetic algorithms were developed by Holland [20] and have been used as computational models of natural evolutionary systems and as adaptive algorithms for solving optimization problems. GAs operate on an evolving population of artificial organisms, or agents. Each agent is comprised of a genotype (often a binary string) encoding a solution to some problem and a phenotype (the solution itself). GAs regularly start with a population of randomly generated agents within which solution candidates are embedded. In each iteration, a new generation is created by applying variations, such as crossover and mutation, to promising candidates selected according to probabilities biased in favor of the relatively fit agents. As a result, evolution occurs by iterated stochastic variation of genotypes, and selection of the best phenotypes in an environment according to how well the respective solution solves a problem (or problem-specific fitness function). Successive generations are created in the same manner until a well-defined termination criterion is met. The core of this class of algorithms lies in the production of new genetic structures along the course of evolution, thereby providing innovations to solutions for the problem at hand. The steps of a simple GA are shown in the following:

Step 1: Randomly generate an initial population of l agents, each being an n-bit genotype (chromosome).
Step 2: Evaluate each agent's fitness.
Step 3: Repeat until l offspring have been created.
  a) select a pair of parents for mating;
  b) apply variation operators (crossover and mutation);
Step 4: Replace the current population with the new population.
Step 5: Go to Step 2 until terminating condition.

C.2 Chromosome encoding and fitness function

Among many paradigms of search algorithms GAs have been proven to have an advantage over traditional optimization methods in problems with many complex, discontinuous constraints in the search space. This methodology contributes for a global, population-based search in the search space, in contrast with the kind of local, greedy search conducted by most rule-induction and decision-tree algorithms. Lower computation cost is a general advantage of local, greedy search algorithms. However, the solution quality achieved by these algorithms can be greatly degraded if there exists a considerable degree of feature interactions, which is usually the case for real-world problems. Since GAs can be designed to perform a global search for various combinations of sets of features that improve given optimization criteria, this class of algorithms are expected to cope better with feature interaction problems. Therefore, we propose to use the GA method to search for optimal subsets of features for the stock selection model.

Apart from feature selection, three sets of free parameters, $\boldsymbol{I}$, $\boldsymbol{W}$ and $\boldsymbol{\theta}$, are to be provided for the stock selection model. Here we employ the GA for simultaneous optimization of these tasks. In our overall encoding design, the composition of a chromosome is devised to consist of four portions - the candidate set of features $\boldsymbol{F}$, the stock sorting indicators $\boldsymbol{I}$, the weighs $\boldsymbol{W}$ and the fuzzy model parameters $\boldsymbol{\theta}$. In this study, the binary coding scheme is used to represent a chromosome. In Fig. 2, loci b_f^1 through b_f^n represent candidate features 1 through n, respectively. For these features, allele '1' or '0' corresponds to the feature being selected or not. Loci b_i^1 through b_i^n represent the sorting indicators, where 0 represents the variable being used for case (1) of our stock sorting scheme, and 1 represents case (2), respectively. On the right-hand side of Fig. 2 is the encoding of the set of parameters $\boldsymbol{W}$. Fig. 3 shows the detailed binary encoding for the weight of each individual variable, where the value of W_i (the weight for variable i) is encoded by loci b_{Wi}^1 through $b_{Wi}^{n_i}$. For the fuzzy model, the rightmost side of Fig. 2 is the encoding of the set of parameters $\boldsymbol{\theta}$. For example, parameter a is encoded (in binary forms) by loci b_a^1 through $b_a^{n_a}$, as shown in Fig. 4.

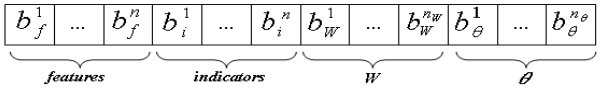

Figure 2. Chromosome encoding

Figure 3. Detail encoding of the weighting terms *Wi's*

Figure 4. Detail encoding of the fuzzy model parameters

In our coding scheme, the portion in the chromosome representing the genotypes of parameter W_i's and $\boldsymbol{\theta}$'s is to be transformed into the phenotype by Eq. (5) for further fitness computation. The precision representing each parameter depends on the number of bits used to encode it in the chromosome, which can be determined as follows:

$$y = \min_y + \frac{d}{2^l - 1} \times (\max_y - \min_y), \tag{5}$$

where y is the corresponding phenotype for the particular parameter; $\min_y$ and $\max_y$ are the minimum and maximum of the parameter; d is the corresponding decimal value, and l is the length of the block used to encode the parameter in the chromosome.

With this encoding scheme, we define the fitness function of a chromosome as the annualized return of the portfolio:

$$fitness = \sqrt[n]{R_c}, \tag{6}$$

where Rc is the cumulative total return computed by Eq. (4).

Our proposed fuzzy-GA model for stock selection is a multi-stage process, including feature selection and parameter optimization by the GA, stock scoring, score fuzzification, stock ranking and selection, as well as performance evaluation. The flowchart of this hybrid algorithm is shown in Fig. 5.

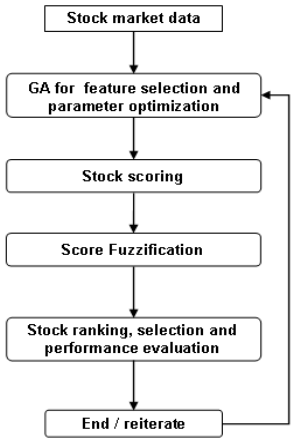

Figure 5. Flow chart of the hybrid fuzzy-GA model

III. DATA AND FUNDAMENTAL VARIABLES

We use the constituent stocks of the 50 largest market capitalizations listed in the Taiwan Stock Exchange as the investment universe. The yearly financial statement data and stock returns used for this research are retrieved from the TEJ

Table I. Attributes used in the stock selection model

Attribute	Ratios	Description	Ref.
Share price rationality	PE ratio	Price-to-earnings ratio = share price / earnings per share	[21, 23-24, 26]
	PB ratio	Price-to-book ratio = share price / book value per share	[21-25]
	PS Ratio	Price-to-sales ratio = share price / sales per share	[21]
Profitability	ROE	Return on equity (after tax) = net income after tax / shareholders' equity	[27-28]
	ROA	Return on asset (after tax) = net income after tax / total assets	[27]
	OPM	Operating profit margin = operating income / net sales	[29]
	NPM	Net profit margin = net income after tax / net sales	[28]
Leverage	DE ratio	Debt-to-equity ratio = total liabilities / shareholders' equity	[27]
Liquidity	CR	Current ratio = current assets / current liabilities	[27]
	QR	Quick ratio = quick assets / current liabilities	[27]
Efficiency	ITR	Inventory turnover rate = cost of goods sold / average inventory	[27]
	RTR	Receivables turnover rate = net credit sales / average accounts receivable	[30]
Growth	OIG	Operating income growth rate = (operating income at the current year – operating income at the previous year) / operating income at the previous year	[31]
	NIG	Net income growth rate = (net income after tax at the current year – net income after tax at the previous year) / net income after tax at the previous year	[32]

(Taiwan Economic Journal Co. Ltd., http://www.tej.com.tw/) database for the period of time from 1995 to 2009. For the choice of fundamental variables, early studies indicated that several financial ratios play key roles in future stock returns. Most of them applied profitability (e.g., ROE, ROA, operating profit margin, and net profit margin), leverage (e.g., DB ratio), liquidity (e.g., current ratio and quick ratio), efficiency (e.g., inventory turnover rate and receivables turnover rate), and growth (e.g., operating rating income growth rate and net income growth rate) related ratios to examine the relationship between fundamentals and stock returns. Mukherji *et al.* [21], Jensen *et al.* [22], Danielson and Dowdell [23], Lewellen [24], Fama and French [25], and Hjalmarsson [26] also showed that the ratios relating to share price rationality, e.g., PE, PB, and PS ratios, are likely to influence future stock returns. According to the previous literature, Table 1 provides the aforementioned six attributes that are to be employed for this study, including fourteen financial ratios. For each year, investable stocks are described by these fourteen financial ratios and their historical returns are provided.

IV. Empirical Results

In this study, standardization was first applied to the research data ─ every original attribute is scaled into the range of [−1, 1] by subtracting the mean, and dividing the result by the standard deviation. This treatment is to ensure that all the attributes lie in the same parameter range, in order to prevent attributes with large ranges from overwhelming others and prediction errors may be reduced.

To examine our proposed model, stock data of all the years is first used for optimization by the GA. Stocks are ranked based on the scores obtained. Top *m* stocks are selected and

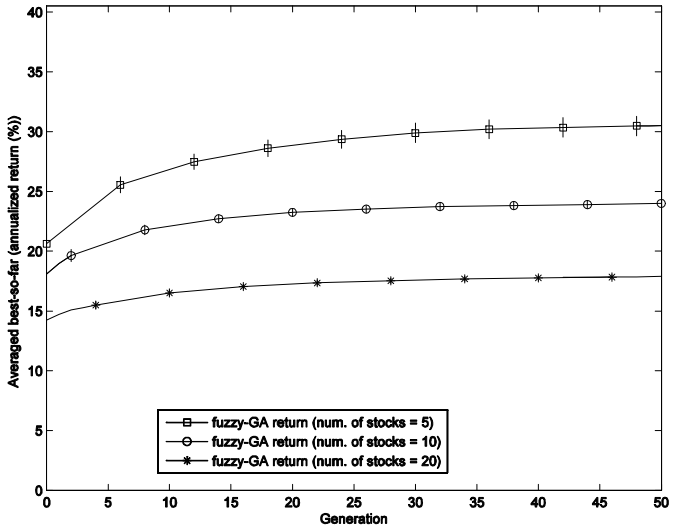

Figure 6. Best-so-far curves by the GA

the average yearly return of these selected stocks are calculated. Fig. 6 displays the averaged best-so-far values for annualized returns over 50 runs attained by the GA over 50 generations.[1] The averaged best-so-far performance curve is calculated by averaging the best-so-fars obtained at each generation for all 50 runs, where the vertical bars overlaying

[1] In order to study the change of the quality of solutions over time, a traditional performance metric for search algorithms is the "best-so-far" curve that plots the fitness of the best individual that has been seen thus far by generation *n* for the GA ─ i.e., a point in the search space that optimizes the objective function thus far. In addition, in this study the GA experiments employ a binary tournament selection [33], one-point crossover and mutation rates of 0.7 and 0.005, respectively.

the curves represent the 95-percent confidence intervals about the means.

Fig. 7 displays an illustration of the cumulative benchmark return (the product of the average yearly returns of the 50 stocks in the investment universe) and the cumulative returns of longing a number of top-ranked stocks recommended by the fuzzy-GA model.[2] This figure shows that the portfolios of maintaining 5, 10 and 20 stocks outperform the benchmark at the end of year 2009. As a result, the optimization on the stock selection model by the GA is advantageous to stock selection.

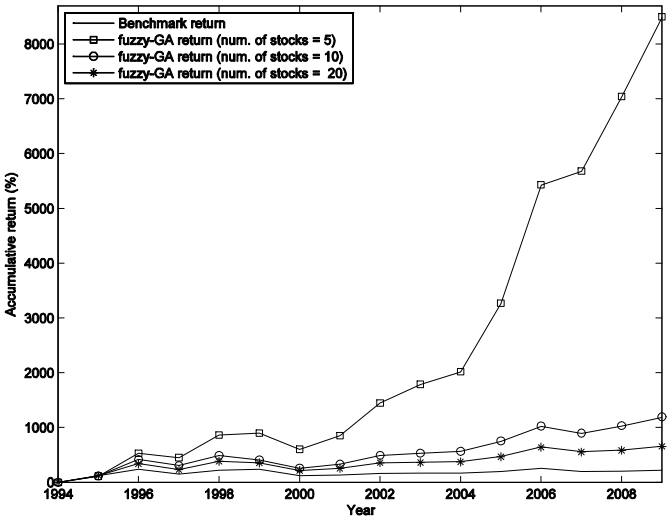

Figure 7. Cumulative returns of benchmark v.s. longing top-ranked stocks by the fuzzy-GA stock selection model

In order to examine the validity of the methodology we proposed, further statistical validation on the model is conducted. In reality, the learned model has to be tested by unseen data. Here, we use the stock data of the first several years to train the fuzzy-GA model, and the remaining years are used for testing the learned model. Thus the average yearly return of the selected stocks for each of the testing year is calculated. The average yearly returns are then compounded to obtain the cumulative total return of the portfolio over the testing years.

Notice that this setup is different from the regular cross-validation procedure where the process of data being split into two independent sets is randomly repeated several times without taking into account the data's temporal order. However, in the stock selection study here, temporal order is critical as practically one would like to use all available data so far to train the model and to apply the models in the future to gain profits.

Here we compare the cumulative benchmark return (the product of the average yearly returns of the 50 stocks in the investment universe) and the cumulative average return of longing a number of top-ranked stocks (5 and 20 stocks) using our stock selection model. Table 2 and 3 show the model validation for selecting 5 and 20 stocks by the fuzzy-GA model for 50 runs. In the 5-stock model, an inspection on the means of annualized model returns shows that 13 out of 14 for the testing cases outperform the annualized benchmark return. For the 20-stock model, in all the 14 testing cases, the means of annualized model returns all outperform the annualized benchmark return.

In the mean time, the standard deviations and standard errors of the annualized model returns decrease as more stocks are being selected into a portfolio. That is, selecting 20 stocks apparently yields more consistent performance on the model

Table II. Statistics of the benchmark and fuzzy-GA stock selection models for 5 stocks

return from various runs than the 5-stock cases do. As a result, these validations provide a statistical evidence that our proposed stock selection methodology is promising for investment in research and practice.

V. CONCLUSIONS

In this paper we presented a hybrid fuzzy-GA methodology for stock selection. Based on the designed scoring mechanism for a set of stocks, top-ranked stocks can be selected as components in a portfolio. In the mean time, the GA was employed for optimization of model parameters and feature selection for the model. We have evaluated the fuzzy-GA models statistically and validated the effectiveness of this method by comparing the investment return of the models with that of the benchmark. The empirical results showed that the investment return provided by our proposed methodology can significantly outperform the benchmark return. Therefore, we expect this hybrid model to advance the research in computational finance and provide a promising solution to stock selection in practice. In the future, a plausible research direction is to employ more advanced fuzzy and scoring models to investigate how performance of portfolios can be further improved. In addition, in our current model, we consider the first several years as the training set and the next several years as the test set. This may not be sufficient to generate a feasible model; e.g., it might be difficult to infer plausible scores for stocks in the period from 1996 till 2009 if the model uses only the stocks of 1995 for training. Therefore, in the future work, we intend to study a model that would be capable of generating more time-dependent patterns to account for the impact of the more recent past of the stocks. Finally, because investment return and risk management appear to be two distinct objectives, in the future work, we expect that a study for simultaneous optimization on these multi-objectives is also a promising research area.

***Abstract*—In this paper, a novel two-phase fuzzy mining approach based on the designed upper-bound multiple fuzzy frequent-pattern (UBMFFP) tree is proposed to obtain all fuzzy frequent itemsets from a quantitative database. It prunes unpromising itemsets in the first phase, and then finds the actual fuzzy frequent itemsets in the second phase. Experimental results indicate that the proposed approach has better performance than some previous ones.**

Keywords- fuzzy data mining; fuzzy set; two-phase mining; FP tree; fuzzy frequent itemsets

I. INTRODUCTION

Depending on the classes of knowledge derived, it may be classified as those finding association rules [1], classification rules [12], clustering rules [16], or sequential patterns [2, 20], among others. Especially, finding association rules in large transaction datasets is most commonly seen in data mining research [4, 18]. In these years, fuzzy sets have been used in many fuzzy data mining approaches for managing quantitative data [5, 8-9]. It used membership functions to transform quantitative values in transactions into linguistic terms through fuzzy theory. Papadimitriou *et al.* proposed a tree structure called the fuzzy frequent pattern tree (FFPT) to mine fuzzy association rules [19]. Lin *et al.* then proposed fuzzy data mining approaches to efficiently mine the fuzzy frequent itesmets from the designed tree structures [13-15]. It only considers the term with the maximum cardinality, thus making the number of fuzzy regions processed equal to the number of original items, which reduces the processing time.

In this paper, an upper-bound multiple fuzzy FP tree (UBMFFP tree) algorithm is proposed, which keeps the fuzzy frequent 1-regions whether they are generated from the same item. In the mining process, the fuzzy regions transformed from the same term (item) cannot be joined into fuzzy frequent itemsets using the combination method. Based on the proposed approach, the mining result are more natural and understandable for human beings.

II. REVIEW OF RELATED WORKS

In this section, the fuzzy association rules mining and the FP-growth algorithm are shortly described.

A. Fuzzy Association Rules Mining

The data mining approach is useful to extract knowledge from real-world databases and represented in a comprehensible form. Linguistic representation produces more understandable knowledge for human beings, which is easily implemented by fuzzy sets. Chan *et al.* proposed the F-APACS algorithm to mine fuzzy association rules [3]. Hong *et al.* proposed a fuzzy aprioritid mining algorithm to mine fuzzy rules from quantitative databases [8]. Papadimitriou *et al.* proposed a fuzzy frequent pattern tree (FFPT) to mine fuzzy association rules [19]. Lin *et al.* then proposed the novel fuzzy data mining approaches to efficiently mine the fuzzy frequent itesmets from the designed tree structures [13-15]. The above algorithms, however, were proposed for handling single region with the maximum cardinality among transformed fuzzy regions of an item, thus generating incomplete fuzzy frequent itemsets.

B. FP-growth Algorithm

Han *et al.* proposed the Frequent-Pattern-tree structure (FP-tree) and the FP-growth algorithm for efficiently mining frequent itemsets without generation of candidate itemsets [7]. Three steps were involved in FP-tree construction. The database to be mined was first scanned to find all the items with their counts. The support of an item was then defined as its count divided by the total number of transactions. The items with their supports equal to or larger than a predefined minimum support were then selected as frequent 1-itemsets (items). Next, the frequent items were sorted in a descending order of their frequencies. At last, the database was scanned again to construct the FP tree according to the sorted order of frequent items. The construction process was executed tuple by tuple, from the first transaction to the last one. After all transactions were processed, the FP tree was completely constructed.

After the FP tree was constructed from a database, the FP-growth mining algorithm was then executed to find all frequent itemsets [7]. Several other algorithms based on the FP-tree structure have also been proposed [6, 10].

III. THE PROPOSED UBMFFP CONSTRUCTION ALGORITHM

A special notation is often used to represent fuzzy sets. Assume that x_1 to x_n are the elements in a fuzzy set A, and μ_1 to

μ_2 are, respectively, their membership grades in A. A is usually represented as follows:

$$A = \frac{\mu_1}{x_1} + \frac{\mu_2}{x_2} + \ldots + \frac{\mu_n}{x_n}.$$

A. The UBMFF- tree construction algorithm

The proposed mining approach integrates the fuzzy-set concepts, the FP-tree-like algorithm and the two-phase processing way to efficiently derive fuzzy frequent itemsets from quantitative transactions. The UBMFFP tree construction algorithm is stated as follows.

***UBMFFP tree construction algorithm*:**

INPUT: A quantitative database consisting of n transactions and m items, a set of membership functions, and a predefined minimum support threshold s.

OUTPUT: A constructed UBMFFP tree.

STEP 1: Transform the quantitative value v_{ij} of each item I_j in the *i-th* transaction into a fuzzy set f_{ij} represented as $(f_{ij1}/R_{j1} + f_{ij2}/R_{j2} + \ldots + f_{ijhj}/R_{jhj})$ using the given membership functions, where h_j is the number of fuzzy regions for I_j, R_{jl} is the l-th fuzzy region of I_j, $1 \le l \le h_j$, and f_{ijl} is v_{ij}'s fuzzy membership value in region R_{jl}.

STEP 2: Calculate the scalar cardinality of each fuzzy region R_{jl} in the transaction data as:

$$count_{jl} = \sum_{i=1}^{n} f_{ijl}.$$

STEP 3: Check whether the value $count_{jl}$ of the fuzzy region R_{jl} is greater than or equal to the user-specific minimum count $n*s$. If the count of a fuzzy region R_{jl} is equal to or greater than the minimum count, put the fuzzy region in the set of fuzzy frequent regions (L_1). That is:

$$L_1 = \{R_{jl} \mid count_{jl} \ge n*s,\ 1 \le j \le m\}.$$

STEP 4: While executing the above steps, also find the occurrence number $o(R_{jl})$ of each fuzzy region R_{jl} in the quantitative database. It is later used to decide the item order.

STEP 5: Build the Header_Table by keeping the fuzzy frequent regions in L_1 in the descending order of their occurrence numbers.

STEP 6: Remove the fuzzy regions of the items not in L_1 from the transactions of the transformed database. Sort the remaining fuzzy regions in each transaction according to the order of the fuzzy regions in Header_Table.

STEP 7: Initially set the root node of the UBMFFP tree as ***root***.

STEP 8: Insert the updated transactions in the transformed databases into the UBMFFP tree tuple by tuple. The following two cases may exist to concern.

Substep 8-1: If a fuzzy region R_{jl} in the currently processed i-th transaction appears in the corresponding path of the UBMFFP tree, add the membership value of the region R_{jl} in the transaction to the node with R_{jl};

Substep 8-2: Otherwise, add a new node with R_{jl} to the end of the corresponding path and set the membership value of the region R_{jl} in the currently processed i-th transaction as the value in the node. Insert a link from the node of R_{jl} in the last branch to the current node. If there is no such branch, insert a link from the entry of R_{jl} in Header_Table to the current node.

After STEP 8, the UBMFFP tree finally constructed.

B. An Example

Assume that the predefined minimum support threshold is set at 30%. The quantitative database is shown in Table I.

TABLE I. QUANTITATIVE DATABASE

TID	Items
1	*A*:2, *C*:8, *E*:10
2	*A*:2, *C*:5, *E*:10
3	*B*:4, *C*:8, *D*:5
4	*B*:9, *D*:4
5	*A*:3, *B*:5, *C*:5, *D*:9
6	*A*:2, *B*:7, *C*:11
7	*B*:5, *C*:3, *D*:3, *E*:9
8	*A*:3, *B*:7, *C*:9, *E*:9

Assume that the fuzzy membership functions are the same for all items shown in Figure 1. The UBMFFP tree is constructed as follows.

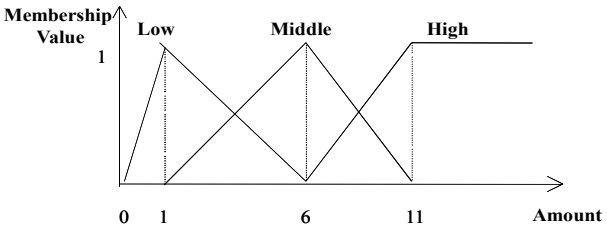

Figure 1. Membership functions used in the example.

The quantitative database in Table I is then transformed into fuzzy sets according to the defined membership function in Figure 1. The results are shown in Table II.

TABLE II. FUZZY SETS TRANSFORMED FROM TABLE I

TID	Items
1	$\frac{0.8}{A.Low}+\frac{0.2}{A.Middle},\frac{0.6}{C.Middle}+\frac{0.4}{C.High},\frac{0.2}{E.Middle}+\frac{0.8}{E.High}$
2	$\frac{0.8}{A.Low}+\frac{0.2}{A.Middle},\frac{0.2}{C.Low}+\frac{0.8}{C.Middle},\frac{0.2}{E.Middle}+\frac{0.8}{E.High}$
3	$\frac{0.4}{B.Low}+\frac{0.6}{B.Middle},\frac{0.6}{C.Middle}+\frac{0.4}{C.High},\frac{0.2}{D.Low}+\frac{0.8}{D.Middle}$
4	$\frac{0.4}{B.Middle}+\frac{0.6}{B.High},\frac{0.4}{D.Low}+\frac{0.6}{D.Middle}$
5	$\frac{0.6}{A.Low}+\frac{0.4}{A.Middle},\frac{0.2}{B.Low}+\frac{0.8}{B.Middle},\frac{0.2}{C.Low}+\frac{0.8}{C.Middle},\frac{0.4}{D.Middle}+\frac{0.6}{D.High}$
6	$\frac{0.8}{A.Low}+\frac{0.2}{A.Middle},\frac{0.8}{B.Middle}+\frac{0.2}{B.High},\frac{1}{C.High}$
7	$\frac{0.2}{B.Low}+\frac{0.8}{B.Middle},\frac{0.6}{C.Low}+\frac{0.4}{C.Middle},\frac{0.6}{D.Low}+\frac{0.4}{D.Middle},\frac{0.4}{E.Middle}+\frac{0.6}{E.High}$
8	$\frac{0.6}{A.Low}+\frac{0.4}{A.Middle},\frac{0.8}{B.Middle}+\frac{0.2}{B.High},\frac{0.4}{C.Middle}+\frac{0.6}{C.High},\frac{0.4}{E.Middle}+\frac{0.6}{E.High}$

The minimum count is then calculated as (8 * 0.3) (= 2.4). The occurrence number of each frequent fuzzy region is calculated and shown in Table III.

TABLE III. COUNTS AND THE OCCURRENCE NUMBERS OF FUZZY REGIONS

Item	Count	Occurrence number
A.Low	3.6	5
B.Middle	4.2	6
C.Middle	3.6	6
C.High	2.4	4
E.High	2.8	4

The fuzzy regions in L_1 are then sorted in descending order of their occurrence numbers and are put in Header_Table. The fuzzy regions not in L_1 are removed from the transactions from Table II. The remaining fuzzy regions in each transaction are then sorted according to the order in the Header_Table. The updated transactions are shown in Table IV.

TABLE IV. THE UPDATED TRANSACTIONS

TID	Fuzzy frequent regions
1	$\frac{0.6}{C.Middle},\frac{0.8}{A.Low},\frac{0.4}{C.High},\frac{0.8}{E.High}$
2	$\frac{0.8}{C.Middle},\frac{0.8}{A.Low},\frac{0.8}{E.High}$
3	$\frac{0.6}{B.Middle},\frac{0.6}{C.Middle},\frac{0.4}{C.High}$
4	$\frac{0.4}{B.Middle}$
5	$\frac{0.8}{B.Middle},\frac{0.8}{C.Middle},\frac{0.6}{A.Low}$
6	$\frac{0.8}{B.Middle},\frac{0.8}{A.Low},\frac{1}{C.High}$
7	$\frac{0.8}{B.Middle},\frac{0.4}{C.Middle},\frac{0.6}{E.High}$
8	$\frac{0.8}{B.Middle},\frac{0.4}{C.Middle},\frac{0.6}{A.Low},\frac{0.6}{C.High},\frac{0.6}{E.High}$

The updated transactions in Table IV are used to construct the UBMFFP tree tuple by tuple from the first transaction to the last one. The results are shown in Figure 2.

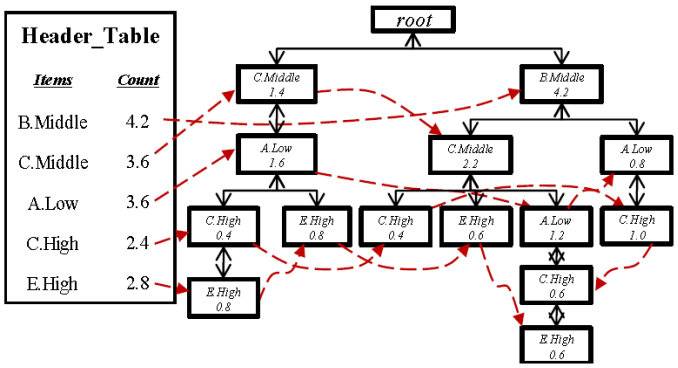

Figure 2. The finally constructed UBMFFP tree.

IV. THE UBMFFP-GROWTH MINING ALGORITHM

After the UBMFFP tree is constructed, the fuzzy frequent itemsets with more than one fuzzy region can then be found by the proposed UBMFFP-growth mining algorithm.

A. Proposed Mining Algorithm

The details of the UBMFFP-growth mining algorithm are as follows.

***UBMFFP-growth mining algorithm*:**

INPUT: The already constructed UBMFFP tree, its corresponding Header_Table, the transferred database, and the predefined minimum support threshold *s*.

OUTPUT: The fuzzy frequent itemsets.

STEP 1: Process the fuzzy regions in Header_Table one by one and bottom-up using the following steps. Let the currently processed fuzzy region be R_{jl}.

STEP 2: Find all the nodes with the fuzzy region R_{jl} in the UBMFFP tree through the links, starting from Header_Table.

STEP 3: Set the variable k = 2, where k is used to keep the number of items in the currently processed itemsets.

STEP 4: Trace the paths with the currently processed fuzzy region R_{jl} to generate the fuzzy k-itemsets except for any of its super-items associated with the same I_j and set their upper-bound fuzzy counts as the minimum of the values in the corresponding nodes, which contain the fuzzy regions in the itemsets.

STEP 5: Sum the upper-bound fuzzy counts of the same fuzzy itemsets from different paths.

STEP 6: If the summed upper-bound fuzzy count of a fuzzy itemset after STEP 5 is larger than or equal to the

predefined minimum count ($n*s$), add it to the candidate set C which will be used to generate fuzzy candidate (k+1)-itemsets.

STEP 7: Set $k = k + 1$ and repeat STEPs 4 to 6 to generate the fuzzy candidate k-itemsets in C based on the downward-closure property recursively. The process is repeated until no more fuzzy itemsets are generated.

STEP 8: Repeat STEPs 2 to 7 for another fuzzy region until all the fuzzy regions in Header_Table are processed.

STEP 9: Rescan the transferred database to get the actual fuzzy counts of the fuzzy candidate itemsets in C and check them against the predefined minimum count.

STEP 10: Output the candidate fuzzy itemsets with their fuzzy counts equal to or larger than the predefined minimum count as the fuzzy frequent itemsets.

B. An Example

For the constructed UBMFFP tree in Figure 2, the proposed UBMFFP-growth mining algorithm finds all the fuzzy frequent itemsets as follows. The variable k is initially set at 2, where k is used to keep the number of items in the currently processed itemsets. The paths with the currently processed fuzzy region are then used to form the candidate fuzzy k-itemsets. The upper-bound fuzzy counts of the same fuzzy itemsets are summed up. The summed upper-bound fuzzy counts of the derived fuzzy itemsets with the currently processed item are checked against the predefined minimum count, which is 2.4. The above steps are repeated for another fuzzy region until all the fuzzy regions in Header_Table are processed. The final candidate fuzzy itemsets with their upper-bound fuzzy counts in C are shown {*A.Low*, *C.Middle*: 2.6}, and {*C.Middle*, *E.High*: 2.8}.

The transferred database is then re-scanned to find the actual fuzzy counts of the derived candidate fuzzy itemsets. The final derived fuzzy frequent itemsets are shown in Table V.

TABLE V. FINAL FUZZY FREQUENT ITEMSETS

1-itemset	*Count*
A.Low	3.6
B.Middle	4.2
C.Middle	3.6
C.High	2.4
E.High	2.8
2-itemset	***Count***
A.Low, *C.Middle*	2.4

V. EXPERIMENTAL RESULTS

A real dataset called FOODMART from an anonymous chain store was used in the experiments [17]. The quantitative database was then transformed into fuzzy 2-regions by the predefined membership functions. Figure 3 shows the comparisons of execution times of the Apriori-based algorithm [1] for mining multiple fuzzy-term frequent itemsets (MF-Apriori), the multiple fuzzy FP tree (MFFP-tree) algorithm [11], and the proposed UBMFFP-tree algorithm. It was obvious to see from Figure 3 that the proposed UBMFFP-tree algorithm ran faster than the other two for the various minimum support thresholds. The experimental results in Figure 4 show the numbers of tree nodes generated from the two algorithms for two fuzzy regions. It reveals that the numbers of nodes in the UBMFFP tree are fewer than the MFFP tree.

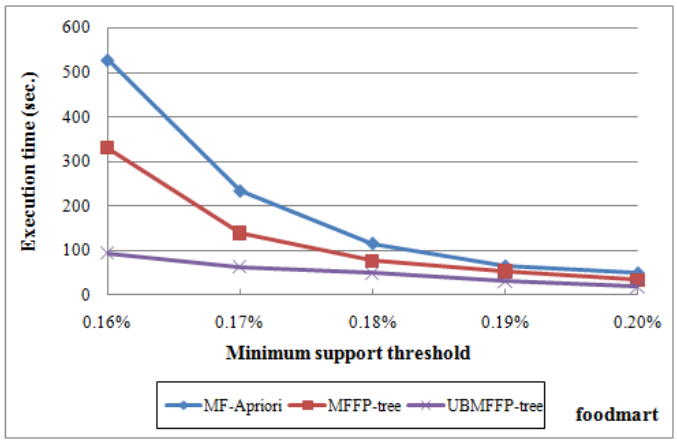

Figure 3. Execution time for three approaches.

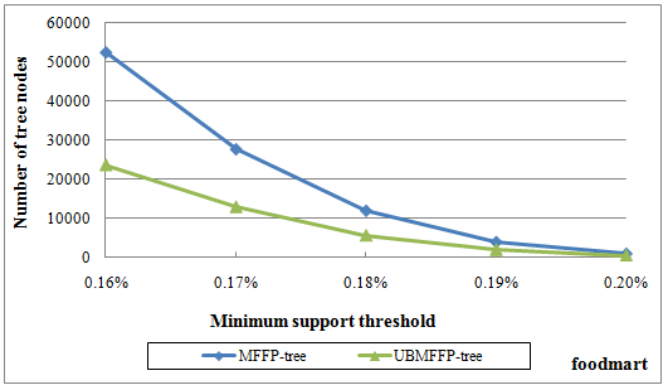

Figure 4. Number of tree nodes generated from the two approaches.

VI. CONCLUSION

In this paper, we proposed a two-phase multiple fuzzy mining algorithm for finding the complete fuzzy frequent itemsets based on the UBMFFP tree. Experimental results show that the proposed approach generates fewer nodes than the fuzzy FP-tree algorithm. In the future, we will further extend the approach to solve other fuzzy mining problems.

***Abstract*—The large-scale deployment of the Smart Grid paradigm will support the evolution of conventional electrical power systems toward active, flexible and self-healing web energy networks composed of distributed and cooperative energy resources. In a Smart Grid platform, the optimal coordination of distributed voltage controllers is one of the main issues to address. In this field, the application of traditional control paradigms has some disadvantages that could hinder their application in Smart Grids where the constant growth of grid complexity and the need for massive pervasion of Distribution Generation Systems (DGSs) require more scalable, more flexible control and regulation paradigms. To try and overcome these challenges, this paper proposes the concept of a decentralized non-hierarchical voltage regulation architecture based on intelligent and cooperative smart entities. The distributed voltage controllers employ traditional sensors to acquire local bus variables and mutually coupled oscillators to assess the main variables that characterize the operation of the global Smart Grid. These variables are then amalgamated by a novel fuzzy inference engine, named Timed Automata based Fuzzy Controllers, in order to identify proper control actions aimed at improving the grid voltage profile and reducing power losses.**

***Index Terms*—Distributed Generation Systems, Voltage regulation, Timed Automata based Fuzzy Controllers.**

I. Introduction

The Smart Grid[1] is the convergence of information and operational technologies applied to the electric grid, providing sustainable options to customers and improved security [2][3]. It could play a strategic role in supporting the evolution of conventional electrical grids toward active, flexible and self-healing web energy networks composed of distributed and cooperative energy resources [4][5]. Advances in research on Smart Grids could increase the efficiency of modern electrical power systems by: (i) supporting large-scale penetration of small-scale Distributed Generation Systems (DGSs); (ii) facilitating the integration of Renewable Energy Sources; (iii) reducing system losses and Green House Gas emissions; (iv) increasing the reliability of electricity supply to customers. From this perspective, a crucial issue is how to increase the penetration of DGS into Smart Grids by properly coordinating their operation and by restricting their negative impact on grid operations and control. In this context, effective network voltage regulation is one of the main issues to address [6][7]. Voltage regulation in electrical grids is normally achieved by the optimal coordination of a large set of regulating devices, all used with the aim of supporting the load buses voltages and improving the power quality at the distribution level [8][9]. The presence of DGSs in electrical grids increases the complexity of this regulation process since their power injections, intrinsically random for generators based on renewable sources, could alter the voltage profiles on network buses. This requires the design of a proper methodology aimed at assuring effective grid operation by the optimal coordination of DGS operations with traditional voltage regulating devices. This methodology should require low computational effort in order to assure an effective on-line solution to the voltage regulation problem. In order to address these needs, the application of fuzzy logic theory has been proposed in the literature [10][11]. Fuzzy logic can handle problems with imprecise and incomplete data, and it can model nonlinear functions of arbitrary complexity [12][13][14].

However, the solution to the voltage regulation problem should be prompt, reliable and accurate, but, above all, it should be highly adaptive in order to effectively manage the intrinsic time varying phenomena affecting the smart grid operation. For this reason, in this work, a novel fuzzy inference engine, named Timed Automata based Fuzzy Controllers (TAFCs)[15], is exploited to regulate the reactive power flows injected by the DGSs into the electrical grid. Thanks to its high dynamic features, a TAFC is capable of modelling a system characterized by frequent changes over the time, and, consequently, it results highly suitable for the application in the electrical power systems context.

As shown in the experimental results section, where our proposal has been compared with a conventional fuzzy controller, the proposed strategy results in an effective and suitable method to solve voltage regulation problem.

II. Problem Formulation

The ultimate goal of the voltage regulation process is to identify the optimal asset of voltage regulating devices required to deliver higher service quality, in terms of voltage profile flattening and power losses minimization. Roughly speaking, the solution of the voltage regulation problem requires the identification of the voltage regulation devices asset that minimizes, for each grid state, a set of objectives subject to a number of inequality constraints.

The voltage regulation devices asset is described by the following vector:

$$y = [Q_{dg,1}, \ldots, Q_{dg,N_g}, \ldots, Q_{cap,1}, \ldots, Q_{cap,N_c}, V_{FTS,N_f}, m] \quad (1)$$

where $Q_{dg,i}$ is the reactive power injected by the i^{th} ($i = 1, \ldots, N_g$)DGS connected to the Smart Grid and available for

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

regulation; $Q_{cap,j}$ is the vector of the reactive power injected by the j^{th} ($j = 1, \ldots, N_c$) capacitor bank; $V_{FTS,k}$ is the set point of the kk^{th} ($k = 1, \ldots, N_f$) Flexible AC Transmission System (FACTS) and m is the tap position of the HV/MV line tap changing transformer. Note that the vector $\mathbf{y}$ takes values in the solution space $\mathbf{\Omega}$:

$$\mathbf{y} \in \mathbf{\Omega} \Leftrightarrow \begin{cases} tap_{min} \leq m \leq tap_{max} \\ Q_{dg,min,i} \leq Q_{dg,i} \leq Q_{dg,max,i} & i = 1, \ldots, N_g \\ Q_{cap,min,j} \leq Q_{cap,j} \leq Q_{cap,max,j} & j = 1, \ldots, N_c \\ Q_{FTS,min,k} \leq Q_{FTS,k} \leq Q_{FTS,max,k} & k = 1, \ldots, N_f \end{cases} \tag{2}$$

When solving the voltage regulation problem, several constraints must be satisfied. They include the technical constraints for correct system operation in terms of allowed voltage ranges for the network buses (i.e. $V_{min,i} \leq V_i \leq V_{max,i}$ $i = 1 : n$) and maximum allowable currents for the n_l power lines (i.e. $I_l \leq I_{max,l}$ $l = 1 : n_l$).

The objectives to be minimized in identifying the optimal voltage regulating devices asset takes into account both technical and economic aspects (i.e. power losses, reactive power costs, voltage magnitude). Since the design objectives are in competition, the voltage regulation problem has no unique solution and a suitable trade-off between objectives has to be identified.

III. The proposed Approach

To address the voltage regulation problem in a Smart Grid, an innovative solution approach is proposed here.

The reactive power flows injected by the DGSs into the electrical grid are regulated according to the following control strategy: The proposed algorithm first acquires the global variables characterizing the actual operation of the Smart Grid. These variables are then processed in order to estimate the current grid state. This could be classified on the basis of the mean grid voltage magnitude according to the following set of minimal states:

1) *Grid Voltage Low*: This state is characterized by high load demand. As a result, high power line loading and, consequently, high power losses and a very low value of the mean grid voltage magnitude are expected on the grid.
2) *Grid Voltage High*: This state is characterized by low load demand. As a result, low power line loading and, consequently, low power losses and a very high value of the mean grid voltage magnitude are expected on the grid.
3) *Normal Operation*: This state represents the nominal operating point of the electrical grid. Both the power losses and the value of the mean grid voltage magnitude lie within allowable intervals.

Once the actual Smart Grid state has been assessed, the algorithm identifies proper voltage control strategies for each node. This is implemented according to the following control rules:

- If the Smart Grid state is classified as *Grid Voltage Low* (respectively *Grid Voltage High*), then the control objective is to raise (respectively reduce) the mean grid voltage magnitude V_m by properly increasing (respectively decreasing) the reactive power injected by the DGSs into the grid. In order to obtain a uniform rise in voltage magnitude, the i^{th} controller compares the local bus voltage magnitude (V_i) with the mean grid voltage magnitude (V_M) and:
  1) If $V_i < V_M$, it increases (respectively decreases) the injected reactive power $Q_{dg,i}$ by a quantity directly (respectively inversely) proportional to $|V_M - V_i|$, namely:
  $$\Delta Q_{dg,i} = \alpha_i(V_i) \cdot (V_M - V_i)$$
  respectively
  $$\Delta Q_{dg,i} = \frac{\alpha_i(V_i)}{V_i - V_M}$$
  2) Otherwise, it increases (respectively decreases) the injected reactive power $Q_{dg,i}$ by a quantity inversely (respectively directly) proportional to $|V_M - V_i|$, namely:
  $$\Delta Q_{dg,i} = \frac{\alpha_i(V_i)}{(V_i - V_M)}$$
  respectively
  $$\Delta Q_{dg,i} = \alpha_i(V_i) \cdot (V_M - V_i)$$
- If the Smart Grid state is classified as *Normal operation*, then the control objective is to improve the voltage profile (namely to reduce the voltage magnitude deviation). To address this issue, the i^{th} controller compares the local bus voltage magnitude (V_i) with the mean grid voltage magnitude (V_M) and:
  1) If $V_i < V_M$, it increases the injected reactive power $Q_{dg,i}$ by a quantity directly proportional to $|V_M - V_i|$, namely:
  $$\Delta Q_{dg,i} = \alpha_i(V_i) \cdot (V_M - V_i)$$
  2) Otherwise, it decreases the injected reactive power $Q_{dg,i}$ by a quantity directly proportional to $|V_M - V_i|$, namely:
  $$\Delta Q_{dg,i} = \alpha_i(V_i) \cdot (V_M - V_i)$$
  where $\alpha_i(V_i)$ is a monotonically increasing function of the actual value of the voltage magnitude of the i^{th} bus.

These user-supplied human language rules could be effectively implemented by a Fuzzy Inference System [16]. This system converts these linguistic rules into their mathematical equivalents, thereby simplifying the job of the system designer and resulting in much more accurate representations of the way systems behave in the real world. However, the solution to voltage regulation problem should be characterized by also other characteristics such as reliably and accuracy, but above

all it should be highly adaptive in order to effectively manage the intrinsic time varying phenomena affecting the smart grid operation. In the light of these needs, our proposal is to use a TAFC in order to face the dynamic changes which highly characterize power systems. The exploited fuzzy inference engine is described in detail in the next section.

IV. Timed Automata-based Fuzzy Controllers

This section is devoted to describe the Timed Automata-based Fuzzy Control. This novel fuzzy inference engine improves classic inference methods in terms of dynamism and ability to model variable structure systems that are characterized from a discontinuous nonlinear behaviour. As mentioned, this kind of behaviour strongly characterizes power systems. Consequently, a standard control system could not be sufficient to manage a so complex framework and an alternative scenario is necessary. This scenario is provided by Timed Automata based Fuzzy Controllers.

Before formally defining TAFCs, it is necessary to introduce *timed fuzzy controllers*, i.e, a novel fuzzy inference engine that extends fuzzy control idea with three additional concepts: *control configuration*, *control era* and *control time*. In detail, a timed fuzzy controller uses the control time as a clock moving the controlled systems through several time intervals, known as *control eras*. Each control era is characterized by a specific *control configuration* which is formed by: 1) the number and typology of fuzzy variables and 2) the number and structure of relationships among variables.

Definition 1 (Fuzzy Logic Controller): A fuzzy logic controller c, with n inputs and m outputs, can be considered as a function mapping a vector $\underline{\mathbf{x}} \in \mathbb{R}^n$ with an output vector $\underline{\mathbf{y}} \in \mathbb{R}^m$:

$$c : \mathbb{R}^n \rightarrow \mathbb{R}^m$$

where $\underline{\mathbf{y}} = c(\underline{\mathbf{x}})$ is computed by applying fuzzy inference operators. ■

Definition 2 (Timed Fuzzy Logic Controller): Let $C = \cup_{n\in\mathbb{N}} \cup_{m\in\mathbb{N}} \{c : \mathbb{R}^n \rightarrow \mathbb{R}^m\}$ be the collection of all possible fuzzy controllers and let

$$E = \{e_i = [t'_i, t''_i[\mid i = 1 \dots k, k \in \mathbb{N}, \\ t'_i, t''_i \in \mathbb{R}^+ \text{ with } t'_1 = 0, t''_i = t'_{i+1} \text{ and } t'_i < t'_{i+1}\}$$

be the set of k disjoint control eras. The i^{th} control era, known as e_i, starts at t'_i and ends at t''_i. Once defined C and E, let $f : E \rightarrow C$ be the function that maps each control era to the corresponding control configuration and let $g : \mathbb{R}^+ \rightarrow E$ a function which associates a time instant t_j with the corresponding control era. Then, a *timed fuzzy control* is a function composition $\varphi = f \circ g : \mathbb{R}^+ \rightarrow C$ that maps a time instant $t_j \in \mathbb{R}^+$ belonging to the i^{th} control era to a fuzzy controller $f_i \in C$ representing the associated control configuration. ■

Observation 1: If two instants t_j and t_{j+1}, with $t_j < t_{j+1}$, belong to the same i^{th} control era, the function φ returns the same function f_i:

$$\varphi(t_j) = f(g(t_j)) = f_i = f(g(t_{j+1})) = \varphi(t_{j+1})$$

$$\text{if} \quad t'_i \leq t_j < t_{j+1} < t''_i \quad ■$$

Observation 2: Each fuzzy controller c is a timed fuzzy controller φ_c on 1 control era with following parameters:

$$E = \{[0, t''_1], t''_1 > 0\}$$
$$C = \{c\}$$
$$f([0, t''_1]) = c$$
$$g(t) = [0, t''_1] \quad \forall t \in \mathbb{R}^+$$
$$\varphi_c = f(g(t)) = c \quad \forall t \in \mathbb{R}^+ \quad ■$$

A TAFC is a particular implementation of the function φ based on a theory deriving from formal language: Timed Automata [17].

A. Timed Automata

A timed automaton is a standard finite-state automaton extended with a finite collection of real-valued *clocks* providing a straightforward way to represent time related events, whereas automata-based approaches cannot offer this feature. The clocks can be reset to 0 (independently of each other) with the transitions of the automaton, and keep track of the time elapsed since the last reset. The transitions of a timed automaton are labeled with a *guard* (a condition on clocks), an *action* or *symbol* on alphabet Σ, and a *clock reset* (a subset of clocks to be reset). Intuitively, a timed automaton starts execution with all clocks set to zero. Clocks increase uniformly with time while the automaton is within a node. A transition may be taken only if the current values of the clocks satisfy the associated constraints. The set of behaviours expressed by a system modeled by means of a timed automaton is defined by a *timed language*, i.e., a collection of *timed words*. Both timed concepts are defined in the follows.

Definition 3: A *time sequence* $\tau = \tau_1\tau_2 \dots$ is an infinite sequence of time values $\tau_i \in \mathbb{R}$ with $\tau_i > 0$, satisfying the following constraints:

1) *Monotonicity*: τ increases strictly monotonically; that is, $\tau_i < \tau_{i+1}$ for all $i \geq i + 1$.
2) *Progress*: For every $t \in \mathbb{R}$, there is some $i \geq 1$ such that $\tau_i > t$.

A *timed word* over an alphabet Σ is a pair (σ, τ) where $\sigma = \sigma_1\sigma_2 \dots$ is an infinite word over Σ and τ is a time sequence. A *timed language* over Σ is a set of timed words on Σ. ■

Definition 4: For a set X of clock variables, the set $\Phi(X)$ of *clock constraints* δ is defined inductively by

$$\delta := x \leq c | c \leq x | \neg\delta | \delta_1 \wedge \delta_2$$

where x is a clock in X and c is a constant in $\mathbb{Q}$, the set of nonnegative rationals.

A *clock interpretation* ν for a set X of clocks assigns a real value to each clock; that is, it is a mapping from X to $\mathbb{R}$. We say that a clock interpretation ν for X satisfies a clock constraint δ over X iff δ evaluates to true using the values given by ν. For $t \in \mathbb{R}$, $\nu + t$ denotes the clock interpretation which maps every clock x to the value $\nu(x) + t$, and the clock interpretation $t \cdot \nu$ assigns to each clock x the value $t \cdot \nu(x)$.

For $Y \subseteq X, [Y \mapsto t]\nu$ denotes the clock interpretation for X which assigns t to each $x \in Y$, and agrees with ν over the rest of the clocks. ■

Now, a precise definition of timed transition table, which determines the timed automaton behaviour, is given:

Definition 5: A *timed transition table* $\mathcal{A}$ is a tuple $\langle \Sigma, S, S_0, C, E \rangle$, where

- Σ is a finite alphabet,
- S is a finite set of states,
- $S_0 \subseteq S$ is a set of start states,
- C is finite set of clocks, and
- $E \subseteq S \times S \times \Sigma \times 2^C \times \Phi(C)$ gives the set of transitions. An edge $\langle s, s', a, \lambda, \delta \rangle$ represents a transition from state s to state s' on input symbol a. The set $\lambda \subseteq C$ gives the clocks to be reset with this transition, and δ is a clock constraint over C. ■

If (σ, τ) is a timed word viewed as an input to an automaton, it presents the symbol σ_i at time τ_i. If each symbol σ_i is interpreted to denote an event occurrence then the corresponding component τ_i is interpreted as the time of occurrence of σ_i. Given a timed word (σ, τ), the timed transition table $\mathcal{A}$ starts in one of its start states at time 0 with all clocks initialized to 0. As time advances, the values of all clocks change, reflecting the elapsed time. At time τ_i, $\mathcal{A}$ state from s to s' using some transition of the form $\langle s, s', \sigma_i, \lambda, \delta \rangle$ reading the input σ_i, if the current values of clocks satisfy δ. With this transition the clocks in λ are reset to 0, and thus start continuing time with respect to the time of occurrence of this transition. Formally, this timed behaviour is captured by introducing *runs* of timed transition tables.

Definition 6: A run r, denoted by $(\bar{s}, \bar{\nu})$, of a timed transition table $\langle \Sigma, S, S_0, C, E \rangle$ over a timed word (σ, τ) is an infinite sequence of the form

$$r : \langle s_0, \nu_0 \rangle \xrightarrow[\tau_1]{\sigma_1} \langle s_1, \nu_1 \rangle \xrightarrow[\tau_2]{\sigma_2} \langle s_2, \nu_2 \rangle \xrightarrow[\tau_3]{\sigma_3} \dots$$

with $s_i \in S$ and $\nu_i \in [C \to \mathbb{R}]$, for all $i \geq 0$, satisfying the following requirements:

- *Initiation*: $s_0 \in S_0$ and $\nu_0(x) = 0$ for all $x \in C$.
- *Consecution*: for all $i \geq 1$, there is an edge in E of the form $\langle s_{i-1}, s_i, \sigma_i, \lambda_i, \delta_i \rangle$ such that $(\nu_{i-1} + \tau_i - \tau_{i-1})$ satisfies δ_i and ν_i equals $[\lambda_i \mapsto 0](\nu_{i-1} + \tau_i - \tau_{i-1})$.

■

The timed transition table together with the run concept are the main notions used in our approach to embed dynamism in the standard FLC definition.

B. Merging Timed Automata and Fuzzy Controllers

In an attempt to provide an instrument to model the function φ and consequently to obtain an implementation of a timed fuzzy controller, Timed Automata based Fuzzy Controllers (TAFCs) are proposed. TAFCs represent an integration between two theories: fuzzy control and timed automata.

A TAFC implements a timed fuzzy controller through a timed automaton whose behaviours define all the potential sequences of control eras (and the related control configurations) which the system may cross during its life-cycle. More in detail, TAFCs are able to manage the control configurations by associating each of them with a state in the timed automaton. Timed Automata support control eras progression by using the *run* concept (definition 6) where the i^{th} transition moves the system from the i^{th} control era to the $(i+1)^{th}$ one.

However, in order to change system's configuration among different automaton states, it is necessary to extend timed automata definition by exploiting a collection of so-called *transformation operators*:

$$C_{op} = \{\oplus, \ominus, \boxplus^k, \boxminus^k, \boxdot^k, \sim, \ltimes, \rtimes, \bowtie, \circledast, \oslash, \circledcirc, \divideontimes, \propto\}$$

where $\oplus$ and $\ominus$, respectively, adds and deletes a fuzzy variable from the current configuration; $\boxplus^k$, $\boxminus^k$ and $\boxdot^k$, respectively, adds, removes and modifies k fuzzy rules related to the current configuration; $\sim$ changes the fuzzy implication method of the rule base related to the current configuration; $\circledast$, $\oslash$ and $\circledcirc$, respectively, adds, deletes and modifies a term to a fuzzy variable in the current configuration; $\propto$ modifies the defuzzify method of configuration; $\bowtie$ modifies the fuzzy aggregation method; $\divideontimes$ changes default value of an output variable in the current configuration; $\ltimes$ and $\rtimes$ change, respectively, the lower bound and upper bound of the universe of discourse of a fuzzy variable in the current configuration.

Once that the automaton computation starts over a given timed word, the state transitions will opportunely modify the current control configuration in the successive one. In this vision, a timed word determines how and when to execute the switching among successive control eras. So, a timed word coincides with the control time concept.

The collection C_{op} will be used to extend timed automata and formally define TAFC as a couple of two components: an extended timed automaton that describes the dynamic evolution of a system and a fuzzy logic controller modeling the control behaviour of system during first phase of its existence.

C. Defining an extended timed automaton

Once defined the set of transformation operators C_{op} it is necessary to redefine the Timed Automaton concept in order to introduce a novel kind of transition edges capable of changing the control configuration of the modeled system. In particular, the standard transitions set of timed automata E is replaced with the following:

$$E_C \subseteq S \times S \times \Sigma \times 2^C \times \Phi(C) \times C_{op}^*$$

where C_{op}^* represents the set of all possible sequences of transformation operators, i.e., $C_{op}^* = \cup_{n \geq 1} C_{op}^n$ where C_{op}^n is the set of all possible sequences of n operators with $n \geq 1$. Now, it is possible to provide an extended definition of a timed automaton:

Definition 7: A *timed control transition table* $\mathcal{A}_C$ is a tuple $\langle \Sigma \cup \{\epsilon\}, S, S_0, C, E_C \rangle$, where

- Σ is a finite alphabet;
- ϵ represents the empty event, that is, when it is on a transition, the crossing of this transition depends only by temporal constraints;

- S is a finite set of states;
- $S_0 \subseteq S$ is a set of start states;
- C is finite set of clocks;
- $E_C \subseteq S \times S \times \Sigma \times 2^C \times \Phi(C) \times C_{op}^*$ gives the set of transitions. An edge $\langle s, s', a, \lambda, \delta, o^n \rangle$ represents a transition from state s to state s' on input symbol a which can be also the empty event. The set $\lambda \subseteq C$ gives the clocks to be reset with this transition, δ is a clock constraint over C and $o^n \in C_{op}^*$ is a sequence of n transformation operators, with $n \geq 1$, defined in order to change the current control configuration of modeled system. ■

In each sequence of transformation operators an operator can be repeated in order to execute the same task on different arguments. Besides, it is important to stablish that the operators are executed in the same order of their definition in the sequence (definition 9).

Definition 8: Let F be a fuzzy controller and let $o \in C_{op}$ be a transformation operator then $G = o(F)$ is the fuzzy controller obtained to apply the operator o on fuzzy controller F. ■

Definition 9: Let F be a fuzzy controller and let $o^n \in C_{op}^*$ be a sequence $o^n = (o_1, o_2, ..., o_n)$ where $o_i \in C_{op} \quad \forall i \in \{1, 2, ..., n\}$ then $G = o^n(F) = (o_n(o_{n-1}(...(o_2(o_1(F))))))$ is the fuzzy controller obtained to apply the operators $o_1, o_2, ..., o_{n-1}, o_n$ on fuzzy controller F in the same order of listing in the sequence o^n. ■

D. TAFC formal definition

At this point, it is possible to give a formal definition of a TAFC and the properties characterizing its dynamic behaviour.

Definition 10: A TAFC T is an ordered pair composed by an initial control configuration, represented by a fuzzy controller named F^0, together with a timed control transition table T_C. Formally:

$$T = (F^0, T_C). \quad ■$$

The TAFC properties which define the dynamic behaviour of a system are: *control evolution* and *control run*.

The control evolution is a mapping among the states S contained in T_C and the collection of possible control configurations obtained starting from F^0. More in detail, the control evolution is a mathematical succession, generated in an inductive way, which maps each state in S with a one or more control configurations obtained by sequentially applying over F^0 the transformation operators in $S \times S \times \Sigma \cup \{\epsilon\} \times 2^C \times \Phi(C) \times C_{op}^*$. Then:

Definition 11 (Control evolution): Let $T = (F^0, T_C)$ be a TAFC defined over a timed control transition table $\langle \Sigma \cup \{\epsilon\}, S, S_0, C, E_C \rangle$ with $S = \{s_0, s_1, ..., s_{|S|-1}\}$ the finite set of automaton states; let F^* be the collection of all possible fuzzy controllers; let $\Omega = \{n_1, n_2, ..., n_{|\Omega|}\}$ be a subset of ordered sequences in C_{op}^*, that is, $n_i = (o_1, o_2, ..., o_{|n_i|}) \ \forall i \in \{1, 2, ..., |\Omega|\}$, employed to define the edges in E_C. Then, the control evolution Ψ over a state $s^0 \in S_0$ is:

$$\Psi : \mathbb{N} \to S \times F^*$$

defined inductively, as follows:
The base case ($i = 0$). Let $s^0 \in S_0$ be an initial state of $\langle \Sigma \cup \{\epsilon\}, S, S_0, C, E_C \rangle$, then:

$$\Psi(0) = (s^0, F^0)$$

The inductive step ($i > 0$). Let $\Psi(i-1)$, with $i > 1$, be defined as:

$$\Psi(i-1) = (s^{i-1}, F^{i-1})$$

where $s^{i-1} \in S$ and $F^{i-1} \in F^*$, then:

$$\Psi(i) = (s^i, F^i)$$

with $s^i \in S$, $F^i = n_i(F^{i-1})$, $n_i \in \Omega$ and $\langle s^{i-1}, s^i, a, \lambda, \delta, n_i \rangle \in E_C$. ■

More intuitively, the expression (3) shows the sequence of pairs composing a control evolution over $s^0 \in S_0$ together with the fuzzy transformations obtained by exploiting the n_i sequences of operators.

$$\begin{array}{rcl} \Psi(0) : s^0 \in S_0 & \to & F^0 \\ & & \downarrow n_0 \\ \Psi(1) : s^1 \in S & \to & F^1 \\ & & \downarrow n_1 \\ \Psi(2) : s^2 \in S & \to & F^2 \\ & & \downarrow n_2 \\ \vdots & & \vdots \\ & & \downarrow n_{j-1} \\ \Psi(j) : s^j \in S & \to & F^j \\ & & \downarrow n_j \\ \vdots & & \vdots \end{array} \tag{3}$$

The image of function Ψ, I_Ψ, can be finite or infinite. This depends upon the topology of graph modeling the component T_C of the TAFC. Indeed, if the topology of T_C contains cycles then various FLCs can be associated with a same state $s_h \in S$. In order to explain it, let $\langle s^k, s^{i-1}, a, \lambda, \delta, n_k \rangle \in E_C$ be an edge entering in the state s^{i-1} already crossed, that is, an edge forming a cycle. If it is crossed the current fuzzy controller stored in the state s^{i-1} is replaced by a new one obtained executing the sequence of operators n_k on fuzzy controller stored in the state s^k. Then, crossing again the edge $\langle s^{i-1}, s^i, a, \lambda, \delta, n_i \rangle \in E_C$ also the controller fuzzy stored in s^i is replaced. Indeed, even if the sequence of operators n_i is unchanged from the previous crossing of the edge, a new controller fuzzy is stored in s^i because n_i is executed on the different fuzzy controller which has been stored in s^{i-1} in the previous step. So, states s^{i-1} and s^i are both associated with a new fuzzy controller because of the cycle formed by the edge $\langle s^k, s^{i-1}, a, \lambda, \delta, n_k \rangle$.

Obviously, the control evolution only represents a mapping between the states of timed automaton T_C and the collection of control configurations computable starting from F^0 by applying different sequences of operators in Ω; no dynamic

aspects are considered in the control evolution definition and, therefore, it is necessary to introduce the idea of control run extending the initial idea of the run of standard timed transition table (definition 6).

Definition 12: Let Ψ be a control evolution, then a control run r_c, denoted by $(\bar{s}, \bar{\nu})$, of a timed transition table $\langle \Sigma \cup \{\epsilon\}, S, S_0, C, E_C \rangle$ over a timed word (σ, τ) and a collection of sequences of transformation operators $\Omega = \{n_1, n_2, ..., n_{|\Omega|}\} \subseteq C^*_{op}$, is an infinite sequence of the form

$$r_c : \langle s^0, \nu_0 \rangle \xrightarrow[\tau_1]{\sigma_1, n_1} \langle s^1, \nu_1 \rangle \xrightarrow[\tau_2]{\sigma_2, n_2} \langle s^2, \nu_2 \rangle \xrightarrow[\tau_3]{\sigma_3, n_3} \dots$$

with $s^i \in S$ and $\nu_i \in [C \to \mathbb{R}]$, for all $i \geq 0$, and $n_i \in C^*_{op}$, for all $i \geq 1$, satisfying the following requirements:

- *Initiation*: $s^0 \in S_0$ and $\nu_0(x) = 0$ for all $x \in C$;
- *Consecution*: for all $i \geq 1$, there is an edge in E_C of the form $\langle s^{i-1}, s^i, \sigma_i, \lambda_i, \delta_i, n_i \rangle$ such that $(\nu_{i-1} + \tau_i - \tau_{i-1})$ satisfies δ_i and ν_i equals $[\lambda_i \mapsto 0](\nu_{i-1} + \tau_i - \tau_{i-1})$;
- *Atomicity*: The operators of sequence $n_i \in C^*_{op}$ are atomic operations and their computation time is equals to 0, i.e, they do not modify the duration of permanence in the automaton state $s^i, (\tau_i - \tau_{i-1})$;
- *Evolution*: each state s^i of a pair $\langle s^i, \nu_i \rangle$ in r_c is mapped on a FLC F^i as described by the control evolution Ψ.

■

If $T = (F^0, T_C)$ is a TAFC which models a given system then the set of control run r_c defined over the timed language L, generated by T_C, completely describes the collection dynamic behaviours of the system, whereas, the control run r_c defined over a single word $w_i \in L$ defines a precise dynamic behaviour of the system, so w_i defines the control time.

Definition 13 (Control Time): If $T = (F^0, T_C)$ is a TAFC and T_C is a timed automaton recognizing the timed language $L = w_1, w_2, w_3, ..., w_i, ...$ and w_i is a timed word and r_c is a control run defined over w_i then w_i is a Control Time of the system. ■

Finally, it is possible to give a formal description of control era and control configuration concepts.

Definition 14 (Control era and control configuration): If r_c is a control run defined over the Control Time $w_i = (\sigma, \tau) \in L$:

$$r_c : \langle s^0, \nu_0 \rangle \xrightarrow[\tau_1]{\sigma_1, n_1} \langle s^1, \nu_1 \rangle \xrightarrow[\tau_2]{\sigma_2, n_2} \langle s^2, \nu_2 \rangle \xrightarrow[\tau_3]{\sigma_3, n_3} \dots$$

then time interval between the instant τ_i and τ_{i+1} is the i^{th} control era of system and the FLC F^i which depicts the system during the same interval is defined as the i^{th} control configuration. ■

Therefore, it is important to notice how a TAFC is an implementation of timed fuzzy controller thanks to the concept of the control evolution and control run which perform the task accomplished by previously defined function φ.

Both the control evolution and the control run are potentially based on the infinite concept. In fact, the control evolution can exploit an infinite application of control operators in Ω to compute the mappings between the state s^i and the FLC F^i, whereas, the control run uses a timed word, defined as an infinite sequence of ordered pairs, to describe the dynamic behaviour of the system. Consequently, in order to simulate the behaviour of a TAFC during the first n control eras, the n^{th}-order control evolution and control run are introduced.

Definition 15 (n^{th}-order Control Evolution): If Ψ is a control evolution then the set

$$\Psi^n = \{\Psi(i) = (s^i, F^i) | i = 1, 2, ..., n\}$$

which contains the first n ordered pairs computed by Ψ through definition 11 is the n^{th}-order control evolution. ■

Definition 16 (n^{th}-order Control Run): Let

$$r_c : \langle s^0, \nu_0 \rangle \xrightarrow[\tau_1]{\sigma_1, n_1} \langle s^1, \nu_1 \rangle \xrightarrow[\tau_2]{\sigma_2, n_2} \langle s^2, \nu_2 \rangle \xrightarrow[\tau_3]{\sigma_3, n_3} \dots$$

be a control run defined over a control evolution Ψ, then n^{th}-order control run r^n_c is the sequence of the first n elements of r_c:

$$r^n_c : \langle s^0, \nu_0 \rangle \xrightarrow[\tau_1]{\sigma_1, n_1} \langle s^1, \nu_1 \rangle \xrightarrow[\tau_2]{\sigma_2, n_2} \dots \xrightarrow[\tau_{n-1}]{\sigma_{n-1}, n_{n-1}} \langle s^n, \nu_n \rangle$$

where the mapping between the automaton states s^i and the FLC F^i is computed by the n^{th}-order control evolution related to Ψ. ■

V. Experimental Results

This section discusses the application of the proposed methodology to the task of voltage regulation for the IEEE 30-bus test system depicted in fig. 1.

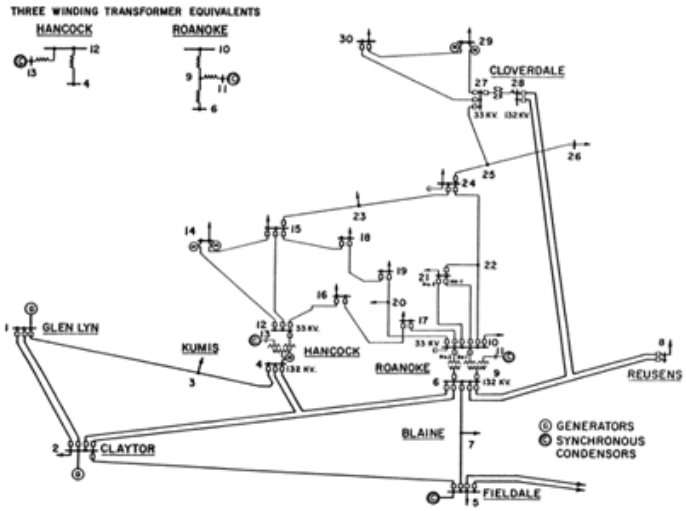

Fig. 1. The IEEE 30-bus test system

Six dispatchable DGSs have been considered in our experiments. The regulating devices asset is, therefore, identified by 6 variables:

$$\mathbf{y} = [Q_{dg,1}, Q_{dg,2}, Q_{dg,3}, Q_{dg,4}, Q_{dg,5}, Q_{dg,6}] \qquad (4)$$

In our experiment, each variable is regulated by an identical voltage TAFC. As far as the regulation performances are

concerned, detailed simulation analyses that consider highly variable load patterns have been developed.

In particular, the TAFC $T = (C, T_A)$ is exploited for regulating the reactive power flows injected by the DGSs where C is a fuzzy logic controller representing the initial configuration of T and modeling the control behaviour of each variable during first phase of its existence, whereas, T_A is the extended timed automaton that describes the dynamic evolution. In particular, in the Fig. 2, the timed automata T_A used to regulate the reactive power flows injected by the DGSs during a simulation run over a time equal to 150 minutes is shown.

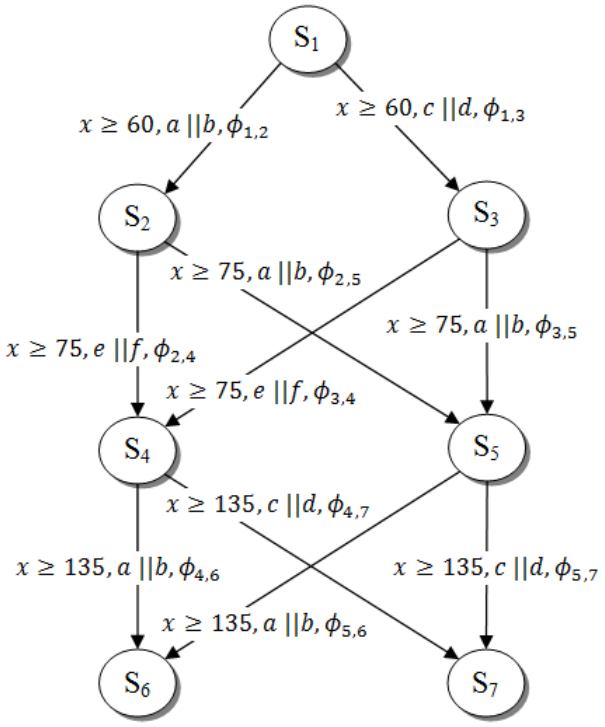

Fig. 2. The timed automata T_A

In details, the timed automaton T_A is composed by seven states $S_1, S_2, \ldots, S_7$. Each state stores a control configuration able to regulate the reactive power flows during the corresponding control era. For sake of simplicity, in the Fig. 2, the description of the transformation operators is replaced by a function $\phi_{i,j}$ capable of calculating the set of operators needed to transform the control configuration related to the state S_i in the control configuration related to the state S_j. The events described through the letters a, b, c, d, e, f on the automaton transitions correspond to the following conditions related to the voltage magnitude M:

- $a \Leftrightarrow M < 0.99$
- $b \Leftrightarrow M > 1.01$
- $c \Leftrightarrow M > 0.99$
- $d \Leftrightarrow M < 1.01$
- $e \Leftrightarrow M < 0.97$
- $f \Leftrightarrow M > 1.03$

In order to show the better performances provided by our strategy, the proposed TAFC T has been compared with a standard fuzzy controller F.

The evaluation of the provided performances has been based on technical and economic aspects, and in particular on the power losses (see fig. 3), reactive power costs (see fig. 4), and voltage magnitude (see fig. 5).

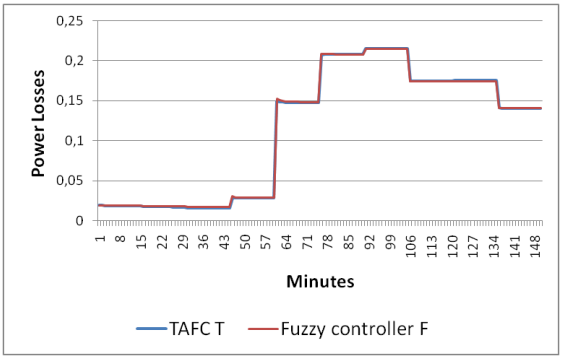

Fig. 3. The power losses values for the TAFC T and the conventional fuzzy controller F

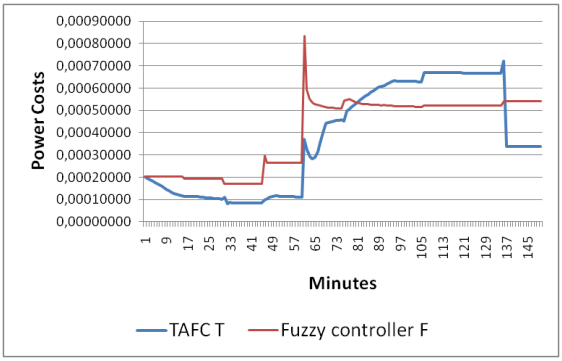

Fig. 4. The reactive power costs values for the TAFC T and the conventional fuzzy controller F

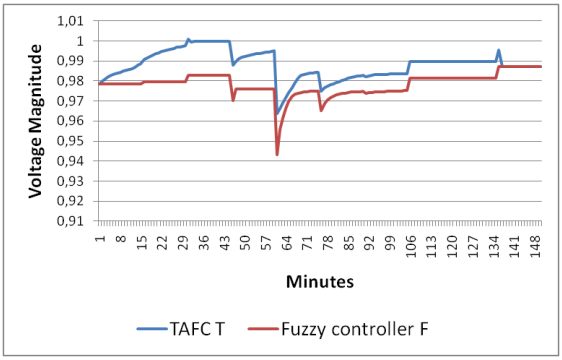

Fig. 5. The voltage magnitude values for the TAFC T and the conventional fuzzy controller F

In order to effectively measure the superiority of the our strategy, the Mean Absolute Errors (MAEs) regarding to the considered performance aspects have been computed for the

compared controllers, T and F. More in detail, the MAE for each aspect has been calculate as:

$$MAE = \frac{1}{N} \cdot \sum_{i=1}^{N} |G(i) - T(i)| \quad (5)$$

where N is the number of iterations of the simulation (equal to the number of minutes of simulation) and $G(i)$ and $T(i)$ are the guessed and the desired value for the performance aspect (power losses, reactive power costs and magnitude voltage) in the i-th iteration, respectively. In particular, the value 0 has been considered as the desired value for the power losses and reactive power costs, whereas, 1 has been considered as the desired value for the magnitude voltage.

The table I shows the computed MAEs concerning the performance aspects for our proposal and the compared conventional fuzzy controller. As highlighted by the perceptual improvement shown in the last column of the table I, the exploited TAFC T provides better performances than a conventional fuzzy controller.

TABLE I
MAEs OF OUR CONTROLLER T AND THE STANDARD F FOR ALL PERFORMANCE ASPECTS. IN THE LAST COLUMN ARE REPORTED THE RELATIVE IMPROVEMENTS.

Performance Aspect	MAE of T_A	MAE of F	Rel. impr.
Power losses	0,1142	0,1146	0,35%
Reactive power costs	3,7245E-4	4,0137E-4	7,2%
Magnitude Voltage	0,0119	0,0216	44,9%

VI. CONCLUSIONS

Modern trends in Smart Grids are oriented toward the employment of advanced regulation architectures that move away from the older centralized paradigm to a system distributed in the field with an increasing pervasion of smart sensors where central controllers play a smaller role. In supporting this complex task, this paper proposes the concept of a decentralized non-hierarchal voltage regulation architecture based on intelligent and cooperative smart entities. The distributed voltage controllers employ traditional sensors to acquire local bus variables and mutually coupled oscillators to assess the main variables that characterize the operation of the global Smart Grid. These variables are then amalgamated by a TAFC in order to identify proper control actions aimed at improving the grid voltage profile and reducing power losses. As far as the regulation performances are concerned, the simulation studies developed confirm the effectiveness of the proposed strategy in solving the voltage regulation problem also in the presence of highly variable load patterns.

***Abstract*— The paper proposes a new fuzzy controller for variable speed wind turbines (WTs) in order to compensate the variations at the point of common coupling (PCC) by controlling the reactive power generated by WTs. A protection system is used to disconnect the WTs from the grid when the controller is unable to compensate the voltage variations. Simulations carried out on a real 37-bus Italian weak distribution network demonstrated that the controller allows compensating voltage variations during voltage sags.**

Keywords- Variable speed wind turbines, weak distribution network, voltage sag, fuzzy controller

I. INTRODUCTION

Nowadays, the penetration of the wind turbines (WTs) into electric grids has been increased. With the growing penetration of WTs into electric grids, voltage control, stability and security of the system have been influenced. In many countries, the new established grid codes demand that variable speed WTs should participate in improving voltage control in the distribution networks [1,2]. WTs are usually located in remote and rural areas with a weak network infrastructure. Weak networks are characterized by low X/R ratio and unbalanced voltage conditions. Connection of WTs to a weak distribution system has effects on voltage waveform, voltage variations and steady state voltage level [3]. The main constraints are related to the effect that WTs has on voltage quality.

According to the previous described problems, the Italian standard CEI 11-32, dealing with production systems connected to the grid has been updated with new indications related to WTs such as: disconnection from the grid, power production curtailment during voltage variations and contribution to active and reactive power control.

With regards to the reactive and voltage control, the Italian standard provides that the WTs should be able to control the reactive power at the terminals so that the power factor can be adjustable between 0.95 lagging and 0.95 leading [4].

Recent grid codes prescribed that WTs must withstand voltage variations to a certain percentage of the nominal voltage and for a specified duration. Such requirements are known as Fault Ride- Through (FRT) capability [5,6].

The variable-speed WTs have the ability to control the active and reactive power independently [7,8]. A DFIG based WT can be used as a reactive power source to voltage control with a fewer costs rather than the reactive power compensation devices.

Many previous works has been carried out on the WT reactive power control methods. A control strategy to increase the reactive power output by DFIG based WTs after the fault for improving the voltage variation had been proposed in [9]. Moreover, a mathematical model based on dynamics of DFIG has been defined. In [10], a proportional-integral (PI)-based control algorithm to control the reactive power generated by WTs has been proposed. In [11], the authors have presented a control method for regulating the reactive power generated by DFIGs in a wind farm in order to control voltage variations in the network. The relation between reactive and active power to maintain DFIG operating inside the maximum rotor and stator currents and the steady state stability limit have been described in [12]. In [13], the authors have proposed active network management to exploit maximum wind energy extraction from WTs.

In this paper, a new fuzzy controller for reactive power control of variable speed WTs is presented. The controller is designed in order to compensate the voltage sags at the PCC by controlling reactive power generated by WTs.

This paper is organized as follow: the considered wind turbine model is presented in Section II. The proposed fuzzy controller is described in Section III. Case studies and simulation results are presented and discussed in Section IV, while conclusions are given in Section V.

II. Wind Turbine Generator System

A. WT Modeling

A DFIG is a wound rotor induction generator with the stator connected to the grid directly and with the rotor connected to

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the network through a back to back converter. The configuration of a DFIG based WT is shown in Fig. 1.

In order to generate active power at constant voltage and frequency, the active power flow between the rotor circuit and the grid must be controlled. Hence, the back to back converter includes two four quadrant IGBT PWM converters (i.e., rotor side converter (RSC) and grid side converter (GSC)) connected back to back by a DC-link capacitor.

The control of the DFIG is obtained by controlling both converters. The aim of the RSC is to control the active and reactive power injected to or absorbed from the grid autonomously, while the GSC has to maintain the DC-link voltage at a set value. A crowbar is also used to short-circuit the RSC in order to protect it from over current in the rotor circuit during disturbances.

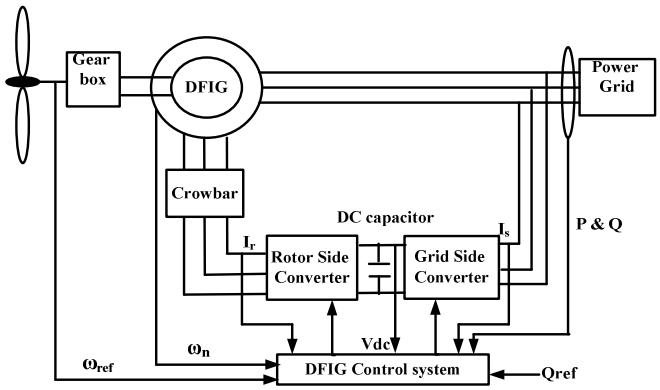

Fig.1. Configuration of DFIG based WT connected to a grid

B. *Grid Side and Rotor Side Converters*

The induction generator converts the power captured by the WT into electrical power and transmits it to the grid. The AC/DC/AC converter consists of the RSC and the GSC. Both RSC and GSC are voltage source converters (VSCs) that use forced commutated power electronic devices to synthesize an AC voltage from a DC voltage source. A capacitor connected on the DC side acts as the DC voltage source and a coupling inductor L is used to connect the GSC to the grid. The three-phase rotor winding is connected to the RSC by slip rings and brushes and the three-phase stator winding is directly connected to the grid.

The pitch angle command and the voltage command signals V_r and V_{gc} for RSC and GSC, respectively, are generated by the control system driving the power of the WT, the DC bus voltage and the voltage at the grid terminals.

The control system for the DFIG, operating under maximum power extraction, is based on a flux oriented control of the induction machine, in which the *d-q* current and voltage values are referred to the reference frame aligned with air-gap flux. The control system is composed by two distinct parts: in the first one, the WT output power and the voltage at the grid terminal are controlled by means of RSC; in the second, the voltage at DC bus capacitor is controlled by means of GSC. The control loop of the RSC, modeled as a voltage source, is shown in Fig. 2(a). The RSC controls both active and reactive power outputs through voltages components V_{qr} and V_{dr}, obtained by two separate Proportional Integral (PI) controllers. The first PI controller, which is the slowest one, controls the sum of the power P_{meas} and the power losses P_{losses} to the reference value P_{ref}, and its output is the reference of the current *d* component I_{dr_ref}. The second PI controller is the rotor current controller tracking the rotor current I_{qr} to the reference value I_{qr_ref} with a faster integration time, typically ten times smaller than the first PI. The aim of the GSC is to keep the DC link voltage constant irrespective of the direction of rotor power flow. Decoupled control of active and reactive powers flowing between rotor and grid is done by using supply voltage vector-oriented control: the scheme of the control is shown in Fig. 2(b). A DC voltage regulator, by comparing the actual voltage and the reference voltage, furnishes the *d*-component of the reference current I_{dgc_ref} for the current regulator. The current regulatory controls the magnitude and phase of the voltage generated by GSC (V_{gc}) from the I_{dgc_ref} produced by the DC voltage regulator and specified by I_{q_ref} reference. A detailed description of the control systems for both the converters and the pitch angle command can be found in [14].

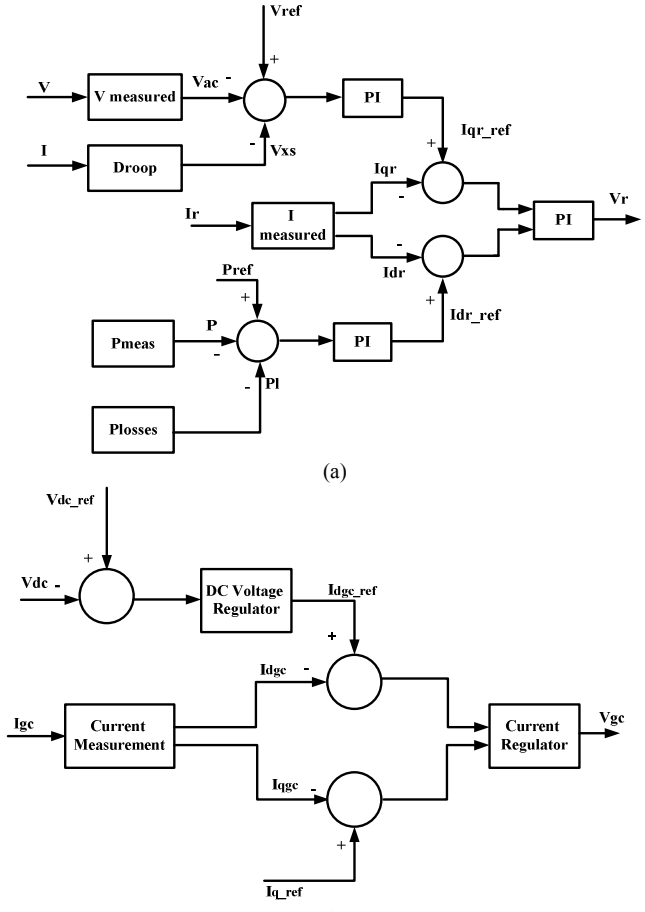

Fig.2. (a) Rotor side converter, (b) Grid side converter

III. Description of the Fuzzy Controller

Due to nonlinearity of power system and linearization problems the control of variable wind speed WTs could be difficult with conventional control methods. For example, Proportional- Integral (PI) controller design requires identifying the WT transfer function, the linear model of the network and defining an accurate tuning process. Because of these reasons, designing a PI controller is not an easy process.

The use of a fuzzy controller can overcome these problems and presents some advantages if compared to a PI controller: it is easy to obtain variable gains depending on the error and to solve problems affected by uncertain models [15-18].

The proposed controller is designed in order to compensate the voltage at the PCC by injecting the reactive power generated by both of the GSC and RSC.

Moreover, it is used in combination with a protection system for disconnecting the WT from the grid when the controller is unable to compensate the voltage variations and respect voltage limits.

The fuzzy controller, as shown in Fig. 3, presents two inputs: the error, the integral of error and one output that is the reference value for the reactive power reference signal (Q_{ref}) sent by the fuzzy controller to the WT local controller.

The error is defined as the difference between the reference voltage (V_{ref}) and the measured voltage at the PCC.

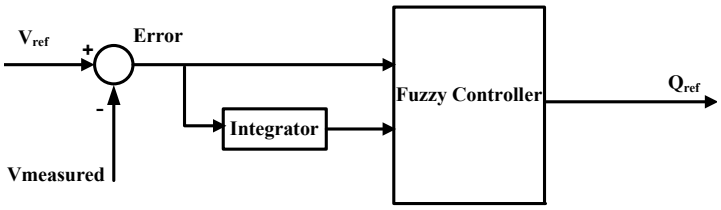

Fig.3. Fuzzy controller

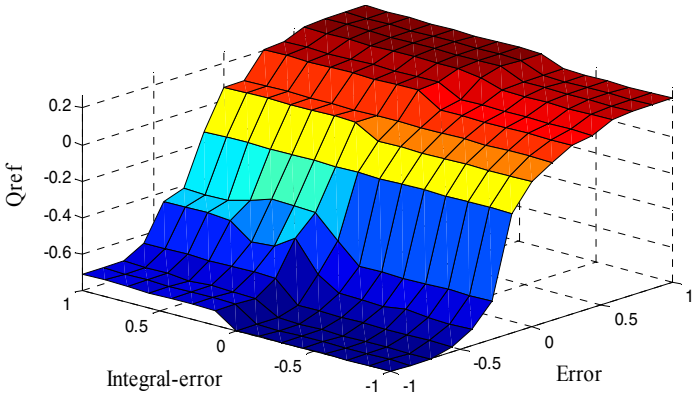

Fig.4. Fuzzy surface of controller

The fuzzy sets of the inputs and outputs assume the following names: "NVB"= Negative-Very-Big, "NB"= Negative-Big, "NM" = Negative-Medium, "NS" = Negative-Small, "ZE" = Zero, and so forth. Nine triangular membership functions have been selected for the inputs and outputs.

A Mamdani-based system architecture is realized; Max-Min and Centroid methods are used in the inference engine and defuzzification process, respectively.

The control surface of the fuzzy controller is provided in Fig.4.

IV. Case Study And Simulation Results

A. Network and WTs data

In order to test the proposed controller, two 1.5-MW WTs connected to a real 20 kV weak distribution system at buses 16, 35 are considered.

The network is characterized by lines with high resistances and low X/R ratios. The WTs and network parameters are provided in the Appendix. The single line diagram of the network is shown in Fig. 5. The base for power and voltage are 1.5/0.9 MVA and 575 V, respectively.

Real wind data sets acquired by the Wind Engineering Research Field Laboratory [19] are considered. The wind speed time history consists of 17500 observations within 50 seconds interval with sampling rate 25 Hz. The wind profile and generated active power profile are shown in Fig.6.

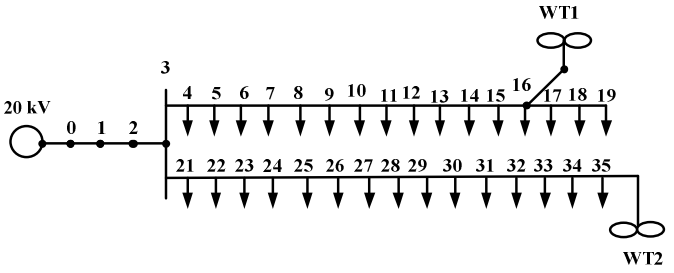

Fig.5. 20kV weak distribution system

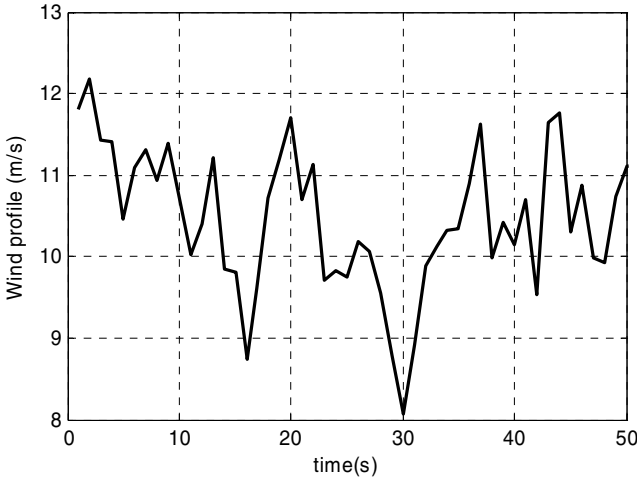
The performance of proposed control method is verified considering a 5% voltage sag with a duration of 10 seconds initiated at t=25.

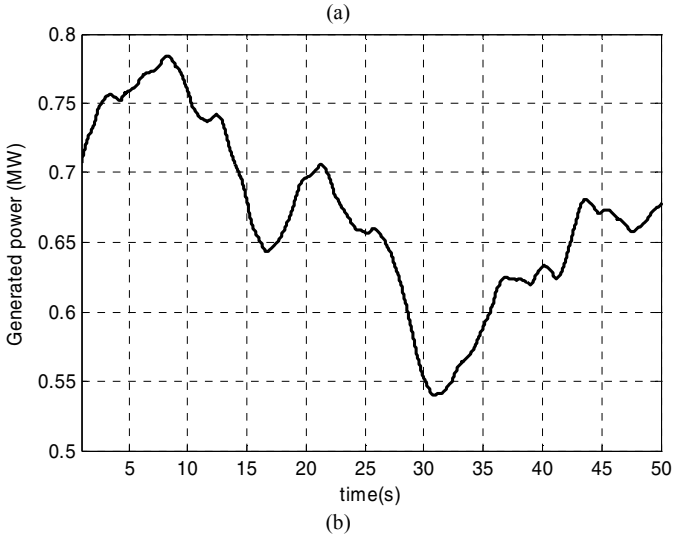
When the voltage at the PCC drops, reactive power is injected by the WTs during the voltage sag in order to help to increase the voltage to about 0.93 and 0.94 p.u., for WT1 and WT2, respectively as shown in Fig. 7.

The injected reactive power varies between about 0.40 MVAR for WT2 to about 0.43 MVAR for WT1, according to the voltages at the connection buses.

It can be also evidenced that the reactive power measured at the PCC follows its reference value as shown in Fig.8.



(a)



(b)

Fig.6. (a) Wind profile (m/s), (b) Generated active power (MW)

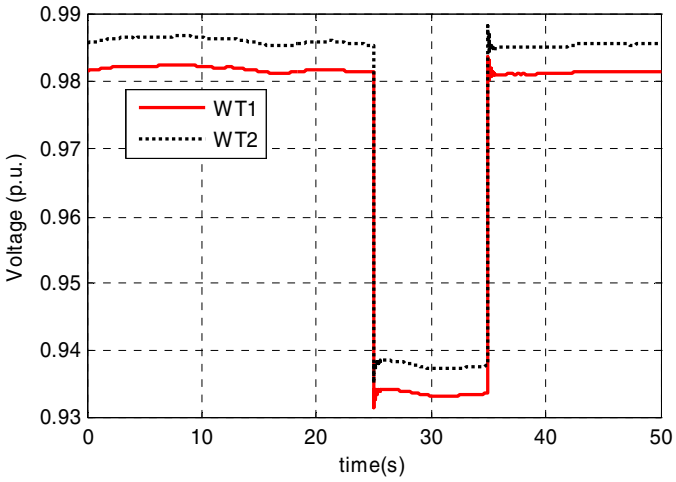


Fig.7. Voltage at the PCC

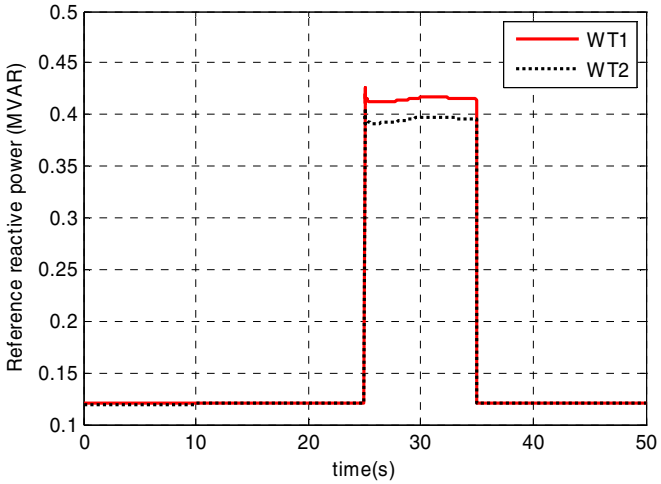

Fig.8. Reference reactive power (MVAR)

In order to evaluate the effectiveness of the proposed controller, its performances are compared with those of a classical PI controller [20] as is shown in Fig. 9.

It can be evidenced that the proposed fuzzy controller exhibits a better voltage compensation compared to the PI controller.

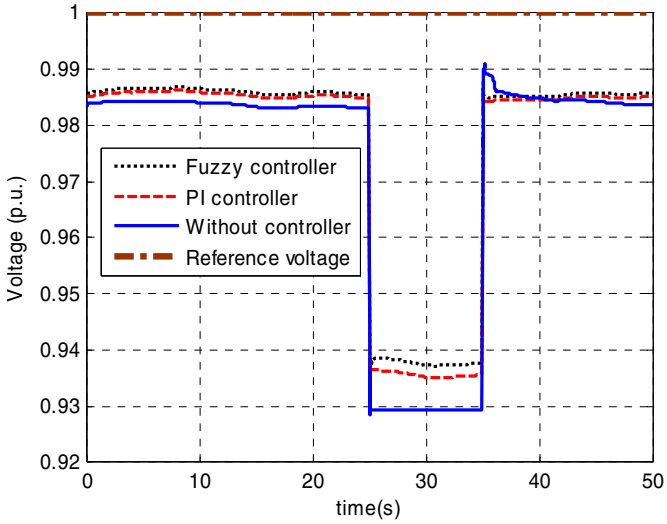

Fig.9. Voltage at bus 35

V. CONCLUSION

This paper proposes a new fuzzy controller for variable speed WTs to compensate voltage variations. at the PCC by controlling the generated reactive power. Simulations carried out on a real 37-bus Italian weak distribution network showed that the proposed controller exhibits good performances and allows compensating voltage variations.

***Abstract*—A control technique called Terminal Sliding Mode Control (TSMC) to generate high-quality sinusoidal output voltage for a constant-voltage constant-frequency (CVCF) inverter is presented in this paper. Conventional Sliding Mode Control (SMC) has used extensively due to its robustness and simplicity, but the convergence of the system states to the equilibrium point is usually asymptotic. TSMC not only has the robustness of the SMC but also guarantees the finite reaching time to the equilibrium point. The presented TSMC adjustable parameters are used to decrease the system state error to zero in finite time. With the better robustness of the proposed controller, the output voltage of the CVCF inverter will have the features of low distortion, and insensitively to parameter variations and external disturbances. Simulation results are given to conform that the proposed controller can achieve satisfactory response under linear and nonlinear loads.**

Keywords- Terminal Sliding Mode Control (TSMC), constant-voltage constant-frequency (CVCF) inverter, finite time, distortion, nonlinear loads.

I. INTRODUCTION

Constant-voltage constant-frequency inverters are being broadly adopted in many AC power conditioning systems, such as uninterruptible power supply (UPS) systems, photovoltaic (PV) energy systems, and programmable AC source (PAS) systems [1], [2]. The CVCF inverters are required to maintain the high-quality AC output voltage of low harmonic distortion (THD) and fast dynamic response even feeding distorting loads (especially highly nonlinear loads such as diode rectifiers with electrolytic capacitors) that can be achieved by employing feedback control technique [3], [4]. The variable structure system with sliding mode was initially proposed in the 1950's [5], [6]. The most attractive advantage of a sliding mode is its insensitively to modeling uncertainly, plant parameter variation, and/or external disturbance [7-12]. The sliding mode control system utilizes a switching control laws to drive the system to reach and remain on the intersection of a set of prescribed switching surface. This indicates that in the design procedure of a sliding mode control, the following steps must be satisfied:

1. There exists a sliding cure whenever the trajectory of the state error will be forced toward the sliding cure.
2. When the state error hits the sliding cure, and then the trajectory of the state error must sliding along the cure to the origin.

However, as the above mentioned, the most commonly used switching surfaces are linear hyperplanes [7-12]. The linear hyperplanes guarantee the asymptotic stability of the sliding mode. The system state will converge to the origin in infinite time. Similarly, in more recent literature, the good inverter performance cannot be achieved on account of the infinite system-state convergence time [13-15]. The tracking control scheme based on fixed-frequency SMC technique is applied to the design of Buck-based inverter. In this case, the resulting output voltage also makes a concession between steady state and transient response [13]. A discrete-time SMC method with dual-loop design for UPS inverter is developed by [14]; the system trajectory could not hit the desired sliding surface accurately, and thus a slight distortion exists in the output voltage waveform with a rectified load. In the work [15], a sliding mode controlled PWM inverter is presented, but incurs steady-state error problems.

Thus, in this paper, a terminal sliding mode control through nonlinear hyperplanes is proposed and the system parameter is designed. TSMC not only has the advantages of the conventional SMC but also takes the system to converge the origin point in finite time [16-23]. By using the proposed controller, the high-quality sinusoidal output voltage for a CVCF inverter can be generated and allow for the system state error converge to zero in finite time.

II. MODELING OF THE CVCF INVERTER

The system structure of CVCF inverter is shown in Fig. 1. The inverter output voltage is generally desired to be maintained as the same as possible to a sinusoidal reference waveform. Thus, design of the inverters can be regarded as a typical tracking problem. Let $v_o(t)$ denote the load voltage, $v_o^*(t)$ is the reference waveform, and $v_{in}(t)$ represents the inverter output voltage that takes three values: ($+V_{dc}$, $-V_{dc}$ or 0).

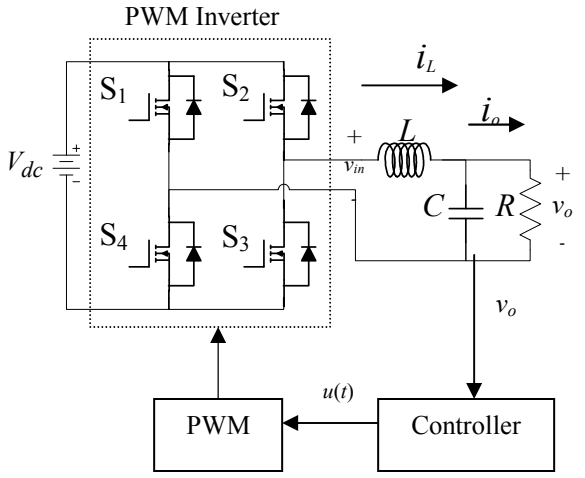

Fig. 1 Block diagram of CVCF inverter

From Fig. 1, we can get two equations:

$$i_L = C\frac{dv_o}{dt} + \frac{v_o}{R} \tag{1}$$

$$L\frac{di_L}{dt} + v_o = v_{in} \tag{2}$$

Substituting (1) into (2) has

$$\frac{d^2v_o}{dt^2} + \frac{1}{RC}\frac{dv_o}{dt} + \frac{1}{LC}v_o = \frac{1}{LC}v_{in} \tag{3}$$

Let

$$\begin{aligned} x_1 &= v_o \\ x_2 &= \dot{x}_1 = \dot{v}_o \\ \dot{x}_2 &= \ddot{x}_1 = \ddot{v}_o \\ u &= v_{in} \end{aligned} \tag{4}$$

$$\therefore \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -\frac{1}{LC} & -\frac{1}{RC} \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} 0 \\ \frac{1}{LC} \end{bmatrix}u \tag{5}$$

If the desired output voltage is $x_1^* = v_o^*$, and new state variables are defined as:

$$\begin{aligned} e_1 &= x_1 - x_o^* = v_o - v_o^* \\ e_2 &= \dot{e}_1 = \dot{x}_1 - \dot{x}_o^* = \dot{v}_o - \dot{v}_o^* \\ \dot{e}_2 &= \ddot{e}_1 = \ddot{x}_1 - \ddot{x}_o^* = \ddot{v}_o - \ddot{v}_o^* \\ &= -\frac{1}{LC}v_o - \frac{1}{RC}\dot{v}_o + \frac{1}{LC}u - \ddot{v}_o^* \\ &= -\frac{1}{LC}e_1 - \frac{1}{RC}e_2 + \frac{1}{LC}u - \frac{1}{LC}v_o^* - \frac{1}{RC}\dot{v}_o^* - \ddot{v}_o^* \end{aligned} \tag{6}$$

Then, the system dynamics can be represented as follows:

$$\begin{bmatrix} \dot{e}_1 \\ \dot{e}_2 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -a_1 & -a_2 \end{bmatrix}\begin{bmatrix} e_1 \\ e_2 \end{bmatrix} + \begin{bmatrix} 0 \\ a_1 \end{bmatrix}u + \begin{bmatrix} 0 \\ -a_1v_o^* - a_2\dot{v}_o^* - \ddot{v}_o^* \end{bmatrix} \tag{7}$$

where a_1 is equal to $1/LC$, a_2 is equal to $1/RC$.

III. CONTROL DESIGN

Define the function as follows:

$$S_0 = e_1 \tag{8}$$

From (8), the terminal sliding surface can be constructed as

$$\sigma = \dot{S}_0 + \beta_1 S_0^{\gamma_1} \tag{9}$$

where $\gamma_1 < 1$. Since γ_1 is less than one, the dynamics will be finite-time convergence; If γ_1 is equal to one, (9) becomes conventional sliding surface, and has an asymptotic convergence time.

Thus, the differentiation of the (9) can be obtained as

$$\begin{aligned} \dot{\sigma} &= \ddot{S}_0 + \beta_1\gamma_1 S_0^{\gamma_1 - 1}\dot{S}_0 \\ &= -\sum_{i=1}^{2} a_i e_i + bu - f(t) + \beta_1\gamma_1 S_0^{\gamma_1 - 1}\dot{S}_0 \\ &= -\sum_{i=1}^{2} a_i e_i + bu - f(t) + \beta_1\frac{d}{dt}S_0^{\gamma_1} \end{aligned} \tag{10}$$

Let

$$\begin{aligned} a_i &= a_{i0} + \Delta a_i \ , \quad i = 1, 2 \\ b &= b_0 + \Delta b \\ f(t) &= a_1 v_o^* + a_2\dot{v}_o^* + \ddot{v}_o^* \end{aligned} \tag{11}$$

where a_{i0} is nominal value of a_i , b_0 is nominal value of b , Δa_i is the variation of a_i , and $f(t)$ is the disturbance.

For system (7), if the control u is designed as

$$u = u_{eq} + u_{tsm} \tag{12}$$

where u_{eq} is the equivalent control input, and is defined as

$$\dot{\sigma}\big|_{u=u_{eq},\, a_1=a_{10},\, a_2=a_{20},\, b=b_0,\, f(t)=0} = 0 \tag{13}$$

$$\therefore u_{eq} = \Big(\sum_{i=1}^{2} a_{i0}e_i - \beta_1\gamma_1 S_0^{\gamma_1 - 1}\dot{S}_0\Big)/b_0 \tag{14}$$

When the system dynamics in sliding motion, $\sigma = 0$, we obtain

$$\dot{S}_0 = -\beta_1 S_0^{\gamma_1} \tag{15}$$

Substitution of equation (15) into (14) yields

$$u_{eq} = \Big(\sum_{i=1}^{2} a_{i0}e_i + \beta_1^2\gamma_1 S_0^{2\gamma_1 - 1}\Big)/b_0 \tag{16}$$

The u_{tsm} is used to eliminate the influence due to the plant parameter variations in Δa_2 to guarantee the existence of a terminal sliding mode as follows:

$$u_{tsm} = \sum_{i=1}^{2}\Omega_i e_i + \sum_{i=1}^{2}\mathrm{H}_i S_0^{2\gamma_1 - 1} + \mathrm{N} \tag{17}$$

The condition for the existence of a sliding motion is $\sigma\dot{\sigma} < 0$, and then

$$\begin{aligned} \sigma\dot{\sigma}\big|_{u=u_{eq}+u_{tsm}} &= \{-\sum_{i=1}^{2} a_i e_i + bu - f(t) + \beta_1^2\gamma_1 S_0^{2\gamma_1 - 1}\}\sigma \\ &= \{-\sum_{i=1}^{2} a_i e_i + [(b_0 + \Delta b)(u_{eq} + u_{tsm})] - f(t) + \beta_1^2\gamma_1 S_0^{2\gamma_1 - 1}\}\sigma \\ &= \{-\sum_{i=1}^{2}\Delta a_i e_i - \Delta a_2 e_2 + [\frac{\Delta b}{b_0}(\sum_{i=1}^{2} a_{i0}e_i)] + [b(\sum_{i=1}^{2}\Omega_i e_i)] \\ &\quad + (b\mathrm{H}_1 + \frac{\Delta b}{b_0}\beta_1^2\gamma_1)S_0^{2\gamma_1 - 1} + (\beta_1^2\gamma_1 S_0^{2\gamma_1 - 1} + bK_2 S_0^{2\gamma_1 - 1}) \\ &\quad + [b\mathrm{N} - f(t)]\}\sigma < 0 \end{aligned} \tag{18}$$

The conditions for satisfying (18) are

$$\Omega_1 = \begin{cases} \rho_1 < (\Delta a_1 - a_{10}\Delta b/b_0)/b & if \quad e_1\sigma > 0 \\ \xi_1 > (\Delta a_1 - a_{10}\Delta b/b_0)/b & if \quad e_1\sigma < 0 \end{cases} \tag{19}$$

$$\Omega_2 = \begin{cases} \rho_2 < (\Delta a_2 - a_{20}\Delta b/b_0)/b & if \quad e_2\sigma > 0 \\ \xi_2 > (\Delta a_2 - a_{20}\Delta b/b_0)/b & if \quad e_2\sigma < 0 \end{cases} \tag{20}$$

$$\mathrm{H}_1 = \begin{cases} h_1 < (-\beta_1^2\gamma_1\Delta b/b_0)/b & if \quad S_0^{2\gamma_1-1}\sigma > 0 \\ \bar{h}_1 > (-\beta_1^2\gamma_1\Delta b/b_0)/b & if \quad S_0^{2\gamma_1-1}\sigma < 0 \end{cases} \tag{21}$$

$$\mathrm{H}_2 = \begin{cases} h_2 < -\beta_1^2\gamma_1/b & if \quad S_0^{2\gamma_1-1}\sigma > 0 \\ \bar{h}_2 > -\beta_1^2\gamma_1/b & if \quad S_0^{2\gamma_1-1}\sigma < 0 \end{cases} \tag{22}$$

$$\mathrm{N} = \begin{cases} \zeta < f(t)/b & if \quad \sigma > 0 \\ \eta > f(t)/b & if \quad \sigma < 0 \end{cases} \tag{23}$$

Remarks:

1. By adjusting the parameters (19) to (23), the system state error can be decrease to zero in finite time.
2. Notice that the control law (12) implies the sign function across the surface σ caused by the derived inequalities form (19) to (23), and thus chattering problem exists. A solution to this problem is to smooth the discontinuous control law in a thin boundary layer. The discontinuous function can be replaced by the following continuous function:

$$\frac{\sigma}{|\sigma| + \varepsilon}, \quad \varepsilon = \begin{cases} \varepsilon_0 & |\sigma| \geq \delta \\ \varepsilon_0 & |\sigma| < \delta \end{cases} \tag{24}$$

where ε_0 and δ are positive constants.

IV. Simulation Results

To demonstrate the feasibility of the single-phase CVCF inverter using the proposed controller, the closed-loop system has been tested by computer simulations. Some key parameters are listed in Table I.

Table I Parameters of the CVCF inverter system

Switching frequency	f_{sw} = 20 kHz
DC source voltage	V_{dc} = 200 V
Rated output voltage	v_O = 110 V
Rated output frequency	f_o = 60 Hz
Rated load	R = 10 Ω
Filter inductor	L = 0.5 mH
Filter capacitor	C = 50 μF

Fig. 2 shows the simulated steady-state output voltage of the inverter with the proposed controller at full resistive load and Fig. 3 shows that with the conventional SMC at the same load condition. Both output voltages show good regulation with low THD sinusoidal waveform. Figure 4 shows the transient response with the load changing from no load to full load at t=0.0208sec. It indicates that the transient response of the proposed control is very fast taking only a few sampling intervals to reach steady-state; On the contrary, the waveforms shown in Fig. 5 with conventional SMC has a significant voltage dip. A final test, as shown in Fig. 6 is done applying a nonlinear load consisting of a diode bridge, a capacitor (200μF) and a resistive load (10 Ω). The %THD computed in the output voltage is 3.11%; The AC voltage is still satisfactory and a good behavior of the inverter is demonstrated also in this critical condition. However, under the same nonlinear loading, Fig. 7 obtained using the conventional SMC exhibits high %THD output voltage (%THD of output voltage is equal to 8.96%). The comparison between TSMC and conventional SMC under linear load and nonlinear load are also given in Table II.

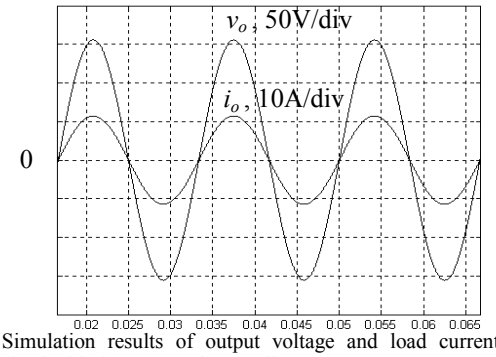

Fig. 2 Simulation results of output voltage and load current under full resistive load with the proposed controller.

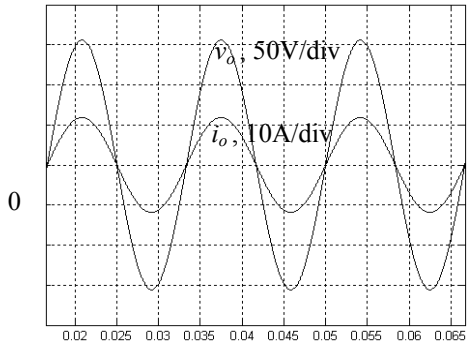

Fig. 3 Simulation results of output voltage and load current under full resistive load with the conventional SMC.

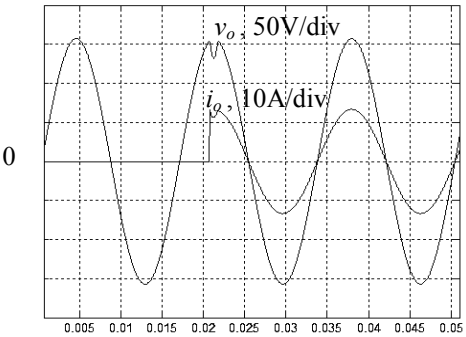

Fig. 4 Simulation results of output voltage and load current under load changing from no load to full load with the proposed controller.

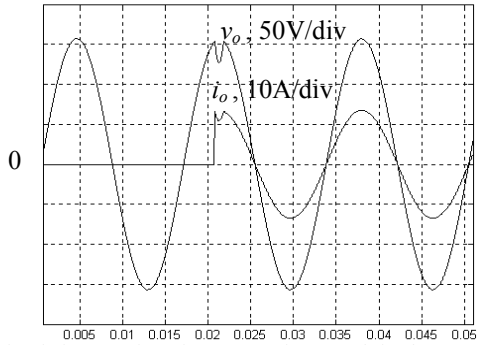

Fig. 5 Simulation results of output voltage and load current under load changing from no load to full load with the conventional SMC.

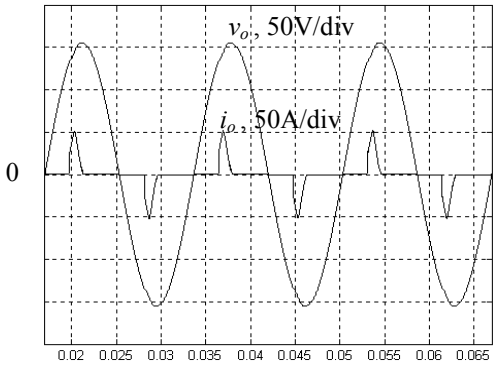

Fig. 6 Simulation results of output voltage and load current under nonlinear load with the proposed controller.

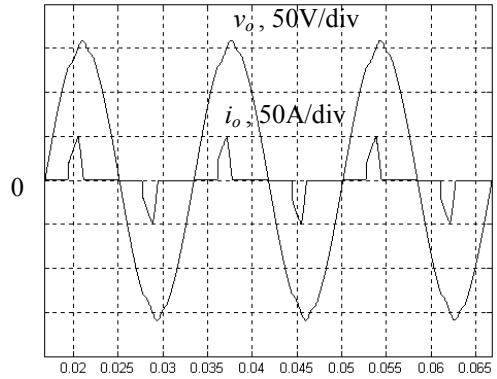

Fig. 7 Simulation results of output voltage and load current under nonlinear load with the conventional SMC.

Table II Comparison of fundamental amplitudes and %THD under linear loads and rectifier loads

		Linear Load	Rectifier Load
		10Ω	
TSMC	Fundamental Amplitude	109.5V	108.1V
	%THD	0.19%	3.11%
SMC	Fundamental Amplitude	109.3V	105.9V
	%THD	0.20%	8.96%

V. CONCLUSIONS

An approach for the control of CVCF inverters is developed on the basis of TSMC with nonlinear switching surface. This method not only possesses the characteristic of SMC but also has the finite time convergence of the system state. Even under nonlinear rectified load, the proposed controller still provides excellent performance. To verify the correct operation of the proposed control method, computer simulation is fulfilled, and good agreement is reported. It is apparent from the simulation results that the proposed CVCF inverter system is robust under different kinds of load conditions

***Abstract*—This paper focuses on the mobile robot localization problems: pose tracking, global localization and robot kidnap. Differential Evolution (DE) applied to extend Monte Carlo Localization (MCL) was investigated to better solve localization problem by increasing localization reliability and speed. In addition, a novel mechanism for effective robot kidnap detection was proposed. Experiments were performed using computer simulations based on the odometer data and laser range finder measurements collected in advance by a robot in real-life. Experimental results showed that integrating DE enables MCL to provide more accurate robot pose estimations in shorter time while using fewer particles.**

Keywords-Monte Carlo Localization; Differential Evolution; particle filter; mobile robot

I. INTRODUCTION

With the advances in intelligent sensing and control, in the near future, robots could take over more and more tasks and provide valuable services. Potential applications are diverse, from cleaning and transportation through enhanced communication (e.g. telepresence) and entertainment to security and military use. Unfortunately, nowadays it is still more likely to find mobile robot in structured environment, such as in a research laboratory or in a factory, rather than at home or at the office. Even though a significant progress in mobile robotics field has been made in the last two decades, the levels of autonomy presented by most of mobile robots are still limited, and the interaction and the cooperation between humans and robots are still challenges. To achieve this state, when mobile robots are commonly present in our everyday lives, one of the first remaining problems is localization, which could involve three sub-problems: global localization, pose tracking and kidnap problems.

There is a number of ways to approach the stated problem, which potentially may yield satisfactory solutions. This paper is dedicated to particle filters and evolutionary algorithms, particularly Monte Carlo Localization (MCL) and Differential Evolution (DE). Although both methods are mature and have long history, they were applied together to mobile robot localization problem only once by Moreno et al. [1]. Combining both methods has the potential of yielding a more effective algorithm. To our best knowledge, there was no other evidence in the literature of research in mobile robotics field regarding specifically MCL and DE. Moreno et al. presented an evolutive localization algorithm for mobile robots combining DE and MCL. Algorithm implementation is based on occupancy grid maps and laser range finder sensor.

Thrun et al. [2] presented a comprehensive paper on MCL, which is a family of MCL algorithms including Mixture-MCL. This algorithm combines classic MCL, where poses are predicted based on robots motion, with dual MCL, where information from sensors is used to predict robot poses. One of the interesting observations on classic MCL limitations are that the algorithm performs poorly if not enough particles are placed close to the true robot pose. This requires proposal distribution, from which particles are drawn, to correspond well to the true distribution of robot poses. Recently, Blanco et al. [3] proposed an optimal filtering algorithm, which dynamically generates the minimum number of particles that best represent the true distribution.

An interesting attempt to combine MCL with evolutionary mechanisms is presented by Ronghua and Bingrong [4]. The main focus in this paper is the problem of premature convergence when using MCL in highly symmetric environments. Another solution to mobile robot localization problem based on MCL and evolutionary approach is presented by Gasparri et al. [5]. The key concept of the algorithm presented in this paper is a dynamic clusterization method, which allows applying the evolutionary filter locally in each particle subset. This approach results in parallel exploration of the environment by a number of subsets.

Although not based on MCL, an interesting genetic algorithm for mobile robot localization is presented by Moreno et al. [6]. It also applies evolutionary filter only locally, but uses Extended Kalman Filter (EKF) instead of MCL to provide an estimate of robots pose. The proposed algorithm was tested indoor using a mobile robot equipped with 24 ultrasonic sensors, and demonstrated remarkable improvement in the results and was less computationally expensive than MCL. In this paper, we propose an algorithm combining MCL and DE that can improve the effectiveness of the algorithm, and discusses the performance improvement compared with the standard MCL method.

The remaining part of this paper is organized as follows. In Section II, the theory of Monte Carlo Localization and Differential Evolution, and recent solutions to mobile robot localization problem using evolutionary approach and particle filters are introduced. An algorithm combining MCL with DE is presented and discussed. In Section III, an improved algorithm based on MCL and DE is presented and explained. Section IV gives experimental results on comparison of DEMCL with MCL in terms of robot pose tracking, and The proposed modifications to DEMCL algorithm is also evaluated in terms of robot kidnap problem and global localization. Finally, conclusions are presented in Section V.

II. Differential Evolution Monte Carlo Localization (DEMCL)

A. Concepts of Monte Carlo Localization and Differential Evolution

Monte Carlo Localization (MCL) represents a sampling-based class of filters in which theoretical probability distribution on the state space is approximated by a finite set of samples

$$X_t = \{x_t^p; p = 1, 2, ...P\} \tag{1}$$

called particles, for each time-step t. Every particle is a single point in the state space and represents a hypothesis (belief) about the true state.

In robot localization, we are interested in estimating the current state of the robot x_t. Typically, two-dimensional case is considered where $x_t = [x, y, \theta]^T$, i.e. x_t represents robot position in XY-coordinates and orientation. State estimation is based on the input data Y_t. Here, Y_t represents all the data gathered from time-step 0 until t. In mobile robotics, typically two types of data are used: sensor readings $Z_t = \{z_0, ..., z_t\}$ and motion readings (odometry) $U_t = \{u_0, ..., u_t\}$. Often in practice both types of data arrive alternately i.e. $Y_t = \{z_t, u_{t-1}, z_{t-1}, u_{t-2}, ..., z_1, u_0, z_0\}$. Since odometry data u_t represents robots movement (motion command) from state x_t to x_{t+1}, at time-step t the most recent available odometry data is u_{t-1}, as indicated in Figure 1. The MCL algorithm providing recursive state estimation of the robot pose is illustrated in Algorithm 1.

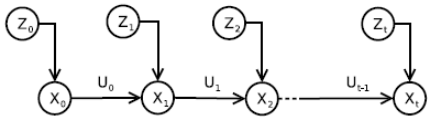

Figure 1. Robot state transformation and input data diagram.

Algorithm 1 MCL(X_{t-1}, u_t, z_t, m)

1: $X'_t = X_t = \phi$
2: **for** $p = 1$ to P **do**
3: x_t^p = **sample_motion_model**(u_t, x_{t-1}^p)
4: w_t^p = **measurement_model**(z_t, x_t^p, m)
5: $X'_t = X'_t + \langle x_t^p, w_t^p \rangle$
6: **end for**
7: **for** $p = 1$ to P **do**
8: draw $p \in [1, \ldots, P]$ with probability $\propto w_t^p$
9: add x_t^p to X_t
10: **end for**
11: **return** X_t

Differential Evolution was proposed by Storn and Price [7] for global optimization problems over continuous spaces. As any other evolutionary algorithm, DE is working with a number of potential solutions, often called a population, rather than a single one. The only requirement for DE is to provide initial population and define an objective function. It allows comparing different solutions in terms of fitness and thus is often referred to as the fitness function. Little requirements result in a wide range of optimization problems which can be addressed with DE. Even the initial requirement for continuous spaces is not valid any more, since in the recent years DE has been extended and successfully applied also to permutation-based combinatorial problems [8].

From the mathematical perspective, DE uses NP parameter vectors

$$x_i^g, i \in [0, NP-1], g \in [0, g_{\max}] \tag{2}$$

forming a population

$$P_g = [x_i^g; i = 1, 2, ..., NP] \tag{3}$$

of potential solutions. Generation index g is an integer equal or greater than zero and limited by g_{max}. P_0 corresponds to initial population, while P_1 represents population after first iteration (step) of the evolutive filter.

Additionally, each parameter vector *i*

$$x_i^g = [x_{i,1}^g, ..., x_{i,D}^g]^T \tag{4}$$

represents a single point in the D-dimensional problem space at generation g.

B. Combination of Monte Carlo Localization and Differential Evolution

Combining MCL with DE is a natural task, because the core concepts of both algorithms are very similar as presented in Table I.

TABLE I. Comparison of core concepts of MCL (particle and set) and DE (individual and population).

MCL	***DE***
$x_t^p = [x, y, \theta]^T$	$x_i^g = [x_{i,1}^g, ..., x_{i,D}^g]^T$
$X_t = \{x_t^p; p = 1, 2, ...P\}$	$P_g = [x_i^g; i = 1, 2, ..., NP]$

If the dimension D of DE parameter vector x_i^g (individual) is set to 3, then it is equivalent to particle x_t i.e. $x_{i,1}^g = x$, $x_{i,2}^g = y$ and $x_{i,3}^g = \theta$. Additionally, particle set X_t becomes equivalent to population P_g, when the number of particles P is equal to the number of parameter vectors NP.

GAs implementation requires a solution space representation and a fitness function. In this case, the most simple and intuitive solution space is $x_t = (x, y, \theta)$, because it can be directly used to represent both particles and individuals. The most obvious choice for fitness function is the measurement model, because it evaluates individual particles in terms of solving the localization problem. Therefore particle weight in MCL can be also considered as a fitness value of individual in DE.

On the algorithm level, DE can successfully replace resampling process in MCL due to crossover and mutation operators [9]. In this way, new algorithm (Algorithm 2) combines DE with MCL and will be referred to as the Differential Evolution Monte Carlo Localization (DEMCL).

As it can be seen in Algorithm 2, each step of DEMCL algorithm starts by updating particles with the most recent robot movement and assigning weights according to the measurement model. This is exactly the same as in MCL, but instead of re-sampling particles are now filtered using DE. In case of Algorithm 2, evolution is performed in a loop for a given number of generations g_{max}. Last generation P_{gmax} becomes the particle set X_t, which estimates robot pose at time t.

Algorithm 2 DEMCL(X_{t-1}, u_t, z_t,m, F,CR, g_{max}))

$X'_t = X_t = \phi$
for $p = 1$ to P do
  $x_t^p = \text{sample_motion_model}(u_t, x_{t-1}^p)$
  $w_t^p = \text{measurement_model}(z_t, x_t^p, m)$
  $X'_t = X'_t + \langle x_t^p, w_t^p \rangle$
end for
$g = 0, P_0 = X'_t$
while $g < g_{max}$ do
  for $p = 1$ to P do
    $v^p = x_t^{r1} + F \cdot (x_t^{r2} - x_t^{r3})$, $r1, r2, r3 \in [1, P]$, $F > 0$
    $u^p = \begin{cases} v_j^p & \text{if } (p_{p,j} \leq CR \text{ or } j = j_{rand}) \\ x_{t,j}^p & \text{otherwise} \end{cases}$ $j = 1, 2, 3$
    $w_u = \text{measurement_model}(z_t, u^p, m)$
    if $w_u > w_t^p$ then
      $P_{g+1} = P_{g+1} + \langle u^p, w_u \rangle$
    else
      $P_{g+1} = P_{g+1} + \langle x_t^p, w_t^p \rangle$
    end if
  end for
  $g = g + 1$
end while
$X_t = P_{g-1}$
return X_t

DE mutation variant used in Algorithm 2 is DE/rand/1/bin with F = 0.5 and CR = 0.7 (which corresponds to ~80% crossover probability).

III. IMPROVED DEMCL

A. Motivation

As demonstrated in the previous chapter, DEMCL is very suitable for solving both global localization and pose tracking problems. However, in the current form it cannot address robot kidnap problem. The main reason is that once population is converged the difference vectors in mutation are small, so evolutionary search is limited only to particles neighborhood. In other words, when all particles are grouped together, new candidate particles are generated by DE only locally. As a result, once the robot is kidnapped to a distant location, the probability of generating a new particle close to its true pose is practically zero and therefore it is almost impossible to recover from the kidnap.

It is evident that in order to solve the kidnap problem it is necessary to modify DEMCL algorithm.

B. Method description

The most straightforward solution to kidnap problem is to extend DE search well beyond the converged population by using high scaling factor F in the mutation operator. Typical F range is (0-1) and in our experiments F=0.5, but theoretically F $\in$ R+. When using high F values, mutated particles are more widely spread in the map and the probability of generating a particle close to the true robot pose after kidnap becomes larger. However, the problem is how to select correct F value. There are two methods for randomizing F via selecting a PDF and deciding how often to draw F, either for each parameter in the vector (jitter) or for every vector (dirther), which require a range of values instead of a single point. However, if the F range is not proper, mutated particles could be often outside the map and this approach would be very inefficient, just as adding random particles to the set.

Taking into account good global localization results of DEMCL, a more efficient solution to kidnap problem would be to reinitialize global localization search once the robot is kidnapped. We propose to modify DEMCL so that the population can be reset by redistributing all particles randomly and uniformly in the map. This approach requires a method to detect the kidnap. We propose following rules to signal when population resetting should be performed:

1. If the average particle weight has decreased recently compared to the long-term average.

2. If the particle set is converged but the long-term average particle weight is low.

3. If the particle set is old and still not converged.

Rule 1 First rule originates from the sensor resetting technique because it also monitors the long term (w_{slow}) and short term (w_{fast}) averages of particles weights using exponential filters. The main purpose of this rule is to signal when the particle set starts to diverge from the true pose distribution. For this rule, the probability of reset is defined as

$$pr_1 = \min(0, 1 - \frac{w_{fast}}{w_{slow}}) \quad (5)$$

where

$$w_{slow} = w'_{slow} + \alpha_{slow}(w_{avg} - w'_{slow}), \alpha_{slow} = 0.2, w_{slow} \in [0,1]$$
$$w_{fast} = w'_{fast} + \alpha_{fast}(w_{avg} - w'_{fast}), \alpha_{fast} = 0.95, w_{fast} \in [0,1]$$

Rule 2 Second rule is designed to assist the first one when the particle set is converged to a wrong pose. In such situations it is reasonable to expect low w_{slow} values, so the probability of reset is defined in this case as

$$pr_2 = \min(0, \alpha_1 - w_{slow}) \quad ()$$

where $1 \in (0, 1)$ is the upper limit of unacceptable w_{slow} values. If w_{slow} 1 than pr2 = 0 and population reset is not triggered by this rule. Parameter1 is introduced in this rule to serve as an adjustable threshold between low and high w_{slow} values. In order to avoid resetting premature populations, for which w_{slow} had not enough time to exceed 1, this rule is applied only to converged populations.

Rule 3 The first two rules cover most of the cases when population reset is needed. However, it is not certain that each population eventually converges and also w_{slow} can be low for an extended period of time, so there is a need for one more rule to trigger population reset in such situations. It would simply reset any population which is old, but not converged. In this case, the probability of reset is defined as

$$pr_3 = \min(\frac{A}{\alpha_2}, 1) \quad ()$$

where A is the population age and $\alpha_2 \in N^+$ is the maximum age, both expressed as the number of simulation steps.

All three rules are defined in probabilistic terms, rather than in deterministic terms, in order to utilize complete range of values of w_{slow} and w_{fast}. We expect such formulation to result in a greater flexibility of our method and ability to work with a wider range of maps. Probabilistic approach is also beneficial from the practical point of view, because the total number of parameters needed to define all rules is reduced to only two α_1 and α_2).

As it can be seen in Algorithm 3, all three rules are independent since the random uniform variable $U(0,1)$ is drawn individually for each rule. Population reset rules are placed at the end of DEMCL algorithm (Algorithm 3).

Algorithm 3 population_reset (X_t, w_{avg}, A, α_1, α_2)

1: $w_{slow} = w'_{slow} + 0.2 \cdot (w_{avg} - w'_{slow})$
2: $w_{fast} = w'_{fast} + 0.95 \cdot (w_{avg} - w'_{fast})$

3: $p_{r1} = \min(0, 1 - \frac{w_{fast}}{w_{slow}})$
4: $p_{r2} = \min(0, \alpha_1 - w_{slow})$
5: $p_{r3} = \min(\frac{A}{\alpha_2}, 1)$

6: **if** $U(0,1) < p_{r1}$ **then**
7: Reset population X_t
8: **end if**
9: **if** X_t is converged AND $U(0,1) < p_{r2}$ **then**
10: Reset population X_t
11: **end if**
12: **if** X_t is not converged AND $U(0,1) < p_{r3}$ **then**
13: Reset population X_t
14: **end if**

Implementation of the resetting rules is relatively simple, since it requires only little additional effort to track population age A and defining convergence criteria (Algorithm 3). In our case, population is being considered as converged if all particles are within 0.25m from the average pose estimated by this population.

IV. EXPERIMANTAL RESULTS

In this section, DEMCL was compared with MCL in terms of robot pose tracking. We are interested in localization speed, pose tracking accuracy and computation time. The proposed modifications to DEMCL algorithm also was evaluated in terms of robot kidnap problem and global localization.

A. *Comparing DEMCL with MCL*

In terms of localization speed, experimental results for MCL and DEMCL are very similar. Figure 2 presents ratio of successful trials which were localized before or exactly at the given step. In other words, all successfully localized trials until given step number are summed up and divided by the total number of successful trials in the experiment.

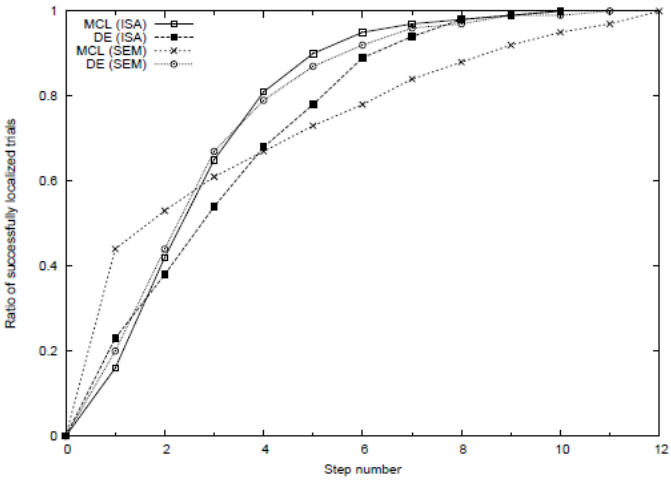

Figure 2. Ratio of successfully localized trials as a function of step number (time).

In terms of localization speed, results obtained show that the number of particles has little influence on pose tracking accuracy, therefore Table II presents only the average results.

On average, DEMCL method is 44% (ISA) and 50% (SEM) more accurate at pose tracking than MCL. Yet, both methods yield results in 0-0.1m range, which should be satisfactory for most real-life applications.

TABLE II. MCL AND DEMCL AVERAGE POSE TRACKING ACCURACY COMPARISON.

MCL	*DEMCL*
ISA 0.072±0.010m	0.050±0.016m
SEM 0.084±0.016m	0.056±0.009m

Increased computation time is the cost of significantly improved DEMCL effectiveness. Table III presents average computation time in ms for 100 particles. In this aspect, DEMCL performance is 53 (ISA map) and 17 (SEM map) times worse than MCL. Such a big difference is surprising, although an increase in computation time could not be avoided due to additional DEMCL calculations in each simulation step. On the other hand, DEMCL was using roughly 10 times less particles than MCL, which reduced the computation effort for DEMCL.

It is important to notice that exact computation time of DEMCL depends highly on the number of generations. Values presented in Table III were calculated using results from experiments with 30 (ISA map) and 10 (SEM map) generations. Any change in the number of generations would influence computation time of DEMCL, so it is not possible to directly compare MCL and DEMCL. Therefore results in Table III should be considered as a general indication of significant computation time increase, rather than as an exact difference.

TABLE III. COMPUTATION TIME IN MS PER 100 PARTICLES.

MCL	*DEMCL (ISA)*	*DEMCL (SEM)*
1.7	89.8	28

The most important observation is DEMCL ability to achieve much better success rates with fewer particles compared to MCL. DEMCL performance is significantly better than MCL in terms of effectiveness and pose tracking accuracy, however it requires much longer computation time.

B. Improved DEMCL

We expect resetting rule 1 to have the most critical influence on the results, therefore two variants of modified DEMCL are tested: with rule 1 only and with all three rules. In addition, global localization results are also presented for DEMCL without modifications. In case of robot kidnap problem, MCL results are included for reference purposes.

Global localization experiment consisted of 100 independent trials with exactly the same setup. At the beginning of each trial particles were initialized randomly and uniformly all over the free space indicated by the map. Next, at each simulation step (single iteration of DEMCL or MCL algorithm) position error was calculated as a distance between the estimated pose and the true robot pose. If this error was less than 0.25m for 5 consecutive steps, global localization was considered to be successful in the particular trial. The maximum length of each trial was set to 50 steps. Starting point in the map was selected randomly for each trial ensuring odometry and sensor data were available at least for 50 steps.

Results presented in Table IV clearly indicate that population resetting with rule 1 gives the best results, except for SEM map. In general, introducing any of the two resetting strategies improves global localization results. The explanation might be the fact that without resetting rules population has only one chance to localize the robot. With resetting there can be numerous attempts to localize the robot as a result of particles being again initialized randomly in the complete map.

TABLE IV. GLOBAL LOCALIZATION RESULTS SUMMARY FOR DEMCL VARIANTS. LGORITHMS ARE ORDERED STARTING FROM THE MOST SUCCESSFUL ONE.

Map	*DEMCL (ISA)*		
ISA	Rule 1	Rule 1-2-3	No resetting
SEM	Rule 1-2-3	Rule 1	No resetting
UWB	Rule 1	No resetting	Rule 1-2-3
COR	Rule 1	Rule 1-2-3	No resetting

Robot kidnap experiment also consisted of 100 independent trials, however the setup was different compared to global localization experiment. First of all, at the beginning of each trial particles were initialized only locally around the random starting position of the robot to avoid the need of global localization. Once the pose tracking was reliable, robot true pose was changed randomly. When pose error decreased to less than 0.25m, within 50 steps from the moment of kidnap, the robot was considered as successfully recovered from kidnap and the trial was counted as successful.

Values of w_{slow} and w_{fast} during a typical trial are presented in Figure 3. In addition, Figure 3 includes the average ratio of new particles created by DE at each generation, which we define as

$$\gamma_{new} = \frac{1}{g_{max}} \sum_{g=1}^{g_{max}} \frac{N_{new}^{g}}{P} \qquad ()$$

where $P = const$ is the total number of particles and N_{new}^{g} is the number of new particles created from population P_g which have higher fitness values than the parents and therefore are added to P_{g+1} (Algorithm 3, lines 13-17). Parameter γ_{new} indicates how effective is the evolutionary search in DE and also how likely it is for a particle to be replaced by a mutated candidate particle.

At the beginning of the trial (Figure 3, steps 1-10), all three parameters are very low. In case of w_{slow} and w_{fast} this is expected because robot is not yet localized, so particle weights are low. Surprisingly, γ_{new} is also very low (~6%), which might

indicate that evolutionary search in DE is not effective, when it is needed the most. However if we take into account the number of generations g_{max}=30, than we can easily calculate that each particle is on average replaced by a better candidate almost twice at each simulation step. This brings us to conclusion that even when γ_{new} is low the particle set is still evolving.

At step 11 w_{fast} rapidly increases which indicates that obtained measurements start to match the expected ones very well. High w_{fast} might signal successful global localization, even though it is not always a sufficient indicator. In general, there might be more than one area in the map resulting in high correlation with obtained measurements. At the same time, also γ_{new} increases from ~6% to ~30%, which suggests that particle set is evolving around five times more often than at the beginning of the trial. This observation might be explained by the fact that it is more likely for a candidate particle to have high fitness value, when particles are converged around the true robot pose, because then mutation acts only locally.

Next, w_{slow} is slowly rising, due to constantly high w_{fast}, and reaches maximum value at step 27. At this point in the simulation, both global localization and pose tracking prove to be successful, so robot kidnap occurs. As a result of sudden change in robot true pose, w_{fast} quickly decreases from 0.97 at step 27 to only 0.07 in the following step, because measurements are not aligned with expectations any more. However, w_{slow} is still quite high (change from 0.94 to 0.76) so the probability of population reset according to rule 1 is high and equal to $p_{rl} = 1 - w_{fast}/w_{slow} = 1 - 0.07/0.76 = 0.91$.

As a consequence of population reset at step 28, both w_{slow} and w_{fast} are set to 0. As seen in Figure 3, at step 35 w_{fast} again suddenly increases and w_{slow} also catches up within steps 35-50, which in this trial indicates successful robot pose recovery after kidnap.

To sum up, in this example trial robot kidnap was quickly detected after one steps (28-29) and after following six steps (29-35) robot pose estimate was successfully recovered.

Overall results from the complete experiment (Table V) prove that DEMCL with resetting rule 1 is clearly the most successful algorithm in solving the kidnap problem. Algorithms are ordered starting from the best.

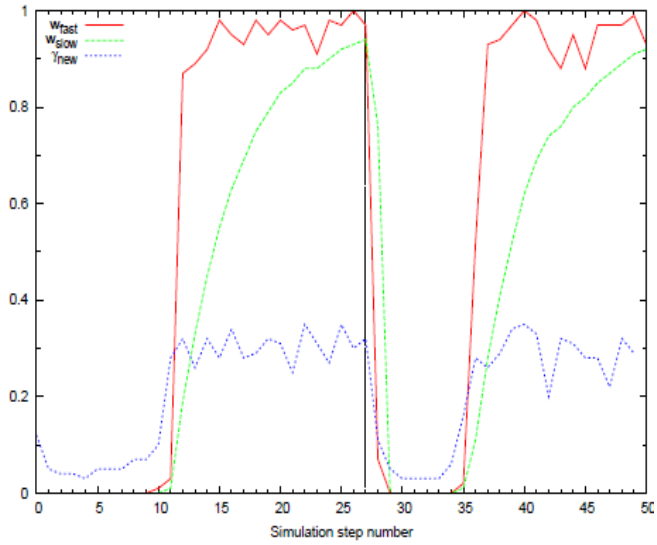

Figure 3. Population parameters in kidnap experiment: long-term (wslow) and short-term (wslow) average particle weights, average ratio of new particles (new) introduced by DE at each generation. Robot kidnap occured at step 27 (indicated by vertical line).

TABLE V. ROBOT KIDNAP OVERALL RESULTS FOR DEMCL AND MCL.

Map	***DEMCL (ISA)***		
ISA	DEMCL (rule 1)	DEMCL (rule 1-2-3)	MCL
SEM	DEMCL (rule 1)	DEMCL (rule 1-2-3)	MCL
UWB	DEMCL (rule 1)	DEMCL (rule 1-2-3)	MCL
COR	DEMCL (rule 1)	DEMCL (rule 1-2-3)	MCL

V. CONCLUSIONS

In this paper, both MCL and DE algorithms have been investigated and demonstrated how they can be easily combined to achieve increased performance. The outcome, modified DEMCL algorithm, is a complete solution for all the localization sub-problems. Experimental evaluation of the proposed algorithm proved significant improvements compared to MCL.

Regarding the challenging robot kidnap problem, the most important advancement was observed, due to the introduced population resetting rule. With sufficient number of particles, modified DEMCL algorithm was able to recover robot pose within 5 to 10 steps after kidnap with effectiveness reaching 100% on 3 out of 4 tested maps (except UWB). Whereas MCL results indicated constantly low effectiveness in recovery from kidnap, with success rates only up to 30% on most favorable map (SEM).

In case of global localization, proposed algorithm demonstrated ability to achieve the same success rates as MCL but with significantly fewer particles. The reduction ratio in particle set size ranges from 14 to 40 times. MCL solution to pose tracking was satisfactory with an average error of 7-8cm.

However modified DEMCL algorithm results in an average error of 5-6cm, which is slightly better.

The future work will focus on the investigation in the following areas: measurement model (fitness function), the improvement in computation cost and efficiency, multiple populations concept applied in DEMCL, and further DE analysis on other mutation and crossover variants or more advanced DE algorithms e.g. based on stochastic ranking. This issue could lead to further improvement of modified DEMCL algorithm and better performance results.

***Abstract*—The paper presents a novel two-step approach for constructing and training of optimally weighted Euclidean distance based Radial-Basis Function (RBF) neural network. Unlike other RBF learning algorithms, the proposed paradigms use Fuzzy C-means for initial clustering and optimal learning factors to train the network parameters (i.e. spread parameter and mean vector). We also introduce an optimized weighted Distance Measure (DM) to calculate the activation function. Newton's algorithm is proposed for obtaining multiple optimal learning factor for the network parameters (including weighted DM). Simulation results show that regardless of the input data dimension, the proposed algorithms are a significant improvement in terms of convergence speed, network size and generalization over conventional RBF models which use a single optimal learning factor. The generalization ability of the proposed algorithm is further substantiated by using k-fold validation.**

Keywords- Fuzzy-C means clustering, Hessian Matrix, Newton's Method, Optimal Learning Factor, Orthogonal Least Square.

I. INTRODUCTION

The Radial Basis function (RBF) network is a three layer supervised feed-forward network [1] used in interpolation, probability density function estimation and approximation of smooth multivariate functions [2]-[7]. The RBF was first introduced as a solution to the real multivariate interpolation problem. The RBF model can approximate any multivariate continuous function arbitrarily well on a compact domain if a sufficient number of radial basis functions are given [4].

Fuzzy clustering has been used in RBF networks for many applications. The model presented in [8] uses it for Traffic status evaluation. Though it has been applied only to the simulated data and real traffic condition is still an "open" problem. Conditional Fuzzy Clustering in the design of RBF networks [9]. The idea in [9] is further extended by using supervised Fuzzy clustering to improve RBF performance in regression task [10]. In [11] Fuzzy Clustering is used for designing a RF network used in Modeling of Respiratory system.

A hybrid learning procedure is proposed in [12] which employs unsupervised clustering algorithm like k-means for determining the center for radial basis function and supervised learning for updating output weights connecting the radial basis function unit (hidden unit) to the output unit. In [13] a gradient training algorithm for updating all the network parameters (mean vector, spread parameter and output weights) is presented. A novel space filling curves with genetically evolving parameters is proposed in [14].

In order to train the RBF network mostly first order methods are used. Gradient descent learning described in [15], [16] offers a balance between performance and training speed. These networks can be compared with sigmoid hidden unit based feed forward neural networks in [16]-[18]. The combination of steepest descent and Newton's method would seem to be more promising for unconstrained optimization problems [19]. This method is convergent and has a high convergence rate. Since Newton's method for the RBF often has non-positive definite or even singular Hessian, Levenberg-Marquardt (LM) or other methods are used instead. However second order methods do not scale well and suffer from heavy computational cost. Although first order methods scale better, they are sensitive to input means and gain factor [20].

Using other permissible radial basis function apart from Gaussian function has also been explored by constructing reformulated radial basis function neural networks trained with gradient descent algorithm [20]-[22]. But again the convergence and performance of the gradient descent algorithm is strongly affected by the spread parameter and the radial basis function mean vector.

To solve these problems we introduce an interesting family of RBF networks based on Newton's method. The paper is organized as follows: conventional RBF structure and parameter determining methods are reviewed in section 2; In Section 3, the theoretical and mathematical treatment for the proposed family of RBF models is presented. Section 4 discusses the learning parameters for the proposed model. In Section 5, learning algorithms for the proposed model are elaborated; a detailed algorithm for the proposed RBF models is presented in Section 6; the training performance of various RBF models are compared in Section 7, with single Optimal Learning Factor based RBF model on several bench mark and real life datasets.

II. REVIEW OF RADIAL BASIS FUNCTION NETWORK

Without the loss of generality, we restrict ourselves to a three layer fully connected RBF with non linear activation function

A. Basic RBF topology and notation

The structure of the RBF is shown in Fig. 1. The training dataset consist of N_v training patterns $\{\mathbf{x_p}, \mathbf{t_p}\}$ where the p^{th} input vector $\mathbf{x}_p$, and the p^{th} desired output vector $\mathbf{t}_p$ have dimensions N and M respectively. The input units are directly connected to the single hidden layer with N_h hidden nodes. The scalar weight $m_k(n)$ connects the n^{th} input node and the k^{th} hidden node. For the p^{th} training pattern, the k^{th} hidden unit *net function* is

$$net_p(k) = \sum_{n=1}^{N} (x_p(n) - m_k(n))^2 \quad (1)$$

In order to handle thresholds in the hidden and output layers, the input vectors are augmented by an extra element $x_p(N+1)$ =1, so that $\mathbf{x}_p = [x_p(1), x_p(2) \ldots, x_p(N+1)]^T$. The size of the hidden layer, N_h, is the number of useful clusters. It should be noted here that N_h is the key factor not only for the performance but also the computational complexity of the network.

The k^{th} cluster mean $\mathbf{m}_k$ *(k=1, 2… N_h)* is the center of the k^{th} subclass. In Fig. 1, the dotted line between input- hidden unit signifies that instead of weighted sum/sigmoid activation, each hidden unit output $\mathbf{O_p}$ is obtained by calculating the 'closeness' of the input $\mathbf{x}$ to N_h dimensional parameter $\mathbf{m_k}$ associated with the k^{th} hidden unit. The hidden layer is fully connected to the output weight $w_{oh}(m,k)$ connecting the k^{th} hidden unit's activation $O_p(k)$ to the m^{th} output $y_p(m)$, which has a linear activation. For the p^{th} pattern, the k^{th} hidden unit output $O_p(k)$ is calculated as *a Gaussian basis function*

$$O_p(k) = e^{-\beta(k) net_p(k)} \quad (2)$$

Here $\beta(k)$ is the *spread parameters* defined as the inverse of the width of the receptive field in the input space for hidden unit k. The mean vector $\boldsymbol{m_k}$ and spread parameter $\beta(k)$ constitute the conventional parameters of RBF.

Once the hidden units training are complete, the output weights are optimized. The M dimensional output vector $\mathbf{y_p}$ is given by

$$\mathbf{y_p} = \mathbf{W_{oh}} \mathbf{O_p} \quad (3)$$

Training an RBF typically involves minimizing the mean squared error between the desired and the actual network outputs, defined as

$$E = \frac{1}{N_v} \sum_{p=1}^{N_v} \sum_{m=1}^{M} [t_p(m) - y_p(m)]^2 \quad (4)$$

Here $t_p(m)$ and $y_p(m)$ respectively denote the m^{th} desired and actual outputs for the p^{th} pattern respectively.

B. Classical parameter determining methods and learning algorithms

Broomhead and Lowe [22] proposed a method where the idea is to populate dense regions of the input space with receptive fields. The spread parameter and mean vector need to be found without propagating the output error back through the

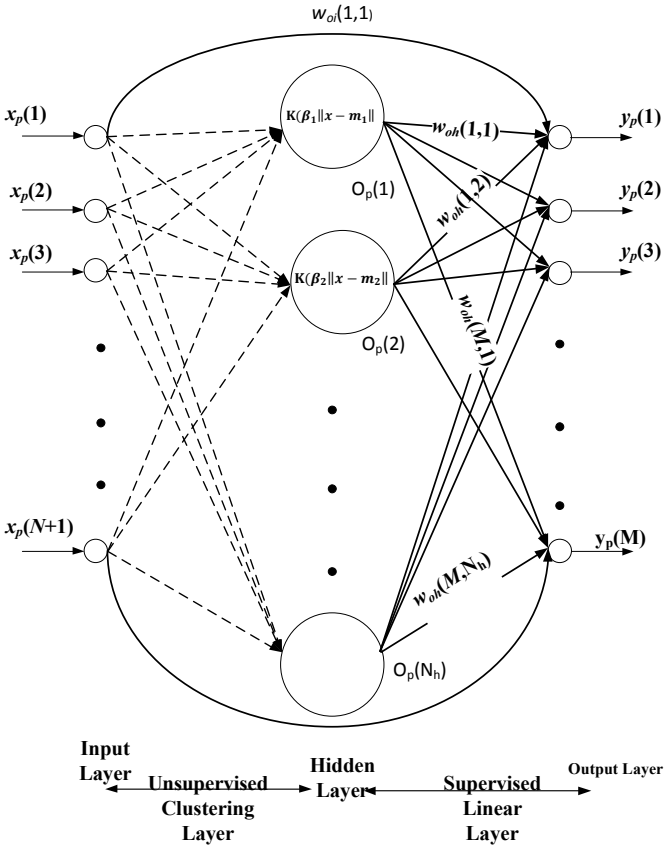

Fig 1: Topology of a fully connected RBF Neural Network

the network. But the disadvantage is for high dimensional space where for 'k' division along each dimension of an N dimensional input space, we require k^{th} basis function to cover the input space. Later Wasserman [23] presented a heuristic that is useful in determining the spread parameters. In [12] a "good" estimate to represent global average over all Euclidean distance between the centers of each unit to its nearest neighbor is suggested.

For mean vector many methods have been suggested, the most popular being choosing the first sample of the training set, some randomly chosen sample from the training set obtained by clustering or classification method.

In [12] unsupervised learning of mean vectors and spread parameters is employed using relatively small number of RBF clusters. Although clustering can be based on statistical model identification, generally competitive learning based clustering methods are used such as self-organizing map (SOM), learning vector quantization (LVQ), neural gas, Adaptive Resonance Theory (ART), C-means, Fuzzy clustering, Fuzzy C-means clustering and mountain/subtractive clustering. Fuzzy based clustering is used in this paper.

To compute the output weight matrix we can use several training algorithms which are classified into three categories: gradient descent methods, conjugate gradient methods, and Newton related method [24]-[26]. The latter is the basis of much of our research in this paper.

III. PROPOSED RBF NETWORK

In this section we illustrate how the second order based Newton's method can be incorporated in the existing RBF network by modifying the conventional RBF Network described in previous section.

Our proposed family of RBF network introduces a new group of network parameters. Referring to the conventional RBF Neural Network shown in Fig. 1; we have bypass weights $w_{oi}(i,n)$ connecting the n^{th} input to the i^{th} output. Including the bypass weights w_{oi}, the linear output response y_p is now given by

$$\mathbf{y_p} = \mathbf{W_{oi}x_p} + \mathbf{W_{oh}O_p} \tag{5}$$

Here the symbols have the usual meaning. The training strategy is a two step procedure, followed in the conventional RBF structure.

A. Phase 1: Initializing the RBF Network

Motivated from the heuristic proposed in [25], we set up the initial parameters for the proposed RBF models as described in following subsection.

1) Setting up initial weighted Distance Measure(DM)

Let elements of vector $\boldsymbol{c}$, of dimension N, denote weights in a weighted Distance Measure (DM). Let elements of $\boldsymbol{\sigma}$ represents the standard deviation of input vector of dimension *N*. Then ***c(n)*** is then defined as :

Then

$$c(n) = \frac{1}{[\sum_{n=1}^{N} 1/\sigma^2(n)]\sigma^2(n)} \tag{6}$$

The input to each hidden unit is now changed to

$$net_p(k) = \sum_{n=1}^{N} c(n)(x_p(n) - m_k(n))^2 \tag{7}$$

where $net_p(k)$ is the weighted DM. Note here that the sum is done over *N,* rather than *N+1*.

2) Setting up initial cluster center using Fuzzy C-means

We use Fuzzy clustering to partition data set into K Fuzzy clusters. The motivation for using Fuzzy clustering is that in several real life applications the data points are on the boundary of two or more classes. Hence they do not belong to any one class. We then assign a membership function which can be seen as a generalization of hard partitions. The Fuzzy C-means clustering algorithm minimizes the cost function J_{fcm} to determine mean vector $'\boldsymbol{m_k}'$ where,

$$J_{fcm} = \sum_{k=1}^{K}\sum_{p=1}^{N_v} (\varepsilon_{kp})^b \left\|x_p - m_k\right\|^2 \tag{8}$$

where $'\varepsilon'$ is the Fuzzy partition and $'b'$ is the free parameter which controls the "bending" of different clusters. If $b > 1$, the cost function allows pattern to belong to multiple cluster. $\boldsymbol{x_p}$ and $\boldsymbol{m_k}$ have their usual meaning.

B. Phase 2: Optimization of network parameters

We now propose a procedure to tune the network parameters via Newton's method which uses first and second order derivatives of the parameters w.r.t the error function.

1) Opimizing weighted DM

A typical error function used in the Training of RBF is described in (4). The hidden unit output is given by

$$O_k(p) = e^{-\beta(k)\overbrace{\sum_{n=1}^{N}(c(n)+d_c(n)).[x_p(n)-(m_k(n)]^2}^{net_p(k)}} \tag{9}$$

where $net_p(k)$ is as defined in (7). $c(n)$ is the weighted DM that will be optimized. The output vector $y_p(i)$ is same as described in (6), i.e

$$y_p(i) = \sum_{k=1}^{N_h} w_o(i,k)\, O_k(p) + \sum_{n=1}^{N} w_{oi}(i,n)\, x_p(n) \tag{10}$$

By calculating the 1st order gradient w.r.t. DM we obtain:

$$g_c(n) = -\frac{\partial E}{\partial d_c(n)} = \frac{2}{N_v}\sum_{p=1}^{N_v}\sum_{i=1}^{M}[t_p(i) - y_p(i)]\frac{\partial y_p(i)}{\partial d_c(n)} \tag{11}$$

where

$$\frac{\partial y_p(i)}{\partial d_c(n)} = -\sum_{k=1}^{N_h} w_o(i,k)O_p(k)(-\beta(k))\big[x_p(n) - m_k(n)\big]^2 \tag{12}$$

calculating the Hessian matrix element we get:

$$h_c(u,v) = -\frac{\partial^2 E}{\partial d_c(u)\partial d_c(v)} = \frac{2}{N_v}\sum_{p=1}^{N_v}\left[\sum_{i=1}^{M}\frac{\partial y_p(i)}{\partial d_c(u)}\frac{\partial y_p(i)}{\partial d_c(v)}\right] \tag{13}$$

One realization that occurs now is that of the following linear equations

$$\boldsymbol{H_c d_c} = \boldsymbol{g_c} \tag{14}$$

This is solved using orthogonal least square (OLS). For n^{th} input unit, $c(n)$ is then changed according to

$$c(n) \leftarrow c(n) + d_c(n) \tag{15}$$

Hence solving (15) we get the optimal d_c via OLS.

2) Optimizing "width" (spread parameter)

Using the same error function as in (4), for p^{th} pattern and k^{th} hidden unit.

$$O_p(k) = e^{(-(\beta(k)+d_\beta(k))\overbrace{\sum_{n=1}^{N} c(n)[x_p(n)-m_k(n)]^2)}^{net_p(k)}} \tag{16}$$

here $d_\beta(k)$ is the learning factor for $\beta(k)$ in each k^{th} hidden unit. For i^{th} output we have,

$$y_p(i) = \sum_{k=1}^{N_h} w_o(i,k) e^{-(\beta(k)+d_\beta(k))\overbrace{\sum_{n=1}^{N} c(n)[x_p(n)-m_k(n)]^2)}^{net_{p(k)}}} \quad (17)$$

We follow the same approach as in the previous sub-section. After calculating $g_\beta(k) = -\frac{\partial E}{\partial d_\beta(k)}$ and Hessian matrix element $h_\beta(u,v) = -\frac{\partial^2 E}{\partial d_\beta(u)\partial d_\beta(v)}$ we obtain

$$\mathbf{H_\beta d_\beta} = \boldsymbol{g_\beta} \quad (18)$$

Solving this again via OLS, $\beta(k)$ is then changed according to

$$\beta(k) \leftarrow \beta(k) + d_\beta(k) \quad (19)$$

3) Optimizing mean vector

In this algorithm we are changing only the mean vectors holding other parameters constant.

$$O_k(p) = e^{-\beta(k)\overbrace{\sum_{n=1}^{N} c(n)[x_p(n)-(m_k(n)+z_k.g_{mean}(k,n)]^2)}^{net_{p(k)}}} \quad (20)$$

For the p^{th} pattern , the i^{th} output unit can be written as

$$y_p(i) = \sum_{k=1}^{N_h} w_o(i,k) e^{-\beta(k)\overbrace{\sum_{n=1}^{N} c(n)[x_p(n)-(m_k(n)+z_k.g_{mean}(k,n)]^2)}^{net_{p(k)}}} \quad (21)$$

Unlike the previous gradients, here we calculate the gradient matrix element $g_{mean}(k,n) = -\frac{\partial E}{\partial m_k(n)}$. In [27] multiple optimal learning factor algorithms (MOLF) is shown to train better than OWO-BP. We therefore update the mean vector $\boldsymbol{m}_k$ based on its own learning factor z_k which is optimal for the k^{th} hidden unit.

The basic idea for MOLF is that while updating the mean vector for every iteration, instead of using a single optimal learning factor 'z' we use a vector $\boldsymbol{z}$ of optimal learning factor called Multiple OLF (MOLF). Each element of $\boldsymbol{z}$ is for each mean vector. We now derive the expression for the MOLF as used in updating mean vector. Using (5), we calculate $g_z(k) = -\frac{\partial E}{\partial z_k}$ and $h_z(u,v) = \frac{\partial^2 E}{\partial z(u)\partial z(v)}$. The Gauss-Newton update guarantees that $\boldsymbol{H_z}$ is non-negative definite. Given the negative gradient vector $\boldsymbol{g}_z = \left[-\frac{\partial E}{\partial z_1}, -\frac{\partial E}{\partial z_2} \ldots, -\frac{\partial E}{\partial z_{N_h}}\right]^T$ and the Hessian $\boldsymbol{H_z}$, we minimize E with respect to the vector $\boldsymbol{z}$ by solving linear equation:

$$\mathbf{H_z z} = \boldsymbol{g_z} \quad (22)$$

Thus we get

$$\boldsymbol{z} = \boldsymbol{H_z^{-1} g_z} \quad (23)$$

During each iteration, the k^{th} mean vector is updated as

$$m_k(n) \leftarrow m_k(n) + z_k.g_{mean}(k,n) \quad (24)$$

Here the MOLF procedure has been used to train the mean vectors. It should also be mentioned here that if MOLF fails then we can combine the optimal learning factors into a single optimal learning factor.

IV. COMBINED LEARNING ALGORITHMS

In this section we describe the construction of advance learning algorithm from the previously described algorithms.

A. Output weight optimization (OWO)

In each iteration of our proposed two stage algorithms we optimize the output weight matrix using a technique called output weight optimization (OWO). Since the outputs have linear activations, finding the weights connected to the outputs is equivalent to solving a system of linear equations. If $\boldsymbol{W_o}$ denotes the output weight matrix, equating $\frac{\partial E}{\partial \boldsymbol{W_o}} = \mathbf{0}$ leads to

$$\boldsymbol{C_a} = \boldsymbol{W_o R_a^T} \quad (25)$$

Where

$$\begin{cases} \boldsymbol{C_a} = \dfrac{1}{N_v}\displaystyle\sum_{p=1}^{N_v} y_p \bar{x}_p^T \\ \boldsymbol{R_a} = \dfrac{1}{N_v}\displaystyle\sum_{p=1}^{N_v} \bar{x}_p \bar{x}_p^T \end{cases} \quad (26)$$

Since the equations in (25) are often ill conditioned [28][29], we solve them using OLS[30] which is equivalent to using the QR decomposition [31].

B. Proposed family of algortihms

In this subsection we combine OWO with the optimization approaches of III (B). In our algorithms we combine a multi-stage training algorithm which can be denote as F[N(*param1*), *param2*] where 'F' represents Fuzzy c-means clustering and 'N' represents Newton's method applied on *param1*, while *param2* are the parameter(s) which have been set during net control and have not been modified or "tuned" during the training process. We also combine all three parameter optimizations where we update weighted DM from (15) and use (19) and (24) to update beta and mean vector. This largest combined algorithms is denotes as F[N(c, β, m.)].

During our investigation we compared our algorithms with RBF models using single OLF (SOLF). Here we discuss the single OLF case for updating spread parameters. Similar equations can be derived for the single OLF for mean vector case. Similar to the proposed algorithms we denote F[SOLF(*param1*), *param2*] where SOLF represents that single OLD has been used for updating the parameters, param1 and param2. We combine both and form a RBF model that will be compared later with the rest of the family of algorithms.

Given the error function as defined in (5) we have,

$$y_p(i) = \sum_{k=1}^{N_h} w_o(i,k) e^{-(\beta(k)+z.g_{\beta(k)})net_p(k)} + \sum_{n=1}^{N} w_{oi}(i,n) x_p(n) \quad (27)$$

Note the similarity in (18) and (23). Instead of using two optimizing parameter, we optimize the performance by using a single parameter $d_\beta(k)$ in (18). By using $g_\beta(u) = -\frac{\partial E}{\partial \beta(k)}$, we calculate $\frac{\partial E}{\partial z}$. The Gauss-Newton approximation of the second partial and 2nd order Taylor series leads to,

$$z = -\frac{\partial E/\partial z}{\partial^2 E/\partial z^2} \quad (28)$$

Instead of using a single optimal learning factor for updating all the parameters, we use Newton's method to estimate a vector of optimal learning factors $\boldsymbol{z}$. One of our investigation aims is to show this novel method to update the parameters to be better than the single optimal learning case

It should be mentioned here that during an iteration, at one time, one parameter is updated followed by OWO and then the next parameter is updated. From a philosophical point of view we modify the two step optimization approach which in turn is similar to EM algorithm where the E denotes expectation as the first step and then in the second step maximization denoted by M.

V. Algorithm for Training the Proposed RBF Network

We follow a two step hybrid learning procedure to train the proposed RBF Network. Contrary to [12] [24], our proposed algorithm efficiently uses Newton Method and Backpropagation algorithm to optimize the network parameters in every epoch. Fig. 2 shows the various stages

VI. Numerical Results

We present the results for the proposed family of algorithms discussed. All algorithm were implemented in MATLAB script. By using different benchmark and real-life dataset we judge the performance of the algorithms by analyzing the effect of applying Newton's method on network parameters. The generalization ability of each algorithm is later shown by using *k-fold* validation procedure all the data set used for the simulation is available from the Image Processing and Neural Networks Lab repository [32] and UCI Machine Learning Repository [33].

For all the figures discussed here, '*B*' denotes the spread parameters $\boldsymbol{\beta}$; $\boldsymbol{m_k}$ as the mean vectors and $\boldsymbol{c}$ is the weighted DM.

For better comparison, initial clusters, initial parameters value and the output synaptic weights of all algorithms are initialized by the same way so that the MSE of the first training iteration is same. The RBF architecture for training each dataset has different number of hidden units, different number of input units and output units. Here, the number of training iterations is fixed as $N_{it} = 50$. In all the data set, the inputs have been normalized to be zero mean and unit variance. The family of networks analyzed, are based on Newton's method with multiple OLF and compared with conventional network based on single OLF for $\boldsymbol{\beta}$ and $\boldsymbol{m_k}$. During our investigation we take two highly correlated ($\rho > 0.8$) and other two as least correlated ($\rho < 0.2$). Here ρ is the correlation coefficient. By doing so, it is found that the performance of the algorithm is severely affected by the data set correlation.

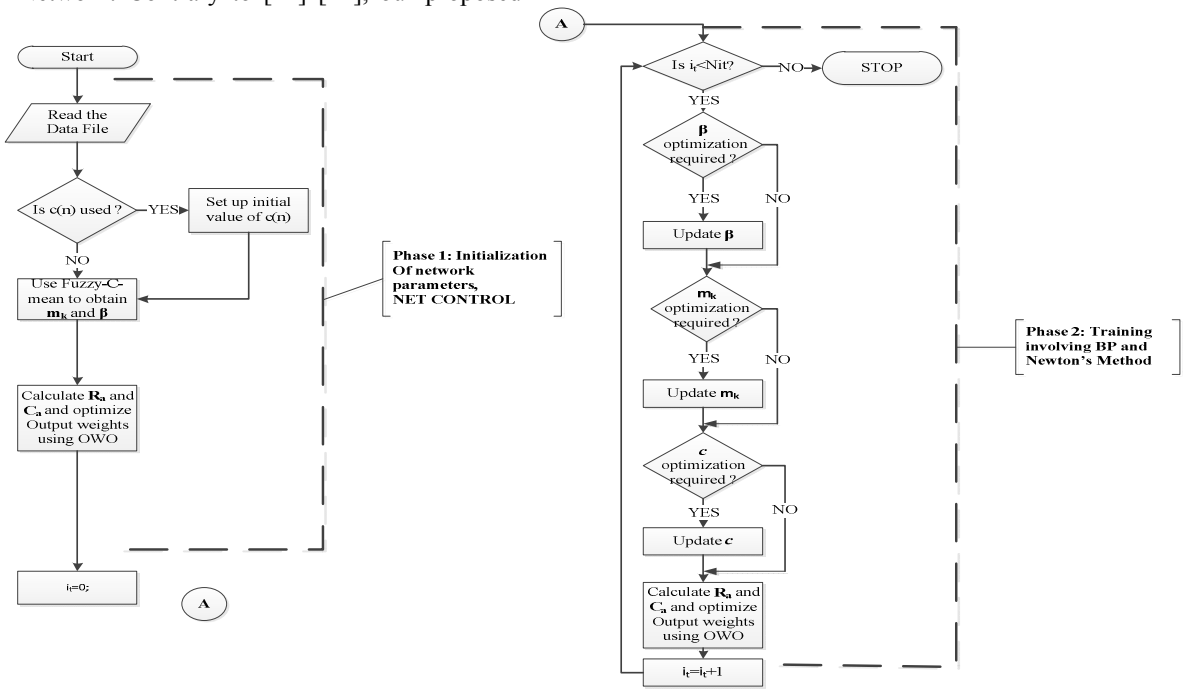

Figure 2: Algorithm for training the proposed family of RBF Network

A. Scattering Parameter Data Set

The training data file contains 1768 patterns. The inputs consist of 8 theoretical values of scattering parameters. The outputs are its 7 corresponding heights, lengths and permittivity. [32] *'twod.tra'* is a highly correlated input data set. We trained all the RBF models with $N_h = 20$. In Fig. 3, the average mean square error (MSE) for training is plotted versus the number of iterations (N_{it}) for each algorithm. From

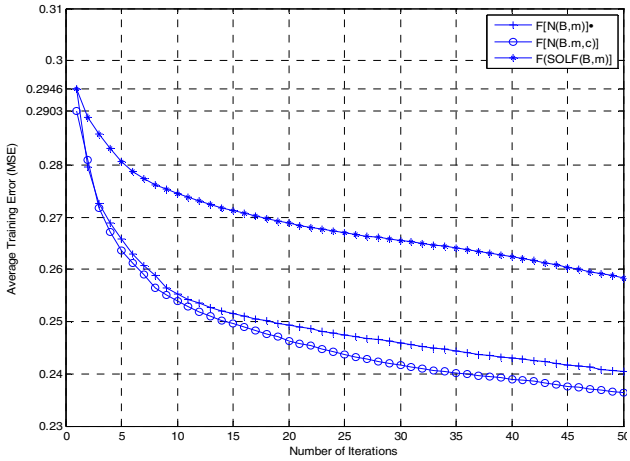

Figure 3 Performance of proposed family of algorithm with single OLF based RBF on twod

The plots we deduce that the network with Newton's method applied on all parameters gives the best performance applied

B. Radar Scattering Data Set

This training set also called '*oh7*', contains polarization at different angles along with the corresponding surface height, surface correlation length, and volumetric soil moisture content [32].

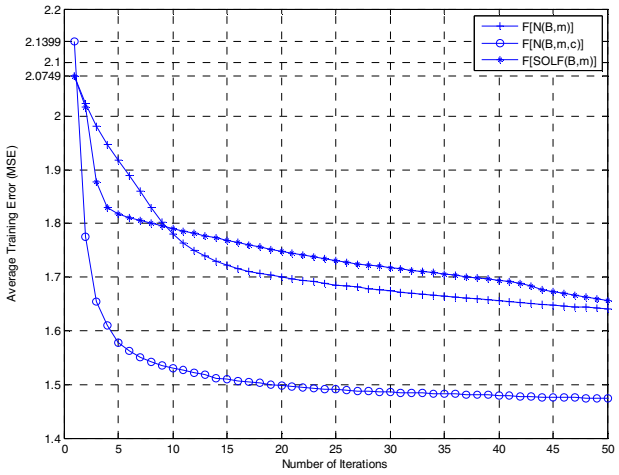

Figure 4 Performance of proposed family of algorithm with single OLF based RBF on oh7

Here not only the input values but also one of the output values is highly correlated with the input values unlike 'twod'. We train all the RBF models with $N_h = 20$. In Fig. 4, the MSE for training is plotted versus N_{it} for each algorithm. The plot shows that the RBF model where we apply Newton's method on all parameters perform best.

C. Inverse Matrix Data Set

Also called '*Mattrn'*, it is an uncorrelated dataset with 2000 training patterns obtained from the inversion of random two-by-two matrices [32]. Each pattern consists of 4 input features and 4 output features. For this data set, all the RBF models are trained with $N_h = 15$. In Fig. 5, MSE for training is plotted versus N_{it} for each algorithm. This data set is uncorrelated and we observe that the model where Newton is applied on $\boldsymbol{\beta}$ and $\boldsymbol{m_k}$*'* performs at par with the model where it is applied on all the parameters.

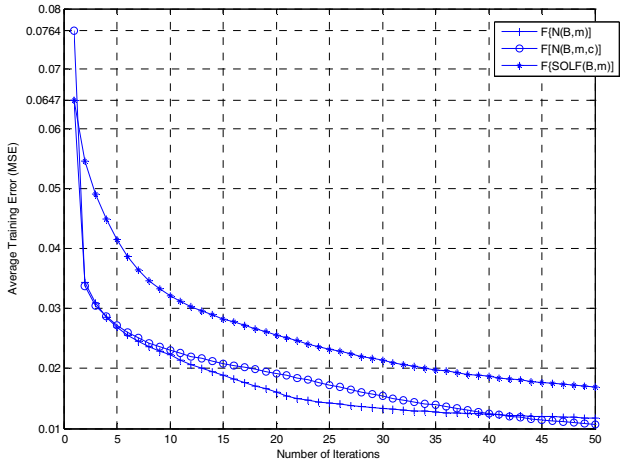

Figure 5 Performance of proposed family of algorithm with single OLF based RBF on mattrn

D. Concrete Compressive Strength Data Set

"Concrete" is an un-correlated dataset used to approximate the nonlinear function of age and ingredients of concrete compressive strength [33]. With a total number of patterns as 1030, this dataset consists of 8 inputs and 1 output and $N_h = 20$.This dataset is also least correlated and we see the same trend as we see in mattrn.tra. The performance of the model with $\boldsymbol{\beta}$ and $\boldsymbol{m_k}$ optimization is close to the model that have weighted DM optimization .

E. K-Fold Crossing Validation

We use the k-fold crossing validation procedure to show the generalization abilities of various RBF models. Choosing *k=10* so for each dataset, we split it randomly into 10 non-overlapping parts of equal size, and use 9 parts of total data for training and leave the remaining one part for testing. This procedure was repeated till we have exhausted all 10 combinations. Then, by training all these combinational datasets, we got the average of training errors. Also, the validation error of each dataset was obtained by averaging all corresponding testing errors on every testing dataset. The training MSEs and test MSEs of k-fold crossing validation on these four datasets are listed as Table 1.

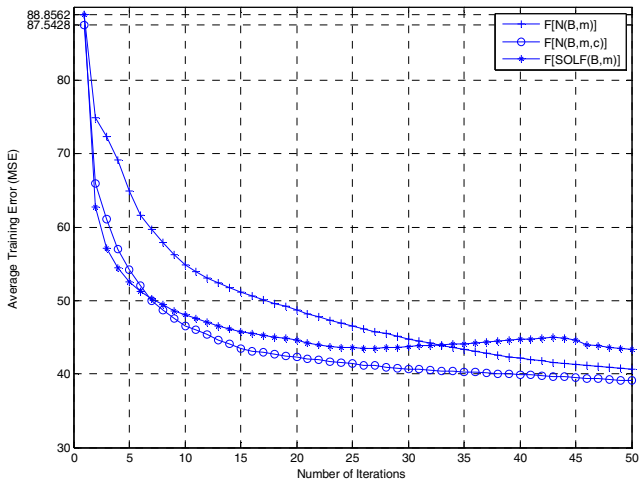

Figure 6 Performance of proposed family of algorithm with single OLF based RBF on concrete

TABLE 1: COMPARISION OF K-FOLD VALIDATION ON DATASET

Data Set	Error	F[N(B,m)]	F[N(B,m,c)]	F[SOLF(B,m)]
Twod	Validation	0.2456	0.2363	0.2587
	Testing	0.2519	0.2433	0.2713
Oh7	Validation	1.6547	1.4738	1.6847
	Testing	1.6843	1.4916	1.7214
mattrn	Validation	0.0118	0.0106	0.0168
	Testing	0.0215	0.0204	0.0181
concrete	Validation	40.5882	39.9854	43.1598
	Testing	41.0689	40.6538	43.2811

VII. CONLCUSION AND FUTURE WORK

The conclusion that we make from our experimental results is that the used of Newton's method on all three parameters helps significantly in improving the performance of RBF networks. Newton's method effect is more pronounced in correlated datasets. Training of the DM weights significantly improves the RBF network. From the experiments we conclude that for un-correlated datasets, optimizing $\boldsymbol{m_k}$ through SOLF has no effects. We have seen that the MOLF training of the $\boldsymbol{m_k}$ is more effective than the training of $\boldsymbol{\beta}$. The experimental results further bolster this conclusion.

***Abstract*—Recent studies in smart homes have proposed methods to use a laser pointer for interacting with home devices, which represents a more user-friendly and less expensive home device control environment. However, detecting the laser spot on the original non-filtered images, using standard and non expensive cameras, and considering real home environments with varying conditions, is currently an open problem.**

In this paper we propose a hybrid technique, combining a classic technique used in image detection processes, such as Template Matching, with an evolutionary learning of a Fuzzy Rule Based Systems for the laser spot detection system in real home environments. This proposal improves the success rate in images without laser spot of the previous classical and non-classical algorithms used for detecting the laser spot in previous works, decreasing the detection of the false offs which could lead to dangerous situations. Experimental results on a real home environment show the effectiveness of the proposed approach.

***Index Terms*—Interaction Systems, Domotic Control Systems, Laser Pointer Detection, Fuzzy rule-based systems, Genetic Learning.**

I. Introduction

Nowadays, a home can be controlled by different devices like special indoors control devices; or by means of mobile phones, personal computer, etc. using Internet if the users are outdoors. Recent research in intelligent homes provide great solutions for controlling home devices [1]–[6].

We can find different kinds of smart homes systems in the specialized literature. Park et al. [2] presented a robotic smart house, by means of which disabled people can be assisted by a robot sending orders with body movements. Other researchers have used non-invasive brain-computer interfaces [3], where a brain computer interface is used to control different devices.

On the other hand, the work presented in [7] makes use of a robot for helping disabled people to pick up different objects. In this work, the authors also proposed an interesting way to point out the desired objects by means of a laser pointer. The robot should then be able to detect the laser spot on an object in order to pick up this object. Since they represent cheap and easy to handle devices, laser pointers have been used as an indicator element for controlling large displays [8]–[11] and now they have been also used in the environment control system.

The main goal in these types of systems is to detect the laser spot effectively. In [7], the authors deal with this problem by using especial physical filters in the video camera while it is taking the environment photos, with the aim of only capturing the laser spot. However, this is still an open problem that can be addressed by using laser spot detection algorithms based on the original non-filtered images avoiding the expenses of using special cameras and filters.

An alternative making use of standard and therefore cheaper cameras can be found in [12] where a set of algorithms, were proposed to detect the laser spot effectively on the image obtained by a standard video camera. Nevertheless, this algorithms present some false offs, when a laser spot is detected by the algorithm but the image does not have any laser spot. In this event, a wrong order is sent to the domotic system which could provoke undesirable, dangerous or at least unexpected, situations. For this reason, in [13] we presented a new approach hybridizing a classic technique with the use of a Fuzzy Rule Based System (FRBS) designed from expert's knowledge [14], [15] for trying to improve the success rate in images without laser spot. Further, this initial FRBS was tuned in [16] by means of a Genetic Algorithm (GA), in order to improve the success rate in images without laser spot.

In this paper, we present a new approach to detect the laser spot in the environment device control system presented in [13], [16] by means of an evolutionary learning of the FRBS for the laser spot detection system. It consists on an embedded evolutionary learning of the Data Base (DB) as the way to effectively obtain a complete Knowledge Base (KB) and it is based on using the linguistic 2-tuples representation [17], which allows the lateral displacement of the labels considering an unique parameter per label, decreasing the complex search space that learning together the Rule Base (RB) and the Data Base (DB) represents. Using this particular representation, the search space is reduced with respect to the classic triangular Membership Functions (MFs) representation in order to easily obtain optimal models. The embedded learning scheme consists of an evolutionary process that learns the DB and wraps a simple method to derive a set of rules for each DB definition. This allows learning the most adequate context for each fuzzy partition (i.e., granularities and MFs displacements) together with the associated RB which will help to significantly improve the performance of the obtained FRBS for the laser spot

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

detection problem. The results obtained by using the proposed approach on a big set of image samples (990 images in total) and following a cross-fold validation model show a better general success rate with respect to the previous techniques, and the most important advantage, the not desired false offs are virtually avoided.

This contribution is arranged as follows. In section II, the environment device system for environment control by using a laser pointer is described together with the previous approaches applied to solve this problem. Section III presents the evolutionary learning of a FRBS for the laser spot detection system used in this work. The results obtained using the classic technique, and the hybrid approaches based on the derivation of a FRBS from expert's knowledge, automatic tuning or automatic learning (respectively) are shown and analyzed by comparing them in section IV. Finally, section V points out some conclusions.

II. System Description and Previous Work

As we mentioned, the laser pointer systems allows to control different home devices. These systems analyze different environment images sent by a video camera, detect the laser spot on these images and automatically recognizes the device which the user has selected with the laser pointer, sending the necessary orders to control the home device by means of a domotic system.

In our case, this system consists of three sections (see figure 1):

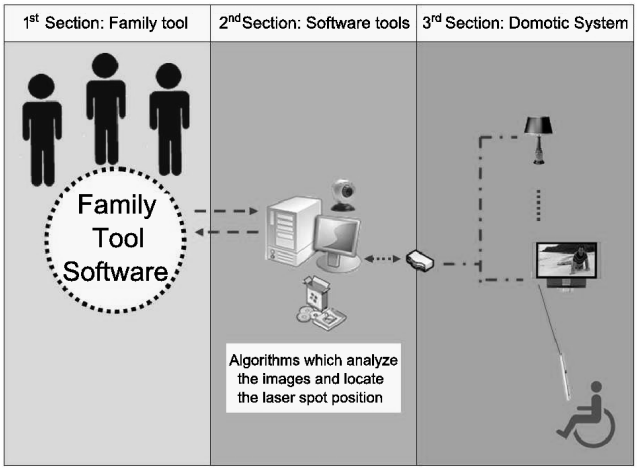

Fig. 1. Environment control system

- 1^{st} *Section*: The configuration tool allows to the users select the home devices that will be controlled by the system. In this tool, they will able to mark the active zone for each home device using the images sent by the video camera.
- 2^{nd} *Section*: In this section the system uses different techniques in order to analyze the image sent by the video camera and to locate the position of the laser spot.
- 3^{rd} *Section*: KNX/EIB architecture [18] let the system to control the different home devices. Once the laser spot is found and it is in an active zone, the system sends to the domotic system the necessary orders to turn on/off the device selected.

This contribution is focused on the 2^{nd} *Section*, in order to improve the laser spot detection ability, which becomes one of the most important tasks in these kinds of systems. In Figure 2, an example of images with and without laser spot is presented.

Fig. 2. Image with laser spot (top), Image without laser spot (bottom)

The algorithms previously used to detect the laser spot on an image have been the following:

1) Dynamic Umbralization (DU)
2) Template Matching (TM)
3) Template Matching + Dynamic Umbralization (TM + DU)
4) Template Matching + FRBS design from Expert's Experience and automatic evolutionary tuning (TM + FRBS).

The home environment control system based on laser pointer presented in [12] used three different classic algorithms, DU, TM and TM + DU. In [13] an initial hybrid model is proposed combining TM with a FRBS obtained from expert's experience, which is after improved by applying a genetic tuning of the FRBS membership functions in [16]. In the following subsections, we will briefly introduce the methods that we have presented in this previous work to detect the laser spot on an image (more information on the 1^{st} and the 3^{rd} *Sections*, and a deeper description of these algorithms can be found in [12], [13], [16]).

A. Dynamic Umbralization

Dynamic Umbralization was the first algorithm used in this system. This algorithm calculates a threshold value, by

means of which, the pixels under this value are eliminated. The threshold value is calculated by means of the following expression:

$$V_{umb} = ((Sv_I_{min}) - (Sv_I_{max})) * \frac{X}{20} + (Sv_I_{min}), \quad (1)$$

where Sv_I_{min} and Sv_I_{max} are the minimum and maximum sub intervals balance, and X is the sum of the balance parameters obtained from the pixel numerical information (see [12], [13] for more information on how this values are calculated). As a consequence of this umbralization, the resultant image has the candidate pixels of the laser spot searched.

B. Template Matching

In order to improve the system performance, we have also used a second technique, namely Template Matching. The algorithm that uses TM is based on convolution techniques. By means of this algorithm, an image named template is searched on the image sent by the video camera. A template is a laser spot image previously stored. Figure 3 shows a template image example.

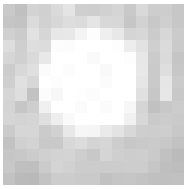

Fig. 3. Laser spot template

Each image sent by the video camera may have a section similar to the used template. The TM algorithm searches for such template on the obtained environment image. This algorithm obtains the probability of coincidence between the analyzed image sections and the template image. This probability ranges between -1 and 1, by using the following expression:

$$\Phi(I_r, I_l) = \frac{\sum_{i,j\in[-w,w]} AB}{\sqrt{\sum_{i,j\in[-w,w]} A^2 \sum_{i,j\in[-w,w]} B^2}},$$

$$A = I_r(x+i, y+j) - \overline{I_r(x,y)},$$

$$B = I_l(x'+i, y'+j) - \overline{I_l(x',y')}, \quad (2)$$

where A contains the set of pixels which are in the principal image section, and B contains the set of laser template pixels (see [12], [13] for more information on how this formula can be applied). The TM algorithm proposes the image section with the highest correlation since, the laser spot should be found in the position of the obtained image section with the highest correlation.

C. Template Matching + Dynamic Umbralization

The algorithm described above has the same problem that the DU algorithm, the false offs. Trying to improve the algorithms and to eliminate the false offs, we proposed a new approach in [12], [13] by joining both techniques in a new algorithm. The first step is to calculate the image section with highest correlation, by using the TM algorithm. The second step is to check if the section calculated is a laser spot image by using the DU algorithm. In this step, if the image calculated has pixels with high energy, these pixels will not be eliminated, and it is possible to say that the image calculated is a laser spot image.

D. Template Matching + Fuzzy Rule Based Systems

In order to improve the results presented in [12], an hybrid approach between TM and FRBSs has been proposed for determining whether an image section provided by TM is detected as a laser spot or not. This way working allows to have a system based on labels [14], [15], with a near human language, making easy the derivation of rules [19] that can provide a positive or negative response for each analyzed image section.

A set of interesting system variables where proposed in [13] by analyzing some example images, with and without laser spots. These variables determined by the expert (five inputs and one output) represent the following information:

- X1: Long standard deviation.
- X2: Cross standard deviation.
- X3: Similarity to perfect circle value.
- X4: Laser spot number of pixels.
- X5: Percentile 80 value.
- Y: Laser spot probability (laser spot is detected if this value is over a threshold).

Once the input variables and their domains were defined, the expert defined useful rules and manually adjusted the membership function definitions for the detection task. The process to determine these variables as well as the finally proposed FRBS from the expert's experience can be found in [13].

The complete recognition task is therefore comprised of two main parts (algorithms). The first algorithm, TM, analyzes the image sent by the video camera together with a template image. This obtains the image section with the highest correlation. The obtained image section is then analyzed by using the FRBS proposed. This new combination of algorithms [13], namely $TM + FRBS_{expert}$, directly presented a better performance than the algorithms described in sections II-A and II-B as we can see in [13].

On the other hand, though that the new approach, $TM + FRBS_{expert}$, presented better results than the previous techniques, it can be further refined by performing a genetic tuning of the MFs [20], i.e., by means of a Genetic Algorithm (GA) [21], [22], the MFs of the FRBS are adjusted. This kind of hybridization between fuzzy logic [14], [15] and GAs is well-known as Genetic Fuzzy Systems (GFSs) [23]–[25].

In this way a new approach, namely $TM + FRBS_{tuned-GA}$, was proposed in [16] to perform an automatic evolutionary tuning of the initial FRBS based on the existence of 105 image samples that were used for training the model. To perform the genetic tuning it was considered a GA that presents a real coding scheme and uses the stochastic universal sampling as selection procedure together with an elitist scheme. The operators employed for performing the individual recombination and mutation were uniform mutation and the max-min-arithmetical crossover.

Once the GA optimizes the MF parameters of the initial FRBS ($FRBS_{expert}$), the new FRBS obtained ($FRBS_{tuned-GA}$) presented better results than the previous techniques used to detect the laser spot, as we can see in [16].

III. Template Matching and Evolutionary Learning of a FRBS for the Laser Spot Detection

In this section, we present a new approach considering the problem to detect the laser spot on an image. This is based on the use of a more advanced technique for a complete learning of the FRBS used to detect the laser spot in the image sections obtained by TM. Therefore, in this work we propose the TM technique in combination with the learning of the complete KB. Learning together the rules and the parameters of the MFs let us consider the interaction between both parts and therefore obtaining more accurate models. Nevertheless, this proposal represents a more complicated search space for the use of a initial RB obtained by an expert and further tuning technique [16].

In order to effectively apply this new approach to our concrete problem, we consider eight input variables: the variables used in the FRBSs presented in subsection II-D, plus 3 input variables which represent the laser spot color (Red, Green and Blue) and one output variable. Using this new approach we obtain a new FRBS named $FRBS_{learning-GA}$ which in combination with the TM technique gives way to a new hybrid approach, namely $TM + FRBS_{learning-GA}$.

In this way, this section presents a learning algorithm of the KB which can efficiently manage the search space. To do that, the learning scheme is presented in the next. Then, a model of representation of the BD is introduced, which decreases the search space with respect to the classical MFs triangular representations. Finally, a specific evolutionary algorithm is proposed, which is applied for machine learning of FRBSs from data.

A. FRBS learning scheme

In addition to the classical approaches, some new directions to apply genetic (evolutionary) techniques to FRBSs can be found in [25]: selection of fuzzy rules, feature selection, learning of KBs via genetic derivation of the DB, interpretability maintenance via multi-objective genetic processes, learning approaches considering different model structures, etc. These kinds of techniques try to find a better trade off between the efficiency of the learning/post-processing process and the dimensionality of the search space.

This is the case of the *learning of KBs via genetic derivation of DBs*, a recent approach involving a simpler search space than the classical learning of KBs. It consists of obtaining the DB and the RB separately, based on the embedded learning of the DB [26]–[29] (see Figure 4). This way to work allows us to learn the most adequate context for each fuzzy partition, which is necessary in different application contexts and different fuzzy rule extraction models.

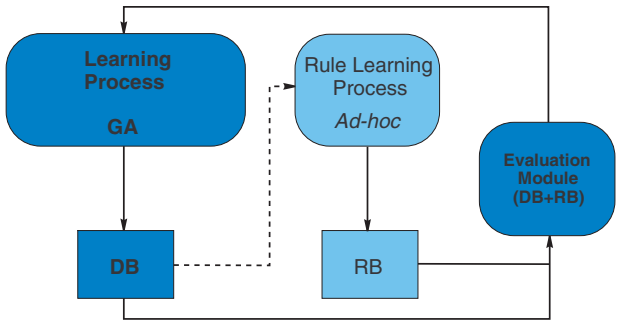

Fig. 4. Learning scheme of the KB

The learning scheme considered in this work belongs to this last group and is comprised of two main components:

- A process to learn the DB, which allows to define:
  - The number of labels for each linguistic variable.
  - The lateral displacements of such labels.

  Triangular membership functions are considered for their simplicity.
- A quick *Ad-hoc data-driven method* to derive the RB [30] considering the DB previously obtained. This method is run from each DB definition generated by a Genetic Algorithm (GA), thus, allowing the proposed hybrid learning process to finally obtain the whole definition of the KB (DB and RB) by means of the cooperative action of both methods.

B. The Linguistic 2-Tuples Representation

In [31], a new model of tuning of FRBSs was proposed considering the linguistic 2-tuples representation scheme introduced in [17], which allows the lateral displacement of the support of a label and maintains the interpretability associated to the obtained linguistic FRBSs. This proposal also introduces a new model for rule representation based on the symbolic translation concept that is a number within the interval [-0.5, 0.5) expressing the domain of a label when it is moving between its two lateral labels. Formally, we have the pair,

$$(s_i, \alpha_i), \;\; s_i \in S, \;\; \alpha_i \in [0.5, -0.5).$$

Figure 5 shows the lateral displacement of the label M. The new label "y_2" is located between B and M, being enough smaller than M but closer to M.

C. Evolutionary Algorithm

In this work, we will consider the use of CHC [32] to design the proposed learning algorithm. CHC is a GA that presents

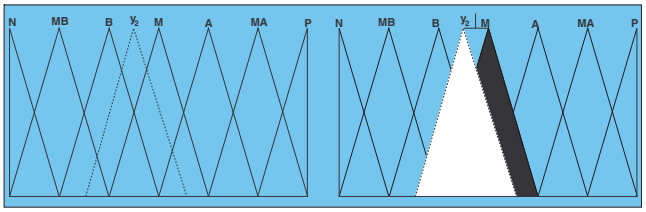

Fig. 5. Lateral Displacement of the Linguistic Label M

a good trade-off between exploration and exploitation, being a good choice in problems with complex search spaces. This genetic model makes use of a mechanism of "Selection of Populations". N parents and their corresponding offspring are combined to select the best N individual to take part of the next population.

Considering this approach, the learning process of the DB have to define both, the granularity of the linguistic partitions and the lateral displacements of the involved labels. For this reason, a double coding scheme is considered (granularity + displacements).

In the following, the components needed to design our FRBS are explained. They are: DB codification, chromosome evaluation, initial gene pool, crossover operator and restarting approach.

1) DB Codification: A double coding scheme ($C = C_1 + C_2$) to represent both parts, *granularity* and *translation parameters*, is considered:

- Number of labels (C_1): This part is a vector of integer numbers with size N (being N the number of system variables). The possible numbers of labels considered are the set $\{3, \ldots, 9\}$:

$$C_1 = (L^1, \ldots, L^N) \ .$$

- Lateral displacements (C_2): This part is a vector of real numbers with size $N*9$ (N variables with a maximum of 9 linguistic labels per variable) in which the displacements of the different labels are coded for each variable. Of course, if a chromosome does not have the maximum number of labels in one of the variables, the space reserved for the values of these labels is ignored in the evaluation process. In this way, the C_2 part has the following structure (where each gene is associated to the tuning value of the corresponding label):

$$C_2 = (\alpha_1^1, \ldots, \alpha_{L^1}^1, \ldots, \alpha_1^N, \ldots, \alpha_{L^N}^N)$$

2) Chromosome Evaluation: To evaluate a determined chromosome we will apply the well-known rule generation method of Wang and Mendel [30] on the DB coded by such chromosome. Once the whole KB is obtained, the following function is minimized:

$$F_C = w_1 \cdot FF + w_2 \cdot NR,$$

where:

- NR is the number of rules of the obtained KB (in order to penalize an excessive number of rules).
- $w_1 = 1$.
- w_2 is computed from the Mean Square Error (MSE) and the number of rules of the KB generated from a DB considering the maximum number of labels (9 labels) and without considering the displacement parameters,

$$w_2 = \alpha \cdot \frac{MSE_{max-lab}}{NR_{max-lab}} \ ,$$

  with α being a weighting percentage given by the system expert that determines the trade-off between accuracy and complexity. Values higher than 1.0 search for linguistic models with few rules, and values lower than 1.0 search for linguistic models with high accuracy. A good neutral choice is for example 1.0 (good accuracy and not too many rules), but in this particular problem we use $\alpha = 1.15$.
- FF is the Fitness Function used to analyze the number of False Negative (FN) and False Positive (FP) obtained with the KB generated,

$$FF = \frac{|FN|}{|D|} + 10 \cdot \frac{|FP|}{|D|}$$

  where $|FN|$ is the number of False Negatives obtained, $|FP|$ is the number of False Positives obtained and $|D|$ is the dataset size. Notice that the number of FPs is penalized in order to avoid the wrong orders to be sent to the domotic system.
  For each input example, the FRBS must generate an output value into interval [0, 1]. If this value is higher than 0.5, the example will be classificated as a laser spot image, in otherwise, it will be classificated as image without a laser spot. Thus, an input example can be considered as:
  - FN: If the example is classified as an image without laser spot and it is a laser spot image.
  - FP: If the example is classified as a laser spot image and it is an image without laser spot.
  - Hit: If the example is correctly classified.

For the fuzzy inference, we have selected the *minimum t-norm* playing the role of the implication and conjunctive operators, and the *center of gravity weighted by the matching* strategy acting as defuzzification operator.

3) Initial Gene Pool: The initial population will be comprised of two different parts (with the same number of chromosomes):

- In the first part, each chromosome has the same number of labels for all the problem variables and considers strong fuzzy partitions with translation parameters initialized to zero.
- In the second part, the only change is that each variable could have a different number of labels.

Since CHC has no mutation operator, the translation parameters remain unchanged and the most promising number of labels is obtained for each linguistic variable. The algorithm operates in this way until the first restarting is reached.

4) Crossover Operator: Two different crossover operators are considered depending on the two parent's scope to obtain two offspring:

- *When the parents encode different granularity levels in any variable*, a crossover point is randomly generated in C_1 and the classical crossover operator is applied on this point in both parts, C_1 and C_2 (exploration).
- *When both parents have the same granularity level per variable*, an operator based on the concept of environments (the offspring are generated around one parent) is applied only on the C_2 part (exploitation). These kinds of operators present a good cooperation when they are introduced within evolutionary models forcing the convergence by pressure on the offspring (as the case of CHC). Particularly, we consider the Parent Centric BLX (PCBLX) operator [33], which is based on the BLX-α.
  The PCBLX is described as follows. Let us assume that $X = (x_1 \cdots x_n)$ and $Y = (y_1 \cdots y_n)$, $(x_i, y_i \in [a_i, b_i] \subset \Re, i = 1 \cdots n)$, are two real-coded chromosomes that are going to be crossed. PCBLX generates the offspring $Z = (z_1 \cdots z_n)$, where z_i is a randomly (uniformly) chosen number from the interval $[l_i, u_i]$, with $l_i = max\{a_i, x_i - I\}$, $u_i = min\{b_i, x_i + I\}$, and $I = \mid x_i - y_i \mid$. The parents X and Y will be named differently: X will be called *female parent*, and Y will be called *male parent*. In this way, by taking X as female parent (Y as male), and then by taking Y as female parent (X as male) our algorithm generates two offspring.
  On the other hand, CHC makes use of an incest prevention mechanism, i.e., two parents are only crossed if their hamming distance divided by 2 is over a predetermined threshold, L. It will be only considered in order to apply the PCBLX operator. Since, we consider a real coding scheme (the C_2 part is going to be crossed), we have to transform each gene considering a Gray Code with a fixed number of bits per gene ($BITSGENE$) determined by the system expert. In this way, the threshold value is initialized as:

$$L = (\#GenesC_2 * BITSGENE)/4.0.$$

Following the original CHC scheme, L is decremented by one when no cross is performed in one generation. In order to avoid very slow convergence, in our case, L will be also decremented by one when no improvement is achieved respect to best chromosome of the previous generation.

5) Restarting approach: To get away from local optima, a restarting mechanism is considered [32] when the threshold value L is lower than cero. In this case, all the chromosomes set up their C_1 parts to that of the best global solution, being the parameters of their C_2 parts generated at random within the interval $[-0.5, 0.5)$. Moreover, if the best global solution had any change from the last restarting point, this is included in the population (the exploitation continues while there is convergence). This operation mode was initially proposed by the CHC authors as a possibility to improve the algorithm performance when it is applied to solve some kinds of problems [32].

IV. Experimental Results

To evaluate the usefulness of the approaches proposed in the previous sections, we have considered the previous environment control system presented in [12]. In order to have a performance measure and to perform the automatic tuning [16] and learning, we extend the 105 example images used in [16] with a big set of data containing 990 images. This set of images has been randomly divided in 5 subsets with the 20 % of the images for each. Applying 5-fold cross-validation method we obtained 5 different sets of images with 792 images for training and 198 images for test.

Table I presents a brief description of the studied methods.

The parameters for the methods $TM + FRBS_{expert}$ and $TM + FRBS_{tuned-GA}$ were selected according to the recommendation of the authors in [13] and [16]. Notice that in the $TM + FRBS_{tuned-GA}$ algorithm, the number of evaluation used by the GA in the tuning process was 50000. The values of the input parameters considered by our proposal are shown in the next:

- Evaluations = 50000
- Population size = 50
- Bits per gene = 30.
- α factor = 1.15

Table II presents the results of $TM + UD$ algorithm using the new set of 990 images divided in 5 subsets and with similar configuration that the algorithm presented in [12].

Tables III and IV show the $TM + FRBS_{expert}$ and $TM + FRBS_{tuned-GA}$ results using the new set of 990 images, with similar input parameters which were presented in [13] and [16] respectively. We can see that classic techniques $TM + UD$ are better than $TM + FRBS_{expert}$ and $TM + FRBS_{tuned-GA}$ using a big set of images. This is due to that the classic technique works with heterogeneous data like brightness and luminosity, otherwise, the FRBS developed by the expert and tuned by GA works with data of the appearance of the image like similarity of circle, etc. This kind of data is useful when we work with learning algorithms, where they are used in corporate form. For this reason, we have combined the classic technique TM with the learning algorithm, obtaining the new hybrid algorithm named $TM + FRBS_{learning-GA}$, the results are the best (see Table V).

We can see that the percentage of success rate in images with laser spot is 70.50 % and in images without laser spot is 98.76 %, very close to 100 %, the optimal success rate.

V. Conclusion

In this paper a new hybrid technique combining Template Matching and an evolutionary learning of the FRBS to detect a laser spot in a home environment is presented. Thanks to the system developed in conjunction with a standard domotic system, we provide a more user-friendly and less expensive home device control environment.

TABLE I
TECHNIQUES USED IN THE EXPERIMENTS

Ref	Method	Year	Description
[12]	$TM + DU$	2008	Template Matching plus Dinamic Umbralization (described in Section II-C)
[13]	$TM + FRBS_{expert}$	2010	Template Matching plus FRBS design from Expert's Experience (described in Section II-D)
[16]	$TM + FRBS_{tuned-GA}$	2010	Template Matching plus FRBS design from Expert's Experience and tuned by GA (described in II-D)
Our proposal	$TM + FRBS_{learning-GA}$		Template Matching plus learning FRBS as explained in Section III.

TABLE II
RESULTS OF $TM + UD$

	Training		Test	
	Average	Standard Deviation	Average	Standard Deviation
General Success Rate	83.48 %	0.01206	83.54 %	0.04705
Success Rate with Laser Sopt	67.86 %	0.01575	68.13 %	0.05705
Success Rate without Laser Spot	98.32 %	0.00481	98.36 %	0.01647

TABLE III
RESULTS OF $TM + FRBS_{expert}$

	Training		Test	
	Average	Standard Deviation	Average	Standard Deviation
General Success Rate	78.59 %	0.01229	78.59 %	0.04917
Success Rate with Laser Sopt	66.21 %	0.01845	66.52 %	0.06770
Success Rate without Laser Spot	90.35 %	0.00821	90.30 %	0.03226

TABLE IV
RESULTS OF $TM + FRBS_{tuned-GA}$

	Training		Test	
	Average	Standard Deviation	Average	Standard Deviation
General Success Rate	75.80 %	1.81965	74.97 %	5.03560
Success Rate with Laser Sopt	51.44 %	3.59527	50.51 %	6.84627
Success Rate without Laser Spot	98.91 %	0.33398	98.35 %	1.34530

An experimental study on a big set of image samples (990 images in total) of the previous algorithms used to detect a laser spot on an image versus the new approach using the evolutionary learning of the FRBS is presented in this paper. We can see how the proposal method has better results than other approaches. However, the most important result is that the new approach has a 98.76 % of success rate in images without laser spot, very close to 100 %, where the false offs will be completely eliminated.

The new approach presented in this paper is particularly useful for remote acting on home devices, the user can reach any device in sight. Moreover, we think the results show the usefulness for any environment where devices are not easily reachable by the user, industrial operation, for instance.

Abstract— **Tens of thousands of classifiers have been proposed so far. There is no best classifier among them for all the existing data sets. The performance of each classifier often depends on the data sets used for comparison. Even for a single classifier, suitable parameters of the classifier also depend on the data sets. That is, there is a possibility that a suited classifier and its parameter specification can be chosen beforehand if the target data sets or their characteristics were known. In recent years, a number of data complexity measures have been proposed to characterize data sets. The aim of this study is to develop a meta-classifier for selecting an appropriate classifier and/or its appropriate parameter specification by means of data complexity measures. In this paper, we focus on the parameter specification of fuzzy classifiers using data complexity measures as a preliminary study. To construct a meta-classifier, we generate a large number of artificial data sets from Keel benchmark data sets. Then we generate meta-patterns which are composed of the values of data complexity measures as inputs and an appropriate fuzzy partition as an output. Using meta-patterns, a meta-classifier is designed by multiobjective genetic fuzzy rule selection. We evaluate the proposed method through leave one-group out cross-validation.**

Keywords-fuzzy classifier design; data complexity measures; meta-learning; pattern classification; knowledge acquisition

I. INTRODUCTION

A lot of comparative studies on pattern classification problems have shown that there is no single best classifier for all the existing data sets. In the practical use of classifiers, we do not know the best classifier for given data sets beforehand. We also do not know an appropriate parameter setting of the classifier used for the data sets. Thus, we usually select a classifier and specify its parameter values in a trial and error manner. This is a very time-consuming task. If we know a best-suited classifier and its appropriate parameter setting, we can reduce the redundant time.

In general, the performance of classifiers strongly depends on the data sets used in the experiments. For example, it would be enough to use a simple classifier for a simple data set. On the other hand, for a complicated data set, it must be necessary to use a complicated classifier which can finely approximate the complicated decision boundaries. It is, however, difficult for us to know whether the data set is simple or complicated. To characterize the data sets, a number of data complexity measures for classification problems have been proposed by Ho and Basu [1,2]. Some researchers analyzed the relationship between the search performance of classifiers and data complexity measures [3-5]. Other researchers utilized data complexity measures to reduce training patterns [6-8].

In this paper, we focus on parameter specification of fuzzy classifiers by means of data complexity measures. We use a Chi-RW classifier which is a Chi's fuzzy classifier [9] with rule weights [10, 11]. The Chi-RW classifier is very famous and useful as a baseline of fuzzy classifiers. The main parameter of the Chi-RW classifiers is the number of fuzzy membership functions (i.e., membership granularity). Thus, we specify the membership granularity by utilizing data complexity measures before constructing fuzzy classifiers in this paper.

In our former study [12], we proposed a meta-classifier that predicts an appropriate granularity by the values of data complexity measures for each data set. While two-dimensional two-class problems were used in [12], we use a large number of data sets derived from Keel data repository in this paper. We propose *Leave one-group out* cross-validation for examining the prediction performance of meta-classifiers. A meta-classifier is obtained by multiobjective genetic fuzzy rule selection with genetic lateral tuning [13-16].

This paper is organized as follows. In Section II, we explain the overall procedure of the proposed framework. From Section III to Section VI, we explain the details on data preparation, data complexity measures, meta-data generation, and multi-objective genetic fuzzy rule selection. Section VII presents computational experiments. Finally, we conclude this paper in Section VIII.

II. OVERALL PROCEDURE OF THE PROPOSED FRAMEWORK

In this section, we briefly explain the overall procedure of the proposed framework by dividing it into two phases: training phase and predicting phase. The basic part of the proposed framework is the same as [12].

A. Training Phase

The procedure of the training phase is as follows:

This study is partially supported by the Japanese Grant-in-Aid for Young Scientists (B) (22700239).

Step 1: A large number of artificial data sets are generated from the real world problems.

Step 2: The values of data complexity measures are calculated for each data set.

Step 3: The performance of a Chi-RW classifier with each candidate parameter setting is examined for each data set.

Step 4: Meta-patterns are generated from the values of data complexity measures and the results on candidate parameter settings.

Step 5: A meta-classifier is obtained by multiobjective genetic fuzzy rule selection using the meta-patterns.

Since existing data sets are limited and too few to cover the wide range of data complexity measures, we generate a large number of artificial data sets by eliminating some patterns from the original data sets, adding small noise into patterns, or generating new patterns nearby the original patterns in Step 1.

As a target classifier, we use a Chi-RW method [9-11] in this paper. It is very famous and well-used as a baseline. We focus on the granularity of fuzzy membership functions (i.e., the number of fuzzy membership functions). A single meta-pattern is corresponding to a single data set. The input vector of a meta-pattern is composed of the values of data complexity measures. The output class of the meta-pattern is the best-suited parameter setting in this paper.

A meta-data set with a large number of meta-patterns is used for designing a meta-classifier. In this paper, we employ multiobjective fuzzy rule selection with genetic lateral tuning [13-16].

B. *Predicting Phase*

The obtained meta-classifier in the training phase is used to predict an appropriate parameter setting of a classifier for unseen data sets. The procedure of the predicting phase is as follows:

Step 1: The values of data complexity measures for an unseen data set are calculated.

Step 2: The meta-classifier predicts class (i.e., an appropriate setting) according to the values of data complexity measures.

It should be noted that it would be possible to select a classifier among alternatives (e.g., RBFN, C4.5, SVM) instead of parameter settings for a Chi-RW classifier. It would be also possible to use other machine learning techniques for designing a meta-classifier.

The details are explained at the subsequent sections.

III. Data Preparation

While we generated two-dimensional artificial data sets in [12], we generate multiple-dimensional artificial data sets from Keel data repository in this paper. Since each artificial data set is derived from one of the real-world data sets, each data structure is not completely meaningless.

To generate artificial data sets, we propose three simple operations. Figure 1 demonstrates a simple example. Each attribute value is normalized within [0.0, 1.0].

1) Random reduction

Randomly remove a number of patterns as in Fig. 1 (b). A prespecified number of data sets are generated by changing the reduction rate.

2) Noise addition

Randomly add noise (e.g., uniform random value [-0.05, 0.05] per variable) to each pattern as in Fig. 1 (c). Each new pattern is replaced with the original patterns. A prespecified number of data sets are generated by changing a random seed.

3) Random generation

Randomly generate new patterns in the neighbor of each pattern as in Fig. 1 (d). A prespecified number of data sets are generated by changing the number of newly-generated patterns.

If the new attribute value is less than 0.0 or more than 1.0, its value is replaced with 0.0 or 1.0, respectively.

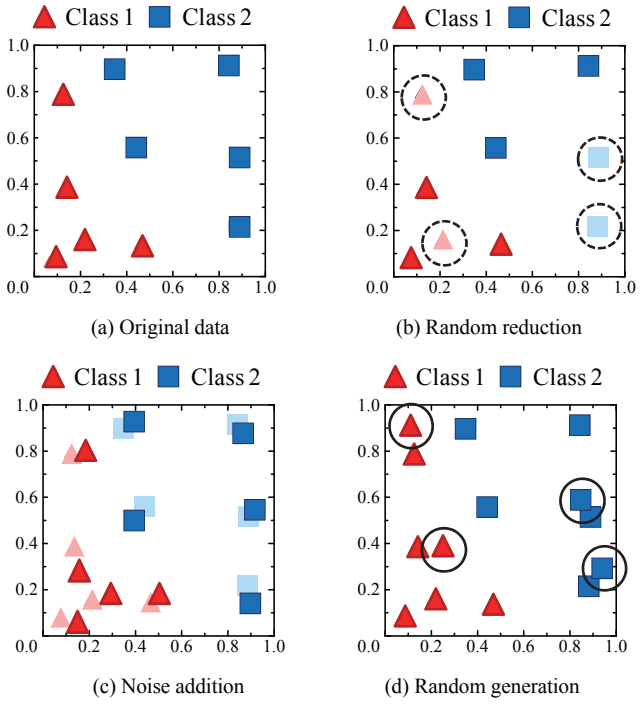

Figure 1. An example of artificial data set generation.

IV. Data Complexity Measures

To describe the characteristics of data sets, this paper uses data complexity measures. In the literature [3-8], some researchers showed the effectiveness of data complexity measures. In this section, we briefly describe representative data complexity measures. Most of them have been originally defined for two-class data sets. The original explanations on the data complexity measures can be found in the literature (Ho and Basu [1, 2] and Orriols-Puig [17]).

A. F1: Maximum Fisher's discriminant ratio

This measure is calculated by the distance and variance between classes. It analyzes the effectiveness of a single attribute. The value is calculated as follows:

$$\mathrm{F1} = \max_{h=1,2,\ldots,d} \frac{(\mu_{h1} - \mu_{h2})^2}{\sigma_{h1}^2 + \sigma_{h2}^2}, \quad (1)$$

where μ_{h1}, μ_{h2}, σ_{h1} and σ_{h2} are the means and the variances of two classes for the h-th attribute, respectively. The d is the number of attributes of the data set.

B. F2: Volume of overlap region

This measure describes how much two classes are overlapping each other, calculating the volume of the overlap region as hypercube of each dimension. This measure is strongly dependent on the number of attributes, because the value of an attribute's overlap region is multiplied as:

$$\mathrm{F2} = \prod_{h=1}^{d} \frac{\mathrm{minmax}_h - \mathrm{maxmin}_h}{\mathrm{maxmax}_h - \mathrm{minmin}_h}, \quad (2)$$

where

$$\mathrm{minmax}_h = \min\{\max(f_h, c_1), \max(f_h, c_2)\},$$
$$\mathrm{maxmin}_h = \max\{\min(f_h, c_1), \min(f_h, c_2)\},$$
$$\mathrm{maxmax}_h = \max\{\max(f_h, c_1), \max(f_h, c_2)\},$$
$$\mathrm{minmin}_h = \min\{\min(f_h, c_1), \min(f_h, c_2)\},$$

where $\max(f_h, c_i)$ and $\min(f_h, c_i)$ are the maximum and minimum values of the h-th attribute in the class c_i (i = 1, 2), respectively (see Fig. 2).

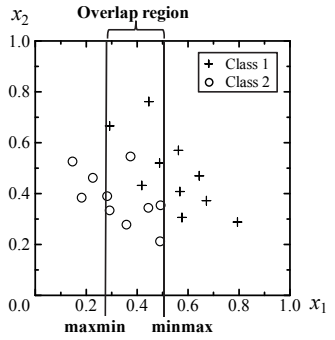

Figure 2. Overlap region of an attribute.

C. F3: Maximum (individual) feature efficiency

This measure describes the level of overlap like F2 measure. Different from F2, it counts the patterns which are falling outside of the overlap region for each attribute and considers the single attribute which has the maximum points. This value is calculated as follows:

$$\mathrm{F3} = \max_{h=1,2,\ldots,d} \frac{|P_h|}{N_e}, \quad (3)$$

$$P_h = \{\mathbf{x}_i \mid x_{ih} \le \mathrm{maxmin}_h \text{ or } x_{ih} \ge \mathrm{minmax}_h\}, \quad (4)$$

where N_e is the number of examples in the data set. x_{ih} is the h-th attribute value of the i-th pattern $\mathbf{x}_i$.

D. F4: Collective feature efficiency

The idea of this measure is derived from F3. In F3, only a single attribute is considered. However, F4 is calculated as follows. First, a single attribute is selected by (3). Then the overlap region on the attribute is calculated. The patterns out of the region are temporally removed. Next, another attribute is selected by (3). This process is repeated until all patterns are removed or all attributes are selected. This measure returns the fraction of all patterns by total removed patterns.

E. L1: The minimized sum of the error distance of a linear classifier.

This measure evaluates how much the training data are linearly separable. Therefore, its value is the sum of the difference between the exception of a linear classifier and the actual class value. Different from Ho and Basu [2], this paper uses a support vector machine (SVM) [18] trained with the sequential minimal optimization (SMO) algorithm [19] to construct the linear classifier. This measure can be used only for two-class problems. For a linearly separable problem, this measure becomes zero.

F. L2: Error rate of linear classifier

This measure is the error rate of the linear classifier designed for L1, measured with the training data set.

G. N1: Fraction of points on class boundary

This measure builds a class-blind minimum spanning tree (see Fig. 3) over the entire data set, and counts the number of points on an edge going across the different classes. This measure returns the fraction of these points over all points in the data set.

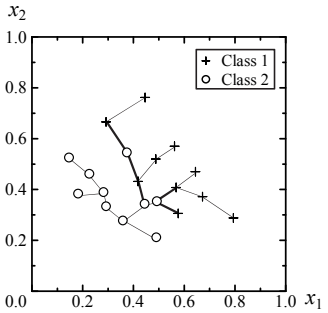

Figure 3. Minimum spanning tree. The bold lines are edges going across the different classes.

H. N2: The ratio of average intra/inter class nearest neighbor distance

This measure compares the spread with distance of within-class to that of the nearest neighbor of other classes. To compute this metric, we first compute the Euclidean distance to the nearest neighbor within the class and to the nearest

neighbor of other classes for all points ($\mathbf{x}_i$) in the data set. Then we compute the average of all the distance to intra class (*intraDist*($\mathbf{x}_i$)) and the average of all the distance to inter class (*interDist*($\mathbf{x}_i$)). This measure returns the ratio of these two averages. This measure is defined as follows:

$$\mathrm{N2} = \frac{\sum_{i=0}^{N_e} intraDist(\mathbf{x}_i)}{\sum_{i=0}^{N_e} interDist(\mathbf{x}_i)}. \quad (5)$$

I. N3: The leave-one-out error rate of 1-NN classifier

This metric simply returns the leave-one-out error rate by the 1-NN classifier.

J. L3: The nonlinearity of a linear classifier

This measure is characterized by a measure of non-linearity proposed by Hoekstra and Duin [20]. When a data set is given, a test set is created by linear interpolation with random coefficients between randomly selected pairs of points which are the same class. A linear classifier used for calculating L1 is also employed. After the classifier trained with the original data set, the error rate is measured by the created test set. This measure returns the error rate.

K. N4: The nonlinearity of 1-NN classifier

This measure creates a test set as proposed by L3, and evaluates the error rate of 1-NN. The value is the error rate.

L. T1: The fraction of maximum covering spheres

Simply speaking, this measure counts the number of balls needed to cover each class. At first, the ball is centered each instances and then grown as much as possible before touching the ball of other classes. The balls included any other ball are removed. This measure returns the fraction of all points by those balls.

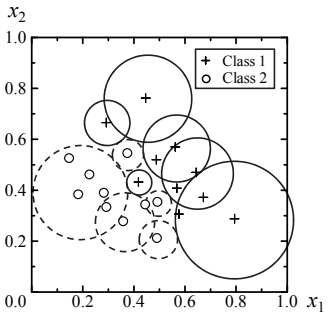

Figure 4. An example of the concept of T1 in the decision space.

Figure 4 shows the concept of T1, where the dashed circle means the balls of Class 2, the other circle means the balls of Class 1. In this example, the number of balls is 11.

M. T2: Average number of points per dimension

This measure represents the density of patterns.

$$\mathrm{T2} = \frac{N_e}{d}. \quad (6)$$

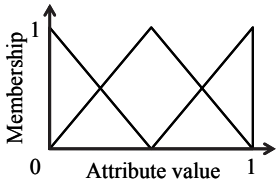
Since the calculation of all the data complexity measure is not computationally costly, we employ these values as inputs. We utilized DCoL (Data Complexity Library in C++) developed by Orriols-Puig et al [16] in order to calculate each data complexity measures.

V. A TARGET CLASSIFIER AND META-DATA GENERATION

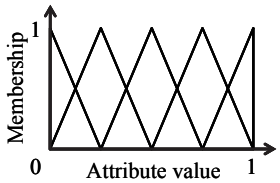
In this section, we explain a target classifier (i.e., Chi-RW) and how to generate a meta-data set.

A. Target Classifier

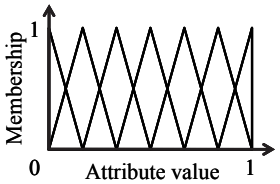
In this paper, as the benchmark classifier, we use a Chi-RW classifier [9-11]. The main parameter of Chi-RW classifiers is the number of fuzzy membership functions (i.e., membership granularity). Thus, we focus on the granularity of fuzzy sets used in the antecedent of Chi-RW classifiers. We examine three different granularity specifications in Fig. 5: (a) coarse granularity (three fuzzy sets), (b) moderate granularity (five fuzzy sets), and (c) fine granularity (seven fuzzy sets). We call the Chi-RW classifiers with those granularities Chi-RW-3, Chi-RW-5, and Chi-RW-7, respectively.



(a) Coarse granularity.



(b) Moderate granularity.



(c) Fine granularity.

Figure 5. Fuzzy membership funcitons used in Chi-RW classifiers.

As explained in introduction, the objective of this paper is to estimate an appropriate granularity of fuzzy membership functions in Chi-RW classifiers for each data set. It can be simply expected that a coarse granularity must be suited for data sets with noisy patterns. On the other hand, a fine granularity must be suited for data sets with complex decision boundaries. For some other data sets, a moderate granularity might be useful.

B. Meta-data generation

We generate a meta-data set composed of a large number of meta-patterns from many data sets. We assume that an appropriate granularity is strongly dependent on each data set. So that, we define each meta-pattern corresponding to one data

set. The input values of each meta-pattern are the values of data complexity measures of a data set explained in Section IV. Let $\mathbf{z}_i = (z_{i1}, z_{i2}, \ldots, z_{ij}, \ldots, z_{in})$, $i = 1, 2, \ldots, D$ be the attribute values (i.e., the values of the data complexity measures) of i-th data set, where D is the number of data sets. We use 13 data complexity measures: F1, F2, F3, F4, N1, N2, N3, N4, L1, L2, L3, T1 and T2 for two-class data sets in this paper (i.e., $n = 13$). For two or more-class data sets, we use nine data complexity measures: F2, F3, F4, N1, N2, N3, N4, T1 and T2. It should be noted that all input values (i.e., the values of data complexity measures) are normalized. This normalization is just to use the same membership functions for each attribute. Since we do not know the actual minimum and maximum values of each data complexity measure, we should examine the effect of this normalization. This is one of our future research issues.

The output class of each meta-pattern is an appropriate granularity of fuzzy membership functions in a Chi-RW classifier for the data set. Let $y_i \in$ {Chi-RW-3, Chi-RW-5, Chi-RW-7} be the consequent class of i-th meta-pattern. For each meta-pattern, three Chi-RW classifiers are performed by a ten-fold cross-validation (10CV). The classifier with the best test data accuracy is chosen as the consequent class of the meta-pattern. We performed 10CV by means of the KEEL data-mining software tool [21].

VI. Meta-Classifier Design by Multiobjective Genetic Fuzzy Rule Selection

From the generated meta-data set, we obtain a meta-classifier that predicts an appropriate fuzzy membership functions. We apply multiobjective genetic fuzzy rule selection (MoGFRS) to the design of a meta-classifier [13-16]. Genetic fuzzy rule selection [22] is one of the well-known methods in the field of genetic fuzzy systems [23,24]. It is a very simple two-stage method [22]. At the first stage, a number of fuzzy if-then rules are generated from numerical data as candidate rules. At the second stage, a subset of candidate rules is chosen by a genetic algorithm with binary strings in which "0" and "1" mean "not selected" and "selected" as a classifier, respectively. By maximizing the classification performance of the classifier and minimizing the complexity of the classifier (e.g., the number of fuzzy rules), an accurate and simple rule set is obtained as the final classifier. Its multiobjective formulation versions have been also studied in [13]. We use the modified version [15] of MoGFRS. There are two modifications: One is the use of a single granularity specification for each attribute [14]. The other is the use of genetic lateral tuning for adjusting fuzzy membership functions [16].

The procedure of our rule selection method is as follows:

Step 1: Rule extraction with multiple granularities.

Step 2: Specification of a single granularity for each attribute based on the extracted rules.

Step 3: Rule extraction with selected single granularities.

Step 4: Multiobjective genetic fuzzy rule selection.

In Step 1, a prespecified number of fuzzy rules of the following type are extracted from the meta-patterns.

$$R_j: \text{If } z_1 \text{ is } A_{j1} \text{ and } \ldots \text{ and } z_n \text{ is } A_{jn} \text{ then Class } y_j \text{ with } CF_j, \quad (7)$$

where R_j is the label of the j-th fuzzy rule, $\mathbf{z} = (z_1, \ldots, z_n)$ is an n-dimensional meta-pattern vector, A_{ji} is an antecedent fuzzy set such as *"Simple"* and *"Complicated"*, y_j is a consequent class, and CF_j is a rule weight. We use 14 fuzzy membership functions shown in Fig. 6 and a *don't care* condition as the antecedent fuzzy set. To obtain interpretable knowledge, we restricted the number of conditions to three or less fuzzy sets.

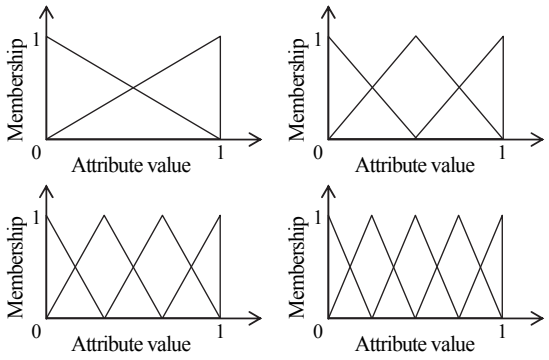


Figure 6. Membership functions for a meta-classifier design.

After extracting the rules, the frequently-used promising granularity is selected for each attribute in Step 2. In Step 3, a prespecified number of fuzzy rules are extracted by using the selected single granularity for each attribute. In Step 4, the combination of extracted rules and the positions of fuzzy membership functions are optimized by NSGA-II of Deb et al. [25].

We use a double coding scheme [15] in our multiobjective genetic fuzzy rule selection with genetic lateral tuning (Fig. 7). Each string includes binary bits and real numbers. Binary bits represent whether each extracted rule is selected for a meta-classifier, or not. Real numbers represent the position of each fuzzy membership function as shown in Fig. 8. The movable range is limited to maintain the interpretability of the fuzzy membership functions.

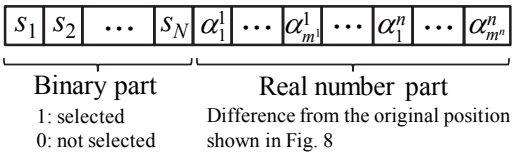

Figure 7. String representation by the double coding scheme. m^n is the total number of linguistic variables (fuzzy membership functions) for n-th input.

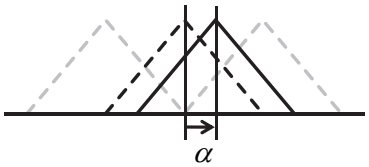

Figure 8. Genetic lateral tuning of fuzzy membership functions.

Each meta-classifier S is evaluated by the following three objective functions.

$f_1(S)$: the number of correctly classified training meta-patterns,

$f_2(S)$: the number of selected fuzzy rules,

$f_3(S)$: the total number of antecedent conditions.

That is, our multiobjective genetic fuzzy rule selection problem is formulated as:

$$\text{Maximize } f_1(S) \text{ and minimize } f_2(S) \text{ and } f_3(S). \quad (8)$$

Uniform crossover and bit-flip mutation are used as genetic operations for the rule selection part.

BLX-α crossover [26] and uniform mutation are used as genetic operations for tuning part.

By our multiobjective genetic fuzzy rule selection, we obtain a number of non-dominated decision systems with respect to the three objective functions. We select the most accurate classifier with respect to the first objective $f_1(S)$ for the training meta-data set, as the final meta-classifier.

VII. Computational Experiments

We examined two cases: One case is the application of the proposed framework to two-class problems. The other case is the application to multiple class problems with two or more classes. We explain the experimental setting and show the experimental results in this section.

A. Experimental Setting

We generated 100 artificial data sets from each data set by each simple operation explained in Section III. Thus, 300 new artificial data sets were generated in total. However, if more than one Chi-RW classifiers with different granularity have the same classification performance, we eliminate such data sets from this experiment.

The parameter settings of data set generation are as follows:

Reduction rate (random reduction): 5%, 10%, ..., 50%,

Generation rate (random generation): 10%, 20%, ..., 100%.

The parameter settings of MoGFRS are as follows:

The number of candidate rules per class: 300,

The number of strings: 200,

The number of generations: 5000,

Crossover probability: 0.9,

Mutation probability: 0.1 (1 to 0), 1/N (0 to 1),

(N is the number of total candidate rules).

Different mutation probabilities are used to select a small number of rules from the candidate ones.

To examine the generalization ability of the obtained meta-classifier, we propose *Leave one-group out* cross-validation shown in Fig. 9. Unlike 10-fold cross-validation (10CV), data sets are not randomly subdivided. All the data sets derived from an original data set are regarded as a group. When some group is used as test data sets, the other groups are used as training data sets. This is because each data set in the same group has somewhat similar data structure to each other. We avoided this affect in our experiments in order to assume the practical use of our proposed framework. As one of future issues, we have to examine whether the generated artificial data sets can cover the input space for unseen data sets or not.

We used the following experimental procedures.

Step 1: Divide artificial data sets into training data sets (T_r) and test data sets (T_s) by leave one-group out cross-validation.

Step 2: Calculate the values of data complexity measures of each artificial data set of T_r.

Step 3: Classify each artificial data set of T_r using each one of three granularities by 10CV.

Step 4: Generate a meta-data set from Step 2 and Step 3.

Step 5: Obtain a meta-classifier by MoGFRS.

Step 6: Calculate the values of data complexity measures of each artificial data set of T_s.

Step 7: Predict an appropriate granularity for each data set.

Step 8: Classify each data set of T_s using the granularity predicted in Step 7.

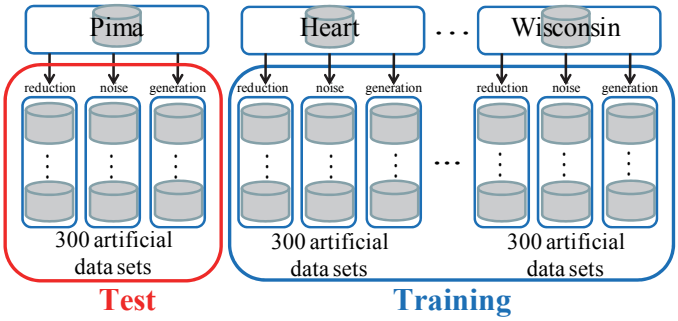

Figure 9. Leave one-group out validation.

B. Experimental Results for Two-class Problems

As two-class problems, we used 13 data sets listed in Table I. They are available from Keel data repository (http://keel.es). By simple operations, we generated 3,900 data sets in total.

The classification rates for test patterns in 10CV are shown in Table II. Chi-RW-3, Chi-RW-5, and Chi-RW-7 represent the results obtained by Chi-RW classifiers with coarse, moderate, and fine granularity, respectively. In those cases, the fixed granularity of fuzzy membership functions was used for all the data sets. "Meta-classifier" represents the result obtained by Chi-RW classifiers in which a granularity was selected by the meta-classifier for each data set. "Best" represents the result obtained by Chi-RW classifiers in which the best granularity was always used for each data set. This is an ideal case and just for a reference. From Table II, we can see that better test data

accuracy was obtained by our proposed method than the classifiers with fixed granularity. Table II also indicates that the result by our proposed method was close to the ideal case.

TABLE I. USED DATA SETS WITH TWO CLASSES

Data sets	Patterns	Attributes	Classes
Appendicitis	106	7	2
Australian	690	14	2
Banana	5300	2	2
Bupa	345	6	2
Haberman	306	3	2
Heart	270	13	2
Mammographic	830	5	2
Monk-2	432	6	2
Pima	768	8	2
Sonar	208	60	2
Titanic	2201	3	2
Wdbc	569	30	2
Wisconsin	683	9	2

TABLE II. CLASSIFICATION RATE OF TWO-CLASS PROBLEMS

	Chi-RW-3	Chi-RW-5	Chi-RW-7	Meta-Classifier	Best
Classification Rate (%)	75.11	65.89	59.77	**77.18**	77.84

The classification rate for test group data sets in *Leave one-group out* cross-validation was 77.00%.

We also analyzed if-then rules of the obtained meta-classifier. Since there were large differences among the meta-classifiers by leave one-group out, we generated a meta-classifier using all the artificial data sets (i.e., there is no test group). Figure 10 shows the best classifier with respect to the first objective $f_1(S)$. It was composed of four fuzzy rules. The black triangles mean the selected fuzzy membership functions. The left end of the x-axis means "simple", while the right end of the x-axis means "complicated".

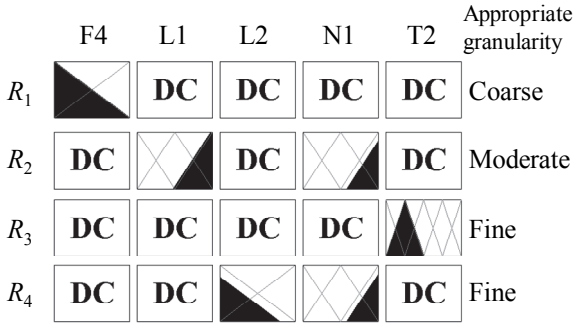

Figure 10. The obtained meta-classifier for two-class problems by MoGFRS.

Figure 10 can be interpreted as follows:

R_1: If the data set is **simple** w.r.t. **F4** then **coarse** fuzzy set is the best.

R_2: If the data set is **complicated** w.r.t. **L1** and **N1** then **moderate** fuzzy set is the best.

R_3: If the data set is **simple** w.r.t. **T2** then **fine** fuzzy set is the best.

R_4: If the data set is **simple** w.r.t **L2** and it is **complicated** w.r.t. **N1** then **fine** fuzzy set is the best.

These rules are counterintuitive except for R_1.

C. Experimental Results for mupliple class Problems

As multiple class problems with two or more classes, we used 24 data sets listed in Table III. They are also available from Keel data repository (http://keel.es). By simple operations, we generated 7,200 data sets in total.

Table IV shows the classification rates for test patterns in 10CV. From Table IV, we can see that better test data accuracy was obtained by our proposed method than the classifiers with fixed granularity. But the difference between our proposed method and Chi-RW-3 seems to be very small.

TABLE III. USED DATA SETS WITH TWO AND MORE CLASSES

Data sets	Patterns	Attributes	Classes
Appendicitis	106	7	2
Australian	690	14	2
Bands	365	19	2
Bupa	345	6	2
Cleveland	297	13	5
Dermatology	358	34	6
Glass	214	9	6

Pima	768	8	2
Saheart	462	9	2
Sonar	208	60	2
Tae	151	5	3
Vehicle	846	18	4
Wdbc	569	30	2
Wine	178	13	3
Wisconsin	683	9	2

TABLE IV. CLASSIFICATION RATE OF MULTI-CLASS PROBLEMS

	Chi-RW-3	Chi-RW-5	Chi-RW-7	Meta-Classifier	Best
Classification Rate (%)	75.63	64.25	55.47	**75.72**	77.02

It should be noted that the ratio of data sets for which Chi-RW-3 was the best among three Chi-RW classifiers was 70.37%. Since the classification rate for test group data sets in *Leave one-group out* cross-validation was 70.83%, we can say

that the meta-classifier successfully selected different granularity to some extent.

Figure 11 shows the best classifier with respect to the first objective $f_1(S)$. No rule with moderate class was included in the meta-classifier. N4 measure seems to be a key data complexity measure for this case.

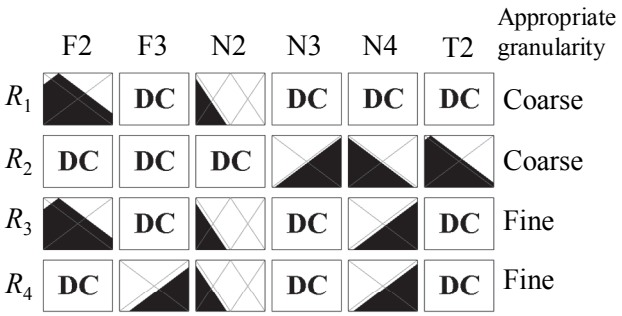

Figure 11. The obtained meta-classifier for multi-class problems by MoGFRS.

VIII. CONCLUSIONS

We proposed a framework for specifying an appropriate parameter setting in the design of Chi-RW classifiers for unseen data sets. The experimental results showed that our proposed framework can correctly predict an appropriate granularity by data complexity measures. The results by our proposed method were better than those by using the same (fixed) granularity for all data sets.

As a future research topic, we will apply this framework to classifier selection in which an appropriate classifier is selected from popular machine learning techniques (e.g., RBFN, SVM, C4.5) by data complexity measures for each data set. It would be necessary to reconsider the artificial data generation in order to generate data sets with various values of data complexity measures. A recent proposal [27] could be an alternative method.

Assessing The Effects Of Zero Abundance Data On Habitat Preference Modelling Using A Genetic Takagi-Sugeno Fuzzy Model

Shinji Fukuda
Institute of Tropical Agriculture
Kyushu University
Fukuoka, Japan
shinji-fkd@agr.kyushu-u.ac.jp

***Abstract*—In this paper, the effects of zero abundance data on fish habitat modelling using a genetic Takagi-Sugeno fuzzy system were assessed with specific focus on habitat preference curves (HPCs) and model performance. Three independent data sets were prepared from a series of fish habitat surveys conducted in an agricultural canal in Japan. To quantify the effects of zero abundance data, two kinds of data (full abundance data and presence-only abundance data) were used, from which a fuzzy habitat preference model (FHPM) were developed. As a result, the HPCs obtained using presence-only abundance data resulted in similar HPCs across the different data sets used, while those obtained using full abundance data differed by the data sets. Because the model performance with regard to generalization ability was higher, the present study concluded that the use of presence-only abundance data can better capture the habitat preference of the target species.**

Keywords-genetic fuzzy systems; species distribution; habitat model; model error; uncertainty

I. INTRODUCTION

Genetic fuzzy systems (GFSs) have been widely applied to various research fields because of their ability to solve different types of problems [1], [2]. The GFSs have been applied to many disciplines using such approach as linguistic fuzzy models [3] and precise fuzzy models [4], [5] (for a review, see [6]). In ecological modelling, GFSs have also been used for tuning the membership functions of Mamdani–Assilian models [7] and the consequent part of Takagi–Sugeno models [8]–[16]. They are data-driven models, which have been reported to outperform knowledge-based models in the case of habitat modelling [17]. These application studies support the strengths of GFSs, i.e., the flexibility of the model structures and their ability to tune knowledge-based systems according to the new data sets for a given problem. Because the applicability of GFSs depends on the target systems and available data, it is necessary to accumulate both theoretical and application studies to better understand the ability and limitations of GFSs and the related modelling approaches.

In practical implementation of species distribution models (SDMs), presence-only data are often used because of the availability compared to presence-absence or abundance data [18]–[21]. On the one hand, presence data indicate clear evidence that target fish were observed at a surveyed point. On the other hand, zero abundance data (also referred to as absence data in presence-absence analysis) contain essential uncertainty. For instance, there could be a case where target species were absent due to the presence of enemy species or simply because the habitat was not yet occupied by the species. This uncertainty has been used as an explanation for the errors in SDM-related studies [17], [22], [23]. Despite the previous researches [24], [25] on the effects of absence data or prevalence of the data on the predictive performance of the models used, no study evaluated the effects of zero abundance data on habitat preference evaluation. Therefore, it is important to understand the behaviour of a target model in response to different qualities of data, from which existing models can be improved and also new models can be further developed.

The aim of this study is to assess the effects of zero abundance data on model performance and habitat preference evaluation using a genetic algorithm (GA) [26]-optimized fuzzy habitat preference model (FHPM). A series of fish habitat surveys focusing on Japanese medaka (*Oryzias latipes*) were conducted, from which three independent data sets were derived for the analyses. The effects of zero abundance data were assessed on the basis of habitat preference curves (HPCs) and predictive accuracy of spatial distribution of the fish.

II. METHODS

A. Study site and target fish

A series of field surveys was carried out in an agricultural canal located in Kurume City, Fukuoka, Japan (33˚20’ N, 130˚42’ E). The spring-fed canal runs through paddy fields and is used for both irrigation and drainage purposes. The Japanese medaka is one of the most common fish in paddy environments in Japan. This fish is considered to be one of the symbols for the conservation and restoration of rural environments, because the fish is vulnerable to changes in physical habitat conditions such as current velocity. This is partly ascribed to the body length of the Japanese medaka (2–4 cm in length for an adult).

B. Fish Habitat Surveys

The field surveys were conducted on 14 October, 5 and 9 November 2004. The surveys were conducted during a non-

This work was supported in part by the Grant-in-aid for Young Scientists B (21780225) of the Ministry of Education, Culture, Sports, Science and Technology (MEXT), Japan.

irrigation period, and thus the discharge in both reaches remained stable. The habitat use of the Japanese medaka and four physical habitat characteristics of water depth (cm, henceforth referred as depth), current velocity (cm s^{-1}, velocity), lateral cover ratio (%, cover) and percent vegetation coverage (%, vegetation) in the study reach were surveyed on sunny days. After mapping the reach, the habitat use of the fish was observed, and then the physical habitat characteristics within the reach were surveyed.

The habitat use of Japanese medaka was observed visually from the bank; the observer moved slowly and carefully to avoid disturbing the fish. The number of the fish was counted in units of five to consider the habit of school formation; fish in a small school (less than five) were not counted. The fish observations were repeated eight times and the results were averaged in order to reduce observational errors.

Immediately after completing the fish observation, the four physical habitat variables of depth, velocity, cover and vegetation were surveyed to establish a relationship between the habitat variables and the habitat preferences of Japanese medaka. First, depth and velocity were measured, in which depth was measured with a stainless steel ruler and velocity was measured with a portable propeller current meter (KENEK, V-303) at three lateral points comprising a midpoint and two near-shore points at longitudinal intervals of 1 m. Next, the study reach were divided into small water units having a similar condition with regard to depth and velocity. The other two factors of cover and vegetation were then calculated at each water unit. The lateral cover ratio is defined as a function of the presence of a lateral cover, which comprises the water's edge, a dike, or anything that emerges from the water surface and surrounds the water body. The cover thus consists of four components (four lateral sides). The maximum cover ratio is 100%, and each of the cover components is assigned a score of 25%. In the definition of the cover, objects attached to more than 90% of the boundary between water units were regarded as cover components. That is, only instream and undersurface cover structures that may have the same effects as the margin of the stream were considered as cover components. Percent vegetation coverage is defined as the percentage of the area covered with aquatic vegetation in each water unit. Both submerged and emergent vegetation were pooled because of their same roles in providing foods and shelters from predators and fast-flowing currents.

The fish distribution data used in the following analyses were the log-transformed fish population density observed at the i^{th} water unit $FPD_{o,i}$ (individuals per square metre), where i (= 1, 2, …, N) denotes the index of the water units and N is the total number of water units (Fig. 1).

C. *Fuzzy Habitat Preference Model*

In the present study, a fuzzy habitat preference model (FHPM; [8]) was employed. The FHPM is a 0-order Takagi-Sugeno model [27] which relates habitat variables to habitat preference by considering uncertainties such as fish behaviour and measurement errors of the physical habitat variables. FHPMs have been applied to modelling the habitat use of Japanese medaka in a laboratory experiment [7] and at a microhabitat scale [9–15]. The FHPMs has also been applied to habitat evaluations at a larger spatial scale [16]. A FHPM can be viewed as a fuzzified version of a GA-optimized piecewise constant model [12], in which simultaneous optimization of all model parameters enables an FHPM to evaluate habitat preference, even under the nonlinear, complex interactions between habitat variables and habitat preference [11]. The brief description of an FHPM follows.

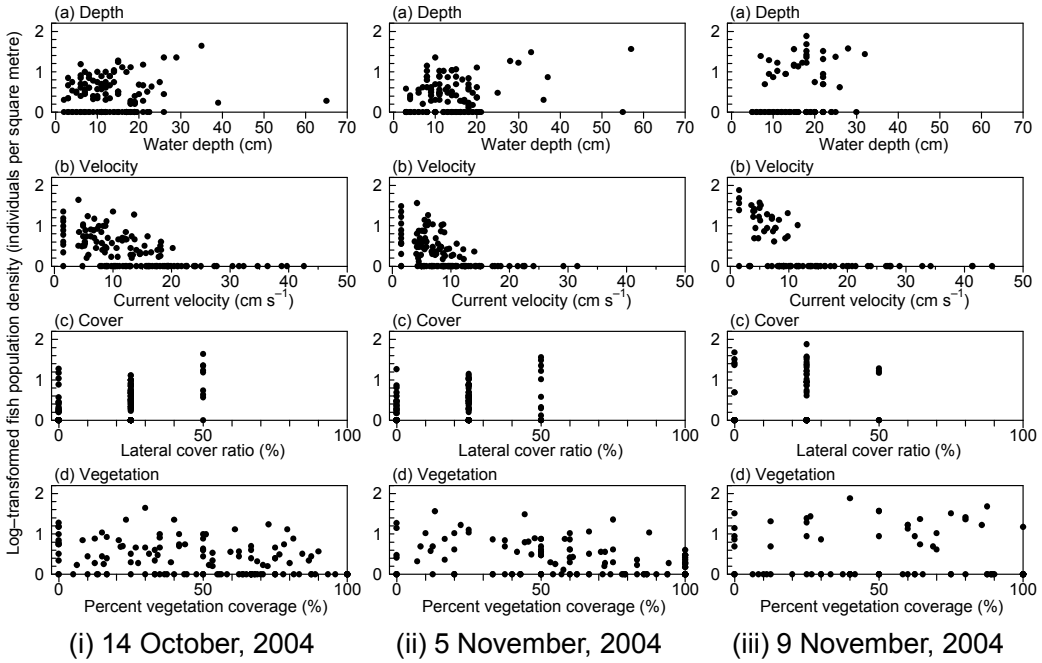

Figure 1. Results of fish habitat surveys.

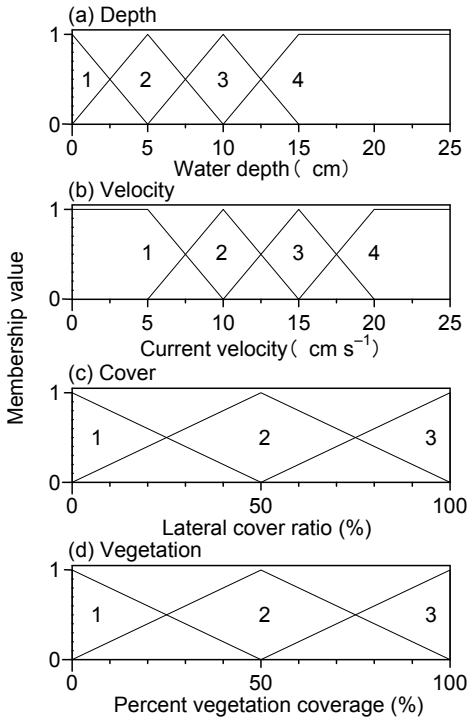

Figure 2. Membership functions.

The present FHPM is a single-input single-output fuzzy system and has 4 sets of if-then rules, comprised of 4 rules for depth and velocity, and 3 rules for cover and vegetation (14 rules in total). The input values (four habitat variables) were expressed by symmetric triangular fuzzy numbers with centre α_m and spread σ_m, where m denotes the habitat conditions of depth, velocity, cover and vegetation, to consider the measurement errors and the spatial variances of the habitat variables. The centre α_m is the observed value and the spread σ_m is determined from the allowable variances when dividing the reach into water units: 1 cm was given for the spread of depth σ_{d}, 1 cm s^{-1} for velocity σ_{v} and 10% each for cover σ_{c} and vegetation σ_{veg}. The abbreviations d, v, c and veg denote depth, velocity, cover and vegetation, respectively. The antecedent parts of the FHPM (the membership functions) were defined to extract habitat requirements of the target fish (Fig. 2). Each membership function has a corresponding singleton value in the consequent part. The habitat preference was calculated by taking a weighted mean of the singleton values in the consequent parts, with the membership degrees as weights. The singleton values in the consequent part are in the range [0, 1] and were determined by a GA so as to minimize the mean squared error (MSE) between the modelled and observed fish population density. That is, the fitness function of the GA is a reciprocal of the MSE. The present GA consisted of a population of 100 individuals, each of which has a 56-bit string (4 bits × 14 singletons). The shape of the habitat preference curves (HPCs), i.e., a set of singletons for a habitat variable, was constrained to have a unimodal or monotone form with maximum preference of one. Specifically, the model was penalized by giving large MSE values when the above regulation was violated. In the estimation of the fish population density, a composite habitat preference according to the four habitat variables was calculated as

$$HP_i = P_{\mathrm{d},i} \times P_{\mathrm{v},i} \times P_{\mathrm{c},i} \times P_{\mathrm{veg},i} \tag{2}$$

where HP_i denotes the habitat preference in the i^{th} water unit, and $P_{\mathrm{d},i}$, $P_{\mathrm{v},i}$, $P_{\mathrm{c},i}$, and $P_{\mathrm{veg},i}$ are the habitat preference to individual habitat variables of depth, velocity, cover and vegetation, respectively. The product operation is reported to produce a FHPM with higher performance with consistent habitat preference curves [16]. The habitat use of Japanese medaka was then estimated using the equation:

$$FPD_{\mathrm{c},i} = \left(HP_i \Big/ \sum_{i=1}^{N} HP_i \right) \cdot \sum_{i=1}^{N} FPD_{\mathrm{o},i} \tag{3}$$

where $\mathrm{FPD}_{\mathrm{c},i}$ is the calculated fish population density in the i^{th} water unit, and $\mathrm{FPD}_{\mathrm{o},i}$ is the observed fish population density. The MSE was calculated accordingly and the GA repeatedly modified the model structure (the singletons in the consequent part) using three genetic operations: roulette wheel selection with an elitist strategy, uniform crossover and mutation at a probability of 5%. After 2,000 iterations, the optimal model was obtained. The GA optimization was repeated using 20 different sets of initial conditions.

D. Model Development and Analysis

To assess the effects of zero abundance data (i.e., data at which no fish was present) on the habitat evaluation of Japanese medaka, two kinds of data were used: full abundance data (henceforth referred to as full data) and the data without zero abundance (henceforth referred to as presence-only abundance data). The full data consist of both abundance data and zero abundance data, whereas presence-only abundance data consist of only abundance data (i.e., full data without zero abundance data). FHPMs were developed using three independent data sets with two kinds (full and presence-only abundance data), in which a data set was used for model calibration and each of the remaining two data sets were used for model validation. HPC for a habitat variable was obtained by providing consecutive values, which were in the range of the corresponding membership functions (in steps of 0.1), to the FHPM of which the output values were plotted against the habitat variable. HPCs were evaluated according to the shapes and variances of all HPCs from 20 different initial conditions. Consistent HPCs indicate that consistent ecological knowledge was extracted by FHPMs. A variance in HPCs reflects the variance in model structures optimized using 20 different initial conditions in the GA optimization, and quantifies the convergence of model parameters. Consistency or a smaller variance in HPCs would thus demonstrate the appropriateness of the model developed.

The accuracy of the model was evaluated based on the MSE between predicted and observed fish population density. The MSE was calculated for the three cases of species distribution modelling of the fish: prediction using full data by FHPMs developed from full data, prediction using full data by FHPMs developed from presence-only abundance data, and prediction using presence-only abundance data by FHPMs

developed from presence-only abundance data. Mean and standard deviation of the MSE values across 20 different initial conditions were used as performance measures. The smaller MSE values in validation data sets indicate the higher generalization ability of the models.

III. RESULTS

The full data and presence-only abundance data result in slightly different HPCs (Figs. 3–4), in which differences are also found across data sets used. The difference can be seen from the shape or trend of HPCs and the degree of preference. For instance, it is observed from the HPCs for depth derived using the full data (Figs. 3a(i)–3a(iii)) that Japanese medaka

Model 3	0.0754 ±0.0028	0.0820 ±0.0020	0.0697 ±0.0005

Mean ±standard deviation are shown.
Model 1 was developed using the data set on 14 October.
Model 2 was developed using the data set on 5 November.
Model 3 was developed using the data set on 9 November.

prefers a larger water depth as a trend, while different degrees of preference around the depth over 10 cm are observed between the three data sets. For velocity, the degrees of preference at the velocity of 10 to 15 cm s^{-1} are found to be different between the data sets of 14 October and the other data sets (Figs. 3b(i)–3b(iii)). The difference of HPCs are not clear for cover (Figs. 3c(i)–3c(iii)), of which the convergence are slightly better in the data sets on 14 October. For vegetation, the degree of preference to the larger vegetation is higher in the data sets on 9 November (Figs. 3d(i)–3d(iii)). These differences between data sets can be the source of errors in validation data sets (Table Ia). Large errors are observed at model 2 for the data set of 14 October and model 3 for the data sets of 14 October and 5 November, which is partly ascribed to the overestimations of fish population density.

In the case where presence-only abundance data were used, the differences in HPCs between data sets are found to be small (Fig. 4). While the degrees of preference are slightly different between the HPCs from different data sets, the trends of HPCs are the same across the data sets. The slight differences in the degree of preference are observed at the HPCs for velocity over 20 cm s^{-1} and those for vegetation (Figs. 4b and 4d). The HPCs for vegetation developed using the presence-only abundance data show weak trend over the variable range (Fig. 4d(iii)), which would indicate a small contribution of the variable in modelling spatial distributions of the fish using the data set. The HPCs obtained from presence-only abundance data result in worse accuracy when testing the FHPMs by the full data (Table Ib) but better accuracy when testing the FHPMs by the presence-only abundance data (Table Ic). Despite the different accuracy between the FHPMs developed using the presence-only abundance data (Table Ib–Ic), the accuracies are better than that of FHPMs developed using the full data (Table Ia).

IV. DISCUSSION

The present results illustrated that the zero abundance data affect model performance of the FHPMs (Figs. 3–4, Table I), which was observed through the HPCs and resulting MSE values. The reduced standard deviation values of MSEs indicate that the zero abundance data can be a source of uncertainties in species distribution modelling (Table I). This is clear, to some extent, because zero abundance contains two possible cases of true and chance absences. The former means that the fish was absent because the fish avoided it, while the latter means that the fish was absent because the habitat was not yet occupied or because of presence of predator or competitive species, even the habitat was preferable for the fish. As a result, model predictions in the former case are evaluated to be perfect fits, while model predictions in the latter case are to be errors. This type of errors is the same as the errors that are reported as false positives in presence-absence modelling [17], [22], [23]. It is also reported that the proportion of presence data to total data, often termed as prevalence, affects the performance of SDMs (see [24], [25] for reviews). Accordingly, it could be concluded that the model performance is affected by not only the prevalence of data but also the proportion of true and chance absences in absence data or zero abundance data. However, it is impossible to distinguish true and chance absences at the moment. Novel methods are, therefore, needed to be developed for better understanding the model behaviour to uncertainties associated with the data used.

The present results demonstrated the higher generalization ability of FHPMs developed using presence-only abundance data, which can be mainly because of the consistent HPCs obtained (Figs 3–4). For instance, the present HPCs show a consistent trend of habitat preference that the fish prefer a larger depth, a slower velocity, a larger cover and a smaller vegetation with a small difference of the degree of preference. This supports the appropriateness of presence-only abundance data in species distribution modelling, especially where HPCs are necessary or important. The differences in HPCs have been reported as a 'transferability' of a habitat model [10], [14], [28]–[31]. References [32], [33] suggested the necessity of a response curve of a model, i.e., a HPC in the present study, for a better understanding towards an improvement of the existing models or development of a new model. Since the response curve of a model illustrate how target species response to a given habitat condition, SDMs should be compared on the basis of both accuracy measures and response curves derived from the models.

V. CONCLUSION

This case study of Japanese medaka demonstrated the effect of zero abundance data in modelling fish habitat preference using a 0-order Takagi-Sugeno fuzzy system. The dual nature of zero abundance (i.e., true and chance absences) would be one of the sources of performance deterioration of the model.

Further studies are needed to develop an approach to distinguish true and chance absences, which contributes to the better understandings of target species and the improvement of SDMs

***Abstract*—In this paper, we propose a multiple-level genetic-fuzzy mining algorithm for mining membership functions and fuzzy association rule on multiple-concept levels. It first encodes the membership functions of each item class (category) into a chromosome according to the given taxonomy. The fitness value of each individual is then evaluated by the summation of large 1-itemsets of each item in different concept levels and the suitability of membership functions in the chromosome. After the GA process terminates, a better set of multiple-level fuzzy association rules can then be expected with a more suitable set of membership functions. Experimental results on a simulation dataset also show the effectiveness of the algorithm.**

Keywords- data mining, genetic algorithm, multiple-concept levels, membership function, fuzzy association rule.

I. INTRODUCTION

Data mining is most commonly used in attempts to induce association rules from transaction data [2]. An association rule is an expression $X \rightarrow Y$, where X and Y are a set of items. It means in the set of transactions, if all the items in X exist in a transaction, then Y is also in the transaction with a high probability. A variety of mining approaches based on the Apriori algorithm [2] have also been proposed [4, 21]. However, most of them are focus on finding association rules on a single-concept level. Thus, many approaches have also been proposed for mining multiple-concept-level association rules to discovery more specific and important knowledge from data [8, 22].

Most of the mentioned approaches above focused on binary valued transaction data. Transaction data in real-world applications usually consist of quantitative values. Thus, fuzzy data mining algorithms have been proposed for handling quantitative transactions and mining fuzzy association rules [5, 11, 17, 24]. As to multiple-concept levels fuzzy mining, according to the given fuzzy generalization hierarchies, Lee first proposed a generalized fuzzy quantitative association rules mining algorithm [16]. In 2003, Hong et al. then proposed a multiple-level fuzzy association rule mining approach [12]. It first transforms quantitative transactions into fuzzy values by using the predefined membership functions and taxonomy. Then, a top-down progressively deepening approach is used to finding large itemsets and rules. Additionally, in order to reduce the time complexity, only the linguistic term with the maximum cardinality of each item is used in later mining processes. In [14], Kaya et al. proposed a weight fuzzy rule mining approach based on Hong's approach. In 2008, Lee et al. proposed a fuzzy mining algorithm for discovering generalized fuzzy association rules with multiple supports of items for extracting implicit knowledge from quantitative transaction data [18, 19].

Those mentioned approaches assumed the membership functions to be known in advance. The given membership functions may, however, have a critical influence on the final mining results. In recent years, the Genetic-Fuzzy Mining (GFM) approaches have then proposed for deriving appropriate membership functions and mining fuzzy association rules [3, 6, 10, 13, 15]. Kaya *et al.* proposed a GA-based approach to derive a predefined number of membership functions for getting a maximum profit within a user specified interval of minimum supports [13]. Hong *et al.* also proposed a genetic-fuzzy data-mining algorithm for extracting both association rules and membership functions from quantitative transactions [10]. Alcalá-Fdez *et al.* then modified Hong's approach to propose an enhanced approach based on the 2-tuples linguistic representation model [3]. Besides, multi-objective genetic-fuzzy mining approaches have also been proposed [6, 15].

However, those mentioned GFM algorithms are focus on one single-concept level. To the best of our knowledge, there is no GFM algorithm for multiple-concept levels until now. In this paper, we thus propose a multiple-level GFM algorithm for mining membership functions and fuzzy association rule on multiple-concept levels. According to the given taxonomy, it first encodes membership functions of each item class (category) into chromosome. The fitness value of each individual is then evaluated by the summation of large 1-itemsets of each item in different concept levels and the suitability of membership functions in the chromosome. After the GA process terminates, a better set of multiple-level fuzzy association rules can then be expected with a more suitable set of membership functions.

II. A MULTIPLE-LEVEL GENETIC-FUZZY MINING FRAMEWORK

In this section, the fuzzy and GA concepts are used to discover both useful association rules and suitable membership functions from quantitative values. We propose a Multiple-level Genetic-Fuzzy Mining (Multiple-level GFM) framework for searching membership functions suitable for multiple-level mining problems and then use the final best set of membership functions to mine multiple-level fuzzy association rules. The proposed framework is shown in Figure 1.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

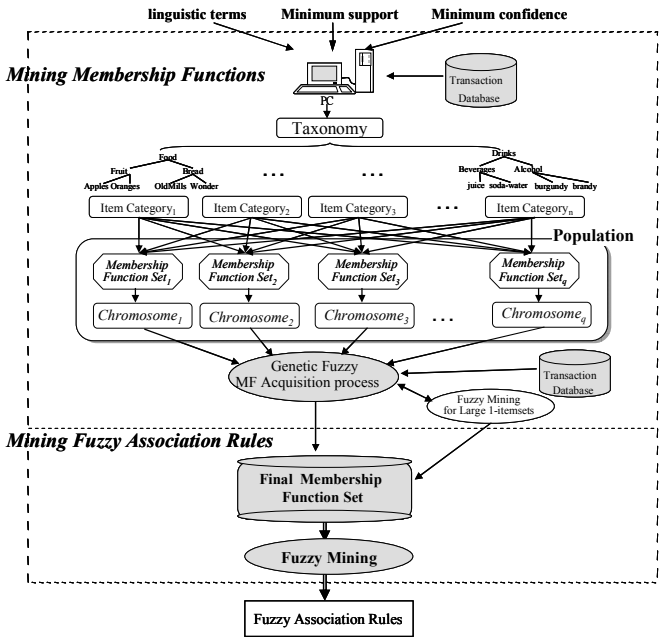

Figure 1. The Multiple-level GFM framework

The proposed framework consists of two phases, namely mining membership functions and mining fuzzy association rules phases. It maintains a population of sets of membership functions, and uses the genetic algorithm to automatically derive the resulting one. In the first phase, according to the given taxonomy, it first transforms each set of membership functions of each item category into a fixed-length string. It then chooses appropriate strings for mating, gradually creating good offspring membership function sets. The offspring membership function sets then undergo recursive evolution until a good set of membership functions has been obtained. In second phase, the derived membership functions are then used to mine multiple-level fuzzy association rules by using rule mining approach [12].

III. COMPONENTS OF THE PROPOSED APPROACHES

In this section, the components of the proposed approach for deriving membership functions and fuzzy association rule on multiple-concept levels are stated. The details of them are described below.

A. Chromosome Representation

It is important to encode membership functions as string representation for GAs to be applied. Several possible encoding approaches have been described in [1, 3, 7, 20, 23]. In this paper, each set of membership functions is encoded as a chromosome and handled as an individual with real-number schema. In order to effectively encode the associated membership functions, we use two parameters to represent each membership function as Parodi and Bonelli did [20]. Thus, in multiple-level fuzzy rule mining, membership functions applied to an item class (category) are then assumed to be isosceles-triangle functions as shown in Figure 2.

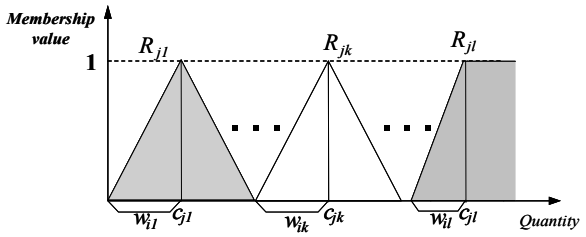

Figure 2. Membership Functions of item class IC_j

where R_{jk} denotes the membership function of the k-th linguistic term of *item class* IC_j, c_{jk} indicates the center abscissa of fuzzy region R_{jk}, and w_{jk} represents half the spread of fuzzy region R_{jk}. As Parodi and Bonelli did, we then represent each membership function as a pair (c, w). Thus, all pairs of (c, w)'s for a certain item class are concatenated to represent its membership functions. Thus the set of membership functions MF_1 for the first item class IC_1 is then represented as a substring of $c_{11}w_{11}\ldots c_{1|IC1|}w_{1|IC1|}$, where $|IC_1|$ is the number of linguistic terms of IC_1.

The entire set of membership functions is then encoded by concatenating substrings of MF_1, MF_2, ..., MF_j. Since c and w are both numeric values, a chromosome is thus encoded as a fixed-length real-number string rather than a bit string.

B. Fitness and Selection

In order to develop a good set of membership functions from an initial population, the genetic algorithm selects *parent* membership function sets with high fitness values for mating. An evaluation function is then used to qualify the derived membership function sets. The performance of membership function sets is then fed back to the genetic algorithm to control how the solution space is searched to promote the quality of the membership functions. In this paper, we thus propose an evaluation function according to the one used in our previous approach [10] as shown below.

$$f(C_q) = \frac{\sum_{k=1}^{levels} | L_{1q}^k |}{suitabilit\,y(C_q)},$$

where the $| L_{1q}^k |$ is the number of large 1-itemsets in level k of chromosome C_q, $1 \le k \le levels$, and the $suitability(C_q)$ is used in the fitness function can reduce the occurrence of the two bad kinds of membership functions, where the first one is too redundant, and the second one is too separate. The suitability of the membership functions in a chromosome C_q is thus defined as:

$$suitability(C_q)$$
$$= \sum_{j=1}^{m} [\, overlap_factor(C_{qj}) + coverage_factor(C_{qj})],$$

where the overlap factor of the membership functions for an item class IC_j in the chromosome C_q is defined as:

$$overlap_factor(C_{qj}) = \sum_{k \ne i} [\max((\frac{overlap(R_{jk}, R_{ji})}{\min(w_{jk}, w_{ji})}), 1) - 1],$$

where the overlap ratio $overlap(R_{jk}, R_{ji})$ of two membership functions R_{jk} and R_{ji} is defined as the overlap length divided by half the minimum span of the two functions. If the overlap length is larger than half the span, then these two membership functions are thought of as a little redundant. Appropriate punishment must then be considered in this case.

The coverage ratio of a set of membership functions for an item class IC_j is defined as the coverage range of the functions divided by the average value of maximum quantity in each level of that item class in the transactions. The larger the coverage ratio is, the better the derived membership functions are. Thus, the coverage factor of the membership functions for an item class IC_j in the chromosome C_q is defined as:

$$coverage_factor(C_{qj}) = \frac{1}{\frac{range(R_{j1}, ..., R_{jl})}{avgmax(IC_j)}},$$

where $range(R_{j1}, R_{j2}, \ldots, R_{jl})$ is the coverage range of the membership functions, l is the number of membership functions for IC_j, and $avgMax(IC_j)$ is the average value of maximum quantity in each level of that item class in the transactions. Note that the overlap factor is designed for avoiding the first bad case "too redundant", and the coverage factor is for the second one "too separate".

C. Genetic Operators

Genetic operators are very important to the success of specific GA applications. Two genetic operators, the *max-min-arithmetical (MMA) crossover* proposed in [9] and the *one-point mutation*, are used in the genetic fuzzy mining framework. In the *max-min-arithmetical (MMA)* crossover operator, it will generate the following four candidate chromosomes from the given two chromosomes. Then, the best two chromosomes of the four candidates are then chosen as the offspring.

The one-point mutation operator will create a new fuzzy membership function by adding a random value ε, for example $\pm w_{jk}$, to the center or to the spread of an existing linguistic term, say R_{jk}. Assume that c and w represent the center and the spread of R_{jk}. The center or the spread of the newly derived membership function will be changed to $c + \varepsilon$ or $w + \varepsilon$ by the mutation operation. Mutation at the center of a fuzzy membership function may however disrupt the order of the resulting fuzzy membership functions. These fuzzy membership functions then need rearrangement according to their center values.

IV. The Proposed Multiple-Level Genetic-Fuzzy Mining Algorithm

According to the above description, the proposed multi-level genetic-fuzzy data mining algorithm for mining both membership functions and fuzzy association rules is described below.

The proposed multiple-level GFM algorithm:

INPUT: A body of n quantitative transaction data, a set of m items, each with a number of linguistic terms, codes of item names, a predefined taxonomy, a support threshold α, and a confidence threshold λ.

OUTPUT: A set of multiple-level fuzzy association rules with its associated set of membership functions.

STEP 1: Encode the predefined taxonomy using a sequence of numbers and the symbol "*", with the t-th number represents the branch number of a certain item on level t.

STEP 2: Translate the item names in the transaction data according to the encoding scheme.

STEP 3: Find level-k representation of the transaction data using following substeps:

SUBSTEP 3.1: Set $k = 1$, where k is used to store the level number being processed.

SUBSTEP 3.2: Group the items with the same first k digits in each transaction datum D_i, where $1 \le i \le$ n. Denote the j-th group on level k in transaction D_i as v^k_{ij}.

SUBSTEP 3.3: If level-k representation is not null, set $k = k + 1$ and go to SUBSTEP 3.2; otherwise, go to next step.

STEP 4: Randomly generate a population of P individuals; each individual is a set of membership functions for items in level-1 classes of the taxonomy.

STEP 5: Encode each set of membership functions into a string representation.

STEP 6: Calculate the fitness value of each chromosome by the following substeps:

SUBSTEP 6.1: Set $k = 1$, where k is used to store the level number being processed.

SUBSTEP 6.2: Transform the quantitative value v^k_{ij} of each transaction datum D_i (i =1 to n) for each encoded group name I^k_j into a fuzzy set f^k_{ij} represented as:

$$\left(\frac{f^{(k)}_{ij1}}{R^k_{j1}} + \frac{f^{(k)}_{ij2}}{R^k_{j2}} + ... + \frac{f^{(k)}_{ijh}}{R^k_{jh}} \right),$$

using the corresponding membership functions represented by the chromosome, where R^k_{jl} is the l-th fuzzy region of item I^k_j, $1 \le l \le$ h, f^k_{ij} is v^k_{ij}'s fuzzy membership value in region R^k_{jl}, and l (= $|I^k_j|$) is the number of linguistic terms for I^k_j.

SUBSTEP 6.3: Calculate the scalar cardinality of each fuzzy region R^k_{jl} in the transactions as follows:

$$count^k_{jl} = \sum_{i=1}^{n} f^k_{ijl} .$$

SUBSTEP 6.4: Check whether the value of each fuzzy region R^k_{jl} is larger than or equal to the predefined minimum support value α. If the value of a fuzzy region R^k_{jl} is equal to or greater than the minimum support value, put it in the large 1-itemsets ($L_1{}^k$) at level k. That is:

$$L_1{}^k = \{ R_{jl}{}^k \mid count_{jl}{}^k \ge \alpha, 1 \le j \le m^k, 1 \le l \le \text{h} \}.$$

SUBSTEP 6.5: If level-k representation is not null, set $k = k + 1$ and go to SUBSTEP 6.1; otherwise, go to next step.

STEP 7: Set the fitness value of the chromosome as the summation of the number of large 1-itemsets in L_1^k for all levels divides by its suitability *suitability*(C_q) as follows:

$$f(C_q) = \frac{\sum_{k=1}^{levels} |L_1^k|}{suitability(C_q)}.$$

STEP 8: Execute crossover operations on the population.
STEP 9: Execute mutation operations on the population.
STEP 10: Using the *selection* criteria to choose individuals for the next generation.
STEP 11: If the termination criterion is not satisfied, go to Step 6; otherwise, do the next step.
STEP 12: Output the set of membership functions with the highest fitness value.

The set of membership functions are then used to mine multiple-level fuzzy association rules from the given transactions. The multiple-level fuzzy mining algorithm proposed in [12] is then adopted to achieve this purpose.

V. Experimental Results

In this section, experiments made to show the performance of the proposed approach are described. They were implemented in Java on a personal computer with Intel Core i5 CUP 661 @ 3.33GHz and 1.8GB RAM. And, 10000 transactions were used in the experiments. The initial population size P was set at 50, the crossover rate p_c was set at 0.8, and the mutation rate p_m was set at 0.001. The parameter d of the crossover operator was set at 0.35 according to [9] and the minimum support α was set at 0.04 (4%).

There were 64 purchased items (terminal nodes) on level 3, 16 generalized items on level 2, and 4 generalized items on level 1. Each non-terminal node had four branches. Only the terminal nodes could appear in transactions. Data sets with different numbers of transactions were run by the proposed algorithm. In the data set, numbers of purchased items in transactions were first randomly generated. The purchased items and their quantities in each transaction were then generated. An item could not be generated twice in a transaction.

After 500 generations, the final membership functions are apparently much better than the original ones. For example, the initial membership functions of four item classes are shown in Figure 3.

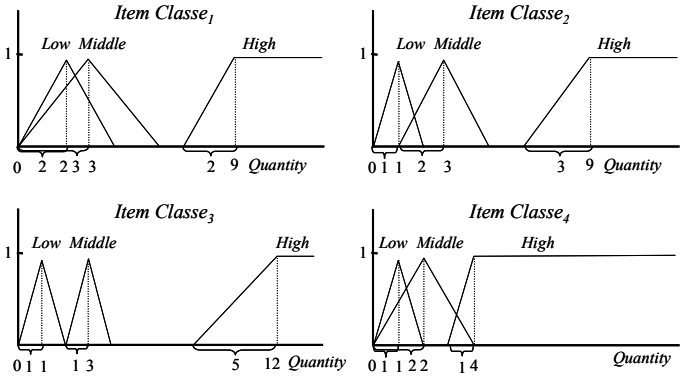

Figure 3. The initial membership functions of four item classes

In Figure 3, the membership functions have the two bad types of shapes according to the definition in the previous section. The membership functions of *Item Class*$_1$, *Item Class*$_2$ and *Item Class*$_3$ are "too separate". The membership functions of *Item Class*$_1$ and *Item Class*$_4$ are "too redundant". After 500 generations, the final membership functions for the four item classes are shown in Figure 4.

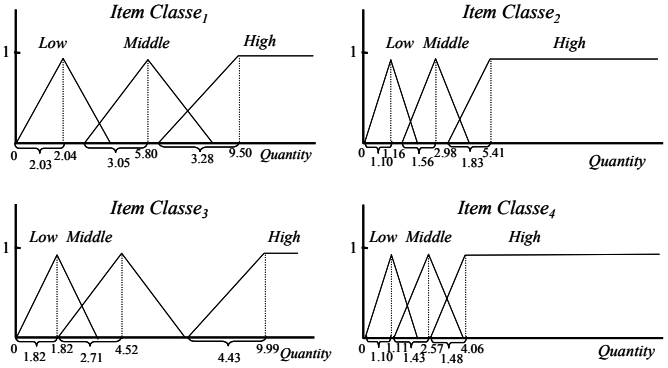

Figure 4. The final membership functions of four item classes after 500 generations

It is easily seen that the membership functions in Figure 4 is better than those in Figure 3. The two bad kinds of membership functions didn't appear in the final results. Then, the five runs average value of average fitness values of the chromosomes along with different numbers of generations are shown in Figure 5.

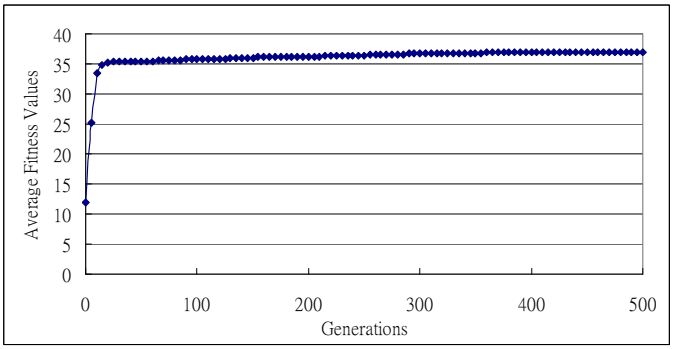

Figure 5. The five runs average values of average fitness values along with different numbers of generations

From Figure 5, we can observe that the curve gradually goes upward, finally converging to a certain value.

VI. Conclusion And Future Works

In this paper, we first propose a Multiple-level Genetic-Fuzzy Mining (Multiple-level GFM) framework for searching membership functions suitable for multiple-level mining problems and then use the final best set of membership functions to mine multiple-level fuzzy association rules. Then, a Multiple-level GFM algorithm is proposed. Experiments on a simulation dataset were also made to show the effectiveness and stableness of the proposed approach. The main contribution of this work is that the proposed algorithm is the first work for mining both membership functions and fuzzy association rules on multiple-concept levels. However, the

proposed approach is just a beginning. In the future, we will continuously to enhance the Multiple-level GFM framework for more complex problems.

Abstract— **This paper presents a new approach to combining multiple fuzzy regression trees, which are induced by applying the modified Elgasir fuzzy regression tree algorithm. This method utilises Trapezoidal membership functions for fuzzification and the Takagi-Sugeno fuzzy inference to obtain the final predicted values. A modified version of Artificial Immune Network model (opt-aiNet) is used for the simultaneous optimization of the membership functions across all trees within the forest. Boston housing and Abalone are two real-world datasets from the UCI repository used to evaluate the proposed approach. The empirical results have showed that fuzzy regression tree forests reduce the error rate compared with single fuzzy regression tree.**

Keywords: *fuzzy regression tree forests***,** *Fuzzy inference system, Fuzzy Regression tree, Data mining, Machine learning, Evolutionary algorithms, Artificial Immune system.*

I. INTRODUCTION

Decision trees are a transparent method of representing a set of IF-THEN rules in a graphical way and are generated by learning and reasoning from feature-based examples. There are two well known and distinctive methods for generating decision trees: Regression trees [1,2,3,4,5,6] which are designed to predict continuous outcomes and Classification trees [7,8,9,10,11] which predict discrete outcome classes. AID [12], CHAID [13] and CART (classification and regression tree) [14,15] are crisp regression trees algorithms that describe the approach of building regression trees based on information theory. A well documented weakness of these algorithms is that they induce trees with sharp decision boundaries when the decision space of continuous attributes is partitioned. Moreover the output of crisp regression trees are generated using a discrete function which clearly decreases the prediction accuracy and affect the robustness of the generation crisp regression trees [1,2,3,4].

The application of fuzzy logic to the crisp regression trees has shown improvement in the performance of the traditional regression trees [1...6,16]. This has been achieved using fuzzy membership functions at each crisp regression tree node to soften the sharp node boundaries. The Fuzzy CHAID Induction Algorithm was first proposed by Fowdar et al [5,6] to generate regression trees by using the CHAID algorithm and optimising the amount of Fuzzification using a Genetic Algorithm (GA). The main weakness of Fowdars' approach was in the defuzzification strategy as it could lead to less accurate prediction as a result of using one of varied defuzzification methods to calculate the final output.

The Elgasir algorithm [2] is a method for creating fuzzy regression trees [1] by formulating trapezoidal membership functions for each node in the pre-generated crisp regression trees. This algorithm has shown the capability of overcoming the weakness of crisp decision trees by applying appropriate membership functions for all branch split points, and using Takagi-Sugeno fuzzy inference technique [17] to generate a final continuous output value. Elgasir has successfully alleviated Fowdar's defuzzification problem as a result of having a single numeric value as the output of fuzzy inference [17]. Fuzzification has been successfully used with multiple decision trees models [16,23…26] to induce fuzzy decision tree forests in order to improve the predictive power of a single fuzzy decision tree. Although the use of multiple regression trees has been used to improve the performance of a single fuzzy regression tree [16], little work has been done in this field.

Immune algorithms have been used to solve optimization problems [18] such as: design optimization task for electromagnetic devices [19], optimizing the dynamic function [20] and optimization of a weapon-target assignment problem [21]. An adapted version of Artificial Immune Network model (opt-aiNet) [22] was proposed in [2] to enable the algorithm to be applied to the optimization of fuzzy regression trees and the algorithm was successfully applied to the Elgasir [2]. The adapted version of an artificial immune network model (opt-aiNet) [2] is used in this work for optimizing the proposed framework.

This paper proposes a new approach which applies a modified version of the Elgasir algorithm to the task of creating fuzzy regression tree forests. The modification of the Elgasir algorithm has been done based on an approach by Crockett et al for growing a fuzzy classification based decision tree forest. In the modified Elgasir algorithm, a number of fuzzy regression trees are generated from one training sample, where each tree represents a different view

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

of the problem domain and will represent different associations of independent variables for the same dataset.

The organisation of this paper as follows: Section II provides some background information on Fuzzy Forests. Section III provides a brief outline of the Elgasir algorithm. Section IV describes the methodology used for constructing fuzzy regression tree forests Section V describes the conducted experiments and section VI presents the results and discussion. Finally the paper is concluded in section VII.

II. Fuzzy Forests

Fuzzy multiple decision trees forests models [16, 23… 26] have been used to combine more than one fuzzy decision tree in order to improve the predictive power of a single fuzzy decision tree. Different approaches have been proposed for classification problems [23…26]. These approaches can be described as tree-based ensemble classifiers [23], but they differ by the way that used to induce multiple trees. Bonissone et al [23] have applied fuzzy logic and fuzzy sets to random forest to produce multiple fuzzy classifier system. In Bonissone's method a fuzzy random forest is created by combining several individual classifiers based on Breiman's methodology [27]. This method used a random subset of the total set of available attributes to construct each node. Marsala and Bouchon-Meunier presented a method for generating forests of fuzzy decision trees [24], where each fuzzy decision tree of the forest is induced from a random subset of the whole training dataset. With theses two methods there is no guarantee that the information space has been explored exhaustively. Cezary and Janikow [25] induced fuzzy decision forests by allowing the usage of more than one test attribute at a non‐leaf node. Although this approach can overcome noisy or missing values problems, but it has been unstable [28]. Crockett et al [26] introduced an approach for growing a fuzzy decision forest. In this approach, multiple classification trees are created from same training sample and the strategy for adding classification tree is by restriction the attribute which has highest-ranking to be the root of the tree. This method was shown to be successful but if the number of trees in the forest has a limit in terms of improving performance and once a certain threshold is reached, overfitting of the training set will start to occur. However it was shown that if the number of trees was kept small, then the results justify the computational expense and provide a practical way of improving the classification accuracy. For regression problems, Haskell [16] proposed a method to induce a fuzzy regression trees forest, which used a new splitting criteria based on a generalized Kolmogorov-Smirnov distance to construct fuzzy regression trees associated with a fuzzy cumulative distribution function. The main problem with this method is that a human expert is needed to provide pre-fuzzified data, despite the number and size of the membership functions being automatically determined in Haskell's method.

III. Elgasir Algorithm

The Elgasir algorithm, originally proposed in [1], combined principles of fuzzy theory and Takagi-Sugeno fuzzy inference [17] to generate fuzzy regression trees. This algorithm does not require pre-fuzzified data and therefore can overcome the problems of unnecessary complexity and poor transparency problems often resulting from algorithms which generate fuzzy trees directly from data which has been pre-fuzzified by experts in the domain. Another advantage of the Elgasir algorithm is that the output of fuzzy inference is a single numeric value as a result of using Takagi-Sugeno fuzzy inference technique. In other words, there is no need for a defuzzification operation to calculate the output of the fuzzy regression tree. This has shown to lead to more accurate results by avoiding doing more calculations to transform the output fuzzy sets into a non-fuzzy output [1,2].

The fuzzy rule base generated by Elgasir is produced by applying Trapezoidal membership function to crisp CHAID regression trees. The algorithm is not restricted to just Trapezoidal membership functions and any other membership function can be applied. In addition, the Elgasir methodology can be applied to any other crisp regression tree algorithm. For the purpose of this work the CHAID regression tree algorithm has been used [13]. Full details of the original Elgasir algorithm can be found in [1].

IV. Modified Elgasir Algorithm for Constructing Fuzzy Regression Tree Forests

The modified Elgasir algorithm is the new version of Elgasir algorithm [1], which is used to induce a fuzzy regression tree forest by combing two or more singular fuzzy regression trees, where each one represents a different view of the same domain. The algorithm is optimized using the adapted version of an artificial immune network model (opt-aiNet) [2] in order to establish the optimum fuzzification throughout the tree.

The modified Elgasir algorithm consists of the following stages:

The first stage: multiple crisp regression trees induction

1.1 Creating a series of crisp regression trees:
The CHAID algorithm [13] is used to construct an optimal singular crisp regression tree by applying various values of CHAID algorithm parameters in order to produce a highly optimised regression tree. The attribute selection, branching strategy and terminate growth criteria for growing a crisp tree are based on the information measure entropy. To induce the second crisp regression tree form the same dataset, the attribute which has the smallest adjusted p-value (the highest ranking) is restricted from formulating the root of the second crisp regression tree. This process is repeated in each creating of crisp regression tree. The result is a combination of crisp regression trees, where each tree is

different in representing the association of independent variables for the same dataset.

1.2 Generating IF-THEN rules:

The combination of crisp regression trees are converted into a set of IF-THEN production rules in-order to create a knowledge base using a one-to-one mapping. Each rule represents a path from the root to the leaf node in each crisp CHAID regression tree. The form of the typical rule as following:

$$R_i : \text{IF } x_1 \text{ is } b_{i1} \text{ and....and } x_k \text{ is } b_{ik} \text{ THEN } y_i = b_{i0} \quad (1)$$

where $R_i (i = 1,2,..., n)$ denotes the ith rule, $x_j (j = 1,2,.....,k)$ are the input (antecedent) variables, y_i are the rule output variables, $b_{i0} (i = 1,2,..., n)$ are real numbers.

Due to method used to create each tree there will be no duplication of rules and hence no redundancy.

The Second Stage: applying membership functions and fuzzy inference technique

Appropriate membership functions are applied for all branch split points i within the antecedent rules and the consequent part of rules (1) are parameterized. Then a typical fuzzy rule can be defined as:

$$R_i : \text{IF } x_1 \text{ is } A_{i1} \text{ and } .... \text{ and } x_k \text{ is } A_{ik} \text{ THEN } y_i = \rho_i b_{i0} + a_{i1}.x_1 + ... + a_{ik}.x_k$$

Let $\rho_i b_{i0}, = a_{i0}$ then

$$R_i : \text{IF } x_1 \text{ is } A_{i1} \text{ and } .... \text{ and } x_k \text{ is } A_{ik} \text{ THEN } y_i = a_{i0} + a_{i1}.x_1 + ... + a_{ik}.x_k \quad (2)$$

where $R_i (i = 1,2,..., n)$ denotes the ith fuzzy rule, $x_j (j = 1,2,.....,k)$ are the input (antecedent) variables, y_i are the rule output variables, $A_{i1}, ..., A_{ik}$ are fuzzy sets defined in the antecedent space, and $a_{i0}, a_{i1}, ..., a_{ik}$ are the consequent parameters.

The inferred global output of the proposed framework is computed by taking the weighted average of the individual rules' contributions defined as:

$$y = \frac{\sum_{i=1}^{n} \tau_i(x).(a_{i0} + a_{i1}.x_1 + ... + a_{ik}.x_k)}{\sum_{i=1}^{n} \tau_i(x)} \quad (3)$$

where $\tau_i(x)$ is the degree of fulfilment of the ith fuzzy rule, defined by

$$\tau_i(x) = \min\{\mu_{A_{i1}}(x_1)....\mu_{A_{ik}}(x_k)\}$$

In order to Identify the consequent parameters

Let β_i be

$$\beta_i = \frac{\tau_i(x)}{\sum_{i=1}^{n} \tau_i(x)} \quad (4)$$

then

$$y = \sum_{i=1}^{n} \beta_i.(a_{i0} + a_{i1}.x_1 + ... + a_{ik}.x_k)$$

$$y = \sum_{i=1}^{n} (\beta_i.a_{i0} + \beta_i.a_{i1}.x_1 + ... + \beta_i.a_{ik}.x_k)$$

When we apply a set dataset $x_{j1}, .x_{j2}, ..., x_{jk}$ then the value of the outputs y_j

where $(j = 1,2,..., m)$ as

$$y_1 = (\beta_{11}.a_{10} + \beta_{11}.a_{11}.x_{11} + ... + \beta_{11}.a_{1k}.x_{1k}) + ... + (\beta_{1n}.a_{n0} + \beta_{1n}.a_{n1}.x_{11} + ... + \beta_{1n}.a_{nk}.x_{1k})$$

.

.

.

$$y_m = (\beta_{m1}.a_{10} + \beta_{m1}.a_{11}.x_{m1} + ... + \beta_{m1}.a_{1k}.x_{mk}) + ... + (\beta_{mn}.a_{n0} + \beta_{mn}.a_{n1}.x_{m1} + ... + \beta_{mn}.a_{nk}.x_{mk})$$

The consequent parameters $a_{i0}, a_{i1}, ..., a_{ik}$ $(i = 1,2,..., n)$ can be obtained using the least square method by combining previous equations

Using matrixes and vectors;

Least square equation can be expressed as:

$$Y = \begin{bmatrix} y_j \\ . \\ . \\ . \\ y_m \end{bmatrix}, X = \begin{bmatrix} \beta_{11}, \beta_{11}.x_{11}, ..., \beta_{11}.x_{1k}, ..., \beta_{1n}, \beta_{1n}.x_{11}, ..., \beta_{1n}.x_{1k} \\ . \\ . \\ . \\ \beta_{m1}, \beta_{m1}.x_{m1}, ..., \beta_{m1}.x_{mk}, ..., \beta_{mn}, \beta_{mn}.x_{m1}, ..., \beta_{mn}.x_{mk} \end{bmatrix}, A = \begin{bmatrix} a_{10} \\ a_{11} \\ \vdots \\ a_{1k} \\ \vdots \\ a_{n0} \\ a_{n1} \\ \vdots \\ a_{nk} \end{bmatrix}$$

Where

$$Y = XA$$

X(m×n(k+1) matrix), Y (m vector) and A (n(k+1) vector).

Then the parameter vector A is given by

$$A = (X^T X)^{-1} X^T Y$$

The Third Stage: Optimization

The modified Elgasir algorithm is optimized using the adapted version of an artificial immune network model (opt-aiNet) [2] which is described in Figure 2

```
Initialization: randomly initialize a population
while (stopping criterion is not met)
 {
     for each network cell
     {
     Determine the fitness
      }
      -Normalize the vector of fitness's in the interval [0,1],
        where 0 is assigned to the highest fitness, while 1 is
        assigned to the lowest fitness.
      for each network cell
      {
          Generate a number of clones Nc
       for each clone
          {
               -Mutate each clone proportionally to the fitness
                of its parent cell.
               -Determine the fitness
               -Select the cell with lowest fitness
               -if fitness of best clone less than its parent
                {
                The clone replaces the parent in the network
                }
           }
          }
         if the average error of the population is not
         significantly different from the previous iteration
       {
                    for each network cell
                    {
                      -calculate the affinity between this
                        network  cell and the other network cells
                      -if two cells have an affinity below a
                        pre-defined threshold
                     {
                          the cell with the highest fitness is
                          deleted from the network
                     }
                    }
                    if maximum iteration reached, or there
                    has been no change in the number of cells
                    in the network since the last iteration

                    }
          }
 }
```

Fig. 2 The modified algorithm opt-aiNet for Elgasir optimization

In order to determine the optimal domain delimiters for the membership function of each node in the regression tree. The membership function $f(x,a,b,c,d)$ is defined as:

$$f(x,a,b,c,d) = \begin{cases} 0 & \text{for } x < a \\ \dfrac{x-a}{b-a} & \text{for } a \le x < b \\ 1 & \text{for } b \le x < c \\ \dfrac{d-x}{d-c} & \text{for } c \le x \le d \\ 0 & \text{for d} < x \end{cases}$$

where

$a = \mathrm{i} - n\sigma$
$b = \mathrm{i} - \alpha$
$c = \mathrm{i} + \alpha$
$d = \mathrm{i} + n\sigma$

where σ is the standard deviation, x is value of attribute A.
$\alpha = m\sigma$ where m = 0.0001, 0.001, 0.01 0.1, n is a real number $n \to [0,\infty]$

The initial membership functions are selected to give fuzzy rules set that are equivalent to crisp rules set where $\sigma = 0$.

Figure.3 shows a generalised example of the tuning of membership function domain delimiters which shows Trapezoidal membership function f of domain $a \ldots d$ that creates a fuzzy region around threshold i.

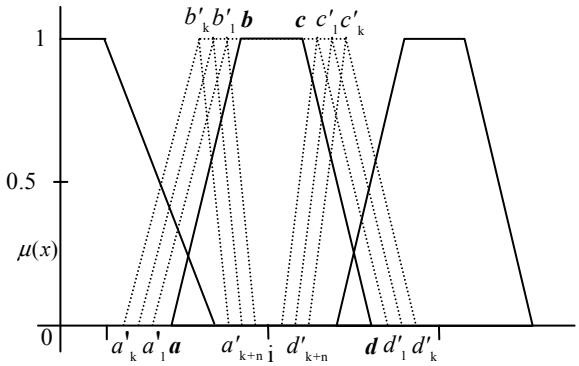

Fig .3 Optimization of Trapezoidal membership function

This optimization system is used to tune the position of the domain delimiters of each membership function, so the points (***a***,***b***,***c***,***d***) can be directed with the constraint $a \le b \le i \le c \le d$ to produce (a'_k, b'_k, c'_k, d'_k). where k and n are natural numbers.

Four domain delimiters (a,b,c,d) are used to represent the membership function within The proposed Elgasir optimization framework as following:
Let Z is a complete set of domain delimiters for a fuzzy regression tree consisting of z branches.

$$Z = \{(a_1,b_1,c_1,d_1), (a_2,b_2,c_2,d_2), \ldots\ldots, (a_z,b_z,c_z,d_z)\}$$

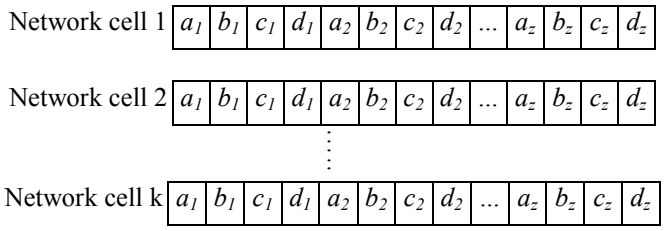

Fig. 4 Network cell representation for fuzzy regression tree.

Figure 4 shows the Network cell representation for membership functions domain delimiters of fuzzy regression tree where *a,b,c,d* real numbers.

The performance of the tree is evaluated by using the MSE (mean square error) which is defined in equation (5).

$$\text{Performance of fuzzy system} = \frac{\sum_{y=1}^{n} (\text{PredictedValue} - \text{ActualValue})^2}{n} \quad (5)$$

Where n = Number of records in the dataset.

V. Experiments

A. Datasets

Experiments were undertaken on two real-valued datasets which known as Boston housing and Abalone datasets. These datasets have numeric outcomes and were retrieved form the well known UCI machine learning repository [29]. The Boston housing dataset consists of 506 records with thirteen continuous attributes and one binary-valued attribute and it has 229 unique outcome values. This dataset is used to predict the Median value of owner occupied homes. The Abalone dataset comprises 4177 instances featuring eight continuous attributes and it has 28 unique outcome values. This data set is concerned with predicting the age of abalone from physical measurements. The main characteristics of these datasets are presented in Table I.

TABLE I
THE MAIN CHARACTERISTICS OF DATASETS

Name	Number of instances	Unique values
boston housing dataset	506	229
abalone dataset	4177	28

B. Methodology

The cross validation approach was used for each experiment. The dataset is divided to n equal-sized disjoint blocks. Each block in turn is used to evaluate both the crisp and the fuzzy trees, which are generated by the remaining $n-1$ blocks. In this work 10-fold cross validation were applied to both datasets. A singular crisp regression tree was first created using the training dataset with various values of the CHAID regression parameters. These parameters include: merge threshold, split threshold, tree depth, node size and child node size. Each parameter was examined in turn to obtain the optimal crisp regression tree. The attribute which has the smallest adjusted p-value (the highest ranking) was restricted from formulating the root of the second crisp regression tree. Hence, this tree will be different in representing the association of independent variables for the same dataset. This process was repeated until 5 crisp regression trees were created. The number of trees was empirically defined by a series of initial experiments which obtained the tree growth saturation threshold of 5. Emperically these experiments showed that no further improvement could be achieved from creating further regression trees of the domain. A set of IF-THEN rules were extracted from the combination of crisp CHAID regression trees. Then the fizzification was applied to these set of IF-THEN rules.

TABLE II- THE OPT-AINET PARAMETERS VALUES

NAME	VALUE
Iterations number	500
Population size	100
Clones number	15
Suppression threshold	0.175
Average error threshold	0.001
Percentage of newcomers	50%
Affinity proportional	75

The adapted version of an artificial immune network model (opt-aiNet) [2] was used to determine the most appropriate domain delimiters of Trapezoidal membership function. Table II presents a summary of the adapted opt-aiNet parameters values which were empirically defined by a series of initial experiments [2].

VI. Results and Discussion

Tables III-VI show the results achieved by the proposed framework for both Abalone and Boston housing datasets. The results show a comparison of results between singular crisp regression trees and fuzzy regression tree forest.

TABLE III
SINGULAR CRISP REGRESSION TREES RESULTS
(ABALONE DATASET)

Tree number	Training dataset (error value)	Test dataset (error value)
1	4.5091	4.5138
2	4.4082	4.4162
3	4.4066	4.4151
4	4.5184	4.5431
5	4.5742	4.6029

TABLE IV
FUZZY REGRESSION TREE FORESTS RESULTS
(ABALONE DATASET)

No of trees	Training dataset (error value)	Test dataset (error value)
1	2.5169	2.8624
2	2.3061	2.4711
3	2.3041	2.4708
4	2.3537	2.4885
5	2.6150	2.9797

TABLE V
SINGULAR CRISP REGRESSION TREES RESULTS
(BOSTON HOUSING DATASET)

Tree number	Training dataset (error value)	Test dataset (error value)
1	21.1749	21.5082
2	20.6497	21.0358
3	20.6562	21.0436
4	20.9841	21.4084
5	21.8231	22.0471

TABLE VI
FUZZY REGRESSION TREE FORESTS RESULTS
(BOSTON HOUSING DATASET)

No of trees	Training dataset (error value)	Test dataset (error value)
1	13.3983	15.9891
2	13.2702	15.6417
3	13.2926	15.6801
4	13.3892	15.7990
5	13.9587	16.3765

For both Abalone and Boston housing datasets the tables III and V show the results of five singular crisp regression trees while the tables IV and VI present the results of combining up to 5 fuzzy regression trees. The tables present the mean square error which was obtained by Equation (5).

The results in Tables III-VI confirmed that the proposed method for creating multiple fuzzy regression trees improves the performance of prediction. The Abalone dataset results show that the combination of three fuzzy regression trees obtained the best rest which reduced the error rate by 14% compared to singular fuzzy regression tree. The biggest improvement in performance for the proposed method with the Boston housing dataset was obtained by the combination of two fuzzy regression trees which reduced the error rate by 2% compared to singular fuzzy regression tree. The proposed framework is most effective on continuous attributes, which is reflected in the improvement of the Abalone dataset. As the number of fuzzy regression tree in the forest increases up to a certain threshold, the prediction accuracy also improves to degree, and once this threshold is reached, overfitting of the training dataset starts to occur, which is dependent on the type, value, distribution and nature of dataset.

VII. CONCLUSION

This study introduced a new framework to creating a fuzzy regression trees forests using the modified Elgasir algorithm. The CHAID algorithm was selected for this work used to induce crisp regression trees. The modified Elgasir algorithm was applied to generate fuzzy regression trees forests using Trapezoidal membership functions to represent tree nodes and the Takagi-Sugeno fuzzy inference technique to combine values down each path. The adapted version of an artificial immune network model (opt-aiNet) was used to optimize the membership functions of the proposed method. The results from two real-valued datasets show that combine fuzzy regression trees can improve the performance by incorporating information from different perspectives of the same dataset. This framework offer promising results in using this kind of technique to reduce the error rate of single fuzzy regression trees. Further studies involve investigating the effects of more complex dataset characteristics in the performance of the proposed method, and comparing the results of the new approach with other approaches to inducing multiple fuzzy regression trees.

***Abstract*— Differential Evolution (DE) is a newly proposed evolutionary algorithm. DE is a stochastic direct search method using a population or multiple search points. DE has been successfully applied to optimization problems including non-linear, non-differentiable, non-convex and multimodal functions. However, the performance of DE degrades in problems having strong dependence among variables, where variables are related strongly to each other. In this study, we propose to utilize partition entropy given by fuzzy clustering for solving the degradation. It is thought that a directional search is desirable when search points are distributed with bias. Thus, when the entropy is low, algorithm parameters can be controlled to make the directional search. Also, we propose to use a species-best strategy for improving the efficiency and the robustness of DE. The effect of the proposed method is shown by solving some benchmark problems.**

***Index Terms*—differential evolution; rotation-invariant; intensive search; extensive search**

I. Introduction

Optimization problems, especially nonlinear optimization problems, are very important and frequently appear in the real world. There exist many studies on solving optimization problems using evolutionary algorithms (EAs). Differential evolution (DE) is a newly proposed EA by Storn and Price [1]. DE is a stochastic direct search method using a population or multiple search points. DE has been successfully applied to optimization problems including non-linear, non-differentiable, non-convex and multimodal functions [2], [3]. It has been shown that DE is a very fast and robust algorithm.

However, the performance of DE degrades in problems having strong dependence among variables, where variables are related strongly to each other. It is very important to know the distribution of search points to solve the degradation. For example, when search points are uniformly distributed as in the left part of Fig. 1, a nondirectional search is the better choice than a directional search. On the contrary, when variables are strongly related as in the right part of the figure, a directional search is the better choice.

In this study, in order to know the distribution, we propose to utilize partition entropy given by fuzzy clustering. If the entropy is very high, search points are often uniformly distributed. If the entropy is low, search points are distributed with a bias. Thus, when the entropy is low, algorithm parameters can be controlled to make the directional search. It is thought that this idea can be applicable to other EAs than DE.

Also, we propose to use a species-best strategy [4] for improving the efficiency and the robustness of DE. In DE, a mutant vector is generated for each parent by using a base vector and one or more difference vectors which are the difference between two individuals. The parent and the mutant vector are recombined by a crossover operation to generate a child, or a trial vector. There are some strategies for selecting the base vector: The best individual is used as the base vector in the best strategy and a randomly selected individual is used in the rand strategy. In the species-best strategy, a population is divided into several species by speciation, and the seed of the species to which the parent belongs is selected as the base vector. It is thought that the efficiency of the species-best strategy is better than the rand strategy and the robustness of the species-best strategy is better than the best strategy. Thus, it is expected that the strategy improves the efficiency and the robustness of the search.

The effect of the proposed method is shown by solving 13 benchmark problems including multimodal problems and problems with strong dependence.

In Section II, some studies on DE using fuzzy set theory or speciation are briefly reviewed. Fuzzy clustering and par-

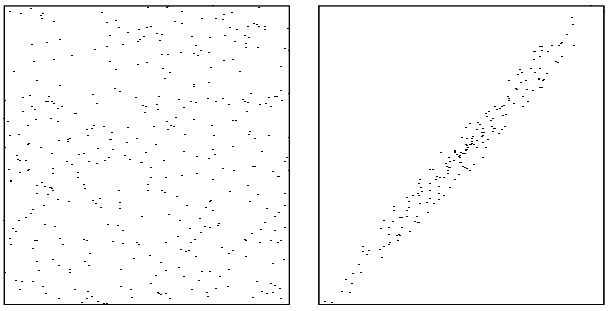

Fig. 1. Uniform Search (left) and Directional Search (right)

tition entropy are explained in Section III. DE and DE with speciation using fuzzy clustering are described in Section IV and V, respectively. In Section VI, experimental results on some problems are shown. Finally, conclusions are described in Section VII.

II. Previous Works

In this section, the optimization problem in this study is defined and some studies on DE using fuzzy set theory or speciation are described.

A. Optimization Problems

In this study, the following optimization problem with lower bound and upper bound constraints will be discussed.

$$\begin{array}{ll} \text{minimize} & f(\boldsymbol{x}) \\ \text{subject to} & l_i \leq x_i \leq u_i,\ i = 1, \ldots, D, \end{array} \tag{1}$$

where $\boldsymbol{x} = (x_1, x_2, \cdots, x_D)$ is a D dimensional vector and $f(\boldsymbol{x})$ is an objective function. The function f is a nonlinear real-valued function. Values l_i and u_i are the lower bound and the upper bound of x_i, respectively. Let the search space in which every point satisfies the lower and upper bound constraints be denoted by $\mathcal{S}$.

B. Fuzzy Set Theory

There exist some studies on optimization by DE using fuzzy set theory.

- Fuzzy logic: Fuzzy logic is used to control the parameters of DE. The fuzzy adaptive differential evolution (FADE) [5] is proposed to control parameters for a mutation operation and a crossover operation. In each generation, the movement of individuals (vectors) and the change of function values over the whole population between the last two generations were nonlinearly depressed and used as the inputs for fuzzy logic controllers.
- Fuzzy clustering: The hybrid DE based on fuzzy c-means clustering (FCDE) [6] is proposed, which uses the one-step fuzzy c-means clustering. The clustering acts as a multi-parent crossover operation to utilize the information of a population efficiently. In [7], fuzzy clustering is used to divide a population into several clusters or niches, which are a kind of species described below, for multimodal optimization.

C. Speciation

Speciation is mainly used for multimodal optimization where multiple optimal or suboptimal solutions are obtained simultaneously in one run. Each species evolves to find an optimal or suboptimal solution. There exist some types of research using speciation in DE [8].

- Radius-based speciation: In this category, a population is sorted in increasing objective value order, first. Then, the best individual in the sorted population becomes a new species seed. The population members that exist within the specified radius from the seed are assigned to the species, and the members are deleted from the population. This process is repeated until the population becomes empty [4], [9], [10].
- Clustering-based speciation
  A population is divided into several clusters using a clustering algorithm such as k-means clustering [11] or fuzzy c-means clustering [7]. Each cluster corresponds to a species. If the seed of a species is necessary, an individual that has the best objective value in the species is selected as the seed.

In this study, the clustering-based speciation using fuzzy c-means clustering is used not to multimodal optimization but to usual optimization for finding one optimal solution and improving the efficiency of DE using the species-best strategy. Also, as a quite new approach, the partition entropy obtained by the clustering is used to control the parameter for crossover operation of DE.

III. Fuzzy C-Means Clustering and Entropy

In this section, fuzzy c-means clustering and partition entropy are briefly explained [7], [12].

A. Fuzzy Partition and Partition Entropy

Fuzzy partition allows a data point to belong to two or more clusters. Let $X = \{\boldsymbol{x}_1, \boldsymbol{x}_2, \cdots, \boldsymbol{x}_N\}$ be a set of N data points. A fuzzy partition of X into C clusters can be defined with a matrix $U = \{\mu_{ij}\}, 1 \leq i \leq N, 1 \leq j \leq C$, which satisfies the following conditions:

$$\mu_{ij} \in [0, 1] \tag{2}$$

$$\sum_{j=1}^{C} \mu_{ij} = 1,\ 1 \leq i \leq N \tag{3}$$

$$0 < \sum_{i=1}^{N} \mu_{ij} < N,\ 1 \leq j \leq C \tag{4}$$

where μ_{ij} is the degree of membership of the i-th data $\boldsymbol{x}_i$ in the j-th cluster. The higher μ_{ij} indicates that the i-th data belongs to the j-th cluster more strongly.

Some evaluation criteria for the fuzzy partition are proposed such as partition entropy and so on. The normalized partition entropy is defined as follows:

$$PE(C) = -\frac{1}{N \log_2 C} \sum_{i=1}^{N} \sum_{j=1}^{C} \mu_{ij} \log_2 \mu_{ij} \tag{5}$$

where $0 \leq PE(C) \leq 1$. The minimum value 0 corresponds to a hard partition, where each data point $\boldsymbol{x}_i$ belongs to only a cluster c_i:

$$\mu_{ij} = \begin{cases} 1 & j = c_i \\ 0 & j \neq c_i \end{cases}, 1 \leq i \leq N \tag{6}$$

The maximum value 1 corresponds to the fuzziest partition, where each data point belongs to all clusters equivalently:

$$\mu_{ij} = \frac{1}{C},\ 1 \leq i \leq N, 1 \leq j \leq C \tag{7}$$

In this study, the entropy is used to detect the distribution of search points and alter the mode of the search by DE.

B. Fuzzy C-Means Clustering

Fuzzy C-Means (FCM) is a clustering method which realizes the fuzzy partition. This method is frequently used in pattern recognition. The FCM algorithm minimizes the following function:

$$J_m(U,V) = \sum_{i=1}^{N}\sum_{j=1}^{C}(\mu_{ij})^m ||\boldsymbol{x}_i - \boldsymbol{v}_j||^2,\ 1 \le m < \infty \quad (8)$$

where m is a real number parameter specifying degree of fuzziness, $\boldsymbol{v}_j$ is the center of the j-th cluster, $V = \{\boldsymbol{v}_1, \boldsymbol{v}_2, \cdots, \boldsymbol{v}_C\}$ is a set of the cluster centers, and $||\cdot||$ represents any norm expressing the distance between a data point and the cluster center.

The FCM algorithm is as follows:

1) Assign membership values μ_{ij} of all data in all clusters randomly.
2) Update cluster centers.

$$\boldsymbol{v}_j = \frac{\sum_{i=1}^{N}(\mu_{ij})^m x_i}{\sum_{i=1}^{N}(\mu_{ij})^m} \quad (9)$$

3) Update membership degrees.

$$\mu_{ij} = \frac{1}{\sum_{k=1}^{C}\left(\frac{||\boldsymbol{x}_i - \boldsymbol{v}_j||^2}{||\boldsymbol{x}_i - \boldsymbol{v}_k||^2}\right)^{\frac{1}{m-1}}} \quad (10)$$

4) The algorithm is terminated, when the following condition is satisfied, or the change of membership degrees between two iterations is no more than ε, the given sensitivity threshold.

$$\sum_{i=1}^{N}\sum_{j=1}^{C}(\mu_{ij}^m(t) - \mu_{ij}^m(t-1))^2 \le \varepsilon \quad (11)$$

where $\mu_{ij}^m(t)$ and $\mu_{ij}^m(t-1)$ are the value at the current iteration and that at the previous iteration, respectively.
5) Go back to 2).

This algorithm minimizes intra-cluster variance, but the minimum is a local minimum and the results depend on the initial choice of membership degrees.

IV. Differential Evolution

In this section, the outline of DE is described.

A. Outline of Differential Evolution

In DE, initial individuals are randomly generated within the given search space and form an initial population. Each individual contains D genes as decision variables. At each generation or iteration, all individuals are selected as parents. Each parent is processed as follows: The mutation operation begins by choosing several individuals from the population except for the parent in the processing. The first individual is a base vector. All subsequent individuals are paired to create difference vectors. The difference vectors are scaled by a scaling factor F and added to the base vector. The resulting vector, or a mutant vector, is then recombined with the parent. The probability of recombination at an element is controlled by a crossover rate CR. This crossover operation produces a trial vector. Finally, for survivor selection, the trial vector is accepted for the next generation if the trial vector is better than the parent.

There are some variants of DE that have been proposed. The variants are classified using the notation DE/$base$/num/$cross$ such as DE/rand/1/bin and DE/rand/1/exp.

"$base$" specifies a way of selecting an individual that will form the base vector. For example, DE/rand selects an individual for the base vector at random from the population. DE/best selects the best individual in the population.

"num" specifies the number of difference vectors used to perturb the base vector. In case of DE/rand/1, for example, for each parent $\boldsymbol{x}^i$, three individuals $\boldsymbol{x}^{p1}$, $\boldsymbol{x}^{p2}$ and $\boldsymbol{x}^{p3}$ are chosen randomly from the population without overlapping $\boldsymbol{x}^i$ and each other. A new vector, or a mutant vector $\boldsymbol{x}'$ is generated by the base vector $\boldsymbol{x}^{p1}$ and the difference vector $\boldsymbol{x}^{p2} - \boldsymbol{x}^{p3}$, where F is the scaling factor.

$$\boldsymbol{x}' = \boldsymbol{x}^{p1} + F(\boldsymbol{x}^{p2} - \boldsymbol{x}^{p3}) \quad (12)$$

"$cross$" specifies the type of crossover that is used to create a child. For example, 'bin' indicates that the crossover is controlled by the binomial crossover using a constant crossover rate, and 'exp' indicates that the crossover is controlled by a kind of two-point crossover using exponentially decreasing the crossover rate. Fig. 2 shows the binomial and exponential crossover. A new child $\boldsymbol{x}^{\text{child}}$ is generated from the parent $\boldsymbol{x}^i$ and the mutant vector $\boldsymbol{x}'$, where CR is a crossover rate.

```
binomial crossover DE/·/·/bin
  j_rand=randint(1,D);
  for(k=1; k≤D; k++) {
    if(k == j_rand || u(0,1) < CR) x_k^child=x'_k;
    else x_k^child=x_k^i;
  }
exponential crossover DE/·/·/exp
  k=1; j=randint(1,D);
  do {
      x_j^child=x'_j;
      k=k+1; j=(j+1)%D;
  } while(k ≤ D && u(0,1) < CR);
  while(k ≤ D) {
      x_j^child=x_j^i;
      k=k+1; j=(j+1)%D;
  }
```

Fig. 2. Binomial and exponential crossover operation, where randint(1,D) generates an integer randomly from $[1, D]$ and $u(l, r)$ is a uniform random number generator in $[l, r]$.

B. The Algorithm of Differential Evolution

The algorithm of DE is as follows:

Step1 Initialization of a population. Initial N individuals $P = \{\boldsymbol{x}^i, i = 1, 2, \cdots, N\}$ are generated randomly in the search space and form an initial population.

Step2 Termination condition. If the number of function evaluations exceeds the maximum number of evaluation $FE_{\max}$, the algorithm is terminated.

Step3 DE operations. Each individual $\boldsymbol{x}^i$ is selected as a parent. If all individuals are selected, go to Step4. A mutant vector $\boldsymbol{x}'$ is generated according to Eq. (12). A trial vector (child) is generated from the parent $\boldsymbol{x}^i$ and the mutant vector $\boldsymbol{x}'$ using a crossover operation shown in Fig. 2. If the child is better than or equal to the parent, or the DE operation is succeeded, the child survives. Otherwise the parent survives. Go back to Step3 and the next individual is selected as a parent.

Step4 Survivor selection (generation change). The population is organized by the survivors. Go back to Step2.

Fig. 3 shows a pseudo-code of DE/rand/1.

```
DE/rand/1()
{
// Initialize a population
 P=N individuals generated randomly in S;
 for(t=1; FE ≤ FE_max; t++) {
  for(i=1; i ≤ N; i++) {
// DE operations
     x^p1=Randomly selected from P(p1 ≠ i);
     x^p2=Randomly selected from P(p2 ∉ {i,p1});
     x^p3=Randomly selected from P(p3 ∉ {i,p1,p2});
     x'=x^p1+F(x^p2 − x^p3);
     x^child=trial vector is generated from
           x^i and x' by the crossover operation;
// Survivor selection
     if(f(x^child) ≤ f(x^i))  z^i=x^child;
     else                     z^i=x^i;
     FE=FE+1;
  }
  P={z^i,  i = 1,2,···,N};
 }
}
```

Fig. 3. The pseudo-code of DE, FE is the number of function evaluations.

V. DE with Speciation using Fuzzy Clustering

In this section, DE with speciation using fuzzy clustering (DESFC) is proposed.

A. Species-Best Strategy

The following steps are executed in each generation to realize the species-best strategy.

1) FCM is applied to a population $P = \{\boldsymbol{x}^1, \boldsymbol{x}^2, \cdots, \boldsymbol{x}^N\}$ where N is the population size. The membership grade of the i-th individual $\boldsymbol{x}^i$ in the j-th cluster, μ_{ij}, $1 \leq i \leq N$, $1 \leq j \leq C$ is obtained where C is the number of clusters.
2) Each cluster j corresponds to one species. The i-th individual is assigned to the cluster or the species S_i where μ_{ij} has the maximum value.

$$S_i = \arg \max_{1 \leq j \leq C} \mu_{ij},\ 1 \leq i \leq N \tag{13}$$

3) The seed of j-th species, $seed_j$ is the best individual in the species.

$$seed_j = \arg \min_{\{i | S_i = j\}} f(\boldsymbol{x}^i),\ 1 \leq j \leq C \tag{14}$$

Thus, the seed for the i-th individual can be obtained as $seed_{S_i}$.

The species-best strategy to $\boldsymbol{x}^i$ can be described as follows:

$$\boldsymbol{x}' = \boldsymbol{x}^{seed_{S_i}} + F(\boldsymbol{x}^{p2} - \boldsymbol{x}^{p3}) \tag{15}$$

where $p2$ and $p3$ are random integers in $[1, N]$ and i, $p2$ and $p3$ are different with each other.

B. Algorithm of DESFC

Fig. 4 shows the pseudo-code of DESFC. Some modifications to standard DE are applied for proposed method as follows:

1) The partition entropy $PE(C)$ for $\{\mu_{ij}\}$ is calculated in each generation. If the entropy is low, or $PE(C) < 0.99$, a directional search is desirable. In this study, the crossover rate is set to 0.95 or 0.1 with equal probability using the binomial crossover to search for an area near the parent or the mutant vector. In order to improve the robustness, the species-best strategy and the rand strategy are adopted probabilistically.
2) Continuous generation model [13], [14] is adopted. Usually discrete generation model is adopted in DE and when the child is better than the parent, the child survives in the next generation. In this study, when the child is better than the parent, the parent is immediately replaced by the child. It is thought that the continuous generation model improves efficiency because the model can use newer information than the discrete model.
3) Reflecting back out-of-bound solutions [15] is adopted. In order to keep bound constraints, an operation to move a point outside of the search space $\mathcal{S}$ into the inside of $\mathcal{S}$ is required. There are some ways to realize the movement: generating solutions again, cutting off the solutions on the boundary, and reflecting points back to the inside of the boundary [16]. In this study, reflecting back is used:

$$x_{ij} = \begin{cases} l_i + (l_i - x_{ij}) - \left\lfloor \frac{l_i - x_{ij}}{u_i - l_i} \right\rfloor (u_i - l_i) & (x_{ij} < l_i) \\ u_i - (x_{ij} - u_i) + \left\lfloor \frac{x_{ij} - u_i}{u_i - l_i} \right\rfloor (u_i - l_i) & (x_{ij} > u_i) \\ x_{ij} & (\text{otherwise}) \end{cases} \tag{16}$$

where $\lfloor z \rfloor$ is the maximum integer smaller than or equal to z. This operation is applied when a new point is generated by DE operations.

VI. Solving Optimization Problems

In this paper, well-known thirteen benchmark problems are solved.

A. Test Problems and Experimental Conditions

The 13 scalable benchmark functions are shown in Table I [17]. All functions have an optimal value 0. Some characteristics are briefly summarized as follows: Functions f_1 to f_4 are continuous unimodal functions. The function f_5 is Rosenbrock function which is unimodal for 2- and 3-dimensions but may have multiple minima in high dimension cases [18]. The

```
DESFC()
{
// Initialize a population
 P=N individuals generated randomly in S;
 for(t=1; FE ≤ FE_max; t++) {
// Speciation using FCM
   {μ_ij}=Fuzzy c-means clustering of P;
   for(i=1; i ≤ N; i++)
     S_i=arg max_{1≤j≤C} μ_ij;
   for(j=1; i ≤ C; j++)
     seed_j=arg min_{i|S_i=j} f(x^i);
// Judge distribution of search points
   PE=partition entropy of {μ_ij};
   if(PE ≥ 0.99) isUniform=TRUE;
   else          isUniform=FALSE;

   for(i=1; i ≤ N; i++) {
     CR=CR_0; Select exponential crossover;
     if(i! = seed_{s_i} && u(0,1) < 0.6) {
       if(isUniform==FALSE) {
         if(u(0,1) < 0.5) CR=0.95;
         else             CR=0.1;
         Select binomial crossover;
       }
// DE/species-best/1/{bin,exp}
       p_1=seed_{S_i};
     }
     else
// DE/rand/1/exp
     x^{p_1}=Randomly selected from P(p_1 ≠ i);
     x^{p_2}=Randomly selected from P(p_2 ∉ {i,p_1});
     x^{p_3}=Randomly selected from P(p_3 ∉ {i,p_1,p_2});
     x'=x^{p_1}+F(x^{p_2} − x^{p_3});
     x^c=trial vector is generated from
               x^i and x' by the selected crossover;
     FE=FE+1;
// Survivor selection
     if(f(x^c) ≤ f(x^i))
       x^i=x^c;
   }
 }
}
```

Fig. 4. The pseudo-code of DESFC where CR_0 is an initial crossover rate.

function f_6 is a discontinuous step function, and f_7 is a noisy quartic function. Functions f_8 to f_{13} are multimodal functions and the number of their local minima increases exponentially with the problem dimension [19].

Independent 30 runs are performed for the 13 problems. The dimension of problems is 40 (D=40). Each run stops when a near optimal solution, which has equivalent objective value to the optimal solution, is found. In this study, when the difference between the best objective value and the optimal value becomes less than 10^{-7}, the run stops. In f_7, it is difficult to find the good objective value, because a random noise is added. It is assumed that the optimal value of f_7 is 10^{-2} in this experiment.

The efficiency of two algorithms DE/rand (continuous generation model) and DESFC are compared where the number of clusters C is changed from 2 to 5 in DESFC. The degree of fuzziness m is fixed to 2. The parameters are: $F = 0.7$, $CR = 0.9$ and the exponential crossover is adopted as usual crossover, because these settings showed very good and stable performance [21]. The population size is twice of the dimension size, $N = 2D = 80$. The number of function evaluations (FEs) until finding a near optimal solution is compared. If the number of FEs exceeds 2,000,000, the run is terminated and regarded as a failure run.

DESFC can solve all problems in all runs successfully. DESFC outperformed the standard DE in all problems and in all settings of C. The value $C = 2$ showed the best results. DESFC with $C = 2$ can solve the problems f_3 and f_4 within 60% FEs compared with the standard DE, solve the problems f_7 and f_{11} in about 70% FEs, and solve the other problems in about 75% FEs except for f_9 in about 80% FEs.

It is shown that the proposed method can solve 4 problems very fast and 9 problems fast. Thus, it is thought that the method is effective to various problems.

To determine the significance of the proposed method, statistical analysis was performed using one-sided Welch's t-test for the mean FEs of the standard DE and that of DESFC with C being 1, 2, 3, 4 and 5. It is thought that the proposed method is significantly better than the standard DE because p-values in all parameter settings and all functions are less than 0.001.

Figures 5 to 17 show the change of best objective value found over the number of FEs within 200,000 evaluations. Apparently, the proposed method can find better objective values faster than the standard DE in all problems.

VII. CONCLUSION

Differential evolution is known as a simple, efficient and robust search algorithm that can solve nonlinear optimization problems. In this study, we proposed the DE with speciation using fuzzy clustering and partition entropy to improve the efficiency and also robustness of DE. Especially, it is a quite new approach to detect the distribution of search points using FCM and to control an algorithm parameter. It was shown that DESFC can reduce the number of function evaluations for

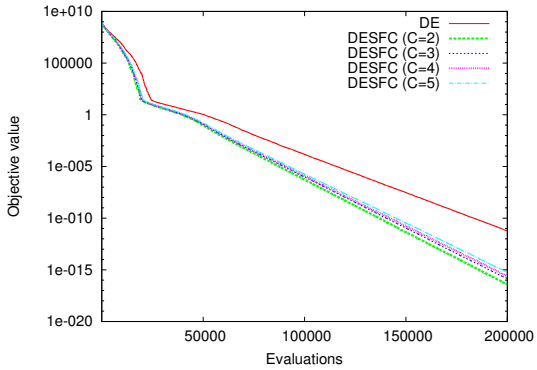

Fig. 16. The graph of f_{12}

finding near optimal solutions more than 25% in 11 problems out of the 13 problems. Thus, it is thought that DESFC is a very efficient optimization algorithm compared with standard DEs.

The effect of the degree of fuzziness m is not studied in this paper. It is thought that a proper value of the degree enhances the ability to discriminate a biased distribution from the uniform distribution. We plan to analyze the effect of the degree.

***Abstract*—This paper investigates the stability of the interval type-2 (IT2) fuzzy-model-based (FMB) control systems. An IT2 T-S fuzzy model is developed to represent the nonlinear plant subject to parameter uncertainties, which are captured by the lower and upper membership functions. An IT2 fuzzy model is then be proposed to close the feedback loop. It is not required that the IT2 fuzzy controller shares the same premise membership functions or the same number of fuzzy rules as those of the IT2 T-S fuzzy model. Consequently, it offers a greater design flexibility to the IT2 fuzzy controllers. However, the mismatched premise membership functions are not favourable to the development of stability conditions and thus leads to a conservative stability analysis result. In this paper, with the consideration of the lower and upper membership functions, which carry the information of the nonlinearities and parameter uncertainties of the nonlinear plant, the stability of the IT2 FMB control systems is investigated based on the Lyapunov stability theory. Stability conditions in terms of linear matrix inequalities are developed to guarantee the stability of the IT2 FMB control systems and synthesize the IT2 fuzzy controller. A simulation example is given to demonstrates the effectiveness of the proposed approach.**

I. Introduction

Type-1 fuzzy-model-based (FMB) control [1] is a promising control approach for complex and ill-defined nonlinear plants, represented by the type-1 Takagi-Sugeno (T-S) fuzzy model [2], [3]. Based on the Lyapunov stability theory, a set of stability conditions in the form of linear matrix inequalities (LMIs) [4], [5] was obtained to guarantee the system stability. The work in [4], [5] provides the basic stability analysis procedure for the type-1 FMB control systems. More relaxed LMI-based stability conditions were obtained in [7]–[12]. Further relaxed stability conditions were obtained in [13]–[20] by considering the information of the type-1 membership functions.

In general, for the type-1 T-S FMB control system under the parallel distributed compensation (PDC) design [4], [5], the fuzzy controller needs to share the same premise membership function as those of the T-S fuzzy model. When the nonlinear plant is subject to parameter uncertainties, the membership functions of the T-S fuzzy model will contain the uncertain parameters and lead to the grades of membership uncertain in value. Consequently, the advantage of the PDC design given to the stability analysis will be vanished.

Type-2 fuzzy sets [21]–[24] have been shown that it is superior to the type-1 ones on dealing with uncertainties. With the lower and upper membership functions, the uncertainties can be captured and the information of the uncertainties is embedded in the footprint of uncertainty (FOU) [21]. In recent years, some properties and theories of type-2 fuzzy sets have been developed to theoretically support the design and implementation of type-2 fuzzy logic systems. However, it is mainly for general type-2 fuzzy logic systems but not mainly for the purposes of fuzzy control. In type-1 FMB control approach, the type-1 T-S fuzzy model [2], [3] plays an important role representing the dynamics of the nonlinear plant to facilitate the stability analysis and control synthesis. A basic interval type-2 (IT2) T-S fuzzy model was proposed in [25] for a limited class of nonlinear plants. We extended the idea and proposed a more general IT2 T-S fuzzy model [26] for a wider class of nonlinear plants to support the analysis and development of IT2 FMB control systems. A preliminary stability analysis result was reported in [26] for an IT2 FMB control systems under perfect premise matching that the IT2 T-S fuzzy model and IT2 fuzzy controller share the same lower and upper membership functions (which implies the same number of fuzzy rules). A set of LMI-based stability conditions was obtained to guarantee the system stability.

In this paper, we investigate the stability of IT2 FMB control systems under imperfect premises matching. As it is not requited that the IT2 T-S fuzzy model and IT2 fuzzy controller share the same lower and upper membership functions, and the same number of fuzzy rules, it enhances the design flexibility of the IT2 fuzzy controller and is able to lower the controller complexity by using a smaller number of fuzzy rules and simple membership functions. However, it makes the stability analysis more difficulty and leads to more conservative stability conditions. To facilitate the stability analysis of IT2 FMB control system, an IT2 T-S fuzzy model [26] is employed to represent the nonlinear plant subject to parameter uncertainties, captured by the lower and upper membership functions. An IT2 fuzzy controller with different lower and upper membership functions is employed to close the feedback loop. We propose a favourable form to represent the lower and upper membership functions for the stability analysis and LMI-based stability conditions are obtained to guarantee the system stability and

synthesize the IT2 fuzzy controller.

The organization of this paper is as follows. In Section II, the IT2 fuzzy model representing the nonlinear plant subject to parameter uncertainties, IT2 fuzzy controller and IT2 FMB control systems are presented. In Section III, LMI-based stability conditions are derived based on the Lyapunov stability theory for the IT2 FMB control systems. In Section IV, a simulation example is given to illustrate the merits of the proposed IT2 FMB control scheme. In Section V, a conclusion is drawn.

II. IT2 TS Fuzzy Model, IT2 Fuzzy Controller and IT2 FMB Control System

An IT2 FMB control system is referred to a closed-loop system consisting of the IT2 T-S fuzzy model [25], [26] and the IT2 fuzzy controller connected in a closed loop.

A. IT2 T-S Fuzzy Model

Consider an IT2 T-S fuzzy model [25], [26] with p rules of the following format of which the antecedent of each rule contains some IT2 fuzzy sets and the consequent is a linear dynamical system.

$$\begin{aligned}\text{Rule } i\text{: IF } f_1(\mathbf{x}(t)) \text{ is } \tilde{M}_1^i \text{ AND } \cdots \text{ AND } f_\Psi(\mathbf{x}(t)) \text{ is } \tilde{M}_\Psi^i \\ \text{THEN } \dot{\mathbf{x}}(t) = \mathbf{A}_i\mathbf{x}(t) + \mathbf{B}_i\mathbf{u}(t)\end{aligned} \tag{1}$$

where $\tilde{M}_\alpha^i$ is an IT2 fuzzy set of rule i corresponding to the function $f_\alpha(\mathbf{x}(t))$, α = 1, 2, $\cdots$, Ψ; i = 1, 2, $\cdots$, p; Ψ is a positive integer; $\mathbf{x}(t) \in \Re^n$ is the system state vector; $\mathbf{A}_i \in \Re^{n\times n}$ and $\mathbf{B}_i \in \Re^{n\times m}$ are the known system and input matrices, respectively; $\mathbf{u}(t) \in \Re^m$ is the input vector. The firing strength of the i-th rule is the following interval sets.

$$W_i(\mathbf{x}(t)) = \left[\ \underline{w}_i(\mathbf{x}(t)),\quad \overline{w}_i(\mathbf{x}(t))\ \right], i = 1, 2, \cdots, p \tag{2}$$

where

$$\underline{w}_i(\mathbf{x}(t)) = \prod_{\alpha=1}^{\Psi} \underline{\mu}_{\tilde{M}_\alpha^i}(f_\alpha(\mathbf{x}(t))) \geq 0, \tag{3}$$

$$\overline{w}_i(\mathbf{x}(t)) = \prod_{\alpha=1}^{\Psi} \overline{\mu}_{\tilde{M}_\alpha^i}(f_\alpha(\mathbf{x}(t))) \geq 0, \tag{4}$$

in which $\underline{w}_i(\mathbf{x}(t))$ and $\overline{w}_i(\mathbf{x}(t))$ denote the lower and upper grades of membership, respectively; $\underline{\mu}_{\tilde{M}_\alpha^i}(f_\alpha(\mathbf{x}(t))) \geq 0$ and $\overline{\mu}_{\tilde{M}_\alpha^i}(f_\alpha(\mathbf{x}(t))) \geq 0$ denote the lower and upper membership functions, respectively. It exhibits the property that $\overline{\mu}_{\tilde{M}_\alpha^i}(f_\alpha(\mathbf{x}(t))) \geq \underline{\mu}_{\tilde{M}_\alpha^i}(f_\alpha(\mathbf{x}(t)))$ leading to $\overline{w}_i(\mathbf{x}(t)) \geq \underline{w}_i(\mathbf{x}(t))$ for all i. The inferred IT2 T-S fuzzy model [26] is defined as follows.

$$\dot{\mathbf{x}}(t) = \sum_{i=1}^{p} \tilde{w}_i(\mathbf{x}(t))(\mathbf{A}_i\mathbf{x}(t) + \mathbf{B}_i\mathbf{u}(t)) \tag{5}$$

where

$$\tilde{w}_i(\mathbf{x}(t)) = \underline{\alpha}_i(\mathbf{x}(t))\underline{w}_i(\mathbf{x}(t)) + \overline{\alpha}_i(\mathbf{x}(t))\overline{w}_i(\mathbf{x}(t)) \geq 0\ \forall\ i, \tag{6}$$

$$\sum_{i=1}^{p} \tilde{w}_i(\mathbf{x}(t)) = 1, \tag{7}$$

in which $0 \leq \underline{\alpha}_i(\mathbf{x}(t)) \leq 1$ and $0 \leq \overline{\alpha}_i(\mathbf{x}(t)) \leq 1$ are nonlinear functions and exhibit the property of $\underline{\alpha}_i(\mathbf{x}(t)) + \overline{\alpha}_i(\mathbf{x}(t)) = 1$ for all i.

B. IT2 Fuzzy Controller

An IT2 fuzzy controller with c rules of the following format is proposed to stabilize the nonlinear plant represented by the IT2 T-S fuzzy model (5).

$$\begin{aligned}\text{Rule } j\text{: IF } g_1(\mathbf{x}(t)) \text{ is } \tilde{N}_1^j \text{ AND } \cdots \text{ AND } g_\Omega(\mathbf{x}(t)) \text{ is } \tilde{N}_\Omega^j \\ \text{THEN } \mathbf{u}(t) = \mathbf{G}_j\mathbf{x}(t)\end{aligned} \tag{8}$$

where $\tilde{N}_\beta^j$ is an IT2 fuzzy set of rule j corresponding to the function $g_\beta(\mathbf{x}(t))$, β = 1, 2, $\cdots$, Ω; j = 1, 2, $\cdots$, c; Ω is a positive integer; $\mathbf{G}_j \in \Re^{m\times n}$, j = 1, 2, $\cdots$, c, are the constant feedback gains to be determined. The firing strength of the j-th rule is the following interval sets.

$$M_j(\mathbf{x}(t)) = \left[\ \underline{m}_j(\mathbf{x}(t)),\quad \overline{m}_j(\mathbf{x}(t))\ \right], j = 1, 2, \cdots, c \tag{9}$$

where

$$\underline{m}_j(\mathbf{x}(t)) = \prod_{\beta=1}^{\Omega} \underline{\mu}_{\tilde{N}_\beta^j}(g_\beta(\mathbf{x}(t))) \geq 0, \tag{10}$$

$$\overline{m}_j(\mathbf{x}(t)) = \prod_{\beta=1}^{\Omega} \overline{\mu}_{\tilde{N}_\beta^j}(g_\beta(\mathbf{x}(t))) \geq 0, \tag{11}$$

in which $\underline{m}_j(\mathbf{x}(t))$ and $\overline{m}_j(\mathbf{x}(t))$ denote the lower and upper grades of membership, respectively; $\underline{\mu}_{\tilde{N}_\beta^j}(g_\beta(\mathbf{x}(t))) \geq 0$ and $\overline{\mu}_{\tilde{N}_\beta^j}(g_\beta(\mathbf{x}(t))) \geq 0$ denote the lower and upper membership functions, respectively. It exhibits the property that $\underline{\mu}_{\tilde{N}_\beta^j}(g_\beta(\mathbf{x}(t))) \geq \overline{\mu}_{\tilde{N}_\beta^j}(g_\beta(\mathbf{x}(t)))$ leading to $\overline{m}_j(\mathbf{x}(t)) \geq \underline{m}_j(\mathbf{x}(t))$ for all j. The inferred IT2 fuzzy controller is defined as follows.

$$\mathbf{u}(t) = \sum_{j=1}^{c} \tilde{m}_j(\mathbf{x}(t))\mathbf{G}_j\mathbf{x}(t) \tag{12}$$

where

$$\begin{aligned}&\tilde{m}_j(\mathbf{x}(t)) \\ &= \frac{\underline{\beta}_j(\mathbf{x}(t))\underline{m}_j(\mathbf{x}(t)) + \overline{\beta}_j(\mathbf{x}(t))\overline{m}_j(\mathbf{x}(t))}{\sum_{k=1}^{c}\left(\underline{\beta}_k(\mathbf{x}(t))\underline{m}_k(\mathbf{x}(t)) + \overline{\beta}_k(\mathbf{x}(t))\overline{m}_k(\mathbf{x}(t))\right)} \geq 0\ \forall\ j,\end{aligned} \tag{13}$$

$$\sum_{j=1}^{c} \tilde{m}_i(\mathbf{x}(t)) = 1, \tag{14}$$

in which $0 \leq \underline{\beta}_j(\mathbf{x}(t)) \leq 1$ and $0 \leq \overline{\beta}_j(\mathbf{x}(t)) \leq 1$ are predefined functions and exhibit the property of $\underline{\beta}_j(\mathbf{x}(t)) + \overline{\beta}_j(\mathbf{x}(t)) = 1$ for all j.

C. IT2 FMB Control Systems

An IT2 FMB control system is formed by connecting the IT2 T-S fuzzy model (5) and the IT2 fuzzy controller (12) in a closed loop. From (5) and (12), considering the property of $\sum_{i=1}^{p}\tilde{w}_i(\mathbf{x}(t)) = \sum_{j=1}^{c}\tilde{m}_j(\mathbf{x}(t)) = \sum_{i=1}^{p}\sum_{j=1}^{c}\tilde{w}_i(\mathbf{x}(t))\tilde{m}_j(\mathbf{x}(t)) = 1$, we have,

$$\begin{aligned}\dot{\mathbf{x}}(t) &= \sum_{i=1}^{p}\tilde{w}_i(\mathbf{x}(t))(\mathbf{A}_i\mathbf{x}(t) + \mathbf{B}_i\sum_{j=1}^{c}\tilde{m}_j(\mathbf{x}(t))\mathbf{G}_j\mathbf{x}(t)) \\ &= \sum_{i=1}^{p}\sum_{j=1}^{c}\tilde{w}_i(\mathbf{x}(t))\tilde{m}_j(\mathbf{x}(t))(\mathbf{A}_i + \mathbf{B}_i\mathbf{G}_j)\mathbf{x}(t). \quad (15)\end{aligned}$$

The control objective is to determine the feedback gains, $\mathbf{G}_j$, such that the IT2 fuzzy controller (12) is able to drive the system states towards the origin, i.e., $\mathbf{x}(t) \to \mathbf{0}$ as time $t \to \infty$.

The stability of the FMB based control system in the form of (15) was investigated in [4] and guaranteed to be asymptotically stable if the LMI-based stability conditions in the following theorem are satisfied.

Theorem 1: [4] The FMB control system in the form of (15) is guaranteed to be asymptotically stable if there exist matrices $\mathbf{N}_j \in \Re^{m\times n}$, $j = 1, 2, \cdots, c$, $\mathbf{X} = \mathbf{X}^T \in \Re^{n\times n}$ such that the following LMIs are satisfied.

$$\mathbf{X} > 0;$$
$$\mathbf{Q}_{ij} = \mathbf{A}_i\mathbf{X} + \mathbf{X}\mathbf{A}_i^T + \mathbf{B}_i\mathbf{N}_j + \mathbf{N}_j^T\mathbf{B}_i^T < 0 \;\forall\, i, j,$$

where the feedback gains are defined as $\mathbf{G}_j = \mathbf{N}_j\mathbf{X}^{-1}$ for all j.

However, without considering the information of the membership functions in the development of the stability conditions in Theorem 1 are very conservative. It can be seen from Theorem 1 that employing different feedback gains does not relax the stability conditions (or make the stability conditions to be satisfied easier). The stability conditions can be reduced to $\mathbf{Q}_{ij} = \mathbf{A}_i\mathbf{X}_j + \mathbf{X}_j\mathbf{A}_i^T + \mathbf{B}_i\mathbf{N} + \mathbf{N}^T\mathbf{B}_i^T < 0$ for all i by choosing a common feedback gain, i.e., $\mathbf{N} = \mathbf{N}_j$ for all j. Consequently, the fuzzy controller becomes a linear controller.

In this paper, the IT2 fuzzy control concept is employed to investigate the stability of the IT2 FMB control system (15). In order to facilitate the stability analysis, the state space of interest denoted as Φ is divided into q connected sub-state spaces denoted as Φ_k, $k = 1, 2, \cdots, q$ such that $\Phi = \bigcup_{k=1}^{q}\Phi_k$. We express the IT2 FMB control system (15) in the following favourable form.

$$\dot{\mathbf{x}}(t) = \sum_{i=1}^{p}\sum_{j=1}^{c}\tilde{h}_{ij}(\mathbf{x}(t))(\mathbf{A}_i + \mathbf{B}_i\mathbf{G}_j)\mathbf{x}(t) \quad (16)$$

where

$$\begin{aligned}&\tilde{h}_{ij}(\mathbf{x}(t)) \equiv \tilde{w}_i(\mathbf{x}(t))\tilde{m}_j(\mathbf{x}(t)) \\ &= \underline{\gamma}_{ij}(\mathbf{x}(t))\underline{h}_{ij}(\mathbf{x}(t)) + \overline{\gamma}_{ij}(\mathbf{x}(t))\overline{h}_{ij}(\mathbf{x}(t)) \geq 0 \;\forall\, i, j; \quad (17)\end{aligned}$$

$$\sum_{i=1}^{p}\sum_{j=1}^{c}\tilde{h}_{ij}(\mathbf{x}(t)) = 1, \quad (18)$$

where $0 \leq \underline{\gamma}_{ij}(\mathbf{x}(t)) \leq 1$ and $0 \leq \overline{\gamma}_{ij}(\mathbf{x}(t)) \leq 1$ are two functions, which are not necessary to be known, exhibiting the property that $\underline{\gamma}_{ij}(\mathbf{x}(t)) + \overline{\gamma}_{ij}(\mathbf{x}(t))$ for all i and j. The main purpose of these two nonlinear functions is to reconstruct $\tilde{h}_{ij}(\mathbf{x}(t)) \equiv \tilde{w}_i(\mathbf{x}(t))\tilde{m}_j(\mathbf{x}(t))$ by representing it as a linear combination of $\underline{h}_{ij}(\mathbf{x}(t))$ and $\overline{h}_{ij}(\mathbf{x}(t))$ as shown in (17). The nonlinear functions $\underline{h}_{ij}(\mathbf{x}(t))$ and $\overline{h}_{ij}(\mathbf{x}(t))$ exhibiting the property of $\underline{h}_{ij}(\mathbf{x}(t)) \leq \tilde{w}_i(\mathbf{x}(t))\tilde{m}_j(\mathbf{x}(t)) \leq \overline{h}_{ij}(\mathbf{x}(t))$ for all i, j and $\mathbf{x}(t)$ (or a predefined state space of interest) denote the lower and upper bounds of $\tilde{w}_i(\mathbf{x}(t))\tilde{m}_j(\mathbf{x}(t))$ (which are characterized by the lower and upper membership functions of the IT2 fuzzy model and the IT2 fuzzy controller, i.e., $\underline{w}_i(\mathbf{x}(t))$, $\overline{w}_i(\mathbf{x}(t))$, $\underline{m}_j(\mathbf{x}(t))$ and $\overline{m}_j(\mathbf{x}(t))$), and are defined as follows.

$$\begin{aligned}\underline{h}_{ij}(\mathbf{x}(t)) = &\sum_{k=1}^{q}\sum_{i_1=1}^{2}\sum_{i_2=1}^{2}\cdots\sum_{i_n=1}^{2} \\ &\times\prod_{r=1}^{n}v_{ri_rk}(x_r(t))\underline{\delta}_{iji_1i_2\cdots i_nk} \;\forall\, i, j, k, \quad (19)\end{aligned}$$

$$\begin{aligned}\overline{h}_{ij}(\mathbf{x}(t)) = &\sum_{k=1}^{q}\sum_{i_1=1}^{2}\sum_{i_2=1}^{2}\cdots\sum_{i_n=1}^{2} \\ &\times\prod_{r=1}^{n}v_{ri_rk}(x_r(t))\overline{\delta}_{iji_1i_2\cdots i_nk} \;\forall\, i, j, k, \quad (20)\end{aligned}$$

where $0 \leq \underline{\delta}_{iji_1i_2\cdots i_nk} \leq 1$ and $0 \leq \overline{\delta}_{iji_1i_2\cdots i_nk} \leq 1$ are constant scalars to be determined. The functions $v_{ri_sk}(x_r(t))$ are defined such that $0 \leq v_{ri_sk}(x_r(t)) \leq 1$ and $v_{r1k}(x_r(t)) + v_{r2k}(x_r(t)) = 1$ for $r, s = 1, 2, \cdots, n$; $i_r = 1, 2$; $\mathbf{x} \in \Phi_k$; otherwise, $v_{ri_sk}(x_r(t)) = 0$. As a result, we have the property that $\sum_{k=1}^{q}\sum_{i_1=1}^{2}\sum_{i_2=1}^{2}\cdots\sum_{i_n=1}^{2}\prod_{r=1}^{n}v_{ri_rk}(x_r(t)) = 1$, which is used in the stability analysis.

III. Stability Analysis

In this section, we will investigate the stability of the IT2 FMB control system (15) through the Lyapunov stability theory. A set of LMI-based stability conditions will be derived to guarantee the system stability and facilitate the control synthesis. For brevity, in the following analysis, the time t associated with the variables is dropped for situation without ambiguity, e.g., $\mathbf{x}(t)$ is denoted as $\mathbf{x}$. The variables $\underline{w}_i(\mathbf{x}(t))$, $\overline{w}_i(\mathbf{x}(t))$, $\tilde{w}_i(\mathbf{x}(t))$, $\underline{m}_j(\mathbf{x}(t))$, $\overline{m}_j(\mathbf{x}(t))$, $\tilde{m}_j(\mathbf{x}(t))$, $\tilde{h}_{ij}(\mathbf{x}(t))$, $v_{1i_1k}(x_1(t))$, $v_{2i_2k}(x_2(t))$, $\cdots$, $v_{ni_nk}(x_n(t))$ are denoted by $\underline{w}_i$, $\overline{w}_i$, $\tilde{w}_i$, $\underline{m}_j$, $\overline{m}_j$, $\tilde{m}_j$, $\tilde{h}_{ij}$, v_{1i_1k}, v_{2i_2k}, $\cdots$, v_{ni_nk}, respectively. Furthermore, the property of $\sum_{i=1}^{p}\tilde{w}_i = \sum_{j=1}^{c}\tilde{m}_j = \sum_{i=1}^{p}\sum_{j=1}^{c}\tilde{w}_i\tilde{m}_j = \sum_{i=1}^{p}\sum_{j=1}^{c}\tilde{h}_{ij} = 1$ is utilized.

We consider the following quadratic Lyapunov function candidate to investigate the stability of the IT2 FMB control systems (15) expressed in the form of (16).

$$V = \mathbf{x}^T\mathbf{P}\mathbf{x}, \quad (21)$$

where $0 < \mathbf{P} = \mathbf{P}^T \in \Re^{n\times n}$.

Denote $\mathbf{z} = \mathbf{P}^{-1}\mathbf{x}$ and $\mathbf{X} = \mathbf{P}^{-1}$. Define the feedback gains $\mathbf{G}_j = \mathbf{N}_j\mathbf{X}^{-1}$ where $\mathbf{N}_j \in \Re^{m\times n}$, $j = 1, 2, \cdots, c$, are matrices to be determined. From (16) and (21), we have,

$$\begin{aligned}\dot{V} &= \dot{\mathbf{x}}^T\mathbf{P}\mathbf{x} + \mathbf{x}^T\mathbf{P}\dot{\mathbf{x}} \\ &= \sum_{i=1}^{p}\sum_{j=1}^{c}\tilde{h}_{ij}\mathbf{x}^T\big((\mathbf{A}_i + \mathbf{B}_i\mathbf{G}_j)^T\mathbf{P} + \mathbf{P}(\mathbf{A}_i + \mathbf{B}_i\mathbf{G}_j)\big)\mathbf{x} \\ &= \sum_{i=1}^{p}\sum_{j=1}^{c}(\underline{\gamma}_{ij}\underline{h}_{ij} + \overline{\gamma}_{ij}\overline{h}_{ij})\mathbf{z}^T\mathbf{Q}_{ij}\mathbf{z}, \end{aligned} \tag{22}$$

where $\mathbf{Q}_{ij} = \mathbf{A}_i\mathbf{X} + \mathbf{X}\mathbf{A}_i^T + \mathbf{B}_i\mathbf{N}_j + \mathbf{N}_j^T\mathbf{B}_i^T$.

Recalling the property that $\overline{h}_{ij} \geq \underline{h}_{ij} \geq 0$, $0 \leq \underline{\gamma}_{ij} \leq 1$, $0 \leq \overline{\gamma}_{ij} \leq 1$ and $\underline{\gamma}_{ij} + \overline{\gamma}_{ij} = 1$ for all i and j, we introduce some slack matrices to the stability analysis through the following inequalities using the S-procedure [6].

$$\big(\sum_{i=1}^{p}\sum_{j=1}^{c}(\underline{\gamma}_{ij}\underline{h}_{ij} + \overline{\gamma}_{ij}\overline{h}_{ij}) - 1\big)\mathbf{M} = \mathbf{0}, \tag{23}$$

$$-\sum_{i=1}^{p}\sum_{j=1}^{c}(1 - \underline{\gamma}_{ij})(\underline{h}_{ij} - \overline{h}_{ij})\mathbf{W}_{ij} \geq 0, \tag{24}$$

where $\mathbf{M} = \mathbf{M}_{ij}^T \in \Re^{n\times n}$ are arbitrary matrices and $0 \leq \mathbf{W}_{ij} = \mathbf{W}_{ij}^T \in \Re^{n\times n}$.

From (22), (23) and (24), we have

$$\begin{aligned}\dot{V} \leq& \sum_{i=1}^{p}\sum_{j=1}^{c}(\underline{\gamma}_{ij}\underline{h}_{ij} + (1 - \underline{\gamma}_{ij})\overline{h}_{ij})\mathbf{z}^T\mathbf{Q}_{ij}\mathbf{z} \\ &- \sum_{i=1}^{p}\sum_{j=1}^{c}(1 - \underline{\gamma}_{ij})(\underline{h}_{ij} - \overline{h}_{ij})\mathbf{z}^T\mathbf{W}_{ij}\mathbf{z} \\ &+ \big(\sum_{i=1}^{p}\sum_{j=1}^{c}(\underline{\gamma}_{ij}\underline{h}_{ij} + (1 - \underline{\gamma}_{ij})\overline{h}_{ij}) - 1\big)\mathbf{z}^T\mathbf{M}\mathbf{z} \\ =& \mathbf{z}^T\big(\sum_{i=1}^{p}\sum_{j=1}^{c}(\overline{h}_{ij}\mathbf{Q}_{ij} - (\underline{h}_{ij} - \overline{h}_{ij})\mathbf{W}_{ij} + \overline{h}_{ij}\mathbf{M}) - \mathbf{M}\big)\mathbf{z} \\ &+ \sum_{i=1}^{p}\sum_{j=1}^{c}\underline{\gamma}_{ij}(\underline{h}_{ij} - \overline{h}_{ij})\mathbf{z}^T(\mathbf{Q}_{ij} + \mathbf{W}_{ij} + \mathbf{M})\mathbf{z}. \end{aligned} \tag{25}$$

It can be seen from (21) that $V > 0$ for all $\mathbf{x} \neq \mathbf{0}$. From (25), if the inequalities, $\sum_{i=1}^{p}\sum_{j=1}^{c}(\overline{h}_{ij}\mathbf{Q}_{ij} - (\underline{h}_{ij} - \overline{h}_{ij})\mathbf{W}_{ij} + \overline{h}_{ij}\mathbf{M}) - \mathbf{M} < 0$ and $\mathbf{Q}_{ij} + \mathbf{W}_{ij} + \mathbf{M} > 0$ (as $\underline{\gamma}_{ij}(\underline{h}_{ij} - \overline{h}_{ij}) \leq 0$) for all i and j are satisfied, we have $\dot{V} < 0$ for all $\mathbf{x} \neq \mathbf{0}$. As a result, the IT2 FMB control system is guaranteed to be asymptotically stable in the sense of Lyapunov. The second set of inequalities is in the form of LMI, however, the first one is not due to the existence of the lower and upper membership functions $\underline{h}_{ij}$ and $\overline{h}_{ij}$. With the expression of (19) and (20), recalling that $\sum_{k=1}^{q}\sum_{i_1=1}^{2}\sum_{i_2=1}^{2}\cdots\sum_{i_n=1}^{2}\prod_{r=1}^{n}v_{ri_rk} = 1$, the second first inequality can be written as follows.

$$\begin{aligned}&\sum_{k=1}^{q}\sum_{i_1=1}^{2}\sum_{i_2=1}^{2}\cdots\sum_{i_n=1}^{2}\prod_{r=1}^{n}v_{ri_rk}\big(\sum_{i=1}^{p}\sum_{j=1}^{c}(\overline{\delta}_{iji_1i_2\cdots i_nk}\mathbf{Q}_{ij} \\ &- (\underline{\delta}_{iji_1i_2\cdots i_nk} - \overline{\delta}_{iji_1i_2\cdots i_nk})\mathbf{W}_{ij} + \overline{\delta}_{iji_1i_2\cdots i_nk}\mathbf{M}) \\ &- \mathbf{M}\big) < 0 \end{aligned} \tag{26}$$

It can be seen that the inequality $\sum_{i=1}^{p}\sum_{j=1}^{c}(\overline{h}_{ij}\mathbf{Q}_{ij} - (\underline{h}_{ij} - \overline{h}_{ij})\mathbf{W}_{ij} + \overline{h}_{ij}\mathbf{M}) - \mathbf{M} < 0$ can be achieved if $\sum_{i=1}^{p}\sum_{j=1}^{c}(\overline{\delta}_{iji_1i_2\cdots i_nk}\mathbf{Q}_{ij} - (\underline{\delta}_{iji_1i_2\cdots i_nk} - \overline{\delta}_{iji_1i_2\cdots i_nk})\mathbf{W}_{ij} + \overline{\delta}_{iji_1i_2\cdots i_nk}\mathbf{M}) - \mathbf{M} < 0$ for all i_1, i_2, $\cdots$, i_n and k.

Referring to (26), the advantages of representing the IT2 FMB control system (15) in the form of (16) can be seen. The membership functions $\tilde{h}_{ij}$ are reconstructed by a linear combination of the lower and upper membership functions $\underline{h}_{ij}$ and $\overline{h}_{ij}$. Consequently, as seen from (25), the stability of the IT2 FMB control system is determined by the lower and upper membership functions $\underline{h}_{ij}$ and $\overline{h}_{ij}$. By expressing $\underline{h}_{ij}$ and $\overline{h}_{ij}$ in the form of (19) and (20), respectively, they are characterized by the constant scalars $\underline{\delta}_{iji_1i_2\cdots i_nk}$ and $\overline{\delta}_{iji_1i_2\cdots i_nk}$. Furthermore, as the cross terms $\prod_{r=1}^{n}v_{ri_rk}(x_r(t))$ are independent of i and j, they can be extracted as shown in (26) to facilitate the stability analysis. With these favourable properties, we only need to check $\sum_{i=1}^{p}\sum_{j=1}^{c}(\overline{\delta}_{iji_1i_2\cdots i_nk}\mathbf{Q}_{ij} - (\underline{\delta}_{iji_1i_2\cdots i_nk} - \overline{\delta}_{iji_1i_2\cdots i_nk})\mathbf{W}_{ij} + \overline{\delta}_{iji_1i_2\cdots i_nk}\mathbf{M}) - \mathbf{M} < 0$ at some discrete points ($\underline{\delta}_{iji_1i_2\cdots i_nk}$ and $\overline{\delta}_{iji_1i_2\cdots i_nk}$) instead of every single point of the lower and upper membership functions $\underline{h}_{ij}$ and $\overline{h}_{ij}$ to guarantee the holding of the inequality (26).

Based on the Lyapunov stability theory, the IT2 FMB control system (15) is guaranteed to be asymptotically stable if the LMI-based stability conditions summarized in the following theorem are satisfied.

Theorem 2: The IT2 FMB control system (15) under imperfect premise matching, formed by a nonlinear plant (represented by the IT2 T-S fuzzy model (5)) and an IT2 fuzzy controller (12) connected in a closed loop, is guaranteed to be asymptotically stable if there exist matrices $\mathbf{M} = \mathbf{M} \in \Re^{n\times n}$, $\mathbf{N}_j \in \Re^{m\times n}$, $\mathbf{X} = \mathbf{X}^T \in \Re^{n\times n}$, $\mathbf{W}_{ij} = \mathbf{W}_{ij}^T \in \Re^{n\times n}$, $i = 1, 2, \ldots, p$; $j = 1, 2, \ldots, c$, such that the following LMIs are satisfied.

$$\mathbf{X} > 0; \tag{27}$$

$$\mathbf{W}_{ij} \geq 0,\ \forall\, i, j; \tag{28}$$

$$\mathbf{Q}_{ij} + \mathbf{W}_{ij} + \mathbf{M} > 0,\ \forall\, i, j; \tag{29}$$

$$\begin{aligned}&\sum_{i=1}^{p}\sum_{j=1}^{c}(\overline{\delta}_{iji_1i_2\cdots i_nk}\mathbf{Q}_{ij} - (\underline{\delta}_{iji_1i_2\cdots i_nk} - \overline{\delta}_{iji_1i_2\cdots i_nk})\mathbf{W}_{ij} \\ &+ \overline{\delta}_{iji_1i_2\cdots i_nk}\mathbf{M}) - \mathbf{M} < 0,\ \forall\, i_1, i_2, \cdots, i_n, k; \end{aligned} \tag{30}$$

where $\underline{\delta}_{iji_1i_2\cdots i_nk}$ and $\overline{\delta}_{iji_1i_2\cdots i_nk}$, $i = 1, 2, \ldots, p$; $j = 1, 2, \ldots, c$; $i_1, i_2, \cdots, i_n = 1, 2$; $k = 1, 2, \cdots, q$ are pre-defined constant scalars satisfying (19) and (20);

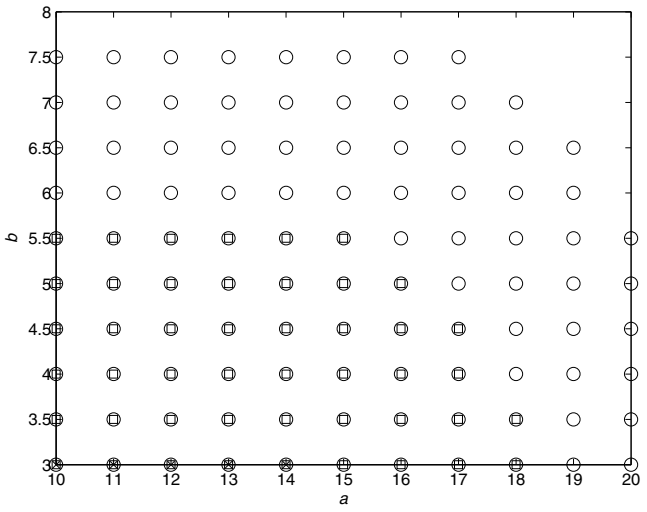

Fig. 1. Stability regions given by the stability conditions in Theorem 2 for Case 1 ('×'); Case 2 ('□'); and Case 3 ('○').

$\mathbf{Q}_{ij} = \mathbf{A}_i\mathbf{X} + \mathbf{X}\mathbf{A}_i^T + \mathbf{B}_i\mathbf{N}_j + \mathbf{N}_j^T\mathbf{B}_i^T$ for all i and j; and the feedback gains are defined as $\mathbf{G}_j = \mathbf{N}_j\mathbf{X}^{-1}$ for all j.

Remark 1: It should be noted that the LMI-based stability conditions in Theorem 2 are for the IT2 FMB control systems under imperfect premise matching that the IT2 fuzzy controller does not require sharing the same lower and upper premise membership functions and the same number of fuzzy rules as those of the IT2 T-S fuzzy model. As a result, compared with the stability conditions for the IT2 FMB control systems under perfect premise matching [26], it offers a higher design flexibility to the IT2 fuzzy controller.

Remark 2: It can be shown that the stability conditions in Theorem 1 is a particular case of Theorem 2 (the solution of the stability conditions in Theorem 1 is that of Theorem 2). Referring to Theorem 1, if there exists a solution, we have $\mathbf{X} > 0$ and $\mathbf{Q}_{ij} < 0$ for all i and j. Referring to Theorem 2, choosing $\mathbf{M} = \varepsilon_1\mathbf{I} > 0$ where $\varepsilon_1 > 0$. The LMIs (28) and (29) must be satisfied by choosing $\mathbf{W}_{ij} = -\mathbf{Q}_{ij} + (-\varepsilon_1 + \varepsilon_2)\mathbf{I} > 0$ for all i and j with sufficiently small non-zero positive value of ε_1 and ε_2. As a result, recalling that $\overline{\delta}_{iji_1i_2\cdots i_nk} \geq \underline{\delta}_{iji_1i_2\cdots i_nk} \geq 0$, the LMIs in (30) become $\sum_{i=1}^{p}\sum_{j=1}^{c}(\overline{\delta}_{iji_1i_2\cdots i_nk}\varepsilon_2\mathbf{I} - \underline{\delta}_{iji_1i_2\cdots i_nk}\mathbf{W}_{ij}) - \varepsilon_1\mathbf{I} < 0$ for all $i_1, i_2, \cdots, i_n$ and k, which will be satisfied by a sufficiently small value of ε_2.

IV. Simulation Example

We consider a nonlinear plant represented by a 3-rule IT2 T-S fuzzy model in the form of (5), with $\mathbf{A}_1 = \begin{bmatrix} 1.59 & -7.29 \\ 0.01 & 0 \end{bmatrix}$, $\mathbf{A}_2 = \begin{bmatrix} 0.02 & -4.64 \\ 0.35 & 0.21 \end{bmatrix}$, $\mathbf{A}_3 = \begin{bmatrix} -a & -4.33 \\ 0 & 0.05 \end{bmatrix}$, $\mathbf{B}_1 = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$, $\mathbf{B}_2 = \begin{bmatrix} 8 \\ 0 \end{bmatrix}$, $\mathbf{B}_3 = \begin{bmatrix} -b+6 \\ -1 \end{bmatrix}$, $\mathbf{x} = [x_1 \quad x_2]^T$, a and b are constant system parameters. For demonstration purposes, the actual membership functions are chosen as $\tilde{w}_1(x_1) = \mu_{M_1^1}(x_1) = 1 - \frac{1}{1+e^{-(x_1+4+\sigma(t))}}$, $\tilde{w}_2(x_1) = \mu_{M_1^2}(x_1) = 1 - \tilde{w}_1(x_1) - \tilde{w}_3(x_1)$ and $\tilde{w}_3(x_1) = \mu_{M_1^3}(x_1) = \frac{1}{1+e^{-(x_1-4+\sigma(t))}}$ where $\sigma(t) \in [-0.1, 0.1]$ represents the parameter uncertainty. The lower and upper membership functions for the IT2 T-S fuzzy model are chosen to be $\underline{w}_1(x_1) = \underline{\mu}_{\tilde{M}_1^1}(x_1) = 1 - \frac{1}{1+e^{-(x_1+4+d_1)}}$, $\underline{w}_3(x_1) = \underline{\mu}_{\tilde{M}_1^3}(x_1) = \frac{1}{1+e^{-(x_1-4-d_1)}}$, $\overline{w}_1(x_1) = \overline{\mu}_{\tilde{M}_1^1}(x_1) = 1 - \frac{1}{1+e^{-(x_1+4-d_1)}}$, $\overline{w}_3(x_1) = \overline{\mu}_{\tilde{M}_1^3}(x_1) = \frac{1}{1+e^{-(x_1-4+d_1)}}$, $\underline{w}_2(x_1) = \underline{\mu}_{\tilde{M}_1^2}(x_1) = 1 - \overline{\mu}_{\tilde{M}_1^1}(x_1) - \overline{\mu}_{\tilde{M}_1^3}(x_1)$ and $\overline{w}_2(x_1) = \overline{\mu}_{\tilde{M}_1^2}(x_1) = 1 - \underline{\mu}_{\tilde{M}_1^1}(x_1) - \underline{\mu}_{\tilde{M}_1^3}(x_1)$ where d_1 is a constant to be determined.

A 2-rule fuzzy controller in the form of (12) is employed to stabilize the nonlinear plant. The lower and upper membership functions are chosen as $\underline{m}_1(x_1) = \underline{\mu}_{\tilde{N}_1^1}(x_1) = 1 - \frac{1}{e^{\frac{-x_1+d_2}{2}}}$, $\overline{m}_1(x_1) = \overline{\mu}_{\tilde{N}_1^1}(x_1) = 1 - \frac{1}{e^{\frac{-x_1-d_2}{2}}}$, $\underline{m}_2(x_1) = \underline{\mu}_{\tilde{N}_1^2}(x_1) = 1 - \overline{\mu}_{\tilde{N}_1^1}(x_1)$ and $\overline{m}_2(x_1) = \overline{\mu}_{\tilde{N}_1^2}(x_1) = 1 - \underline{\mu}_{\tilde{N}_1^1}(x_1)$. From (13), we have $\tilde{m}_j(x_1) = \frac{\underline{\beta}_j\underline{m}_j(x_1) + \overline{\beta}_j\overline{m}_j(x_1)}{\sum_{k=1}^{c}(\underline{\beta}_k\underline{m}_k(x_1) + \overline{\beta}_k\overline{m}_k(x_1))}$ for $j = 1, 2$, where $\underline{\beta}_j$ and $\overline{\beta}_j$ are chosen to be a constant; d_2 is a constant to be determined, in this example.

To determine the lower and upper membership functions $\underline{h}_{ij}(x_1)$ and $\overline{h}_{ij}(x_1)$, we consider $x_1 \in [-10, 10]$ and divide the state space of x_1 into 20 regions, i.e., $\phi_k : \underline{x}_{1,k} \leq x_1 < \overline{x}_{1,k}$, $k = 1, 2, \cdots, 19$ and $\phi_{20} : \underline{x}_{1,20} \leq x_1 \leq \overline{x}_{1,20}$, where $\underline{x}_{1,k} = (k - 11)$ and $\overline{x}_{1,k} = (k - 10)$. The lower and upper membership functions $\underline{h}_{ij}(x_1)$ and $\overline{h}_{ij}(x_1)$ can be defined by choosing $v_{11k}(x_1) = 1 - \frac{x_1 - \underline{x}_{1,k}}{\overline{x}_{1,k} - \underline{x}_{1,k}}$ and $v_{12k}(x_1) = 1 - v_{11k}(x_1)$; and the constant scalars as $\underline{\delta}_{ij1k} = \underline{w}_i(\underline{x}_{1,k})\underline{m}_j(\underline{x}_{1,k})$, $\underline{\delta}_{ij2k} = \underline{w}_i(\overline{x}_{1,k})\underline{m}_j(\overline{x}_{1,k})$, $\overline{\delta}_{ij1k} = \overline{w}_i(\underline{x}_{1,k})\overline{m}_j(\underline{x}_{1,k})$, $\overline{\delta}_{ij2k} = \overline{w}_i(\overline{x}_{1,k})\overline{m}_j(\overline{x}_{1,k})$ for all k.

TABLE I
Parameter values for $\underline{\beta}_j$, $\underline{\beta}_j$, d_1 and d_2.

	Case 1	Case 2	Case 3
$\underline{\beta}_j$	1	0.5	0
$\underline{\beta}_j$	0	0.5	1
d_1	0.3	0.3	0.25
d_2	0.25	0.15	0.15

The stability conditions in Theorem 2 are employed to check the stability of the IT2 FMB control system with the Matlab LMI toolbox. We consider three cases with different values of $\underline{\beta}_j$, $\underline{\beta}_j$, d_1 and d_2, as shown in Table I, to test the stability conditions in Theorem 2. The values of d_1 and d_2 are chosen such that $\tilde{h}_{ij}(x_1)$ in the form of (17) are withing the lower and upper membership functions defined in (19) and (20), respectively. Considering $10 \leq a \leq 20$ at the interval of 1 and $3 \leq b \leq 8$ at the interval of 0.5, with the $\underline{\beta}_j = \overline{\beta}_j = 0.5$, the stability regions are shown in Fig. 1 indicated by '×',

'□' and '○' corresponding to Case 1 to Case 3, respectively. It can be seen that different values of $\underline{\beta}_j$ and $\overline{\beta}_j$, leading to different values of d_1 and d_2, will produce different size of stability regions. It demonstrates a trend that Case 3 produces a larger stability region than Case 2 while Case 3 produces a larger stability region than Case 1 due to different values of d_1 and d_2. For comparison purposes, Theorem 1 is employed to check the stability of the IT2 FMB control system. However, no feasible solution can be obtained. It should be noted that the IT2 FMB control system is under imperfect premise matching, the stability conditions in [26] for perfect premise matching cannot be applied in this example.

V. Conclusion

The stability of IT2 FMB control systems subject to parameter uncertainties under imperfect matching has been investigated. It is not required that both the IT2 T-S fuzzy model and the IT2 fuzzy controller share the same number of rules and/or the same set of premise membership functions. Thus, it offers a greater design flexibility for the IT2 fuzzy controller and is possible to lower the controller complexity by employing a smaller number of rules and simple membership functions. Through the lower and upper membership functions, the information of the nonlinearity and parameter uncertainties embedded in the footprint of uncertainty are brought to the stability analysis. Based on the Lyapunov stability theory, LMI-based stability conditions are obtained to guarantee the stability of the IT2 FMB control system and synthesize the IT2 fuzzy controller. Simulation examples have been given to demonstrate the merits of the proposed approach.

***Abstract*—In this paper, a robust H_∞ fuzzy observer is proposed for a class of time-delay discrete fuzzy bilinear systems with parameter uncertainties. Utilizing the Lipschitz conditions, a linear matrix inequality approach is developed and a sufficient condition is obtained to design the robust H_∞ fuzzy observer. Besides, the robust H_∞ fuzzy observer for time-delay discrete fuzzy bilinear systems with parameter uncertainties can be obtained through the LMIs without any pre-assigned gain matrices. Finally, a numerical example is illustrated the feasibility and effectively of proposed observer design method.**

Keywords- Time-delay, fuzzy observer, linear matrix inequalities; fuzzy bilinear system.

I. INTRODUCTION

During the last decade, fuzzy technique has attracted great attention from both the academic and industrial applications. Among various fuzzy controls, a so-called Takagi–Sugeno (T–S) fuzzy model [1-3] becomes a popular and convenient tool in analyzing the nonlinear system. Through fuzzy modeling procedure, the T-S fuzzy model can be obtained from a nonlinear system. In addition, the obtained T-S fuzzy model is composed of many linear models; therefore, there are many linear system theories which can be utilized to analyze the T-S fuzzy model. By examining controller design, the parallel distributed compensation (PDC) scheme is adopted for each rule to stabilize the overall T-S fuzzy model. For the problems of stability and stabilization of T-S fuzzy models, the Lyapunov direct method [4-7] is mainly investigated to yield the stability/stabilization conditions. Furthermore, the solutions can be found via linear matrix inequalities (LMIs) techniques [8-11] for the T-S fuzzy control system under consideration. Due to the systematic design procedure, different methodologies have been also proposed for the stabilization problem of T-S fuzzy model [4], [12-13].

Even though T-S fuzzy model is composed of linear models blended together with nonlinear scalar positive functions sharing the convex sum property, and can be utilized the linear system theory to analyze the T-S fuzzy model. But unfortunately, there are many real-world nonlinear systems cannot be adequately approximated by linear models [14], [15]. Due to this reason, [16] first proposed a novel fuzzy modeling method to modelize the nonlinear system into a T-S fuzzy bilinear system (FBS). Besides, [17] studied the H_∞ control problem for a class of discrete fuzzy bilinear systems (DFBSs). Furthermore, [18-20] explored the stabilization problem of T-S FBS with time-delay. In addition to the stabilization problem, [21] investigated the observer design for T-S FBS. [22] explored the output feedback control and proposed an observer for T-S time-delay FBS, but in this paper, some matrices still needs to be pre-assigned for obtaining the observer gains. Moreover, there is no any study proposed a LMI method to obtain the observer gains without any pre-assigned matrices for time-delay FBS/DFBS. Furthermore, there is no any literature to investigate the robust H_∞ fuzzy observer for time-delay DFBS with parameter uncertainties and additive disturbance. Hence, we will explore the robust fuzzy H_∞ observer problem in this paper. The main contributions of this paper include i) Proposing a robust fuzzy H_∞ observer for time-delay DFBSs with parameter uncertainties; ii) The stability conditions for time-delay DFBSs with parameter uncertainties can be formulated as LMIs, and iii) The robust fuzzy H_∞ observer gain for time-delay DFBSs with parameter uncertainties can be obtained from LMIs without any pre-assigned parameter/matrix.

Following the introduction, the paper is organized as follows. In Section II the observer design problem for the time-delay DFBS with parameter uncertainties is introduced. Applying the Lipschitz conditions and some variable transformations, the sufficient conditions for time-delay DFBSs with parameter uncertainties can be transformed into the forms of LMI in Section III. In Section IV, a simulation example is provided to illustrate the effectiveness of the proposed design approach. Finally, in Section V, conclusions are drawn.

II. PROBLEM DESCRIPTION

The T-S fuzzy dynamic model is described by fuzzy IF-THEN rules, which locally represent input-output relations of

The authors would like to thank the National Science Council for financially supporting this research under contract NSC-99-2221-E-027-101 and NSC-98-2622-E-168-013-CC3.

nonlinear systems. Similar to [2], [4], the i th rule of the uncertain DFBS with disturbance can be represented by the following form:

Plant Rule i : IF $s_1(k)$ is F_{i1} and $\cdots$ and $s_g(k)$ is F_{ig}

THEN

$$x(k+1) = (A_i + \Delta A_i)x(k) + (A_{di} + \Delta A_{di})x(k-\tau) + N_i x(k)u(k) + N_{di}x(k-\tau)u(k) + D_{1i}w(k) \quad (1a)$$

$$y(k) = (C_i + \Delta C_i)x(k) + (C_{di} + \Delta C_{di})x(k-\tau) + D_{2i}w(k) \quad (1b)$$

$$z(k) = R_i e(k) + R_{di}e(k-\tau) \quad (1c)$$

$$x(k) = \phi(k) \quad \forall k \in [-\tau, 0],\ i = 1, \cdots r$$

where F_{ij} is the fuzzy set, and r is the number of IF-THEN rules; $s_1(t), s_2(t), \cdots s_g(t)$, are the premise variables. $x(k) \in R^{n\times 1}$ is the system state; $u(k) \in R^{1\times 1}$ is the input and satisfies $|u(k)| \le 1$ for all $k \in \mathbf{Z}$, $w(k) \in R^{q\times 1}$ is the exogenous disturbance which belongs to $l_2[0,\infty)$; $\tau > 0$ is an integer representing the time delay of the fuzzy system; $y(k) \in R^{p\times 1}$ is the measured output; $z(k) \in R^{m\times 1}$ is the controlled output of the error state, A_i , A_{di} , N_i , N_{di} , C_i , C_{di} , D_{1i} , D_{2i} , R_i , and R_{di} are known real matrices with appropriate dimensions. ΔA_i , ΔA_{di} , ΔC_i , and ΔC_{di} are unknown matrices representing time-varying parameter uncertainties, and are assumed to be of the following matched form:

Assumption 1: [8,] [10]

$$[\Delta A_i \quad \Delta A_{di}] = G_{1i}F_{1i}[E_{1i} \quad E_{2i}] \quad (2a)$$

$$[\Delta C_i \quad \Delta C_{di}] = G_{2i}F_{2i}[E_{3i} \quad E_{4i}] \quad (2b)$$

where G_{1i} , G_{2i} , E_{1i} , E_{2i} , E_{3i} , and E_{4i} are known real constant matrices of appropriate dimensions, and $F_{1i}(k)$, and $F_{2i}(k)$ are unknown matrix function with Lebesgue-measurable elements and satisfy $F_{1i}^T(k)F_{1i}(k) \le I$ and $F_{2i}^T(k)F_{2i}(k) \le I$. The parameter uncertainties ΔA_i , ΔA_i , ΔC_i , and ΔC_{di} are said to be admissible if Assumption 1 hold. Similar to [4] and [10], using a center average defuzzifier, product inference, and singleton fuzzifier, the discrete fuzzy bilinear system with time-delay can be expressed as (3a)-(3c).

Where $\mu_i(s(k)) = \prod_{j=1}^{g} F_{ij}(s(k))$, $h_i(s(k)) = \dfrac{\mu_i(s(k))}{\sum_{j=1}^{r}\mu_j(s(k))}$, $F_{ij}(s_j(k))$ is the grade of membership of $s_j(k)$ in F_{ij} , and $s(k) = [s_1(k) \quad s_2(k) \quad \cdots \quad s_n(k)]^T$. Some basic properties of $\mu_i(s(k))$ are $\mu_i(s(k)) \ge 0$ and $\sum_{i=1}^{r}\mu_i(s(k)) > 0$. It is clear that $h_i(s(k)) \ge 0$ and $\sum_{j=1}^{r} h_j(s(k)) = 1$. According to the conception of observer for linear system, we consider the H_∞ fuzzy observer as follows:

$$\hat{x}(k+1) = \sum_{i=1}^{r} h_i(s(k))\big(A_i\hat{x}(k) + A_{di}\hat{x}(k-\tau) + N_i\hat{x}(k)u(k) + N_{di}\hat{x}(k-\tau)u(k) + L_i[y(k) - C_i\hat{x}(k) - C_{di}\hat{x}(k-\tau)]\big) \quad (4)$$

where $\hat{x}(k)$ is the estimated state vector of $x(k)$, and $L_i \in R^{n\times 1}$ are observer parameters to be determined. Besides, $N_i^*(u(k), x(k), x(k-\tau), k) = (N_i x(k)u(k) + N_{di}x(k-\tau)u(k))$ is assumed to satisfy the following global Lipschitz conditions: $N_i^*(u(k), 0, 0, k) = 0$, and

$$\left\| N_i^*(u(k), x, \underset{\sim}{x}, k) - N_i^*(u(k), \hat{x}, \underset{\sim}{\hat{x}}, k) \right\| \quad (5)$$

For all $k \in \mathbf{Z}$, $u(k) \in R^{1\times 1}$ and x , $\underset{\sim}{x}$, $\hat{x}$, $\underset{\sim}{\hat{x}} \in R^{n\times 1}$, where $\bar{N}_i$, $\bar{N}_{di}$ are known matrices with appropriate dimensions.

$$x(k+1) = \sum_{i=1}^{r}\mu_i(s(k))\big((A_i + \Delta A_i)x(k) + (A_{di} + \Delta A_{di})x(k-\tau) + N_i x(k)u(k) + N_{di}x(k-\tau)u(k) + D_{1i}w(k)\big) / \sum_{i=1}^{r}\mu_i(s(k))$$
$$= \sum_{i=1}^{r} h_i(s(k))\big((A_i + \Delta A_i)x(k) + (A_{di} + \Delta A_{di})x(k-\tau) + N_i x(k)u(k) + N_{di}x(k-\tau)u(k) + D_{1i}w(k)\big) \quad (3a)$$

$$y(k) = \sum_{i=1}^{r}\mu_i(s(k))\big((C_i + \Delta C_i)x(k) + (C_{di} + \Delta C_{di})x(k-\tau) + D_{2i}w(k)\big) / \sum_{i=1}^{r}\mu_i(s(k))$$
$$= \sum_{i=1}^{r} h_i(s(k))\big((C_i + \Delta C_i)x(k) + (C_{di} + \Delta C_{di})x(k-\tau) + D_{2i}w(k)\big) \quad (3b)$$

$$z(k) = \sum_{i=1}^{r}\mu_i(s(k))\big(R_i e(k) + R_{di}e(k-\tau)\big) / \sum_{i=1}^{r}\mu_i(s(k))$$
$$= \sum_{i=1}^{r} h_i(s(k))\big(R_i e(k) + R_{di}e(k-\tau)\big) \quad (3c)$$

Let $e(k)=x(k)-\hat{x}(k)$; from (1) and (4) so that we have the fuzzy observer error dynamics as follows:

$$\begin{aligned} e(k+1)=\sum_{i=1}^{r}\sum_{j=1}^{r}h_i(s(k))h_j(s(k))\big((A_i-L_iC_j)e(k) \\ +(A_{di}-L_iC_{dj})e(k-\tau)+\delta_{fi}(k)+G_{1i}\delta_{ai}(k) \\ +L_iG_{2j}\delta_{cj}(k)+(D_{1i}+L_iD_{2j})w(k)\big) \end{aligned} \tag{6}$$

where

$$\delta_{ai}=F_{1i}\left(E_{1i}x(k)+E_{2i}x(k-\tau)\right) \tag{7a}$$

$$\delta_{ci}=F_{2i}\left(E_{3i}x(k)+E_{4i}x(k-\tau)\right) \tag{7b}$$

$$\begin{aligned} \delta_{fi}&=\left(N_ix(k)u(k)+N_{di}x(k-\tau)u(k)\right) \\ &\quad-\left(N_i\hat{x}(k)u(k)+N_{di}\hat{x}(k-\tau)u(k)\right) \\ &=\left(N_ie(k)+N_{di}e(k-\tau)\right)u(k) \end{aligned} \tag{7c}$$

According to (2), (5) and (7a)-(7c), we have the following results

$$\delta_{ai}^T(k)\delta_{ai}(k)\le\begin{bmatrix}x(k)\\x(k-\tau)\end{bmatrix}^T\Lambda_{ai}\begin{bmatrix}x(k)\\x(k-\tau)\end{bmatrix} \tag{8a}$$

$$\delta_{ci}^T(k)\delta_{ci}(k)\le\begin{bmatrix}x(k)\\x(k-\tau)\end{bmatrix}^T\Lambda_{ci}\begin{bmatrix}x(k)\\x(k-\tau)\end{bmatrix} \tag{8b}$$

$$\delta_{fi}^T(k)\delta_{fi}(k)\le\begin{bmatrix}e(k)\\e(k-\tau)\end{bmatrix}^T\Lambda_{fi}\begin{bmatrix}e(k)\\e(k-\tau)\end{bmatrix} \tag{8c}$$

where

$$\Lambda_{ai}=\begin{bmatrix}E_{1i}^TE_{1i} & E_{1i}^TE_{2i}\\ E_{2i}^TE_{1i} & E_{2i}^TE_{2i}\end{bmatrix} \tag{9a}$$

$$\Lambda_{ci}=\begin{bmatrix}E_{3i}^TE_{3i} & E_{3i}^TE_{4i}\\ E_{4i}^TE_{3i} & E_{4i}^TE_{4i}\end{bmatrix} \tag{9b}$$

$$\Lambda_{fi}=\begin{bmatrix}\bar{N}_i^T\bar{N}_i & \bar{N}_i^T\bar{N}_{di}\\ \bar{N}_{di}^T\bar{N}_i & \bar{N}_{di}^T\bar{N}_{di}\end{bmatrix}. \tag{9c}$$

The purpose of this paper is to design the robust fuzzy observer parameters L_i such that the fuzzy observer error dynamics (6) are globally stable independent of the time delay τ and the following conditions $H_\infty-$norm upper-bound constraint is simultaneously guaranteed:

$$\|z(k)\|_{[0,\infty)}\le\gamma\|w(k)\|_{[0,+\infty)} \tag{10}$$

for all nonzero $w(k)\in l_2[0,+\infty)$ and all admissible uncertainties.

III. Main Results

In this section, an LMI approach will be developed to solve the problem of robust H_∞ fuzzy observer for T-S time-delay DFBS with parameter uncertainties formulated in the previous section. Before discussing the theorem, we first give the following results which will be used in our main results.

Lemma 1: [6], [7], [23]: Given any matrices X, Y and ε with appropriate dimensions such that $\varepsilon>0$ we have

$$X^TY+XY^T\le\varepsilon X^TX+\varepsilon^{-1}Y^TY.$$

Theorem 1: Consider the uncertain DFBS with disturbance (1). Given a prescribed H_∞ performance index $\gamma>0$, if there exist positive scalars ε_{1ij}, ε_{2ij} λ, and ρ_{ij} and matrices $P_1>0$; $P_2>0$; $Q_1>0$; $Q_2>0$ and X_i, satisfying the LMIs (11) and (12), shown at the next page, then the fuzzy observer error dynamics (6) with the fuzzy observer (4) with $L_i=P_1^{-1}X_i$ is globally asymptotically stable and with an H_∞ performance bound $\gamma>0$.

Proof: Based on the Lyapunov direct method, Lipschitz conditions, and Lemma 1, one can obtain the LMIs (11) and (12). (Due to the limitation of space, we omit the proof.)

IV. Numerical Example

Consider the time-delay DFBS with parameter uncertainty as follows:

Rule 1:

IF x_1 is about -1

THEN

$$\begin{aligned} x(k+1)&=(A_1+\Delta A_1)x(k)+(A_{d1}+\Delta A_{d1})x(k-\tau) \\ &\quad+(N_1+\Delta N_1)x(k)u(k) \\ &\quad+(N_{d1}+\Delta N_{d1})x(k-\tau)u(k)+D_{11}w(k) \end{aligned} \tag{13a}$$

$$y(k)=(C_1+\Delta C_1)x(k)+(C_{d1}+\Delta C_{d1})x(k-\tau)+D_{21}w(k)$$

$$z(k)=R_1e(k)+R_{d1}e(k-\tau)$$

Rule 2:

IF x_1 is about 1

THEN

$$\begin{aligned} x(k+1)&=(A_2+\Delta A_2)x(t)+(N_2+\Delta N_2)x(t)u(t) \\ &\quad+(A_{d2}+\Delta A_{d2})x(k-\tau) \\ &\quad+(N_{d2}+\Delta N_{d2})x(k-\tau)u(k)+D_{12}w(k) \end{aligned} \tag{13b}$$

$$y(k)=(C_2+\Delta C_2)x(k)+(C_{d2}+\Delta C_{d2})x(k-\tau)+D_{22}w(k)$$

$$z(k)=R_2e(k)+R_{d2}e(k-\tau).$$

$$\begin{bmatrix} -\begin{bmatrix} \Pi_{1ii} & 0 & 0 \\ 0 & \Pi_{2ii} & 0 \\ 0 & 0 & \Pi_{3ii} \end{bmatrix} + \zeta_1 I & \Xi_{ii}^T(k) & \mathbf{0} \\ \Xi_{ii}(k) & -P & PS_{ii} \\ \mathbf{0} & S_{ii}^T P & -\begin{bmatrix} \varepsilon_{1ii} I & 0 \\ 0 & \varepsilon_{2ii} I \end{bmatrix} \end{bmatrix} < 0 \quad (1 \le i \le r) \tag{11}$$

$$\begin{bmatrix} -\begin{bmatrix} \Psi_{1ij} & 0 & 0 \\ 0 & \Psi_{2ij} & 0 \\ 0 & 0 & \Psi_{3ij} \end{bmatrix} + \varsigma_2 I & \Xi_{ij}^T(k) & \mathbf{0} \\ \Xi_{ij}(k) & -\begin{bmatrix} P & 0 \\ 0 & P \end{bmatrix} & \begin{bmatrix} P & 0 \\ 0 & P \end{bmatrix} S_{ij} \\ \mathbf{0} & S_{ij}^T \begin{bmatrix} P & 0 \\ 0 & P \end{bmatrix} & -\begin{bmatrix} \varepsilon_{1ij} I & 0 & 0 & 0 \\ 0 & \varepsilon_{2ij} I & 0 & 0 \\ 0 & 0 & \varepsilon_{1ji} I & 0 \\ 0 & 0 & 0 & \varepsilon_{2ji} I \end{bmatrix} \end{bmatrix} < 0 \quad (1 \le i < j \le r) \tag{12}$$

where $P = \begin{bmatrix} P_1 & 0 \\ 0 & P_2 \end{bmatrix}$, $Q = \begin{bmatrix} Q_1 & 0 \\ 0 & Q_2 \end{bmatrix}$, $\Pi_{1ii} = \begin{bmatrix} P_1 - Q_1 & 0 \\ 0 & Q_1 \end{bmatrix} - \left[\varepsilon_{1ii} \left(\Lambda_{ai} + \Lambda_{fi} \right) + \varepsilon_{2ii} \Lambda_{ai} + \lambda \Lambda_{ci} \right]$, $S_{ii} = \begin{bmatrix} S_i & 0 \\ 0 & S_i \end{bmatrix}$,

$S_{ij} = \begin{bmatrix} S_i & 0 & 0 & 0 \\ 0 & S_j & 0 & 0 \\ 0 & 0 & S_i & 0 \\ 0 & 0 & 0 & S_j \end{bmatrix}$, $S_i = \begin{bmatrix} G_{1i} & I \end{bmatrix}$, $\Lambda_{ci} = \begin{bmatrix} E_{3i}^T E_{3i} & E_{3i}^T E_{4i} \\ E_{4i}^T E_{3i} & E_{4i}^T E_{4i} \end{bmatrix}$, $\Pi_{2ii} = \begin{bmatrix} P_2 - Q_2 & 0 \\ 0 & Q_2 \end{bmatrix} - (\varepsilon_{2ii} \Lambda_{fi} + \Lambda_{ri})$, $\Pi_{3ii} = \begin{bmatrix} \lambda I & 0 \\ 0 & \gamma^2 I \end{bmatrix}$,

$$\Psi_{1ij} = 2\begin{bmatrix} P_1 - Q_1 & 0 \\ 0 & Q_1 \end{bmatrix} - \left[\varepsilon_{1ij} \left(\Lambda_{ai} + \Lambda_{fi} \right) + \varepsilon_{1ji} \left(\Lambda_{aj} + \Lambda_{fj} \right) + \varepsilon_{2ij} \Lambda_{ai} + \varepsilon_{2ji} \Lambda_{aj} + \lambda (\Lambda_{ci} + \Lambda_{cj}) \right],$$

$$\Psi_{2ij} = 2\begin{bmatrix} P_2 - Q_2 & 0 \\ 0 & Q_2 \end{bmatrix} - \left(\varepsilon_{2ij} \Lambda_{fi} + \varepsilon_{2ji} \Lambda_{fj} + \Lambda_{rij} \right), \ \Psi_{3ij} = \begin{bmatrix} \lambda I & 0 & 0 \\ 0 & \lambda I & 0 \\ 0 & 0 & 2\gamma^2 I \end{bmatrix},$$

$$\Xi_{ii}(k) = \Xi_{ii} = \begin{bmatrix} P_1 A_i & P_1 A_{di} & 0 & 0 & 0 & P_1 D_{1i} \\ 0 & 0 & P_2 A_i - X_i C_i & P_2 A_{di} - X_i C_{di} & X_i G_i & P_2 D_{1i} + X_i D_{2i} \end{bmatrix},$$

$$\Xi_{ij}(k) = \Xi_{ij} = \begin{bmatrix} P_1 A_i & P_1 A_{di} & 0 & 0 & 0 & 0 & P_1 D_{1i} \\ 0 & 0 & P_2 A_i - X_i C_j & P_2 A_{di} - X_i C_{dj} & 0 & X_i G_{2j} & P_2 D_{1i} + X_i D_{2j} \\ P_1 A_j & P_1 A_{dj} & 0 & 0 & 0 & 0 & P_1 D_{1j} \\ 0 & 0 & P_2 A_j - X_j C_i & P_2 A_{dj} - X_j C_{di} & X_j G_{2i} & 0 & P_2 D_{1j} + X_j D_{2i} \end{bmatrix},$$

$$\Lambda_{ri} = \begin{bmatrix} R_i^T R_i & R_i^T R_{di} \\ R_{di}^T R_i & R_{di}^T R_{di} \end{bmatrix}, \ \Lambda_{rij} = \frac{1}{2} \begin{bmatrix} (R_i + R_j)^T (R_i + R_j) & (R_i + R_j)^T (R_{di} + R_{dj}) \\ (R_{di} + R_{dj})^T (R_i + R_j) & (R_{di} + R_{dj})^T (R_{di} + R_{dj}) \end{bmatrix}.$$

where $A_1 = \begin{bmatrix} 0.4 & 0.01 \\ 0.02 & -0.55 \end{bmatrix}$, $A_2 = \begin{bmatrix} 0.35 & 0.02 \\ -0.2 & -0.5 \end{bmatrix}$,
$N_1 = \begin{bmatrix} -0.5 & 0 \\ 0 & -0.1 \end{bmatrix}$, $N_2 = \begin{bmatrix} 0.1 & 0 \\ 0 & 0.1 \end{bmatrix}$, $A_{d1} = \begin{bmatrix} 0.1 & 0 \\ 0 & 0.1 \end{bmatrix}$,
$A_{d2} = \begin{bmatrix} -0.1 & 0.1 \\ 0 & 0.1 \end{bmatrix}$, $N_{d1} = \begin{bmatrix} 0.1 & 0 \\ 0 & 0.05 \end{bmatrix}$, $N_{d2} = \begin{bmatrix} 1 & 0 \\ 0 & 0.03 \end{bmatrix}$,
$D_{11} = \begin{bmatrix} 0.3 & 0 \\ 0 & 0.2 \end{bmatrix}$, $D_{12} = \begin{bmatrix} 0.1 & 0 \\ 0 & 0.1 \end{bmatrix}$, $C_1 = \begin{bmatrix} 0.1 & 0 \end{bmatrix}$,
$C_2 = \begin{bmatrix} 0.1 & 0 \end{bmatrix}$, $C_{d1} = \begin{bmatrix} -0.2 & -0.3 \end{bmatrix}$, $C_{d2} = \begin{bmatrix} 0.1 & -0.1 \end{bmatrix}$,
$D_{21} = \begin{bmatrix} 0.2 & 0.7 \end{bmatrix}$, $D_{22} = \begin{bmatrix} 0.3 & 0.5 \end{bmatrix}$, $R_1 = \begin{bmatrix} 0 & 0.2 \end{bmatrix}$,
$R_2 = \begin{bmatrix} 0.3 & 0 \end{bmatrix}$, $R_{d1} = \begin{bmatrix} -0.2 & -0.1 \end{bmatrix}$, $R_{d2} = \begin{bmatrix} 0.1 & -0.2 \end{bmatrix}$ and $\tau = 1$. The membership functions of the state x_1 are defined as $\mu_1(k) = (1 - x_1)/2$ and $\mu_2(k) = (1 + x_1)/2$.

Based on Assumption 1, we can define the matrices G_{ij}, $F_i(t)$, E_{1i}, E_{2i}, E_{3i}, and E_{4i}, where $i, j = 1, 2$, as follows.

$G_{11} = \begin{bmatrix} 0.01 & -0.1 \\ 0.1 & 0.1 \end{bmatrix}$, $G_{12} = \begin{bmatrix} 0.02 & 0.1 \\ 0.1 & 0.1 \end{bmatrix}$, $G_{21} = \begin{bmatrix} 0.02 & 0.1 \end{bmatrix}$,
$G_{21} = \begin{bmatrix} 0.01 & 0.1 \end{bmatrix}$

$$F_1(t) = F_2(t) = 0.1 \times \begin{bmatrix} rand & 0 \\ 0 & rand \end{bmatrix}$$

where *rand* is a random number taken from a normal distribution over $[-1, 1]$.

$$E_{11} = E_{12} = E_{31} = E_{32} = \begin{bmatrix} 0.1 & 0 \\ 0 & 0.1 \end{bmatrix}$$

$$E_{21} = E_{22} = E_{41} = E_{42} = \begin{bmatrix} 0.01 & 0 \\ 0 & 0.01 \end{bmatrix}.$$

By solving the solution to the stability conditions in Theorem 1 using MATLAB LMI toolbox, with $\gamma = 1$, $\lambda = 1$ and $\zeta_1 = \zeta_2 = 0.0001$, where $i, j = 1, 2$, we have

$P_1 = \begin{bmatrix} 0.4332 & 0.0061 \\ 0.0061 & 0.4188 \end{bmatrix}$, $P_2 = \begin{bmatrix} 0.5421 & -0.0191 \\ -0.0191 & 0.4226 \end{bmatrix}$,
$Q_1 = \begin{bmatrix} 0.1333 & -0.0008 \\ -0.0008 & 0.0894 \end{bmatrix}$, $Q_2 = \begin{bmatrix} 0.1458 & -0.0245 \\ -0.0245 & 0.1054 \end{bmatrix}$,
$X_1 = \begin{bmatrix} -0.1373 \\ -0.1201 \end{bmatrix}$, $X_2 = \begin{bmatrix} -0.0312 \\ -0.1830 \end{bmatrix}$ and the robust H_∞ fuzzy observers is (4) with

$$L_1 = P_1^{-1} X_1 = \begin{bmatrix} -0.2991 \\ -0.2824 \end{bmatrix}$$

$$L_2 = P_1^{-1} X_2 = \begin{bmatrix} -0.0629 \\ -0.4361 \end{bmatrix}.$$

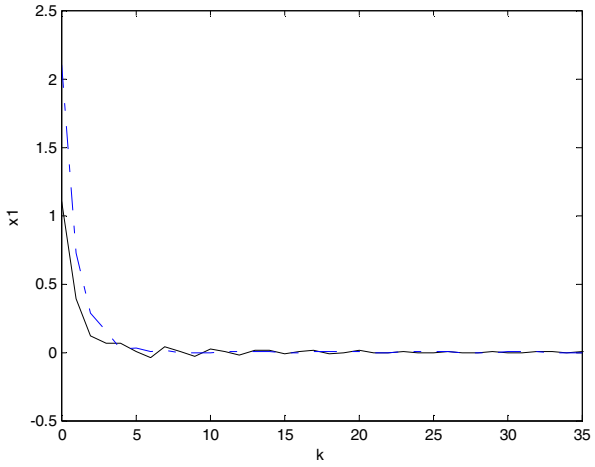

Fig. 1. Responses of $x_1(k)$ and $\hat{x}_1(k)$ for time-delay DFBS with parameter uncertainties.

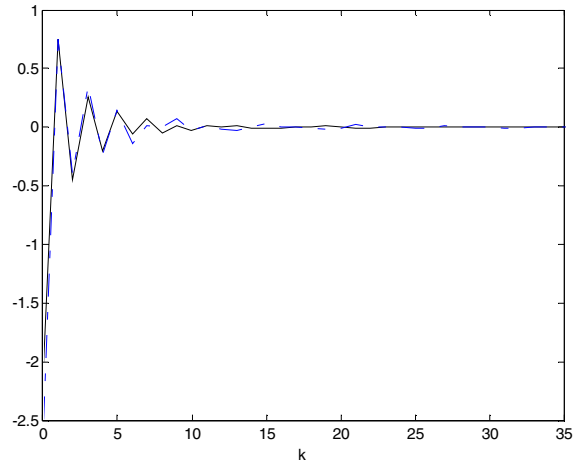

Fig. 2. Responses of $x_2(k)$ and $\hat{x}_2(k)$ for time-delay DFBS with parameter uncertainties.

Applying the controller proposed in [20] with $\rho = 0.3$ and control gain $K_1 = [-0.275 \quad -0.35]$ and $K_2 = [-0.35 \quad -0.25]$ to time-delay DFBS with parameter uncertainties (13). The time-delay DFBS with parameter uncertainties was simulated by choosing a system's initial conditions $x(0) = [1.1 \quad -2.0]^T$ and observer's initial condition $\hat{x}(0) = [2.1 \quad -2.5]^T$ and the exogenous disturbance input $w(k) = \left[0.5e^{-0.1k}\sin(2k) \quad 0.3e^{-0.08k}\cos(k)\right]^T$ are illustrated in Fig. 1 and Fig. 2. From the simulation results, one can find that the state variables of time-delay DFBSs with parameter uncertainties (13) and their estimated by time-delay DFBS observer are almost the same after a short transient instant. Fig. 3 shows the control input. Fig. 4 shows that the designed fuzzy observer ensures the robust asymptotic stability of fuzzy observer error dynamics (6) and guarantees a prescribed H_∞ performance level.

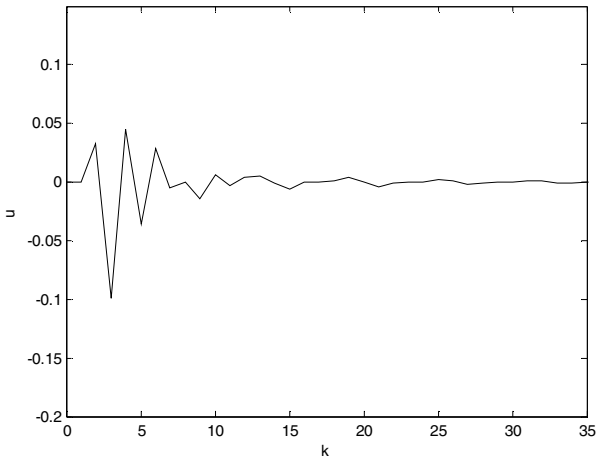

Fig. 3. Control input $u(k)$ for time-delay DFBS with parameter uncertainties.

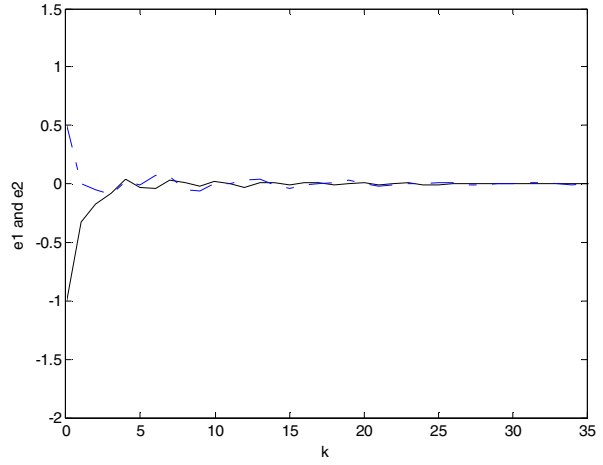

Fig. 4. Responses of e_1 and e_2 for initial conditions $x(0)=[1.1 \quad -2.0]^T$ and $\hat{x}(0)=[2.1 \quad -2.5]^T$.

V. CONSLUSION

In this paper, a robust H_∞ fuzzy observer has been presented for a class of time-delay DFBSs with parameter uncertainties. Based on the Lipschitz condition, the design problem of the H_∞ fuzzy observer can be reformulated as an LMI problem. Besides, the robust H_∞ fuzzy observer for time-delay DFBSs with parameter uncertainties can be obtained from the proposed LMIs without any pre-assigned matrices. The simulation has shown the effectiveness and feasibility of the proposed method to the reconstruction of the state.

***Abstract*—A new stability condition in terms of SOS is studied in this paper for discrete-time fuzzy systems. Based on a parameter-dependent Lyapunov function, we study asymptotically SOS relaxation families, reducing the conservatism that commonly exists in the quadratic stability approaches.**

***Index Terms*—TS fuzzy model; Copositive relaxations; Premise-dependent Lyapunov function; Linear matrix inequality; Sum of Squares.**

I. Introduction

For decades a large number of literature on fuzzy control are TS model-based control where, mostly, the common P approach searching for a single Lyapunov function remains active [1], [2], [3]. Another category emphasizes parameter-dependent functions with multiple P_j matrices as a candidate of Lyapunov function [4], [5], [6]. To remove the time-derivative dependence, progress has been made in obtaining less conservative results using non-quadratic approach (multiple Lyapunov functions) [7], [8], [9], [10], [11] where a fuzzy Lyapunov candidate is used for continuous-time T-S fuzzy models and the resulting stability condition is shown to be more relaxed than the condition derived from the common P approach. Although LMI approaches remain the most favorite tool of choice when a Lyapunov-based stability analysis is used, we, in this paper, propose a copositive relaxation combined with premise-dependent Lyapunov functions to derive necessary and sufficient conditions for the TS fuzzy model stability tests. Inspired by recent advances [10]-[20], [21], [22], we investigate copositive relaxation associated to fuzzy stability and control design from sum of squares viewpoints. The main contribution is that the proposed method takes the firing strength into account and

The paper is organized as follows. Section II rehearses some useful results which forms the foundation for later developments. Sum of squares is also introduced. Section III derives the stability conditions for discrete-time fuzzy systems via a parameter-dependent Lyapunov function. SOS relaxation addressed in Section IV. An example is illustrated in Section V and conclusion is drawn in Section VI.

This work was supported in part by the National Science Council of the ROC under grant NSC-98-2221-E-008-110.

Notations: The symbol $\star$ denotes transposed elements in a symmetric matrix. The notation Y_μ stands for $\sum_{i=1}^{r}\mu_i Y_i$ where $\mu_i \geq 0$ and $\sum_{i=1}^{r}\mu_i = 1$. ! denotes factorial for combinatoric expression. Let $\mathcal{K}(h)$, where h is the degree of a polynomial in μ, be the set of r-tuples defined below:

$$\mathcal{K}(h) = \{(k_1, k_2, \cdots, k_r) : k_1 + k_2 + \cdots + k_r = h \quad (1)$$

$$\forall k_i \in I^+(non-negative\ integers), i = 1, 2, \cdots, r\}.$$

Since the number of rules in the fuzzy base is r, the number of elements in $\mathcal{K}(h)$ is given by $J(h) = (r+h-1)!/(h!(r-1)!)$. To ease the presentation, we adopt the short hand notations displayed below:

$$\begin{aligned}
k &= (k_1, k_2, \cdots, k_r)\\
\mu^k &= \mu_1^{k_1}\mu_2^{k_2}\cdots\mu_r^{k_r}\\
e_i &= 0\cdots\underbrace{1}_{i^{th}}\cdots 0\\
k - e_i &= k_1 k_2 \cdots (k_i - 1)\cdots k_r\\
\pi(k) &= (k_1!)(k_2!)\cdots(k_r!)\\
\mathcal{C}_{ii}^k(h) &= \frac{(h!)k_i(k_i-1)}{\pi(k)},\ \mathcal{C}_{ij}^k(h) = \frac{(h!)k_i k_j}{\pi(k)}.
\end{aligned}$$

and

$$\mathcal{C}_{iii}^k(h) = \frac{(h!)k_i(k_i-1)(k_i-2)}{\pi(k)}$$

$$\mathcal{C}_{iij}^k(h) = \frac{(h!)k_i(k_i-1)k_j}{\pi(k)},\ \mathcal{C}_{ijl}^k(h) = \frac{(h!)k_i k_j k_l}{\pi(k)}.$$

II. Preliminaries

To begin with, we introduce the following definitions and terminologies which serve as the entry point to this paper.

Definition 1 (SOS functions): [23] A multivariate polynomial $f(x), x \in R^r$, is a sum of squares if there exist polynomials $g_1(x), g_2(x), \cdots, g_t(x)$ such that

$$f(x) = \sum_{i=1}^{t} g_i^2(x).$$

Definition 2 (Monomials): [23] A monomial in x is a function of the form $x_1^{\alpha_1}x_2^{\alpha_2}\cdots x_r^{\alpha_r}$ where $\alpha_1, \alpha_2, \cdots \alpha_r$ are nonnegative integers and the degree of the monomial is given

by α which is the sum of all α_i. In short, $\alpha = \alpha_1 + \alpha_2 + \cdots + \alpha_r$.

Given the aforementioned definition, it is shown in the articles [23], [24] that $f(x)$ is an SOS if and only if there exists a positive semidefinite matrix $Q \geq 0$ such that

$$f(x) = \tilde{x}' Q \tilde{x} \tag{2}$$

where $\tilde{x}$ is a column vector whose entries are all monomials in x. Terminologically, (2) is referred to the Gram matrix method. It is interesting to know that when $\tilde{x} = x$, $f(x)$ in (2) is a quadratic function.

One can search for such a Q by solving a semidefinite program which is done using SOSTOOLS [25], [26] that uses SeDuMi [27] as the semidefinite programming solver. Note that a function that is SOS always implies the underlying function is nonnegative, the converse is not true. However, numerical experiments seem to indicate that the gap between SOS and nonnegativity is small [24]. We note in passing that an extension of scalar polynomial optimization by SOS decomposition to optimization with scalar polynomial objective and nonlinear matrix constraints is stated in [12], [28].

III. Stability Analysis

In this section, we derive stability conditions for discrete-time open loop fuzzy systems that are displayed below:

$$z(t+1) = \sum_{i=1}^{r} \mu_i A_i z = A_\mu z(t) \tag{3}$$

where A_i is a system matrix of each rule i and $\mu_i \geq 0$ is the firing strength of rule i. z is the state vector.

Considering a premise-dependent non-quadratic Lyapunov function

$$V(z(\cdot)) = z^T(\cdot) X_\mu^{-1} z(\cdot) \tag{4}$$

where $X_\mu = \sum_{j=1}^{r} \mu_j X_j$ and $X_j > 0$ are symmetric, positive definite matrices for all discrete-time index t, we have the following Lemmas.

Lemma 1 (Discrete-time Stability, LMI): The open loop system (3) is stable if there exist matrices $X_j = X_j' > 0, j = 1, \cdots, r$ satisfying the following HPPD:

$$f(\mu) := \sum_{i=1}^{r} \sum_{j=1}^{r} \sum_{l=1}^{r} \mu_i \mu_j \mu_l^+ M_{ijl} < 0 \tag{5}$$

where

$$M_{ijl} = \begin{bmatrix} -X_j & X_j A_i' \\ A_i X_j & -X_l \end{bmatrix}$$

Proof: Given the non-quadratic Lyapunov function (4), it is straightforward to verify

$$\begin{aligned} \Delta V(t) &= V(t+1) - V(t) \\ &= z'(t+1) X_{\mu^+}^{-1} z(t+1) - z'(t) X_\mu^{-1} z(t) \\ &< 0 \end{aligned}$$

where μ^+ means $\mu(t+1)$. Recalling Schur complement and congruence transformation with $diag[X_\mu \ I]$, we have an equivalent form

$$\begin{bmatrix} -X_\mu & X_\mu A_\mu' \\ A_\mu X_\mu & -X_{\mu^+} \end{bmatrix} < 0$$

For Lyapunov stability, a sufficient condition is (5). ■

Notice that the matrices M_{ijl} are real symmetric, matrix-valued and linear functions of decision variables (multiple Lyapunov matrices) X_j.

Up to now, we have the following stability condition expressed by matrix-valued homogeneous polynomial function in μ for discrete-time systems.

$$f(\mu) < 0 \tag{6}$$

By applying matrix-valued Pólya's Theorem [29], [30], [31], (6) leads to an equivalent form

$$\begin{aligned} 0 &> (\sum_{i=1}^{r} \mu_i)^d f(\mu) \\ &= \sum_{k \in \mathcal{K}(d+3)} H^k \mu^k \end{aligned} \tag{7}$$

where $\mathcal{K}(d+3)$ is defined in 1 and

$$\begin{aligned} H^k &= \sum_{i=1}^{r} C_{iii}^k(d) M_{iii} \\ &+ \sum_{i=1}^{r-1} \sum_{j=i+1}^{r} C_{iij}^k(d)(M_{iij} + M_{iji} + M_{jii}) \\ &+ \sum_{i=1}^{r-2} \sum_{j=i+1}^{r-1} \sum_{l=j+1}^{r} C_{ijl}^k(d)(M_{ijl} + M_{jil} \\ &+ M_{ilj} + M_{jli} + M_{lij} + M_{lji}) \end{aligned}$$

For Lemmas 1, the challenge lies on how the above conditions (5) can be verified. We observe that the matrices involved are copositive. The brief review in the preliminaries motivates the following research. Unlike existing LMI-based relaxations, we require Lemma 1 to be sum of squares, asking when (7) has an SOS decomposition.

IV. SOS Relaxations

The sum of squares circumvents the NP-hard problem proving positivity of a polynomial function and provides a computationally tractable technique for the existence of an SOS decomposition [23], [12], [13], [32].

Based on Pólya and Lyapunov theorem, we have established that sufficient conditions for the existence of Parameter-dependent Lyapunov function assuring stability is to verify (5), which is a non-convex problem and NP-hard. Most existing LMI-based relaxations in the literature ignore μ and solve the underlying stability problem as an SDP problem. Unlike those approaches, we take μ into consideration. Particularly *instead of asking*

$$-\sum_{k \in \mathcal{K}(d+3)} H^k \mu^k > 0, \quad \mu \in R_+^r$$

we require them to be sums of squares (SOS) [26]. Having established the rationale, the idea is to find a homogeneous polynomially parameter-dependent (HPPD) function such that

$$-\sum_{k\in\mathcal{K}(d+3)} H^k x^{2k} \text{ is SOS} \tag{8}$$

where $\mu = x^2, x \in R^r$ and v_1 is vector independent of x. We emphasize that the HPPD (8) takes the membership μ into accounts, collects the interactions among the subsystems and yields less conservative results.

Therefore by deliberately working on polynomials consisting of basis monomials, the positive definiteness of the negated condition in Lemma 1 can be relaxed to the existence of SOS decomposition. Under this relaxation, the search for a bounded degree d can be efficiently solved by checking the maximum eigenvalues of Q in 2 [33]. The SOS program is therefore formally stated below.

Theorem 1 (SOS Relaxation): There exist a matrix $X_j = X_j' > 0$ solving (6) if for each $k \in \mathcal{K}(d+3)$ and a sufficiently large $d > 0$ there exist matrices $X_j = X_j' > 0$ such that

$$-\sum_{k\in\mathcal{K}(d+3)} H^k x^{2k} > 0 \tag{9}$$

which is verifiable by SOS displayed below

$$-v_1'\left(\sum_{k\in\mathcal{K}(d+3)} (H^k - \phi_1)x^{2k}\right) v_1 \text{ is SOS}$$
$$v_2'\left(X_i - \phi_2\right) v_2, i = 1, \cdots r \text{ is SOS}$$

where ϕ_1, ϕ_2 are sufficiently small positive constants NEEDED to guarantee positive definiteness of HPPD function. v_1, v_2 are vectors independent of x.

Proof: The sufficiency is readily seen from HPPD (7) and lemma 1. ■

More details are documented in [22] whilst the corresponding LMI details are documented in [21].

V. An Example

In order to appreciate the efficiency of the proposed method, we consider an example where the T-S fuzzy models are borrowed from existing papers.

A. Discrete fuzzy systems

Consider a discrete-time fuzzy system borrowed from [10] in which the system matrices are given as

$$A_1 = \begin{bmatrix} b & -0.5 \\ a & -0.9 \end{bmatrix}, A_2 = \begin{bmatrix} 0.9 & -a \\ -0.6 & 0.8 \end{bmatrix}$$

where the (a, b) parameters are varied during numerical experiments for feasibility test. Also, compared with the relaxation method proposed in [10], the proposed SOS relaxation generates more feasible regions than that of the cited paper.

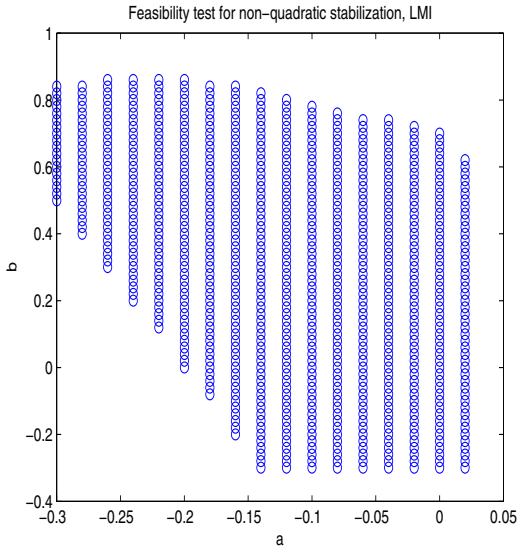

Fig. 1. Feasible regions found by LMI

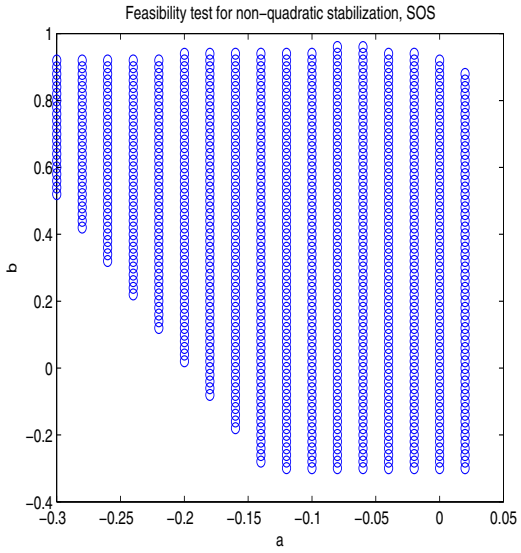

Fig. 2. SOS explores more feasible regions.

VI. Conclusion

In this paper, a stability condition based on sum of squares are developed for discrete-time T-S fuzzy systems. The proposed approach utilizes a premise-dependent Lyapunov function to prove the non-quadratic Lyapunov stability of the underlying fuzzy systems, leading to a family of SOS relaxations that assures existence of non-quadratic Lyapunov function. It is shown and demonstrated via an example that the stability can be cast and solved by SOS .

***Abstract*—This paper is concerned with output feedback control design for a discrete-time fuzzy system with immeasurable premise variables. It is well known that Takagi-Sugeno fuzzy model describes a wide class of nonlinear systems especially when its premise variables include immeasurable functions. However, when it comes to control design of such a fuzzy system with immeasurable premise variables, a conventional parallel distributed compensator(PDC) is not feasible because it shares the same premise variables as those of a fuzzy system. In this paper, we introduce an output feedback controller with the estimate of the premise variables of an original fuzzy system. We then formulate the stabilization problem for a discrete-time fuzzy system with immeasurable premise variables. Our control design method is based on a set of strict LMI conditions. No tuning parameter is necessary a priori to solve LMI conditions. Our method includes tuning matrices for control gains in a controller and hence they can be chosen to optimize the control performance of the system. Furthermore, we extend our results to a class of discrete-time fuzzy systems with uncertain parameters. A design method of robust controller for such uncertain systems is also given. Numerical examples are finally given to illustrate our control design method.**

keywords-Takagi-Sugeno fuzzy systems, Stabilization, Output feedback control

I. Introduction

It is well-known that the Takagi-Sugeno fuzzy model is one of the efficient mathematical models that describe a wide class of nonlinear systems([6], [10]). Hence, its analysis and control synthesis are important. In the past years, sufficient stability conditions were given, and control design methods were proposed([7], [11], [12], [13]). A conventional approach to control design for a fuzzy system is to employ a parallel distributed compensator(PDC). It is shown that a PDC works well for a fuzzy system because it shares the same premise variables as those of the original fuzzy system. The papers [7] and [13] gave stability conditions and proposed a control design method by a PDC. Furthermore, relaxed stability conditions have been investigated in [11] and [12]. These results were only concerned with the state feedback control design, and the premise variables were assumed to be available. However, this is not always the case in many situations. Especially, in practical situations, the state of the system is not measurable and we need an output feedback control design. In this case, the above mentioned results are infeasible. In fact, if the premise variable is the state, a conventional PDC, which feeds back the state variables, is infeasible. Furthermore, when the premise variable is the state, the Takagi-Sugeno model describes the widest class of nonlinear systems. In other words, a conventional PDC can work only for a limited class of nonlinear systems([16]).

In this paper, we propose a design method of a stabilizing output feedback controller for a discrete-time fuzzy system with immeasurable premise variables. Such a fuzzy system describes a large class of nonlinear systems. The results in [3], [8], [9], [16] do not take care of such a class of fuzzy systems. Yoneyama et al. [16] gave an approximate stabilizing output feedback controller. Assawinchaichote et al. [1] and Yoneyama [15] proposed an uncertain fuzzy system approach. Guerra et al. [2] gave a design method based on non-strict LMI conditions. These results are conservative and are not easy to solve controller design conditions. The paper by Yoneyama [17] proposed a design method based on strict LMI conditions. It gives a two-step procedure to solve the design problem. The paper [17] considers only a class of continuous-time fuzzy systems with immeasurable premise variables. This paper is concerned with a discrete-time counterpart. A control design procedure is also based on strict LMI conditions. No tuning parameter is required in the control design, which is much easier than others in the literature. In addition, we have free scaling matrices that can tune control gain matrices.

We also consider the robust stabilization for fuzzy systems with uncertain parameters. Our method can easily be extended to such a robust stabilization problem. For this robust stabilization problem, we also give a similar two-step procedure with strict LMI conditions, which can easily be calculated via numerical software. Finally, some numerical examples are given to illustrate our design procedure and the effectiveness of our design method.

II. Fuzzy Systems

In this section, we introduce discrete-time Takagi-Sugeno fuzzy systems. Consider the discrete-time Takagi-Sugeno fuzzy model, described by the following IF-THEN rules:

$$\begin{array}{ll} \textbf{IF} & \xi_1 \ is \ M_{i1} \ and \ \cdots \ and \ \xi_p \ is \ M_{ip}, \\ \textbf{THEN} & x(k+1) = A_i x(k) + B_i u(k), \\ & y(k) = C_i x(k), \quad i = 1, \cdots, r \end{array}$$

where $x(k) \in \Re^n$ is the state, $u(k) \in \Re^m$ is the control input and $y(k) \in \Re^q$ is the measurement output. The matrices A_i, B_i

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

and C_i are constant matrices of appropriate dimensions. r is the number of IF-THEN rules. M_{ij} are fuzzy sets and $\xi_1, \cdots, \xi_p$ are premise variables. We set $\xi = [\xi_1 \quad \cdots \quad \xi_p]^T$. The premise variable $\xi(k)$ is assumed to be a function of the state, which is immeasurable.

For simplicity, we define the following notations:

$$X_\xi = \sum_{i=1}^{r} \lambda_i(\xi(k)) X_i,$$
$$X_{\hat{\xi}} = \sum_{i=1}^{r} \lambda_i(\hat{\xi}(k)) X_i,$$
$$X_{\xi\hat{\xi}} = \sum_{i=1}^{r}\sum_{j=1}^{r} \lambda_i(\xi(k))\lambda_j(\hat{\xi}(k)) X_{ij}.$$

and so on.

Then, the state equation and the output equation are described, respectively, by

$$\begin{aligned} x(k+1) &= \sum_{i=1}^{r} \lambda_i(\xi(k))\{A_i x(k) + B_i u(k)\} \\ &\triangleq A_\xi x(k) + B_\xi u(k), \\ y(k) &= \sum_{i=1}^{r} \lambda_i(\xi(k)) C_i x(k) \\ &\triangleq C_\xi x(k), \end{aligned} \tag{1}$$

where $\lambda_i(\xi(k))$

$$\lambda_i(\xi(k)) = \frac{\beta_i(\xi(k))}{\sum_{i=1}^{r} \beta_i(\xi(k))}, \quad \beta_i(\xi(k)) = \prod_{j=1}^{p} M_{ij}(\xi_j(k))$$

and $M_{ij}(\cdot)$ is the grade of the membership function of M_{ij}. We assume

$$\beta_i(\xi(k)) \geq 0, \ i = 1, \cdots, r, \ \sum_{i=1}^{r} \beta_i(\xi(k)) > 0$$

for any $\xi(k)$. Hence $\lambda_i(\xi(k))$ satisfy

$$\lambda_i(\xi(k)) \geq 0, \ i = 1, \cdots, r, \ \sum_{i=1}^{r} \lambda_i(\xi(k)) = 1$$

for any $\xi(k)$.

As stated in [15], [16], a fuzzy system covers a wider class of nonlinear systems when its premise variables are the state variables than the measurement output. In order to design a stabilizing controller for a fuzzy system, a PDC is traditionally used for stabilization because it shares the same premise variables as those of a fuzzy system([7], [13]). However, a PDC is feasible only if the premise variables are measurable or available functions. Thus, most existing results have assumed that the premise variables are measurable([3], [8], [9], [16]). In this paper, we consider an output feedback stabilization where the state is not directly measurable. A fuzzy system is supposed to have the premise variables that are functions of the states, which are immeasurable. In this case, actual values of the premise variables are not available. Hence, we employ the following rules for an output feedback controller with the premise variables being their estimates:

IF $\hat{\xi}_1$ *is* M_{i1} *and* $\cdots$ *and* $\hat{\xi}_p$ *is* M_{ip},
THEN $\hat{x}(k+1) = \hat{A}_i \hat{x}(k) + \hat{B}_i y(k)$
$u(k) = \hat{C}_i \hat{x}(k), \quad i, j = 1, \cdots, r.$

where $\hat{A}_i = \sum_{j=1}^{r} \lambda_j(\hat{\xi}(k)) \hat{A}_{ij}$, and $\hat{A}_{ij}$, $\hat{B}_i$ and $\hat{C}_i$ are constant matrices to be determined. Then the natural choice of a controller is given by

$$\begin{aligned} \hat{x}(k+1) &= \sum_{i=1}^{r}\sum_{j=1}^{r} \lambda_i(\hat{\xi})\lambda_j(\hat{\xi})\{\hat{A}_{ij}\hat{x}(k) + \hat{B}_j y(k)\} \\ &\triangleq \hat{A}_{\hat{\xi}\hat{\xi}}\hat{x}(k) + \hat{B}_{\hat{\xi}} y(k), \\ u(k) &= \sum_{i=1}^{r} \lambda_i(\hat{\xi})\hat{C}_i \hat{x}(k) \triangleq \hat{C}_{\hat{\xi}}\hat{x}(k). \end{aligned} \tag{2}$$

Remark 2.1: One might consider the following controller:

$$\begin{aligned} \hat{x}(k+1) &= \sum_{i=1}^{r} \lambda_i(\hat{\xi})\{\hat{A}_i\hat{x}(k) + \hat{B}_j y(k)\}, \\ u(k) &= \sum_{i=1}^{r} \lambda_i(\hat{\xi})\hat{C}_i\hat{x}(k). \end{aligned}$$

However, this class of controllers is limited, and a general class of controller is given as in (2)(see [10] for more detail.).

The closed-loop system (1) with (2) becomes

$$x_e(k+1) = \bar{A}_{\xi\hat{\xi}\hat{\xi}} x_e(k), \tag{3}$$

where $x_e(k)$ and $\bar{A}_{\xi\hat{\xi}\hat{\xi}}$ are given by

$$x_e(k) = \begin{bmatrix} x(k) \\ \hat{x}(k) \end{bmatrix}, \ \bar{A}_{\xi\hat{\xi}\hat{\xi}} = \begin{bmatrix} A_\xi & B_\xi \hat{C}_{\hat{\xi}} \\ \hat{B}_{\hat{\xi}} C_\xi & \hat{A}_{\hat{\xi}\hat{\xi}}. \end{bmatrix}$$

Our problem is to find an output feedback controller (2) such that the closed-loop system (3) is asymptotically stable.

The following lemma is useful to prove our main results.

Lemma 2.1: ([12])

$$\sum_{i=1}^{r}\sum_{j=1}^{r} \lambda_i(\xi(k))\lambda_j(\xi(k))\Phi_{ij} < 0$$

holds if the followings are satisfied:

$$\begin{aligned} \Phi_{ii} &< 0, \qquad i = 1, \cdots, r, \\ \frac{2}{r-1}\Phi_{ii} + \Phi_{ij} + \Phi_{ji} &< 0, \quad i, j = 1, \cdots, r, \ i \neq j \end{aligned}$$

III. Stability and Stabilization

Here, we consider an output feedback control of a discrete-time fuzzy system. We first give sufficient conditions for the closed-loop system (3) to be asymptotically stable. Then, we propose a design method of an output feedback controller for a discrete-time fuzzy system.

A. Stabilization Analysis

We make the stability analysis of the closed-loop system (3).

Theorem 3.1: An output feedback controller of the form (2) stabilizes the fuzzy system (1) if there exist matrices $X > 0,\ Y > 0,\ L_{\hat{\xi}\hat{\xi}},\ W_{\hat{\xi}},\ Z_{\hat{\xi}}$ such that

$$\left[\begin{array}{cc} X & I \\ I & Y \end{array} \right] > 0, \tag{4}$$

$$\Psi_{\xi\hat{\xi}\hat{\xi}} = \left[\begin{array}{cccc} -X & -I & \Psi_{13\xi\hat{\xi}} & A_{\xi} \\ -I & -Y & \Psi_{23\xi\hat{\xi}\hat{\xi}} & \Psi_{24\xi\hat{\xi}} \\ \Psi_{13\xi\hat{\xi}}^T & \Psi_{23\xi\hat{\xi}\hat{\xi}}^T & -X & -I \\ A_{\xi}^T & \Psi_{24\xi\hat{\xi}}^T & -I & -Y \end{array} \right] < 0. \tag{5}$$

where

$$\begin{array}{rcl} \Psi_{13\xi\hat{\xi}} & = & A_{\xi}X + B_{\xi}Z_{\hat{\xi}}, \\ \Psi_{23\xi\hat{\xi}\hat{\xi}} & = & YA_{\xi}X + YB_{\xi}Z_{\hat{\xi}} + W_{\hat{\xi}}C_{\xi}X + L_{\hat{\xi}\hat{\xi}}, \\ \Psi_{24\xi\hat{\xi}} & = & YA_{\xi} + W_{\hat{\xi}}C_{\xi}. \end{array}$$

Proof: We investigate the stability of the closed-loop system (3). A condition for the system (3) to be asymptotically stable is that there exists a matrix $P > 0$ such that

$$\bar{A}_{\xi\hat{\xi}\hat{\xi}}^T P \bar{A}_{\xi\hat{\xi}\hat{\xi}} - P < 0$$

or equivalently

$$\Lambda = \left[\begin{array}{cc} -P^{-1} & \bar{A}_{\xi\hat{\xi}\hat{\xi}} \\ \bar{A}_{\xi\hat{\xi}\hat{\xi}}^T & -P \end{array} \right] < 0. \tag{6}$$

To solve the matrix inequality (6), we follow the idea of [5] and partition P and P^{-1} as

$$P = \left[\begin{array}{cc} Y & N \\ N^T & V \end{array} \right], \quad P^{-1} = \left[\begin{array}{cc} X & M \\ M^T & U \end{array} \right]. \tag{7}$$

Define a transformation matrix Π as

$$\Pi = \left[\begin{array}{cc} X & I \\ M^T & 0 \end{array} \right]. \tag{8}$$

Then, it can be inferred from $PP^{-1} = I$ that

$$YX + NM^T = I. \tag{9}$$

We take a congruence transformation with Π for P to obtain

$$\Pi^T P \Pi = \left[\begin{array}{cc} X & I \\ I & Y \end{array} \right] > 0,$$

which is exactly the same as (4).

Pre- and post-multiplying Λ by $S = diag[P\Pi\ \Pi]$, we obtain

$$\Psi_{\xi\hat{\xi}\hat{\xi}} = S^T \Lambda S = \left[\begin{array}{cc} -\Pi^T P \Pi & \Pi^T P \bar{A}_{\xi\hat{\xi}\hat{\xi}} \Pi \\ \Pi^T \bar{A}_{\xi\hat{\xi}\hat{\xi}}^T P \Pi & -\Pi^T P \Pi \end{array} \right] < 0,$$

or more exactly we get (5) where we define

$$L_{\hat{\xi}\hat{\xi}} = N\hat{A}_{\hat{\xi}\hat{\xi}}M^T,\ W_{\hat{\xi}} = N\hat{B}_{\hat{\xi}},\ \text{and}\ Z_{\hat{\xi}} = \hat{C}_{\hat{\xi}}M^T. \tag{10}$$

B. Stabilization

This section gives sufficient conditions for the closed-loop system (3) to be asymptotically stable, and a method of controller design base on such stability conditions.

Theorem 3.2: An output feedback controller of the form (2) stabilizes the fuzzy system (1) if there exist matrices $X > 0,\ Y > 0,\ L_{jk},\ W_j,\ Z_j,\ j,k = 1,\cdots,r$ such that (4) holds and

$$\begin{array}{ll} \Psi_{ijj} < 0, & i,j = 1,\cdots,r, \\ \dfrac{2}{r-1}\Psi_{ijj} + \Psi_{ijk} + \Psi_{ikj} < 0, & i,j,k = 1,\cdots,r, \\ & j \neq k. \end{array} \tag{11}$$

where

$$\Psi_{ijk} = \left[\begin{array}{cccc} -X & \Psi_{13ij}^T & \Psi_{23ijk}^T & -I \\ \Psi_{13ij} & -X & -I & A_i \\ \Psi_{23ijk} & -I & -Y & \Psi_{24ij} \\ -I & A_i^T & \Psi_{24ij}^T & -Y \end{array} \right],$$

$$\begin{array}{rcl} \Psi_{13ij} & = & A_iX + B_iZ_j, \\ \Psi_{23ijk} & = & YA_iX + YB_iZ_j + W_jC_iX + L_{jk}, \\ \Psi_{24ij} & = & YA_i + W_jC_i. \end{array}$$

In this case, control gain matrices in (2) are given by

$$\begin{array}{l} \hat{A}_{jk} = N^{-1}L_{jk}M^{-T}, \\ \hat{B}_j = N^{-1}W_j, \\ \hat{C}_j = Z_jM^{-T}, j,k = 1,\cdots,r \end{array} \tag{12}$$

where M and N can be found from the equation $NM^T = I - YX$.

Proof: If conditions (11) are satisfied, it follows from Lemma 2.1 that

$$\sum_{i=1}^{r}\sum_{j=1}^{r}\sum_{k=1}^{r} \lambda_i(\xi(k))\lambda_j(\hat{\xi}(k))\lambda_k(\hat{\xi}(k))\Psi_{ijk} = \Psi_{\xi\hat{\xi}\hat{\xi}} < 0.$$

Taking a congruence transformation with the following T:

$$T = \left[\begin{array}{cccc} 0 & 0 & I & 0 \\ I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & 0 & I \end{array} \right]$$

and calculating $T^T\Psi_{\xi\hat{\xi}\hat{\xi}}T < 0$, we obtain (5).

By Theorem 3.1, the stability is established. Control gain matrices (12) follow from the relations (10).

Theorem 3.2 does not give LMI conditions. However, the following algorithm provides an efficient LMI-based approach to solve for (4) and (11).

Algorithm 3.1: **Step 1**: Solve $Y > 0,\ W_j,\ j = 1,\cdots,r$ for the following LMI conditions

$$\left[\begin{array}{cc} -Y & \Psi_{24ij} \\ \Psi_{24ij}^T & -Y \end{array} \right] < 0, \quad i,j = 1,\cdots,r.$$

Step 2: Insert matrices $Y,\ W_j,\ j = 1,\cdots,r$, which are obtained in **Step 1**, into Ψ_{ijk}. Solve $X > 0,\ Z_j,\ L_{jk},\ j,k = 1,\cdots,r$ for (4) and (11).

Step 3: If there exists a solution, obtain gain matrices as in (12).

Remark 3.1: It follows from (4) that $Y - X^{-1} > 0$ and hence $NM^T = I - YX$ is nonsingular. M and N can tune control gain matrices in (2), which reflect trajectories of the states of the controlled system. One way to find M is to choose $M = X$. In this case, $\hat{x}$ in (2) becomes an estimate of the state x(see [4] for more detail.), and $N = X^{-1} - Y$.

Remark 3.2: Assawinchaichote et al. [1] and Yoneyama [15] considered the grade $\lambda_i(\xi)$ as uncertainty, and then gave stability conditions. Since their results depend on the maximum upper bound of $\lambda(\xi)$, they are rather conservative. The result of Guerra et al. [2] is based on non-LMI conditions with four scaling parameters, which must be chosen a priori. Algorithm 3.1 is involved with only strict LMI conditions, which are much easier to be solved than other methods.

C. Robust Stabilization

Now, we extend the results in the previous sections to a class of uncertain discrete-time fuzzy systems. Consider the uncertain discrete-time Takagi-Sugeno fuzzy model, described by the following IF-THEN rules:

$$\begin{array}{ll}\textbf{IF} & \xi_1 \ is \ M_{i1} \ and \ \cdots \ and \ \xi_p \ is \ M_{ip}, \\ \textbf{THEN} & x(k+1) = (A_i + \Delta A_i)x(k) \\ & \qquad +(B_i + \Delta B_i)u(k), \\ & y(k) = (C_i + \Delta C_i)x(k), \quad i = 1, \cdots, r\end{array}$$

where ΔA_i, ΔB_i and ΔC_i, $i = 1, \cdots, r$ are uncertain matrices that have the following structures:

$$\left[\begin{array}{cc} \Delta A_i & \Delta B_i \\ \Delta C_i & * \end{array}\right] = \left[\begin{array}{c} H_{1i} \\ H_{2i} \end{array}\right] F_i(k) \left[\begin{array}{cc} E_{1i} & E_{2i} \end{array}\right], \quad i = 1, \cdots, r. \tag{13}$$

and $F_i(k)$ is an uncertain matrix satisfying

$$F_i^T(k)F_i(k) \le I, \ i = 1, \cdots, r,$$

and H_{1i}, H_{2i}, E_{1i} and E_{2i} are constant matrices of appropriate dimensions.

The state and output equations are described by

$$\begin{aligned} x(k+1) = & \sum_{i=1}^{r} \lambda_i(\xi)\{(A_i + H_{1i}F_i(k)E_{1i})x(k) \\ & +(B_i + H_{1i}F_i(k)E_{2i})u(k)\}, \\ \triangleq & A_{\Delta\xi}x(k) + B_{\Delta\xi}u(k), \\ y(k) = & \sum_{i=1}^{r} \lambda_i(\xi)\{(C_i + H_{2i}F_i(k)E_{1i})x(k)\} \\ \triangleq & C_{\Delta\xi}x(k). \end{aligned} \tag{14}$$

If there exists a controller of the form (2) that stabilizes the system (14) for all admissible uncertain matrices ΔA_i, ΔB_i and ΔC_i satisfying (13), then it is called a robust stabilizing controller.

For the system (14), we will find a robust stabilizing controller. To this end, we use the following lemma.

Lemma 3.1: ([14]) Given matrices $Q = Q^T$, H, E and $R = R^T > 0$ of appropriate dimensions

$$Q + HF(k)E + E^TF^T(k)H^T < 0$$

for all $F(k)$ satisfying $F^T(k)F(k) \le R$ if and only if there exists a scalar $\varepsilon > 0$ such that

$$Q + \frac{1}{\varepsilon}HH^T + \varepsilon E^TRE < 0.$$

The closed-loop system (14) with (2) is given by

$$x_e(k+1) = \bar{A}_{\xi\hat{\xi}\hat{\xi}}x_e(k) \tag{15}$$

where $x_e(k)$ and $\bar{A}_{\xi\hat{\xi}\hat{\xi}}$ is given by

$$x_e(k) = \left[\begin{array}{c} x(k) \\ \hat{x}(k) \end{array}\right], \quad \bar{A}_{\xi\hat{\xi}\hat{\xi}} = \left[\begin{array}{cc} A_{\Delta\xi} & B_{\Delta\xi}\hat{C}_{\hat{\xi}} \\ \hat{B}_{\hat{\xi}}C_{\Delta\xi} & \hat{A}_{\hat{\xi}\hat{\xi}} \end{array}\right].$$

Theorem 3.3: An output feedback controller of the form (2) robustly stabilizes the uncertain fuzzy system (14) if there exist matrices $X > 0$, $Y > 0$, L_{jk}, W_j, Z_j, $j, k = 1, \cdots, r$ and scalars $\varepsilon_i > 0$ such that (4) holds and

$$\left[\begin{array}{ccccc} -\frac{1}{\varepsilon_{ij}}I & 0 & \bar{E}_{1ij} & 0 & 0 \\ 0 & -\frac{1}{\varepsilon_{ij}}I & \bar{E}_{2i} & 0 & 0 \\ \bar{E}_{1ij}^T & \bar{E}_{2i}^T & \Xi_{ijj} & \bar{H}_{1i} & \bar{H}_{2ij} \\ 0 & 0 & \bar{H}_{1i}^T & -\varepsilon_{ij}I & 0 \\ 0 & 0 & \bar{H}_{2ij}^T & 0 & -\varepsilon_{ij}I \end{array}\right] < 0, \quad i, j = 1, \cdots, r, \tag{16}$$

$$\left[\begin{array}{ccccc} -\frac{1}{\varepsilon_{ij}}I & 0 & \hat{E}_{1ijk} & 0 & 0 \\ 0 & -\frac{1}{\varepsilon_{ij}}I & \bar{E}_{2i} & 0 & 0 \\ \hat{E}_{1ijk}^T & \bar{E}_{2i}^T & \hat{\Xi}_{ijk} & \bar{H}_{1i} & \hat{H}_{2ijk} \\ 0 & 0 & \bar{H}_{1i}^T & -\varepsilon_{ij}I & 0 \\ 0 & 0 & \hat{H}_{2ijk}^T & 0 & -\varepsilon_{ij}I \end{array}\right] < 0, \quad i, j, k = 1, \cdots, r, \ j \ne k, \tag{17}$$

where

$$\begin{aligned} \Xi_{ijk} &= \left[\begin{array}{cccc} -X & \Xi_{13ij}^T & \Xi_{23ijk}^T & -I \\ \Xi_{13ij} & -X & -I & A_i \\ \Xi_{23ijk} & -I & -Y & \Xi_{24ij} \\ -I & A_i^T & \Xi_{24ij}^T & -Y \end{array}\right], \\ \Xi_{14ij} &= A_iX + B_iZ_j, \\ \Xi_{24ijk} &= YA_iX + YB_iZ_j + W_jC_iX + L_{jk}, \\ \Xi_{25ij} &= YA_i + W_jC_i, \\ \hat{\Xi}_{ijk} &= \tfrac{2}{r-1}\Xi_{ijj} + \Xi_{ijk} + \Xi_{ikj}, \\ \bar{H}_{1i} &= \left[\begin{array}{cccc} 0 & H_{1i}^T & H_{1i}^TY & 0 \end{array}\right]^T, \\ \bar{H}_{2ij} &= \left[\begin{array}{cccc} 0 & 0 & H_{2i}^TW_j^T & 0 \end{array}\right]^T, \\ \hat{H}_{2ijk} &= \tfrac{r+1}{r-1}\bar{H}_{2ij} + \bar{H}_{2ik}, \\ \bar{E}_{1ij} &= \left[\begin{array}{cccc} E_{1i}X + E_{2i}Z_j & 0 & 0 & E_{1i} \end{array}\right]^T, \\ \bar{E}_{2i} &= \left[\begin{array}{cccc} E_{1i}X & 0 & 0 & E_{1i} \end{array}\right]^T, \\ \hat{E}_{1ijk} &= \tfrac{r+1}{r-1}\bar{E}_{1ij} + \bar{E}_{1ik}. \end{aligned}$$

In this case, control gain matrices in (2) are given by (12).

Proof: Replacing A_i, B_i and C_i by $A_i + H_{1i}F_iE_{1i}$, $B_i + H_{1i}F_iE_{2i}$ and $C_i + H_{2i}F_iE_{1i}$, respectively in the first LMI (11), we get

$$\begin{aligned} &\Psi_{ijj} + \bar{H}_{1i}F_i\bar{E}_{1ij} + \bar{E}_{1ij}^TF_i^T\bar{H}_{1i}^T \\ &\quad +\bar{H}_{2ij}F_i\bar{E}_{2i} + \bar{E}_{2i}^TF_i^T\bar{H}_{2ij}^T < 0, \ i, j = 1, \cdots, r. \end{aligned}$$

We apply Lemma 3.1, and obtain an equivalent condition that there exists $\varepsilon_i > 0$ such that

$$\Psi_{ijj} + \varepsilon_i \bar{E}_{1ij}^T \bar{E}_{1ij} + \varepsilon_i \bar{E}_{2i}^T \bar{E}_{2i} + \frac{1}{\varepsilon_i} \bar{H}_{1i} \bar{H}_{1i}^T + \frac{1}{\varepsilon_i} \bar{H}_{2ij} \bar{H}_{2ij}^T < 0, \ i,j = 1, \cdots, r.$$

By Schur complement formula, we finally obtain the LMI in (16).

The LMI in (17) can be obtained in a similar manner. In fact, it follows from (17) that

$$\begin{aligned} &\frac{2}{r-1}\Psi_{ijj} + \Psi_{ijk} + \Psi_{ikj} + \frac{\varepsilon_i(r+1)}{r-1}\bar{E}_{1ij}^T \bar{E}_{1ij} \\ &+\varepsilon_i \bar{E}_{1ik}^T \bar{E}_{1ik} + \frac{2r\varepsilon_i}{r-1}\bar{E}_{2i}^T \bar{E}_{2i} + \frac{2r}{\varepsilon_i(r-1)}\bar{H}_{1i}\bar{H}_{1i}^T \\ &+\frac{r+1}{\varepsilon_i(r-1)}\bar{H}_{2ij}\bar{H}_{2ij}^T + \frac{1}{\varepsilon_i}\bar{H}_{2ik}\bar{H}_{2ik}^T < 0, \\ &\qquad i = 1, \cdots, r, \quad j \neq k = 1, \cdots, r. \end{aligned}$$

Then, the results follow.

The following algorithm is used for the control design.

Algorithm 3.2: **Step 1**: Solve $Y > 0, \ W_j, \ j = 1, \cdots, r$ and $\varepsilon_i > 0, \ i = 1, \cdots, r$ for the following LMI conditions

$$\begin{bmatrix} -Y & \Xi_{24ij} & YH_{1i} & W_j H_{2i} \\ \Xi_{24ij}^T & -Y & 0 & 0 \\ H_{1i}^T Y & 0 & -\varepsilon_{ij} I & 0 \\ H_{2i}^T W_j^T & 0 & 0 & -\varepsilon_{ij} I \end{bmatrix} < 0, \quad i,j = 1, \cdots, r,$$

$$\begin{bmatrix} -\frac{2r}{r-1}Y & \hat{\Xi}_{24ijk} & YH_{1i} & \tilde{H}_{ijk} \\ \hat{\Xi}_{24ijk}^T & -\frac{2r}{r-1}Y & 0 & 0 \\ H_{1i}^T Y & 0 & -\varepsilon_{ij} I & 0 \\ \tilde{H}_{ijk}^T & 0 & 0 & -\varepsilon_{ij} I \end{bmatrix} < 0, \quad i,j,k = 1, \cdots, r, \ \ j \neq k$$

where

$$\begin{aligned} \hat{\Xi}_{24ijk} &= \frac{r+1}{r-1}\Xi_{24ij} + \Xi_{24ik}, \\ \tilde{H}_{ijk} &= \frac{r+1}{r-1} W_j H_{2i} + W_k H_{2i}, \end{aligned}$$

Step 2: Insert matrices $Y, \ W_j, \ j = 1, \cdots, r$ and $\varepsilon_i > 0, \ i = 1, \cdots, r$, which are obtained in **Step 1**, into Ψ_{ijk}. Then, solve $X > 0, \ L_{jk}, \ Z_j, \ j,k = 1, \cdots, r$ for (4), (16) and (17).

Step 3: If there exists a solution, obtain gain matrices as in (12).

Remark 3.3: Algorithm 3.2 also gives LMI approach to solving an output feedback control problem.

IV. Examples

We give two examples. The first one illustrates stabilization for a nominal fuzzy system. The second example is concerned with an uncertain fuzzy system. We note that the results in [3], [8], [9], [16] cannot be applied to these problems because these papers assume the measurable premise variables.

Example 4.1 Consider the fuzzy system (1) with following matrices:

$$\begin{aligned} A_1 &= \begin{bmatrix} 1.2 & -0.2 \\ 0.1 & -0.4 \end{bmatrix}, \\ A_2 &= \begin{bmatrix} 1.2 & -0.2 \\ 0.2 & 0 \end{bmatrix}, \\ B_1 &= \begin{bmatrix} 1.3 \\ 0.7 \end{bmatrix}, \\ B_2 &= \begin{bmatrix} 1.5 \\ 1.0 \end{bmatrix}, \\ C_1 = C_2 &= \begin{bmatrix} 10 & -2 \end{bmatrix}, \\ \lambda_1(x_1) &= \frac{1}{1+e^{-x_1}}, \\ \lambda_2(x_1) &= 1 - \lambda_1(x_1). \end{aligned}$$

The system is descretized with sampling time $t_s = 0.01$. We attempt to obtain a stabilizing output feedback controller of the form (2). In this problem, the output y is the only measurable and premise variable x_1 is immeasurable. Algorithm 3.1 guarantees the existence of a stabilizing output feedback controller. According to the result in [4], we choose $M = X$. In this case, then a stabilizing controller (2) is given with

$$\begin{aligned} \hat{A}_{11} &= \begin{bmatrix} -0.7815 & 0.0775 \\ -0.4765 & -0.1442 \end{bmatrix}, \\ \hat{A}_{12} &= \begin{bmatrix} -1.4191 & 0.7697 \\ 0.4761 & -3.4518 \end{bmatrix}, \\ \hat{A}_{21} &= \begin{bmatrix} -0.4473 & -0.5188 \\ -1.3826 & 3.2341 \end{bmatrix}, \\ \hat{A}_{22} &= \begin{bmatrix} -0.9619 & 0.0924 \\ -0.5902 & -0.1377 \end{bmatrix}, \\ \hat{B}_1 &= \begin{bmatrix} 0.1251 \\ 0.0130 \end{bmatrix}, \\ \hat{B}_2 &= \begin{bmatrix} 0.1471 \\ 0.0274 \end{bmatrix}, \\ \hat{C}_1 &= \begin{bmatrix} -0.5381 & 0.0250 \end{bmatrix}, \\ \hat{C}_2 &= \begin{bmatrix} -0.5253 & 0.0088 \end{bmatrix}. \end{aligned}$$

Simulation results of x_1 and $\hat{x}_1$ with the initial conditions

$$x(0) = \begin{bmatrix} 10 \\ 5 \end{bmatrix}, \ \hat{x}(0) = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

are depicted in Fig. 1. The solid lines show the state x and the dotted lines the estimate $\hat{x}$. The controller stabilizes the system. No tuning parameter is necessary for solving LMI conditions in Algorithm 3.1, while several tuning parameters are required to be given to solve design conditions in [2].

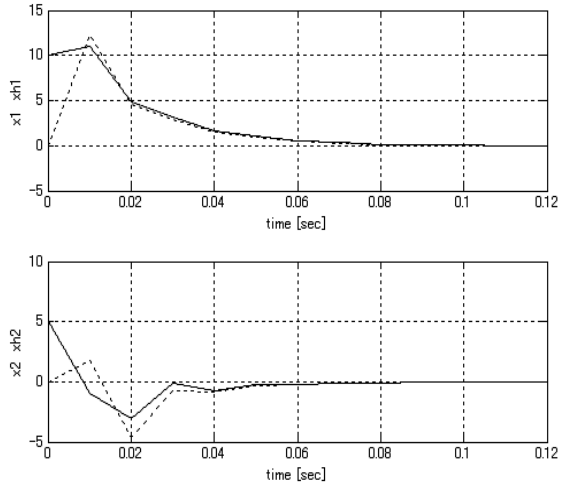

Fig. 1. States of the system

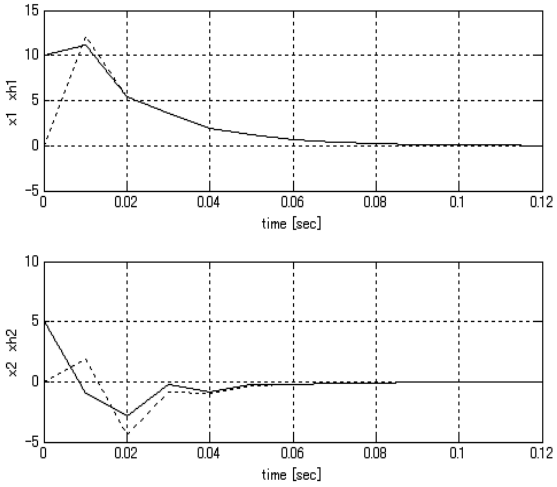

Fig. 2. States of the system

Example 4.2 We consider the system (14) with the following matrices:

$$A_1 = \begin{bmatrix} 1.2 & -0.2 \\ 0.1 & -0.4 \end{bmatrix},$$
$$A_2 = \begin{bmatrix} 1.2 & -0.2 \\ 0.2 & 0 \end{bmatrix},$$
$$B_1 = \begin{bmatrix} 1.3 \\ 0.7 \end{bmatrix},$$
$$B_2 = \begin{bmatrix} 1.5 \\ 1.0 \end{bmatrix},$$
$$C_1 = C_2 = \begin{bmatrix} 10 & -2 \end{bmatrix},$$
$$\lambda_1(x_1) = \frac{1}{1+e^{-x_1}},$$
$$\lambda_2(x_1) = 1 - \lambda_1(x_1),$$
$$H_{11} = H_{12} = 0.1I,$$
$$H_{21} = H_{22} = \begin{bmatrix} 0.1 & 0.1 \end{bmatrix},$$
$$E_{11} = E_{12} = 0.1I,$$
$$E_{21} = E_{22} = \begin{bmatrix} 0.1 \\ 0 \end{bmatrix}.$$

The system is descretized with sampling time $t_s = 0.01$.

Algorithm 3.2 gives a stabilizing output feedback controller (2) with $\hat{\xi} = \hat{x}_1$. Choosing $M = X$, we obtain control gains:

$$\hat{A}_{11} = \begin{bmatrix} -0.7862 & 0.0180 \\ -0.5132 & -0.1761 \end{bmatrix},$$
$$\hat{A}_{12} = \begin{bmatrix} -1.0024 & -0.6752 \\ -1.1031 & -2.2682 \end{bmatrix},$$
$$\hat{A}_{21} = \begin{bmatrix} -0.8287 & 0.8416 \\ 0.2020 & 2.0217 \end{bmatrix},$$
$$\hat{A}_{22} = \begin{bmatrix} -0.8223 & 0.0216 \\ -0.5389 & -0.1751 \end{bmatrix},$$
$$\hat{B}_1 = \begin{bmatrix} 0.1328 \\ 0.0195 \end{bmatrix},$$
$$\hat{B}_2 = \begin{bmatrix} 0.1371 \\ 0.0227 \end{bmatrix},$$
$$\hat{C}_1 = \begin{bmatrix} -0.5091 & -0.0145 \end{bmatrix},$$
$$\hat{C}_2 = \begin{bmatrix} -0.5104 & -0.0184 \end{bmatrix}.$$

Simulation results with the initial conditions and uncertain parameter:

$$x(0) = \begin{bmatrix} 10 \\ 5 \end{bmatrix},\ \hat{x}(0) = \begin{bmatrix} 0 \\ 0 \end{bmatrix},\ F(k) = cos(10k).$$

are shown in Fig. 2. The solid lines show the state x and the dotted lines the estimate $\hat{x}$. The controller robustly stabilizes the system.

V. Conclusions

We have proposed a stabilizing output feedback controller for discrete-time fuzzy systems with immeasurable premise variables. Our design method was based on LMI approach. No tuning parameter is necessary to solve the output feedback controller design problem. Furthermore, we extended the results to the case of robust output feedback controller for a class of uncertain fuzzy systems. Finally, some numerical examples are given to illustrate our design methods.

Abstract— **This paper deals with decentralized stabilization of large scale switched nonlinear systems under arbitrary switching laws. A global large scale switched system can be split into a set of smaller interconnected switched Takagi Sugeno fuzzy subsystems. Then, in order to stabilize the overall closed-loop system, a set of switched non-PDC controllers is employed. The latter is designed based on Linear Matrix Inequalities (LMI) conditions obtained from a multiple switched non quadratic like-Lyapunov candidate function. A numerical example is proposed to illustrate the effectiveness of the suggested decentralized switched controller design approach.**

Keywords- switched fuzzy system, decentralized control, stabilizing non-PDC control law, arbitrary switching laws, multiple switched non quadratic like-Lyapunov functional.

I. INTRODUCTION

Among control theory, switched linear systems has grown interest since they provide a convenient modeling approach for many physical systems such as computer networks, embedded control systems, traffic control systems, automatic highway systems, chemical process [1-4]. This special class of hybrid system is represented by a family of time-invariant systems switching together in accordance to a stabilizing or an arbitrary law.

In the past decades, many studies focused on the stability analysis and stabilization issue for both linear and nonlinear switched systems [5-10]. The main challenge in treating such problems is to guaranty the stability of the whole system at the switching time. Indeed, the well-know example in [11] show that the stability of each subsystem may not involve the stability of the whole switched system. Hence, switching between subsystems may introduce instable behavior.

Attempting to solve this problem, several primary results dealing with switched linear systems propose to find a common quadratic Lyapunov function satisfying some linear matrix inequality (LMI) conditions [11]. Despite the simplicity of the obtained LMI formulation, finding a common Lyapunov function leads to conservatism. Thus, in order to reduce the conservatism, some relaxed approaches has been proposed by using piecewise quadratic Lyapunov functions [12] or multiple Lyapunov functions [13-16]. In [14], besides to the conditions ensuring the decreasing behaviors for each local Lyapunov function, an additional condition at the switching time to ensure the stability of the whole switched system. Some other works suggest verifying the decreasing behaviour of like-Lyapunov function's switching sequences, see e.g. [8] for more details.

In this study, the problem of designing decentralized switched controllers ensuring the stability of continuous time large scale switched nonlinear systems is addressed. Based on the well-known universal approximator property of Takagi-Sugeno (TS) fuzzy models for nonlinear problems [17,18], there is a growing attention on studying switched nonlinear systems based on TS fuzzy modeling, see e.g. [19]. This kind of systems, known as switched fuzzy systems, involves TS models to represent nonlinear continuous modes. This class of hybrid dynamical systems may be useful to describe precisely both continuous and discrete dynamics as well as their interactions in real-world systems [19,20]. Despite switched linear systems, few studies have been done in the switched nonlinear case. A common Lyapunov candidate function has been firstly employed to ensure the stabilization of switched fuzzy systems [11]. In [21], authors propose to employ a switched PDC controller as well as a switched fuzzy Lyapunov candidate function. However, the authors don't mention any condition to guarantee the stability of the whole system at the switching times.

According to the above described studies and since complex physical configuration and high dimension of many real systems, several works have dealt with stability and stabilization issues of large scale dynamical systems; see e.g. [22-26]. Nevertheless, few investigations can be found in the literature dealing with stability and stabilization problems of large scale switched systems [24,27,28]. In our previous works, one has proposed LMI based stabilization for large scale switched linear systems [24]. Moreover, to the best of the authors' knowledge, the stabilization issue of interconnected switched nonlinear systems hasn't yet been investigated.

Note also that, regarding to TS based approaches, the fuzzy Lyapunov function remains one of the least conservative in terms of LMI. However, the appearance of the membership function derivatives is often considered as a drawback. For more details on some recent results in TS based nonquadratic state feedback controller design, one can refer to [29-31]. Nevertheless, the meaning of this paper is not to cope with this problem. Hence, the goal is to propose a LMI based

This work has been supported by the GIS 3SGS within the framework of the project COSMOS II and by the Région Champagne-Ardenne and the FEDER within the CPER MOSYP.

methodology, in the nonquadratic framework, for the design of decentralized switched non-PDC controllers for a class of large scale switched nonlinear systems under arbitrary switching laws.

This paper is organized as follows: First, the studied class of continuous-time interconnected switched fuzzy systems will be described. Then, a set of decentralized switched non-PDC controller is proposed. Hence, LMI stability conditions are provided based on a switched fuzzy like-Lyapunov function candidate. Finally, a simulation example is proposed to illustrate the efficiency of the designed approach.

II. PROBLEM STATEMENT

Let us consider the class of nonlinear hybrid systems S composed of n continuous time switched nonlinear subsystem S_i based on TS modelling. The n state equations of the whole interconnected switched fuzzy system S are given as follows:

$$\text{For } i=1,...,n:$$
$$\dot{x}_i(t)=\sum_{j_i=1}^{m_i}\sum_{s_{j_i}=1}^{r_{j_i}}\xi_{j_i}(t)h_{s_{j_i}}\left(z_{j_i}(t)\right)\left[A_{s_{j_i}}x_i(t)+B_{s_{j_i}}u_i(t)+\sum_{\substack{\alpha=1\\ \alpha\neq i}}^{n}F_{i,\alpha,s_{j_i}}x_\alpha(t)\right] \tag{1}$$

where $x_i(t)\in\mathbb{R}^{\eta_i}$, $u_i(t)\in\mathbb{R}^{\upsilon_i}$ represent respectively the state and the input vectors associated to the i^{th} subsystem; m_i is the number of switching modes of the i^{th} subsystem; r_{j_i} is the number of fuzzy rules associated to the i^{th} subsystem in the j_i^{th} mode; for $i=1,...,n$, $j_i=1,...,m_i$ and $s_{j_i}=1,...,r_{j_i}$, $A_{s_{j_i}}\in\mathbb{R}^{\eta_i\times\eta_i}$, $B_{s_{j_i}}\in\mathbb{R}^{\eta_i\times\upsilon_i}$ and $F_{i,\alpha,s_{j_i}}\in\mathbb{R}^{\eta_i\times\eta_\alpha}$ are constant matrices describing the local dynamics of each polytops; $F_{i,\alpha,s_{j_i}}$ express the interconnections between subsystems, i.e. the influence of the α^{th} subsystem on the i^{th} one; $z_{j_i}(t)$ are the premises variables and $h_{s_{j_i}}\left(z_{j_i}(t)\right)$ are positive membership functions satisfying the convex sum proprieties $\sum_{s_{j_i}=1}^{r_{j_i}}h_{s_{j_i}}\left(z_{j_i}(t)\right)=1$; $\xi_{j_i}(t)$ is the switching rules of the i^{th} subsystem, considered arbitrary but assumed to be real time available, these are defined such that the active system in the l_i^{th} mode lead to:

$$\begin{cases}\xi_{j_i}(t)=1 & \text{if } j_i=l_i\\ \xi_{j_i}(t)=0 & \text{if } j_i\neq l_i\end{cases} \tag{2}$$

In order to ensure the stabilization of the overall closed-loop fuzzy switched S, a set of decentralized state feedback switched non-PDC control laws is proposed as:

$$\text{For } i=1,...,n:$$
$$u_i(t)=\sum_{j_i=1}^{m_i}\sum_{k_{j_i}=1}^{r_{j_i}}\xi_{j_i}(t)h_{s_{j_i}}\left(z_{j_i}(t)\right)K_{k_{j_i}}\left(\sum_{s_{j_i}=1}^{r_{j_i}}h_{s_{j_i}}\left(z_{j_i}(t)\right)X_{s_{j_i}}\right)^{-1}x_i(t) \tag{3}$$

where $K_{k_{j_i}}$ and $X_{s_{j_i}}=X_{s_{j_i}}^T>0$ are the gain matrices to be synthesized.

Notations : The time t will be omitted when there is no ambiguity. However, one denotes $t_{j_i\to j_i^+}$ the switching instants of the i^{th} subsystem between the current mode j_i (at time t) and the upcoming mode j_i^+ (at time t^+), therefore:

$$\begin{cases}\xi_{j_i}(t)=1\\ \xi_{j_i^+}(t)=0\end{cases}\text{ and }\begin{cases}\xi_{j_i}(t^+)=0\\ \xi_{j_i^+}(t^+)=1\end{cases} \tag{4}$$

In order to lighten the mathematical expression, the premises entries z_{j_i} will be omitted and the following notations will be employed in the sequel:

$$G_{h_{j_i}}=\sum_{s_{j_i}=1}^{r_{j_i}}h_{s_{j_i}}G_{s_{j_i}}\text{ and }Y_{h_{j_i},h_{i_i}}=\sum_{s_{j_i}=1}^{r_{j_i}}\sum_{k_{j_i}=1}^{r_{j_i}}h_{s_{j_i}}h_{k_{j_i}}Y_{s_{j_i},k_{j_i}}\ .$$

We will also distinguish, for a regular quantity $\Gamma_{s_{j_i}}$ of appropriate dimension:

$$\left(\Gamma_{h_{j_i}}\right)^{-1}=\left(\sum_{s_{j_i}=1}^{r_{j_i}}h_{s_{j_i}}\Gamma_{s_{j_i}}\right)^{-1}.$$

For matrices of appropriate dimensions we will denote :

$$\dot{X}_{h_{j_i}}=\frac{dX_{h_{j_i}}}{dt}\text{ and }\left(\dot{X}_{h_{j_i}}\right)^{-1}=\frac{d\left(X_{h_{j_i}}\right)^{-1}}{dt}.$$

As usual, a star (*) indicates a transpose quantity in a symmetric matrix.

The basic idea is to synthesize a global decentralized (3) controller composed of n local switched non-PDC controllers ensuring the stability of each subsystem S_i regarding to the influence of the others subsystems' dynamics. Hence, substituting (3) into (1), one expresses the overall closed-loop dynamics S_{cl} described by:

$$\text{For } i=1,...,n:$$
$$\dot{x}_i=\sum_{j_i=1}^{m_i}\xi_{j_i}\left\{\left[A_{h_{j_i}}+B_{h_{j_i}}K_{h_{j_i}}\left(X_{h_{j_i}}\right)^{-1}\right]x_i+\sum_{\substack{\alpha=1\\ \alpha\neq i}}^{n}F_{i,\alpha,h_{j_i}}x_\alpha\right\} \tag{5}$$

The following lemma will be useful in the sequel.

Lemma [32]: Let us consider two matrices A and B with appropriate dimension, the following inequality is satisfied with the scalar $\tau > 0$:

$$A^T B + B^T A \le \tau A^T A + \tau^{-1} B^T B \tag{6}$$

III. LMI Based Decentralized Controller Design

In this section, the goal is to propose a methodology for the design of decentralized switched non-PDC controller (3) ensuring the closed-loop stability of (5). The main result is given in the following theorem.

Theorem : Assume that for each subsystem i of (1), the active mode is denoted by j_i and, for $j_i = 1,...,m_i$ and $s_{j_i} = 1,...,r_{j_i}$, $\dot{h}_{s_{j_i}}\left(z(t)\right) \ge \lambda_{s_{j_i}}$. The overall interconnected switched Takagi-Sugeno system (1) is stabilized by a set of n decentralized switched non-PDC control laws (3), if there exists, for all combinations of $i = 1,...,n$, $j_i = 1,...,m_i$ $j_i^+ = 1,...,m_i$, $s_{j_i} = 1,...,r_{j_i}$, $k_{j_i} = 1,...,r_{j_i}$ and $l_{j_i} = 1,...,r_{j_i}$, the matrices $X_{k_{j_i}} = \left(X_{k_{j_i}}\right)^T > 0$, $W_{s_{j_i},k_{j_i}}$, $K_{k_{j_i}}$ and the positive scalars, $\tau_{1,i}$, … $\tau_{i-1,i}$, $\tau_{i+1,i}$,…, $\tau_{n,i}$ (excepted $\tau_{i,i}$ which don't exist since there is no interaction between a subsystem and himself), such that the LMIs described by (7), (8) and (9)are satisfied.

$$X_{k_{j_i}} - \mu_{j_i \to j_i^+} X_{k_{j_i}} \le 0 \tag{7}$$

$$X_{l_{j_i}} + W_{s_{j_i},k_{j_i}} > 0 \tag{8}$$

$$\left(\begin{array}{c|ccccc|ccccc} \Gamma_{s_{j_i},k_{j_i}} & X_{k_{j_i}} & \cdots & \cdots & X_{k_{j_i}} & X_{k_{j_i}} & \cdots & \cdots & X_{k_{j_i}} \\ \hline X_{k_{j_i}} & -\tau_{1,i} I & 0 & \cdots & 0 & 0 & \cdots & \cdots & 0 \\ \vdots & 0 & \ddots & \ddots & \vdots & \vdots & \ddots & 0 & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 & \vdots & 0 & \ddots & \vdots \\ X_{k_{j_i}} & 0 & \cdots & 0 & -\tau_{i-1,i} I & 0 & \cdots & \cdots & 0 \\ \hline X_{k_{j_i}} & 0 & \cdots & \cdots & 0 & -\tau_{i+1,i} I & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & 0 & \vdots & 0 & \ddots & \ddots & \vdots \\ \vdots & \vdots & 0 & \ddots & \vdots & \vdots & \ddots & \ddots & 0 \\ X_{k_{j_i}} & 0 & \cdots & \cdots & 0 & 0 & \cdots & 0 & -\tau_{n,i} I \end{array}\right) < 0 \tag{9}$$

with

$$\Gamma_{s_{j_i},k_{j_i}} = X_{k_{j_i}} \left(A_{s_{j_i}}\right)^T + A_{s_{j_i}} X_{k_{j_i}} - \Phi_{s_{j_i},k_{j_i}} + \left(K_{k_{j_i}}\right)^T \left(B_{s_{j_i}}\right)^T + B_{s_{j_i}} K_{k_{j_i}} + \sum_{\substack{\alpha=1 \\ \alpha \ne i}}^{n} \tau_{i,\alpha} F_{i,\alpha,s_{j_i}} \left(F_{i,\alpha,s_{j_i}}\right)^T$$

and

$$\Phi_{s_{j_i},k_{j_i}} = \sum_{l_{j_i}=1}^{r_{j_i}} \lambda_{l_{j_i}} \left(X_{l_{j_i}} + W_{s_{j_i},k_{j_i}}\right).$$

Proof: Let us define the following multiple like-Lyapunov functional candidate:

$$V\left(x_1, x_2, ..., x_n\right) = \sum_{i=1}^{n} \sum_{j_i=1}^{m_i} \xi_{j_i} v_{j_i}\left(x_i\right) > 0 \tag{10}$$

where $v_{j_i} = x_i^T \left(X_{h_{j_i}}\right)^{-1} x_i = x_i^T \left(\sum_{s_{j_i}=1}^{r_{j_i}} h_{s_{j_i}} X_{s_{j_i}} \right)^{-1} x_i$

with $X_{h_{j_i}} = \left(X_{h_{j_i}}\right)^T > 0$.

According to the overview [15], the closed-loop interconnected switched system (5) is asymptotically stable if:

$$\forall t \ne t_{j_i \to j_i^+}, \ \dot{V}\left(x_1, x_2, ..., x_n\right) < 0 \tag{11}$$

and

$$v_{j_i^+}\left(t_{j_i \to j_i^+}\right) \le \mu_{j_i \to j_i^+} v_{j_i}\left(t_{j_i \to j_i^+}\right) \tag{12}$$

where $\mu_{j_i \to j_i^+}$ are positive scalars.

First, let us focus on the inequalities (12). Their aim is to ensure the global behaviour of the like-Lyapunov function (10) at the switching time $t_{j_i \to j_i^+}$. These inequalities are verified if :

For $i = 1,...,n$:

$$\left(X_{h_{j_i^+}}\right)^{-1} \le \mu_{j_i \to j_i^+} \left(X_{h_{j_i}}\right)^{-1} \tag{13}$$

which can be rewritten in its extended form as:

For $i = 1,...,n$:

$$\sum_{s_{j_i}=1}^{r_{j_i}} \sum_{s_{j_i^+}=1}^{r_{j_i^+}} h_{s_{j_i}} h_{s_{j_i^+}} \left(X_{s_{j_i}} - \mu_{j_i \to j_i^+} X_{s_{j_i^+}}\right) \le 0 \tag{14}$$

Inequality (14) is verified if (7) hold for all $i = 1,...,n$, $j_i = 1,...,m_i$, $j_i^+ = 1,...,m_i$, $s_{j_i} = 1,...,r_{j_i}$ and $s_{j_i^+} = 1,...,r_{j_i^+}$.

Now, let us deal with (11), with the above defined notations, it can be rewritten as, $\forall t \ne t_{j_i \to j_i^+}$:

$$\sum_{i=1}^{n} \left[\dot{x}_i^T \left(X_{h_{j_i}}\right)^{-1} x_i + x_i^T \left(X_{h_{j_i}}\right)^{-1} \dot{x}_i + x_i^T \left(\dot{X}_{h_{j_i}}\right)^{-1} x_i \right] < 0 \tag{15}$$

Substituting (5) into (15), one can write, $\forall t \ne t_{j_i \to j_i^+}$:

$$\sum_{i=1}^{n}\Bigg\{x_i^T\Bigg[\left(A_{h_{ji}}\right)^T\left(X_{h_{ji}}\right)^{-1}+\left(X_{h_{ji}}\right)^{-1}A_{h_{ji}}+\left(\dot{X}_{h_{ji}}\right)^{-1}$$
$$+\left(X_{h_{ji}}\right)^{-1}\left(K_{h_{ji}}\right)^T\left(B_{h_{ji}}\right)^T\left(X_{h_{ji}}\right)^{-1}+\left(X_{h_{ji}}\right)^{-1}B_{h_{ji}}K_{h_{ji}}\left(X_{h_{ji}}\right)^{-1}\Bigg]x_i$$
$$+\sum_{\substack{\alpha=1\\ \alpha\neq i}}^{n}\Bigg[\left(x_\alpha\right)^T\left(F_{i,\alpha,h_{ji}}\right)^T\left(X_{h_{ji}}\right)^{-1}x_i+x_i^T\left(X_{h_{ji}}\right)^{-1}F_{i,\alpha,h_{ji}}x_\alpha\Bigg]\Bigg\}<0 \tag{16}$$

From (6), the inequality (16) can be bounded by, $\forall t\neq t_{j_i\to j_i^+}$:

$$\sum_{i=1}^{n}x_i^T\Bigg\{\left(A_{h_{ji}}\right)^T\left(X_{h_{ji}}\right)^{-1}+\left(X_{h_{ji}}\right)^{-1}A_{h_{ji}}+\left(\dot{X}_{h_{ji}}\right)^{-1}$$
$$+\left(X_{h_{ji}}\right)^{-1}\left(K_{h_{ji}}\right)^T\left(B_{h_{ji}}\right)^T\left(X_{h_{ji}}\right)^{-1}+\left(X_{h_{ji}}\right)^{-1}B_{h_{ji}}K_{h_{ji}}\left(X_{h_{ji}}\right)^{-1}$$
$$+\sum_{\substack{\alpha=1\\ \alpha\neq i}}^{n}\tau_{i,\alpha}\left(X_{h_{ji}}\right)^{-1}F_{i,\alpha,h_{ji}}\left(F_{i,\alpha,h_{ji}}\right)^T\left(X_{h_{ji}}\right)^{-1}\Bigg\}x_i+\sum_{i=1}^{n}\sum_{\substack{\alpha=1\\ \alpha\neq i}}^{n}\tau_{i,\alpha}^{-1}x_\alpha^Tx_\alpha<0 \tag{17}$$

where, for $i=1,...,n$, $\alpha=1,...,n$ and $\alpha\neq i$, $\tau_{i,\alpha}$ are positive scalars (note that, $\tau_{i,i}$ don't exist).

Since $\sum_{i=1}^{n}\sum_{\substack{\alpha=1\\ \alpha\neq i}}^{n}\tau_{i,\alpha}^{-1}x_\alpha^Tx_\alpha=\sum_{i=1}^{n}\sum_{\substack{\alpha=1\\ \alpha\neq 1}}^{n}\tau_{\alpha,i}^{-1}x_i^Tx_i$, $\forall x_i$, (17) is satisfied if, for $i=1,...,n$ and $\forall t\neq t_{j_i\to j_i^+}$:

$$\left(A_{h_{ji}}\right)^T\left(X_{h_{ji}}\right)^{-1}+\left(X_{h_{ji}}\right)^{-1}A_{h_{ji}}+\left(\dot{X}_{h_{ji}}\right)^{-1}$$
$$+\left(X_{h_{ji}}\right)^{-1}\left(K_{h_{ji}}\right)^T\left(B_{h_{ji}}\right)^T\left(X_{h_{ji}}\right)^{-1}+\left(X_{h_{ji}}\right)^{-1}B_{h_{ji}}K_{h_{ji}}\left(X_{h_{ji}}\right)^{-1} \tag{18}$$
$$+\sum_{\substack{\alpha=1\\ \alpha\neq i}}^{n}\Bigg[\tau_{i,\alpha}\left(X_{h_{ji}}\right)^{-1}F_{i,\alpha,h_{ji}}\left(F_{i,\alpha,h_{ji}}\right)^T\left(X_{h_{ji}}\right)^{-1}+\tau_{\alpha,i}^{-1}I\Bigg]<0$$

Left and right multiplying the inequalities (18) respectively by $X_{h_{ji}}$ and since $-\left(\dot{X}_{h_{ji}}\right)^{-1}=\left(X_{h_{ji}}\right)^{-1}\dot{X}_{h_{ji}}\left(X_{h_{ji}}\right)^{-1}$, it yields, for $i=1,...,n$ and $\forall t\neq t_{j_i\to j_i^+}$:

$$X_{h_{ji}}\left(A_{h_{ji}}\right)^T+A_{h_{ji}}X_{h_{ji}}-\dot{X}_{h_{ji}}+\left(K_{h_{ji}}\right)^T\left(B_{h_{ji}}\right)^T+B_{h_{ji}}K_{h_{ji}}$$
$$+\sum_{\substack{\alpha=1\\ \alpha\neq i}}^{n}\Bigg[\tau_{i,\alpha}F_{i,\alpha,h_{ji}}\left(F_{i,\alpha,h_{ji}}\right)^T+\tau_{\alpha,i}^{-1}X_{h_{ji}}X_{h_{ji}}\Bigg]<0 \tag{19}$$

Let us now focus on the term $\dot{X}_{h_{ji}}$. Since the inequality (19) is a double sum ($h_{j_i}h_{j_i}$) and, by extension to the relaxation scheme proposed in [20], additional slack decision matrices can be introduced. Indeed, since the membership functions holds the convex sum property, one has $\sum_{s_{ji}=1}^{r_{ji}}\dot{h}_{j_i}=0$ and so $\sum_{l_{ji}=1}^{r_{ji}}\dot{h}_{l_{ji}}W_{h_{ji},h_{ji}}=0$. Therefore, one can write:

$$\dot{X}_{h_{ji}}=\sum_{l_{ji}=1}^{r_{ji}}\dot{h}_{l_{ji}}\left(X_{l_{ji}}+W_{h_{ji},h_{ji}}\right) \tag{20}$$

Then, let us assume that, for $i=1,...,n$, $j_i=1,...,m_i$, $s_{j_i}=1,...,r_{j_i}$, $\lambda_{s_{ji}}$ are the lower bound of $\dot{h}_{l_{ji}}$, one can write :

$$-\dot{X}_{h_{ji}}\leq-\Phi_{h_{ji},h_{ji}} \tag{21}$$

with $\Phi_{h_{ji},h_{ji}}=\sum_{s_{ji}=1}^{r_{ji}}\sum_{k_{ji}=1}^{r_{ji}}h_{s_{ji}}h_{k_{ji}}\sum_{l_{ji}=1}^{r_{ji}}\lambda_{l_{ji}}\left(X_{l_{ji}}+W_{s_{ji},k_{ji}}\right)$ and :

$$X_{l_{ji}}+W_{s_{ji},k_{ji}}>0 \tag{22}$$

Thus, from (21) and applying the Schur complement, (19) is satisfied if, for $i=1,...,n$ and $\forall t\neq t_{j_i\to j_i^+}$:

$$\left(\begin{array}{c|ccccc|ccccc}
\Gamma_{h_{ji},h_{ji}} & X_{h_{ji}} & \cdots & \cdots & X_{h_{ji}} & X_{h_{ji}} & \cdots & \cdots & X_{h_{ji}} \\
\hline
X_{h_{ji}} & -\tau_{1,i}I & 0 & \cdots & 0 & 0 & \cdots & \cdots & 0 \\
\vdots & 0 & \ddots & \ddots & \vdots & \vdots & \ddots & 0 & \vdots \\
\vdots & \vdots & \ddots & \ddots & 0 & \vdots & 0 & \ddots & \vdots \\
X_{h_{ji}} & 0 & \cdots & 0 & -\tau_{i-1,i}I & 0 & \cdots & \cdots & 0 \\
\hline
X_{h_{ji}} & 0 & \cdots & \cdots & 0 & -\tau_{i+1,i}I & 0 & \cdots & 0 \\
\vdots & \vdots & \ddots & 0 & \vdots & 0 & \ddots & \ddots & \vdots \\
\vdots & \vdots & 0 & \ddots & \vdots & \vdots & \ddots & \ddots & 0 \\
X_{h_{ji}} & 0 & \cdots & \cdots & 0 & 0 & \cdots & 0 & -\tau_{n,i}I
\end{array}\right)<0 \tag{23}$$

with

$$\Gamma_{h_{ji},h_{ji}}=X_{h_{ji}}\left(A_{h_{ji}}\right)^T+A_{h_{ji}}X_{h_{ji}}-\Phi_{h_{ji},h_{ji}}$$
$$+\left(K_{h_{ji}}\right)^T\left(B_{h_{ji}}\right)^T+B_{h_{ji}}K_{h_{ji}}+\sum_{\substack{\alpha=1\\ \alpha\neq i}}^{n}\tau_{i,\alpha}F_{i,\alpha,h_{ji}}\left(F_{i,\alpha,h_{ji}}\right)^T.$$

Then, (22) and (23) are satisfied if respectively (8) and (9) hold. That ends the proof. ■

Remark: When $\mu_{j_i\to j_i^+}$ are unknown, conditions of theorem above are not LMI. In order to obtain LMI conditions, one may choose the positive decreasing rates $\mu_{j_i\to j_i^+}$ according to :

$$\prod_{\substack{j_i=1 \\ j_i^+ \neq j_i}}^{m_i} \mu_{j_i \to j_i^+} \leq 1 \qquad (24)$$

IV. NUMERICAL EXAMPLE

This section is dedicated to illustrate the efficiency of the proposed approaches. We consider the following system composed of two interconnected switched takagi-sugeno subsystems given by:

Subsystem 1:

$$\dot{x}_1 = \sum_{j_1=1}^{2} \sum_{s_{j_1}=1}^{2} \xi_{j_1} h_{s_{j_1}} \left[A_{s_{j_1}} x_1 + B_{s_{j_1}} u_1 + F_{1,2,s_{j_1}} x_2 \right] \qquad (25)$$

with

$$x_1 = \begin{bmatrix} x_{11} \\ x_{12} \end{bmatrix} A_{1_{1_1}} = \begin{bmatrix} -2 & 1 \\ 0.1 & -2.1 \end{bmatrix}, A_{2_{1_1}} = \begin{bmatrix} -2 & 1 \\ 0.1 & -1.1 \end{bmatrix},$$

$$A_{1_{2_1}} = \begin{bmatrix} -1 & 1 \\ 0.1 & -2 \end{bmatrix}, A_{2_{2_1}} = \begin{bmatrix} -1 & 1 \\ 0.1 & -3 \end{bmatrix}, B_{1_{1_1}} = \begin{bmatrix} -1.2 \\ 0.2 \end{bmatrix},$$

$$B_{2_{1_1}} = \begin{bmatrix} -1.2 \\ 1.2 \end{bmatrix}, B_{1_{2_1}} = \begin{bmatrix} -1.5 \\ -0.5 \end{bmatrix}, B_{2_{2_1}} = \begin{bmatrix} -1.5 \\ -1.5 \end{bmatrix},$$

$$F_{1,2,1_{1_1}} = \begin{bmatrix} 0.01 & 0.001 & 0.1 \\ 0.01 & 0.01 & 0.1 \end{bmatrix}, F_{1,2,2_{1_1}} = \begin{bmatrix} 0.01 & 0.01 & 0.1 \\ 0.01 & 0.01 & 0.1 \end{bmatrix},$$

$$F_{1,2,1_{2_1}} = \begin{bmatrix} 0.01 & 0.01 & 0.01 \\ 0.07 & 0.2 & 0.2 \end{bmatrix}, F_{1,2,2_{2_1}} = \begin{bmatrix} 0.01 & 0.001 & 0.01 \\ 0.08 & 0.02 & 0.2 \end{bmatrix}$$

and the membership functions:

$$h_{1_{1_1}}\left(x_1(t)\right) = \sin^2\left(x_{11}(t)\right),\ h_{2_{1_1}}\left(x_1(t)\right) = \sin^2\left(x_{12}(t)\right),$$

$$h_{1_{2_1}}\left(x_1(t)\right) = 1 - h_{1_{1_1}}\left(x_1(t)\right), \text{ and } h_{2_{2_1}}\left(x_1(t)\right) = 1 - h_{2_{1_1}}\left(x_1(t)\right).$$

Subsystem 2:

$$\dot{x}_2 = \sum_{j_2=1}^{2} \sum_{s_{j_2}=1}^{2} \xi_{j_2} h_{s_{j_2}} \left[A_{s_{j_2}} x_2(t) + B_{s_{j_2}} u_2(t) + F_{2,1,s_{j_2}} x_1(t) \right] \qquad (26)$$

with

$$x_2 = \begin{bmatrix} x_{21} \\ x_{22} \\ x_{23} \end{bmatrix} A_{1_{1_2}} = \begin{bmatrix} -2 & 2 & 0 \\ 0 & -1 & 0 \\ 1 & 0.1 & -1.1 \end{bmatrix}, A_{2_{1_2}} = \begin{bmatrix} -2 & 2 & 0 \\ 0 & -1 & 0 \\ 0 & 0.1 & -2.1 \end{bmatrix},$$

$$A_{1_{2_2}} = \begin{bmatrix} -2 & 1 & 0 \\ 1 & -2 & 0 \\ 0 & 1.1 & -1 \end{bmatrix}, A_{2_{2_2}} = \begin{bmatrix} -2 & 1 & 0 \\ 1 & -3 & 0 \\ 0 & 0.1 & -1 \end{bmatrix}, B_{1_{2_2}} = \begin{bmatrix} -0.1 \\ 0.5 \\ 0.1 \end{bmatrix},$$

$$B_{2_{1_2}} = \begin{bmatrix} -0.1 \\ 0.5 \\ 1.1 \end{bmatrix}, B_{1_{2_2}} = \begin{bmatrix} 0.1 \\ 0.5 \\ 0.2 \end{bmatrix}, B_{2_{2_2}} = \begin{bmatrix} 0.1 \\ 0.5 \\ 1.2 \end{bmatrix}, F_{2,1,1_{1_2}} = \begin{bmatrix} 0.01 & 0.6 \\ 0.3 & 0.2 \\ 0.2 & 0.1 \end{bmatrix},$$

$$F_{2,1,2_{1_2}} = \begin{bmatrix} 0.01 & 0.6 \\ 0.3 & 0.2 \\ 0.02 & 0.1 \end{bmatrix}, F_{2,1,1_{2_2}} = \begin{bmatrix} 0.01 & 0.5 \\ 0.1 & 0.4 \\ 0.2 & 0.2 \end{bmatrix},$$

$$F_{2,1,2_{2_2}} = \begin{bmatrix} 0.01 & 0.5 \\ 0.1 & 0.04 \\ 0.2 & 0.2 \end{bmatrix}$$

and the membership functions

$$h_{1_{1_2}}\left(x_2(t)\right) = \sin^2\left(x_{21}(t)\right),\ h_{2_{1_2}}\left(x_2(t)\right) = \sin^2\left(x_{22}(t)\right),$$

$$h_{1_{2_2}}\left(x_2(t)\right) = 1 - h_{1_{1_2}}\left(x_2(t)\right),\ h_{2_{2_2}}\left(x_2(t)\right) = 1 - h_{2_{1_2}}\left(x_2(t)\right).$$

Let us assume that each subsystem switches under within the frontier defined by: $\mathrm{H}_{11} = 0.9x_{11} + x_{12}$, $\mathrm{H}_{12} = -0.2x_{11} + 9x_{12}$, $\mathrm{H}_{21} = -x_{21} + x_{22}$ and $\mathrm{H}_{22} = x_{21} - 2x_{22}$.

A set of decentralized switched controllers (3) is synthesized based on theorem 1 via the Matlab LMI toolbox. To do so, the decreasing rates are chosen as $\mu_{1_1 \to 2_1} = 0.4$, $\mu_{2_1 \to 1_1} = 2$, $\mu_{1_2 \to 2_2} = 0.4$, $\mu_{2_1 \to 1_1} = 2$ according to (24) and the lower bounds of membership functions as $\lambda_{1_{1_1}} = -4$, $\lambda_{1_{2_1}} = -1$, $\lambda_{1_{1_2}} = -6.5$ and $\lambda_{1_{2_2}} = -1.5$.

The close-loop subsystem dynamics are shown in Figure 1 for the initial states $x_1(0) = \begin{bmatrix} 2 & 2 \end{bmatrix}^T$ and $x_2(0) = \begin{bmatrix} -1 & 1.5 & -1 \end{bmatrix}^T$.

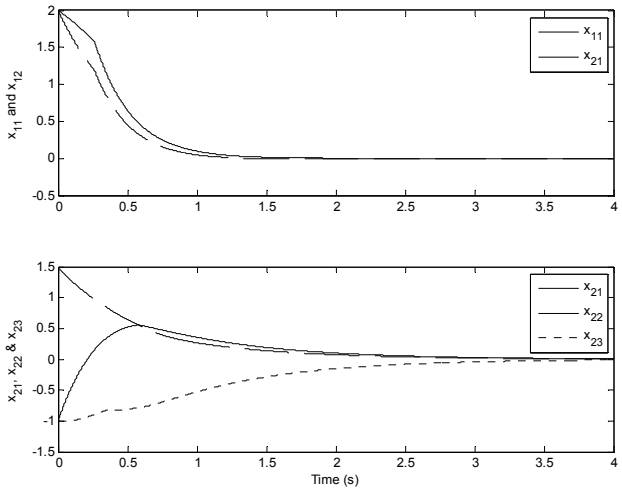

Figure 1. States dynamics of the overall closed-loop interconnected switched Takagi-Sugeno system.

Figure 2 shows the control signals as well as the switching modes' evolution. As expected, the synthesized decentralized switched controller stabilizes the overall large scale switched system composed of (25) and (26).

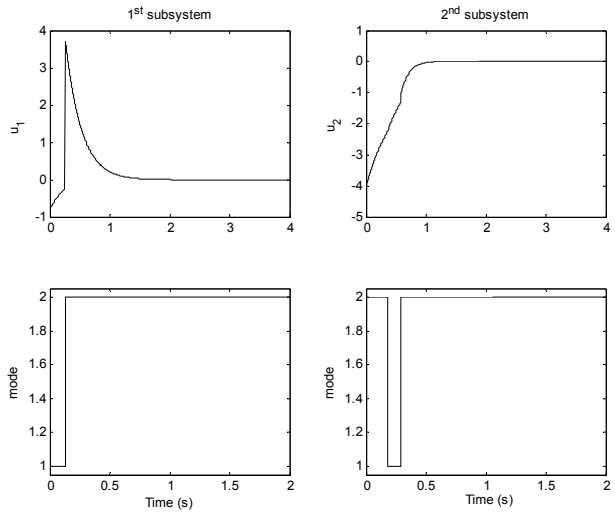

Figure 2. Control signals and switched laws' evolutions.

Figure 3 shows that like-Lyapunov functions $v_1(x_1)$ and $v(x_2)$ of both the subsystems, as well as the global like-Lyapunov function $V(x_1, x_2, ..., x_n)$, have a global decreasing behavior along the systems' trajectories.

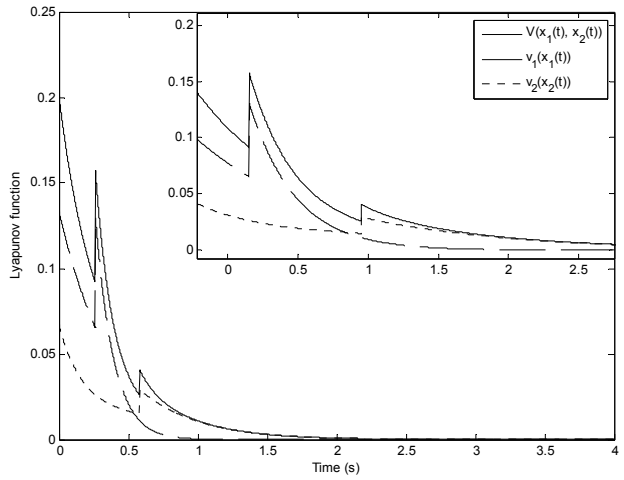

Figure 3. Behaviour of the like-Lyapunov functions.

Figure 4 provides the time evolution of the membership functions derivatives $\dot{h}_{1_{1_1}}(x_1(t))$, $\dot{h}_{2_{1_1}}(x_1(t))$, $\dot{h}_{1_{1_2}}(x_2(t))$ and $\dot{h}_{2_{1_2}}(x_2(t))$. This shows that the assumed lower bounds are verified in simulation for the considered initial conditions.

V. CONCLUSION

This study has focused on large scale switched nonlinear systems where, due to their well-known universal approximator properties, each nonlinear mode has been represented by a fuzzy Takagi-Sugeno system. Hence, the considered class of hybrid dynamical systems is composed by a set of interconnected switched Takagi-Sugeno subsystems. To ensure the stability of the whole system in closed-loop, a set of decentralized switched non-PDC controllers has been proposed. Therefore, LMI based conditions for the decentralized controller design has been obtained through the consideration of a candidate multiple switched non quadratic like-Lyapunov functional. Finally, a numerical example has been proposed to show the effectiveness of the proposed approach.

Abstract – Quadratic stability / stabilization / estimation for Takagi-Sugeno models have now reached maturity. Lots of results concerning performances (H_2, H_∞, D-stability) for TS models with uncertainties, noise, time-delays … exist in the literature. Nevertheless, it is illusive thinking to solve every nonlinear problem of stability using a simple quadratic Lyapunov function. Moreover, most of the nonlinear systems only have properties of local stability. This work follows the idea of using non quadratic Lyapunov functions for continuous Takagi-Sugeno models restricting the global asymptotic stability to a local one. Therefore, it tries to estimate the best stabilization domain possible. A rather "simple" LMI constraints problem is derived to answer to this question.

I. INTRODUCTION

The so-called Takagi-Sugeno models [1] have reached a very big attention in the control community. The results for stability, stabilization, estimation [2, 3, 4] are now converging towards quasi-LPV models results [5]. A global view of the last works can give the conclusion that more or less, lots of new results just represent outperforming previous ones, using the same techniques. Of course, some of these improvements are particularly important and allows dealing with problems that were unfeasible before. Among these nice improvements, we can cite the Polya's approach that gives sufficient and necessary conditions for the copositivity problem [6], piecewise Lyapunov functions when restricted to specific TS models [7, 8], non quadratic Lyapunov functions for discrete TS models with important results [9, 10, 11, 12].

The paper focuses on non quadratic stabilization for continuous TS models where the results are not satisfactory, especially when compared with the discrete case. Two families of results have to be described. As the derivative of the Lyapunov function will involve the derivative of the membership function of the TS model, several results propose just to bound them a priori [13, 14, 15]. This way of doing is not satisfactory because the verification of these bounds can only be done a posteriori on a case by case approach. On another side, independent path Lyapunov functions were used in [16] that present a fine result but restricted to specific TS models. Notice also that for stabilization, the problem remains BMI. All these approaches consider the problem of global stability which is far to be the general rule for nonlinear systems. Therefore, some works proposed to reduce this goal to local stability and estimate a domain of convergence [17, 18]. A tentative for stabilization has been presented in [19] which introduced bounds on the control law and complicated treatments of the problem. The work presented therein allows solving the stabilization problem in a local stabilization framework without this drawback.

The work is organized as follows. Part 1 recalls some properties; part 2 presents the problem of NQ stabilization and part 3 introduces the main result of the paper. An example illustrates the interest of the results and a conclusion ends the paper.

II. PRELIMINARIES

First, we will present some notations and properties helpful to derive the main result of the work.

As usual, a star $(*)$ in a symmetric matrix denotes the transpose element. When suitable, the next notations are used. Consider nonlinear functions $h_i(z) \geq 0$ sharing the convex sum property, i.e. $\sum_{i=1}^{r} h_i(z) = 1$, then:

$$\Upsilon_z = \sum_{i=1}^{r} h_i(z(t))\Upsilon_i, \qquad \Upsilon_z^{-1} = \left(\sum_{i=1}^{r} h_i(z(t))\Upsilon_i\right)^{-1}$$

and for multiple sums: $\Upsilon_{zz} = \sum_{i=1}^{r}\sum_{j=1}^{r} h_i(z(t))h_j(z(t))\Upsilon_{ij}$.

Property 1: for $y \in \mathbb{R}^n$ and $\beta > 0$ the following equivalence holds:

$$y^T y - \beta < 0 \Leftrightarrow yy^T - \beta I < 0 \qquad (1)$$

Proof: it follows directly using the Schur complement:

$$y^T y < \beta \Leftrightarrow \begin{bmatrix} \beta & y^T \\ y & I \end{bmatrix} > 0 \Leftrightarrow \beta^{-1} yy^T - I < 0 \Leftrightarrow yy^T < \beta I .$$

Property 2: with $P = P^T > 0$ and $\delta \in \mathbb{R}$, $\delta > 0$ the following property holds:

$$P_z \geq \delta I \Rightarrow P_z^2 \geq \delta P_z . \quad (2)$$

Proof: consider $x^T P_z x \geq \delta x^T x$ and the change of variable: $x = P_z^{1/2} y$, it follows directly: $y^T P_z^2 y \geq \delta y^T P_z y$.

Property 3 [18]: with X, Y two matrices of appropriate dimension $\delta, \lambda \in \mathbb{R}$, $\lambda > 0$ and $|\delta| \leq \lambda$ the following implication holds:

$$S = S^T > 0, \quad Y + \frac{1}{2}\left(\lambda^2 S + X S^{-1} X\right) \leq 0 \quad \Rightarrow \quad Y + \delta X \leq 0 . \quad (3)$$

Proof: use the completion of squares, i.e. with $S = S^T > 0$, $U^T V + V^T U \leq U^T S U + V^T S^{-1} V^T$. Thus, with $U = \delta I$ and $V = X$ it is direct.

Property 4 [20]: (relaxation lemma).
Let Υ_{ij}, $i, j \in \{1, \cdots, r\}$ be matrices of appropriate dimensions.

$\Upsilon_{zz} = \sum_{i=1}^{r} \sum_{j=1}^{r} h_i(z(t)) h_j(z(t)) \Upsilon_{ij} \geq 0$ holds if

$$\frac{2}{r-1} \Upsilon_{ii} + \Upsilon_{ij} + \Upsilon_{ji} > 0, \; i, j \in \{1, \cdots, r\}. \quad (4)$$

Remark: conditions (4) represent one of the numerous possible relaxations, see [6] for example. Notice that once the quantities Υ_{ij} defined and being LMI constraints, any relaxation can be used.

Recall that the open loop TS model [1] writes:

$$\dot{x}(t) = A_z x(t) + B_z u(t), \quad (5)$$

with $x(t) \in \mathbb{R}^n$ the state vector, $u(t) \in \mathbb{R}^m$ the input vector, $z(t) \in \mathbb{R}^p$ the premise vector. This latter is linked to the state vector $x(t)$ via a linear or a nonlinear mapping.

Consider also the validity domain of the TS model [21] which is a compact set of the state space:

$$C = \left\{ x \in \mathbb{R}^n, \underline{x}_i \leq x \leq \overline{x}_i, i = 1, \ldots, n \right\}; \quad (6)$$

and $0 \in C$, as the equilibrium point is 0 without lack of generality. It is supposed that the functions $h_i(z) \geq 0$ are obtained via the sector nonlinearity approach [2]. Therefore, we can write [18]:

$$h_i = h_{1+i_1+i_2 \times 2 + \cdots + i_p \times 2^{p-1}} = \prod_{j=1}^{p} w_{i_j}^j (z_j), \quad (7)$$

with $i \in \{1, \ldots, 2^p\}$, $i_j \in \{0, 1\}$ and $w_1^j(\cdot) = 1 - w_0^j(\cdot)$.

Remark: other possible compact sets are possible, such as for example: $C = \left\{ x \in \mathbb{R}^n, \|x\| \leq \lambda_x \right\}$, the form (6) is classically used because of the sector nonlinearity approach [2].

Hypothesis 1: In this work the functions $h_i(z)$ and the mapping between the premise vector $z(t)$ and the state vector $x(t)$ are of class C^1 on the defined compact set C; i.e. the partial derivatives are well-defined.

III. NON QUADRATIC STABILIZATION

This section recalls some basics on NQ stabilization for continuous TS models. First of all, a non-PDC control law is used:

$$u(t) = F_z P_z^{-1} x(t). \quad (8)$$

Therefore, the closed loop writes:

$$\dot{x}(t) = \left(A_z + B_z F_z P_z^{-1}\right) x(t), \quad (9)$$

whose stability properties will be investigated through the following non-quadratic fuzzy Lyapunov function candidate:

$$V(x(t)) = x^T(t) P_z^{-1} x(t), \quad (10)$$

where $P_z > 0$. Its derivative along the trajectories of the closed-loop TS model (9) is:

$$\dot{V}(x) = x^T \left(P_z^{-1} \left(A_z + B_z F_z P_z^{-1} \right) + \left(A_z + B_z F_z P_z^{-1} \right)^T P_z^{-1} + \dot{P}_z^{-1} \right) x$$

Since elementary matrix manipulations show that is verified if

$$A_z P_z + B_z F_z + \left(A_z P_z + B_z F_z \right)^T - \dot{P}_z < 0 . \quad (11)$$

Recall now that $\dot{P}_z$ writes:

$$\dot{P}_z = \sum_{i=1}^{r} \dot{h}_i P_i = \sum_{i=1}^{r} \left(\frac{\partial h_i(z)}{\partial z} \right)^T \dot{z} P_i . \quad (12)$$

Using the definition of the functions $h_i(z)$ and w_0^j equation (7) and after some manipulations see [17, 18], (12) can be written as:

$$\begin{aligned} \dot{P}_z &= \sum_{i=1}^{r} \sum_{k=1}^{p} h_i \frac{\partial w_0^k}{\partial z_k} \dot{z}_k \left(P_{g_1(i,k)} - P_{g_2(i,k)} \right) \\ &= \sum_{k=1}^{p} \frac{\partial w_0^k}{\partial z_k} \dot{z}_k \left(P_{g_1(z,k)} - P_{g_2(z,k)} \right) \end{aligned} \quad (13)$$

with $g_1(i,k) = \left\lfloor (i-1)/2^{p+1-k} \right\rfloor \times 2^{p+1-k} + 1 + (i-1) \bmod 2^{p-k}$ and $g_2(i,k) = g_1(i,k) + 2^{p-k}$, $\lfloor . \rfloor$ being the floor function.

Remark: it is ***very important*** to notice that the expression (13) shows that if a quadratic Lyapunov function exists than $\dot{P}_z = 0$ is guaranteed via $P_{g_1(\alpha,k)} = P_{g_2(\alpha,k)}$ for each $i \in \{1, \cdots, r\}$ and $k \in \{1, \cdots, p\}$. This remark will hold also for the LMI constraints thereinafter. Therefore, every conditions derived in this work are ***always*** including the quadratic case.

Theorem 1 (Local stabilizability): If there exist matrices of the proper size $P_i = P_i^T > 0$, F_i, $i \in \{1, \ldots, r\}$ such that $A_z P_z + B_z F_z + P_z A_z^T + F_z^T B_z^T < 0$, then there exists a domain D, $0 \in D$, such that TS model (5) is locally asymptotically stabilizable under control law (8).

Proof: The NQLF candidate (10) satisfies $V(0)=0$ and $V(x)\geq 0$ in $\mathbb{R}^n$. Its time-derivative (11) holds $\dot{V}(0)=0$. Provided that $A_zP_z+B_zF_z+P_zA_z^T+F_z^TB_z^T<0$ it is implied that there exists a sufficiently small $\lambda>0$ such that $A_zP_z+B_zF_z+P_zA_z^T+F_z^TB_z^T+\lambda I<0$ which can be used to define $D=\{x: x\in B, \|\dot{P}_z\|<\lambda\}$. The origin belongs to domain D since

$$\begin{aligned}\dot{P}_z &= \sum_{i=1}^{r}\dot{h}_iP_i=\sum_{i=1}^{r}\left(\frac{\partial h_i}{\partial z}\right)^T\frac{\partial z}{\partial x}^T\dot{x}P_i \\ &= \sum_{i=1}^{r}\left[\left(\frac{\partial h_i}{\partial z}\right)^T\frac{\partial z}{\partial x}^T\left(A_z+B_zF_zP_z^{-1}\right)x(t)\right]P_i\end{aligned} \tag{14}$$

depends on the state vector $x(t)$. Since $V(x)>0$ and $\dot{V}(x)<0$ in $D-\{0\}$, the equilibrium point $x=0$ is locally asymptotically stable, thus concluding the proof.

Remark: conditions for theorem 1 can be ensured for example with property 4, i.e. define $\Upsilon_{ij}=A_iP_j+B_iF_j+P_jA_i^T+F_j^TB_i^T$, find $P_i=P_i^T>0$, F_i, $i\in\{1,\ldots,r\}$ such that:

$$\frac{2}{r-1}\Upsilon_{ii}+\Upsilon_{ij}+\Upsilon_{ji}>0,\ i,j\in\{1,\cdots,r\}. \tag{15}$$

IV. MAIN RESULT

A precedent work [19] used a bound on the control law to derive conditions of stabilization. Therein a more interesting way to cope with the stabilization problem is used in order to remove this drawback. Let us focus on the real $\dot{z}_k\in\mathbb{R}$. In a general framework, the premise vector $z(t)$ depends linearly or not on the state vector $x(t)$. Thus:

$$\dot{z}_k=\left(\frac{\partial z_k}{\partial x}\right)^T\dot{x}=\left(\frac{\partial z_k}{\partial x}\right)^T\left(A_z+B_zF_zP_z^{-1}\right)x. \tag{16}$$

Therefore the goal is to find a "nice" bound $\beta_k>0$ for:

$$\left|\frac{\partial w_0^k}{\partial z_k}\dot{z}_k\right|\leq\beta_k, \tag{17}$$

which is equivalent to:

$$\left|\frac{\partial w_0^k}{\partial z_k}\left(\frac{\partial z_k}{\partial x}\right)^T\left(A_zP_z+B_zF_z\right)P_z^{-1}x\right|\leq\beta_k. \tag{18}$$

Remark: it is also important to note that this is ***not equivalent*** to other approaches found in the literature [13, 14, 15] where the required condition is in the form of: $\left|\dot{h}_i(z(t))\right|\leq\phi_i$. In this later case, ϕ_i is given a priori and can only be checked a posteriori. In the presented case, the bounds β_k are ***included*** in the problem to solve.

In order for (18) to hold, we will introduce (19):

$$\left(\frac{\partial w_0^k}{\partial z_k}\left(\frac{\partial z_k}{\partial x}\right)^T\left(A_zP_z+B_zF_z\right)P_z^{-1}x\right)^2\leq\beta_k^2. \tag{19}$$

Or equivalently:

$$\left(\frac{\partial w_0^k}{\partial z_k}\right)^2\left(\frac{\partial z_k}{\partial x}\right)^T\left(A_zP_z+B_zF_z\right)P_z^{-1}xx^TP_z^{-1}\left(A_zP_z+B_zF_z\right)^T\frac{\partial z_k}{\partial x}-\beta_k^2\leq 0 \tag{20}$$

Knowing that $\|x\|^2\leq\lambda_x^2 \Leftrightarrow xx^T\leq\lambda_x^2I$ (property 1 (1)), (20) holds if:

$$\lambda_x^2\left(\frac{\partial w_0^k}{\partial z_k}\right)^2\left(\frac{\partial z_k}{\partial x}\right)^T\left(A_zP_z+B_zF_z\right)P_z^{-1}P_z^{-1}\left(A_zP_z+B_zF_z\right)^T\frac{\partial z_k}{\partial x}-\beta_k^2\leq 0 \tag{21}$$

Applying again property 1 to (21) gives:

$$\lambda_x^2\left(\frac{\partial w_0^k}{\partial z_k}\right)^2P_z^{-1}\left(A_zP_z+B_zF_z\right)^T\frac{\partial z_k}{\partial x}\left(\frac{\partial z_k}{\partial x}\right)^T\left(A_zP_z+B_zF_z\right)P_z^{-1}-\beta_k^2I\leq 0 \tag{22}$$

At last, as the functions w_0^k are known explicitly, thus bounding $\frac{\partial w_0^k}{\partial z_k}$ is direct. On the other side, $\frac{\partial z_k}{\partial x}$ represents the linear or nonlinear mapping between $z(t)$ and $x(t)$, and it is also known. Therefore we can compute easily the bounds: $\left(\frac{\partial w_0^k}{\partial z_k}\right)^2\left\|\frac{\partial z_k}{\partial x}\right\|^2\leq\lambda_k^2 \Leftrightarrow \left(\frac{\partial w_0^k}{\partial z_k}\right)^2\frac{\partial z_k}{\partial x}\left(\frac{\partial z_k}{\partial x}\right)^T\leq\lambda_k^2I$.

These bounds define regions in the state space:

$$R_k=\left\{x\in\mathbb{R}^n,\left(\frac{\partial w_0^k}{\partial z_k}\right)^2\left\|\frac{\partial z_k}{\partial x}\right\|^2\leq\lambda_k^2\right\}, \tag{23}$$

and it follows that:

$$\lambda_x^2\lambda_k^2P_z^{-1}\left(A_zP_z+B_zF_z\right)^T\left(A_zP_z+B_zF_z\right)P_z^{-1}-\beta_k^2I\leq 0 \tag{24}$$

Then, multiplying left and right with P_z gives:

$$\lambda_x^2\lambda_k^2\left(A_zP_z+B_zF_z\right)^T\left(A_zP_z+B_zF_z\right)-\beta_k^2P_z^2\leq 0. \tag{25}$$

Considering now that $P_z\geq\delta I$ and using property 2 (2), (17) is satisfied if:

$$\lambda_x^2\lambda_k^2\left(A_zP_z+B_zF_z\right)^T\left(A_zP_z+B_zF_z\right)-\beta_k^2\delta P_z\leq 0.$$

Thus with the help of the Schur complement:

$$\begin{aligned}&\lambda_x^2\lambda_k^2\left(A_zP_z+B_zF_z\right)^T\beta_k^{-2}\delta^{-1}\left(A_zP_z+B_zF_z\right)-P_z\leq 0\\ &\Leftrightarrow\begin{bmatrix}P_z & (*)\\ \lambda_x\lambda_k\left(A_zP_z+B_zF_z\right) & \beta_k^2\delta I\end{bmatrix}>0\end{aligned} \tag{26}$$

Now, coming back to (11) we can use

$$A_z P_z + B_z F_z + \left(A_z P_z + B_z F_z\right)^T - \sum_{k=1}^{p} \frac{\partial w_0^k}{\partial z_k} \dot{z}_k \left(P_{g_1(z,k)} - P_{g_2(z,k)}\right) < 0 \tag{27}$$

And we have the bound: $\left|\frac{\partial w_0^k}{\partial z_k} \dot{z}_k\right| \le \beta_k$.

Thus using property 3 second part (3) we can derive the theorem 2. Note that introducing matrices $S_{zz}^k > 0$ we can write:

$$\begin{aligned} &\frac{\partial w_0^k}{\partial z_k} \dot{z}_k \left(P_{g_1(z,k)} - P_{g_2(z,k)}\right) \\ &\le \frac{1}{2}\left(\beta_k^2 S_{zz}^k + \left(P_{g_1(z,k)} - P_{g_2(z,k)}\right)\left(S_{zz}^k\right)^{-1}\left(P_{g_1(z,k)} - P_{g_2(z,k)}\right)\right) \end{aligned} \tag{28}$$

Therefore, let us consider the following quantities:

$$\Gamma_{ij} = \begin{bmatrix} A_i P_j + B_i F_j + P_j A_i^T + F_j^T B_i^T + \frac{1}{2}\sum_{k=1}^{p} \beta_k^2 S_{ij}^k & (*) & \cdots & & (*) \\ P_{g_1(i,1)} - P_{g_2(i,1)} & -2S_{ij}^1 & 0 & \cdots & 0 \\ \vdots & 0 & \ddots & \ddots & \vdots \\ & \vdots & \ddots & \ddots & 0 \\ P_{g_1(i,p)} - P_{g_2(i,p)} & 0 & \cdots & 0 & -2S_{ij}^p \end{bmatrix} \tag{29}$$

$$\Upsilon_{ij} = \begin{bmatrix} P_i & (*) \\ \lambda_x \lambda_k \left(A_i P_j + B_i F_j\right) & \beta_k^2 \delta I \end{bmatrix} \tag{30}$$

Theorem 2: consider the TS closed loop model (9) and expressions defined in (30) and (29). If there exist matrices P_i, F_i, $S_{ij}^k > 0$, $i, j \in \{1, \cdots, r\}$, $k \in \{1, \cdots, p\}$ such that the following LMI are satisfied:

$$P_i \ge \delta I \,,\ i \in \{1, \cdots, r\} \tag{31}$$

$$\frac{2}{r-1}\Upsilon_{ii} + \Upsilon_{ij} + \Upsilon_{ji} > 0 \,,\ i, j \in \{1, \cdots, r\} \tag{32}$$

$$\frac{2}{r-1}\Gamma_{ii} + \Gamma_{ij} + \Gamma_{ji} < 0 \,,\ i, j \in \{1, \cdots, r\} \tag{33}$$

Then, the control law (8) stabilizes the TS open loop model (5) in a local domain. An estimation of this domain is given by the outermost Lyapunov level contained in $R = C \cap \left\{\bigcap_{k=1}^{p} R_k\right\}$ with C defined in (6) and R_k in (23).

Proof: from (27), repeating (28) for each term of the sum, gives and applying the Shur complement gives directly $\Gamma_{zz} < 0$.

(26) represents $\Upsilon_{zz} > 0$. Thus, conditions (32) and (33) just expresses the sum relaxation (4) to $\Upsilon_{zz} > 0$ and $\Gamma_{zz} < 0$.

Remark: notice that (31)~(33) are LMI constraints only if the scalars β_k^2 and δ are known.

A procedure to determine these values is possible, inspired from [22] for static output feedback. Recall that if the conditions of theorem 1 are satisfied it ensures the existence of a local stability domain for theorem 2. Therefore, the procedure is based on this remark.

A first step consists in obtaining a solution to theorem 1 conditions (15). The obtained gains give a control law that can be seen as stabilizing the "frozen" time-invariant continuous TS model. Thus bounds β_k^2 and δ can be directly obtained from this first step.

The second step is the solution to the theorem 2 conditions (31)~(33).

V. Example

Example 1: Consider the following TS model [23]:

$$\dot{x}(t) = A_z x(t) = \sum_{i=1}^{2} h_i\left(z(t)\right)\left(A_i x(t) + B_i u(t)\right) \tag{34}$$

with $A_1 = \begin{bmatrix} 3.6 & -1.6 \\ 6.2 & -4.3 \end{bmatrix}$, $A_2 = \begin{bmatrix} -0.35 & -1.6 \\ 6.2 & -4.3 \end{bmatrix}$, $B_1 = \begin{bmatrix} -0.45 \\ -3 \end{bmatrix}$, $B_2 = \begin{bmatrix} -0.5 \\ -3 \end{bmatrix}$, $z_1(t) = x_1(t)$, $h_1 = w_0^1 = \frac{1 - \sin x_1}{2}$ and $h_2 = w_1^1 = \frac{1 + \sin x_1}{2}$ defined in the compact set $C = \left\{x : |x_i| \le \pi/2\right\}$, $i = 1, 2$.

Fig. 1 shows the stabilization region (region $R_0 = \left\{x : x^T P_z^{-1} x \le r\right\}$ enclosed by a solid line).

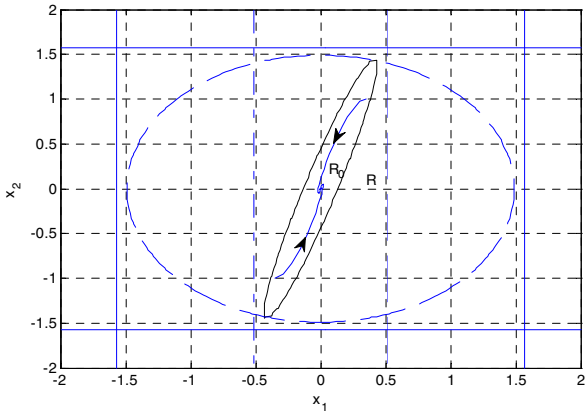

Figure 1: Stabilization region for TS model

The gains and the matrices involved in the control law are :

$$F_1 = \begin{bmatrix} -30.9367 & -64.6603 \end{bmatrix},\ F_2 = \begin{bmatrix} -7.9679 & 0.8826 \end{bmatrix}$$

$$P_1 = \begin{bmatrix} 14.1439 & 44.8202 \\ 44.8202 & 156.7774 \end{bmatrix}, P_2 = \begin{bmatrix} 14.0601 & 44.4733 \\ 44.4733 & 155.5855 \end{bmatrix}$$

$$\lambda_k = 0.19\ ,\ \gamma = 1\ ,\ \beta_k = 370 \text{ and } \lambda_x = 2.2214\ .$$

The control law evolution for initial states $x_0 = \begin{bmatrix} 0.35 & 1 \end{bmatrix}$ can be seen in Fig. 2.

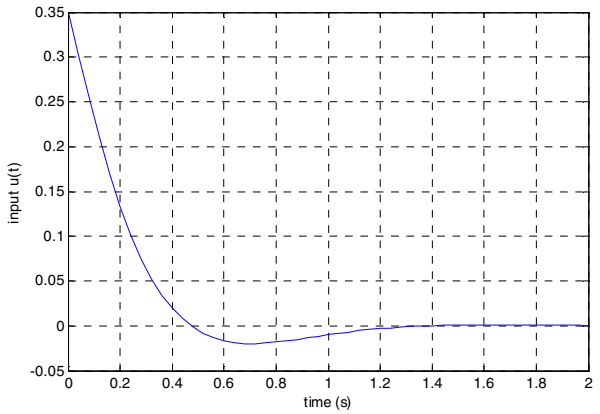

Fig. 2: Control law evolution.

***Abstract*—This paper is concerned with fault estimation design for continuous-time Takagi-Sugeno (T-S) fuzzy systems with time delay by using adaptive fault diagnostic observer. Through constructing an appropriate type of Lyapunov function, criteria is established to reduce the conservatism of the design procedure. Based on appropriate type of Lyapunov function, new sufficient delay-dependent conditions are given to guarantee the stability of error dynamics in terms of Linear Matrix Inequalities (LMI). Finally, the effectiveness of the proposed approach is illustrated through a simulation example.**

Keyword: Linear Matrix Inequalities, Takagi-Sugeno fuzzy systems, fault tolerant control.

I. Introduction

In many applications the problem of fault detection and isolation FDI is a crucial issue that has been theoretically and experimentally investigated with different types of approaches. Adaptive Fault Diagnostic Observer (AFDO) approach has the advantage to estimate the state vector and actuator faults simultaneously. As consequence, the use of this approach has attracted an increasing interest in the last decade ([2], [3], [4]). Recent years have witnessed rapidly growing in the study of T-S fuzzy model since it is well known that this model is a powerful tool in approximating a wide class of nonlinear systems ([6], [7], [8], [9]). Still, time delay is one of the instability sources of dynamical processes. For this reason, T-S fuzzy model has been extended to deal with nonlinear systems with time delay. Different delay-independent methodologies have been proposed for analysis and synthesis for T-S fuzzy systems with time delay ([10], [11], [12]). It is generally recognized that delay-dependent results are usually less conservative than delay-independent ones. That's why, delay-dependent techniques have been reported in ([13], [14], [15]).

Considering the AFDO design, the problem of fault estimation for linear system are treated in [3]. This idea is extended to deal with T-S fuzzy models with constant time delay in [4]. The obtained result is delay-independent. By adopting the free weighting matrix technique, delay-dependent results are obtained for linear systems with bounded time delay [5]. However, the price under additional variables is the growth of computational burden in the meantime. In this paper, we investigate the delay-dependent AFDO design for T-S fuzzy systems with interval time varying delay without using any free weighting matrices. The advantages of the developed criteria are: (1) the reduction of conservatism; (2) the reduction of computational complexity and (3) the removing of condition $\dot{\tau}(t) < 1$ which makes it applicable to both slow and fast time varying delay.

Notations $W + W^T$ is denoted as $W + (*)$ for simplicity.

II. Problem formulation and preliminaries

Consider a nonlinear system with time delay which could be approximated by a time delay T-S fuzzy model.

The i^{th} rule of the system is expressed in the following IF-THEN rules.

Plant Rule $i(i = 1, 2, \cdots, r)$: If θ_1 is μ_{i1} and $\cdots$ and θ_p is μ_{ip} THEN

$$\begin{aligned} \dot{x}(t) &= A_i x(t) + A_{\tau i} x(t - \tau(t)) + B_i u(t) \\ &\quad + E_i f(t) \\ y(t) &= Cx(t) \\ x(t) &= \psi(t), \quad t \in [-\tau,\ 0] \end{aligned} \tag{1}$$

where $\theta_j(x(t))$ and $\mu_{ij}(i = 1, \cdots, r, j = 1, \cdots, p)$ are respectively the premise variable and the fuzzy sets; $\psi(t)$ is the initial condition; $x(t) \in \Re^{n_x}$ is the state; $u(t) \in \Re^{n_u}$ is the control input; $f(t) \in \Re^{n_f}$ represents the actuator fault vector. It is assumed that the derivative of $f(t)$ with respect to time is norm bounded, i.e. $\|\dot{f}(t)\| \leq f_1$ and $0 \leq f_1 < \infty$. r is the number of IF-THEN rules.

The AFDO is constructed as

Observer Rule $i(i = 1, 2, \cdots, r)$: If θ_1 is μ_{i1} and $\cdots$ and θ_p is μ_{ip} THEN

$$\begin{aligned} \dot{\hat{x}}(t) &= A_i \hat{x}(t) + A_{\tau i} \hat{x}(t - \tau(t)) + B_i u(t) \\ &\quad + E_i \hat{f}(t) - L_i(\hat{y}(t) - y(t)) \\ \hat{y}(t) &= C\hat{x}(t) \end{aligned} \tag{2}$$

Denote $e_x(t) = \hat{x}(t) - x(t)$, $e_y(t) = \hat{y}(t) - y(t)$, $e_f(t) = \hat{f}(t) - f(t)$

then the error dynamic is given by

$$\begin{aligned} \dot{e}_x(t) &= (A(t) - L(t)C)e_x(t) \\ &\quad + A_\tau(t)e_x(t - \tau(t)) + E(t)e_f(t) \\ e_y(t) &= Ce_x(t) \end{aligned}$$

where

$$A(t)=\sum_{i=1}^{r}h_iA_i;A_\tau(t)=\sum_{i=1}^{r}h_iA_{\tau i};E(t)=\sum_{i=1}^{r}h_iE_i$$

The following result has been given in [4] which treats the case of constant delay ($\tau(t)=\tau$).

Theorem 1: [4] If there exist symmetric positive definite matrices $P>0$, $Q>0$, $M>0$, Y_i and F_i such that the following LMI hold:

$$\Psi_{ij}+\Psi_{ji}<0,\qquad i,j=1,2,\cdots,r,i\leq j \tag{3}$$

$$E_i^TP=F_iC,\qquad i=1,2,\cdots,r \tag{4}$$

then the fuzzy Fast Adaptive Fault Estimation (FAFE) algorithm

$$\dot{\hat{f}}(t)=-\Gamma\sum_{i=1}^{r}h_iF_i(\dot{e}_y(t)+e_y(t)) \tag{5}$$

can realize $e_x(t)$ and $e_f(t)$ uniformly ultimately bounded, where

$$\Psi_{ij}=\begin{bmatrix}\Psi_{ij}^{11} & PA_{\tau i} & -A_i^TPE_j+C^TY_i^TE_j\\ * & -Q & -A_{\tau i}^TPE_j\\ * & * & -E_i^TPE_j-E_j^TPE_i+M\end{bmatrix}$$

in which

$$\Psi_{ij}^{11}=PA_i+A_i^TP-Y_iC-C^TY_i^T+Q$$

In this case, the gains L_i are given by

$$L_i \;=\; Y_iP^{-1} \tag{6}$$

the symmetric positive definite matrix Γ is the learning rate.

In this paper, we will develop another design method which improves that in theorem (1).

III. Improved result

In this section, we first present useful lemma and then present the main result.

Lemma 1: Given matrices x and y.
For a symmetric positive definite matrix P, the following inequality holds

$$2x^Ty\leq x^TPx+y^TP^{-1}y$$

Lemma 2 Consider a negative definite matrix $\Pi<0$.
Given a symmetric matrix X of appropriate dimension such that $X^T\Pi X<0$, then, $\exists\lambda\in\Re^+$ such that

$$X^T\Pi X\leq-2\lambda X-\lambda^2\Pi^{-1}$$

Lemma 3 Given matrices $M,E,F(t)$ with compatible dimensions and $F(t)$ satisfying $F(t)^TF(t)\leq I$.
Then, the following inequalities hold for any $\epsilon>0$
$MF(t)E+E^TF(t)^TM^T\leq\epsilon MM^T+\epsilon^{-1}E^TE$

The following theorem gives the new LMI-based conditions in order to reduce the conservatism in theorem (1). Furthermore, we consider interval time-varying delay rather than constant delay.

the interval time varying delay satisfies

$$0<\tau_m\leq\tau(t)\leq\tau_M,\dot{\tau}(t)\leq\beta \tag{7}$$

Denote

$$\tau_1=\frac{\tau_m+\tau_M}{2};\tau_2=\frac{\tau_M-\tau_m}{2}$$

Theorem 2: For given positif scalar λ, if there exist matrices $P>0$, $Q_l>0(l=1,2,3,4,5)$, $R_m>0(m=1,2,3,4)$ such that (4) and the following LMI hold

$$\Xi_{ij}+\Xi_{ji}<0,\qquad i,j=1,2,\cdots,r,i\leq j \tag{8}$$

where

$$\Xi_{ij}=\begin{bmatrix}\xi_{ij}^{11} & R_4 & PA_{\tau i} & 0\\ * & \xi_{22} & R_3 & Q_2+R_1\\ * & * & \xi_{33} & 0\\ * & * & * & \xi_{44}\\ * & * & * & *\\ * & * & * & *\\ * & * & * & *\end{bmatrix}\begin{bmatrix}0 & \xi_{ij}^{16} & \xi_{ij}^{17}\\ 0 & 0 & 0\\ R_3 & -A_{\tau i}^TPE_j & A_{\tau i}^TP\\ -Q_2+R_2 & 0 & 0\\ \xi_{55} & 0 & 0\\ * & \xi_{ij}^{66} & E_i^TP\\ * & * & \xi_{ij}^{77}\end{bmatrix}$$

in which

$$\begin{aligned}
\xi_{ij}^{11} &= PA_i-Y_iC+A_i^TP-C^TY_i^T+Q_4+Q_5-R_4;\\
\xi_{ij}^{16} &= -A_i^TPE_j+C^TY_i^TE_j;\\
\xi_{ij}^{17} &= A_i^TP-C^TY_i^T\\
\xi^{22} &= Q_1-Q_5-R_1-R_3-R_4;\\
\xi^{33} &= -(1-\beta)Q_4-2R_3;\\
\xi^{44} &= Q_3-Q_1-R_1-R_2;\\
\xi^{55} &= -Q_3-R_2-R_3;\\
\xi_{ij}^{66} &= -E_i^TPE_j-E_j^TPE_i+M;\\
\xi_{ij}^{77} &= -2\lambda P\\
&\quad+\lambda^2((\tau_2)^2R_1+(\tau_2)^2R_2+(2\tau_2)^2R_3+(\tau_m)^2R_4)
\end{aligned}$$

then the fuzzy Fast Adaptive Fault Estimation (FAFE) algorithm (5) can realize $e_x(t)$ and $e_f(t)$ uniformly ultimately bounded,

In this case, the L_i are given by (6).

Proof:
Consider the following Lyapunov function

$$V(t)=\sum_{i=1}^{6}V_i(t) \tag{9}$$

where

$$\begin{aligned} V_1(t) &= e_x(t)^T P e_x(t) + \int_{t-\tau_1}^{t-\tau_m} \{e_x(s)^T Q_1 e_x(s) \\ &\quad +2e_x(s)^T Q_2 e_x(s-\tau_2) \\ &\quad +e_x(s-\tau_2)^T Q_3 e_x(s-\tau_2)\} ds \\ &\quad + \int_{t-\tau(t)}^{t} e_x(s)^T Q_4 e_x(s) ds \\ &\quad + \int_{t-\tau_m}^{t} e_x(s)^T Q_5 e_x(s) ds \end{aligned}$$

$$\begin{aligned} V_2(t) &= \tau_2 \int_{-\tau_1}^{-\tau_m} \int_{t+\sigma}^{t} \dot{e}_x(s)^T R_1 \dot{e}_x(s) ds d\sigma \\ V_3(t) &= \tau_2 \int_{-\tau_M}^{-\tau_1} \int_{t+\sigma}^{t} \dot{e}_x(s)^T R_2 \dot{e}_x(s) ds d\sigma \\ V_4(t) &= 2\tau_2 \int_{-\tau_M}^{-\tau_m} \int_{t+\sigma}^{t} \dot{e}_x(s)^T R_3 \dot{e}_x(s) ds d\sigma \\ V_5(t) &= \tau_m \int_{-\tau_m}^{0} \int_{t+\sigma}^{t} \dot{e}_x(s)^T R_4 \dot{e}_x(s) ds d\sigma \\ V_6(t) &= e_f(t)^T \Gamma^{-1} e_f(t) \end{aligned}$$

Taking the derivation of $V(t)$, we have

$$\dot{V}_1(t) = 2e_x(t)^T P \dot{e}_x(t) + \Delta$$

where

$$\begin{aligned} &\Delta = e_x(t-\tau_m)^T Q_1 e_x(t-\tau_m) + 2e_x(t-\tau_m) Q_2 e_x(t-\tau_1) \\ &+e_x(t-\tau_1) Q_3 e_x(t-\tau_1) - e_x(t-\tau_1)^T Q_1 e_x(t-\tau_1) \\ &-2e_x(t-\tau_1)^T Q_2 e_x(t-\tau_M) - e_x(t-\tau_M)^T Q_3 x(t-\tau_M) \\ &+e_x(t)^T Q_4 e_x(t) - (1-\dot{\tau}(t)) e_x(t-\tau(t)) Q_4 e_x(t-\tau(t)) \\ &+e_x(t)^T Q_5 e_x(t) - e_x(t-\tau_m)^T Q_5 e_x(t-\tau_m) \end{aligned}$$

$$\begin{aligned} \dot{V}_2(t) &= \tau_2 \{\dot{e}_x(t)^T R_1 \dot{e}_x(t) \\ &\quad - \int_{t-\tau_1}^{t-\tau_m} \dot{e}_x(s)^T R_1 \dot{e}_(s) ds\} \end{aligned} \quad (10)$$

Similarly, we obtain

$$\begin{aligned} \dot{V}_3(t) &= \tau_2 \{\tau_2 \dot{e}_x(t)^T R_2 \dot{e}_x(t) \\ &\quad - \int_{t-\tau_M}^{t-\tau_1} \dot{e}_x(s)^T R_2 \dot{e}_x(s) ds\} \\ \dot{V}_4(t) &= 2\tau_2 \{2\tau_2 \dot{e}_x(t)^T R_3 \dot{e}_x(t) \\ &\quad - \int_{t-\tau_M}^{t-\tau_m} \dot{e}_x(s)^T R_3 \dot{e}_x(s) ds\} \\ \dot{V}_5(t) &= \tau_m \{\tau_m \dot{e}_x(t)^T R_4 \dot{e}_x(t) \\ &\quad - \int_{t-\tau_m}^{t} \dot{e}_x(s)^T R_4 \dot{e}_x(s) ds\} \end{aligned}$$

By using the FAFE algorithm given in (5), we obtain

$$\begin{aligned} \dot{V}_6(t) &= -2e_f(t)^T F(t) C(\dot{e}_x(t) + e_x(t)) \\ &\quad -2e_f(t)^T \Gamma^{-1} \dot{f}(t) \end{aligned}$$

By considering equality (4), we obtain:

$$\begin{aligned} &\dot{V}_1(x(t)) + \dot{V}_6(x(t)) \\ &= 2e_x(t)^T P[(A(t) - L(t)C)e_x(t) + A_\tau(t) e_x(t-\tau(t)) \\ &+E(t) e_f(t)] \\ &+\Delta - 2e_f(t)^T F(t) C(\dot{e}_x(t) + e_x(t)) - 2e_f(t)^T \Gamma^{-1} \dot{f}(t) \\ &= 2e_x(t)^T P[(A(t) - L(t)C)e_x(t) + A_\tau(t) e_x(t-\tau(t))] \\ &+\Delta - 2e_f(t)^T F(t) C \dot{e}_x(t) - 2e_f(t)^T \Gamma^{-1} \dot{f}(t) \\ &+ \underbrace{2e_x(t)^T P E(t) e_f(t) - 2e_f(t)^T F(t) C e_x(t)}_{0} \end{aligned}$$

From lemma (1), we can obtain that

$$\begin{aligned} &-2e_f(t)^T \Gamma^{-1} \dot{f}(t) \leq \\ &e_f(t)^T M e_f(t) + \dot{f}(t)^T \Gamma^{-1} M^{-1} \Gamma^{-1} \dot{f}(t) \leq \\ &e_f(t)^T M e_f(t) + \delta \end{aligned} \quad (11)$$

where

$$\delta = f_1^2 \lambda_{max}(\Gamma^{-1} M^{-1} \Gamma^{-1})$$

Applying Jensen's integral inequality [1] to deal with the cross product items, we have

$$\begin{aligned} &-\tau_2 \int_{t-\tau_1}^{t-\tau_m} \dot{e}_x(s)^T R_1 \dot{e}_x(s) ds \\ &\leq \begin{bmatrix} e_x(t-\tau_m) \\ e_x(t-\tau_1) \end{bmatrix}^T \begin{bmatrix} -R_1 & R_1 \\ * & -R_1 \end{bmatrix} \begin{bmatrix} e_x(t-\tau_m) \\ e_x(t-\tau_1) \end{bmatrix} \end{aligned}$$

$$\begin{aligned} &-\tau_2 \int_{t-\tau_M}^{t-\tau_1} \dot{e}_x(s)^T R_2 \dot{e}_x(s) ds \\ &\leq \begin{bmatrix} e_x(t-\tau_1) \\ e_x(t-\tau_M) \end{bmatrix}^T \begin{bmatrix} -R_2 & R_2 \\ * & -R_2 \end{bmatrix} \begin{bmatrix} e_x(t-\tau_1) \\ e_x(t-\tau_M) \end{bmatrix} \end{aligned}$$

$$\begin{aligned} &-2\tau_2 \int_{t-\tau_M}^{t-\tau_m} \dot{e}_x(s)^T R_3 \dot{e}_x(s) ds \\ &\leq -(\tau(t) - \tau_m) \int_{t-\tau(t)}^{t-\tau_m} \dot{e}_x(s)^T R_3 \dot{e}_x(s) ds \\ &-(\tau_M - \tau(t)) \int_{t-\tau_M}^{t-\tau(t)} \dot{e}_x(s)^T R_3 \dot{e}_x(s) ds \\ &\leq \begin{bmatrix} e_x(t-\tau_m) \\ e_x(t-\tau(t)) \\ e_x(t-\tau_M) \end{bmatrix}^T \begin{bmatrix} -R_3 & R_3 & 0 \\ * & -2R_3 & R_3 \\ * & * & -R_3 \end{bmatrix} \\ &\begin{bmatrix} e_x(t-\tau_m) \\ e_x(t-\tau(t)) \\ e_x(t-\tau_M) \end{bmatrix} \end{aligned}$$

$$-\tau_m \int_{t-\tau_m}^{t} \dot{e}_x(s)^T R_4 \dot{e}_x(s) ds$$
$$\leq \begin{bmatrix} e_x(t) \\ e_x(t-\tau_m) \end{bmatrix}^T \begin{bmatrix} -R_4 & R_4 \\ * & -R_4 \end{bmatrix} \begin{bmatrix} e_x(t) \\ e_x(t-\tau_m) \end{bmatrix}$$

Let $\eta(t) = [e_x(t)^T, e_x(t-\tau_m)^T, e_x(t-\tau(t))^T, e_x(t-\tau_1)^T, e_x(t-\tau_M)^T, e_f(t)^T]^T$.

$$\dot{V}(t) \leq \eta(t)^T \Omega(t) \eta(t) \quad (12)$$
$$+\dot{e}_x(t)^T((\tau_2)^2 R_1 + (\tau_2)^2 R_2 + (2\tau_2)^2 R_3 + (\tau_m)^2 R_4)\dot{e}_x(t) + \delta$$

where

$$\Omega(t) = \begin{bmatrix} \omega_{11}(t) & R_4 & PA_\tau(t) & 0 & 0 & \omega_{16}(t) \\ * & \xi_{22} & R_3 & Q_2+R_1 & 0 & 0 \\ * & * & \xi_{33} & 0 & R_3 & A_\tau(t)^T PE(t) \\ * & * & * & \xi_{44} & -Q_2+R_2 & 0 \\ * & * & * & * & \xi_{55} & 0 \\ * & * & * & * & * & \omega_{66}(t) \end{bmatrix}$$

in which

$$\begin{aligned} \omega_{11}(t) &= P(A(t)-L(t)C) + (A(t)-L(t)C)^T P \\ &\quad +Q_4 + Q_5 - R_4; \\ \omega_{16}(t) &= -(A(t)-L(t)C)^T PE(t); \\ \omega_{66}(t) &= -2E(t)^T PE(t) + M \end{aligned}$$

By the Schur complement, we obtain

$$\Phi(t) = \begin{bmatrix} \Omega(t) & \phi_{12}(t) \\ * & -P((\tau_2)^2 R_1 + (\tau_2)^2 R_2 \\ & +(2\tau_2)^2 R_3 + (\tau_m)^2 R_4)^{-1} P \end{bmatrix}$$

where

$$\phi_{12}(t)^T = \begin{bmatrix} P(A(t)-L(t)C) & 0 & PA_\tau(t) \\ 0 & 0 & PE(t) \end{bmatrix}^T \quad (13)$$

Applying lemma 2, if $\Xi_{ij}+\Xi_{ji} < 0, i,j = 1,2,\cdots,r, i \leq j$, then there exist a scalar $\epsilon > 0$ such that $\dot{V}(t) < -\epsilon\|\eta(t)\|^2 + \delta$. It follows that $\dot{V}(t) < 0$ for $\epsilon\|\eta(t)\|^2 > \delta$, which means that $\eta(t)$ converges to a small set $S = \{\eta(t) | \|\eta(t)\|^2 \leq \frac{\delta}{\epsilon}\}$ according to Lyapunov stability theory. Therefore, estimation errors of both the state and the fault are uniformly ultimately bounded.

We can extend the result in theorem 2 to the uncertain case: A_i and $A_{\tau i}$ are replaced by $A_i + \Delta A_i$ and $A_{\tau i} + \Delta A_{\tau i}$, respectively.

$$\Delta A_i = M_{Ai} F_i(t) E_{Ai}, ; \quad \Delta A_{\tau i} = M_{A\tau i} F_i(t) E_{A\tau i}$$

We obtain the following theorem

Theorem 3 For given positif scalar λ, if there exist matrices $P, Q_l (l = 1,2,3,4,5), R_m (m = 1,2,3,4)$ and scalars ϵ_{Ai} and $\epsilon_{A\tau i}$ such that (4) and the following LMI hold

$$\Upsilon_{ij} + \Upsilon_{ji} < 0, \qquad i,j = 1,2,\cdots,r, i \leq j \quad (14)$$

where

$$\begin{aligned} \Upsilon_{ij} &= \begin{bmatrix} \Xi_{ij} & U_i & V_i \\ * & -\epsilon_{Ai} I & 0 \\ * & * & -\epsilon_{A\tau i} I \end{bmatrix} \\ &\quad +diag(\epsilon_{Ai} E_{Ai}^T E_{Ai}, 0, \epsilon_{A\tau i} E_{A\tau i}^T E_{A\tau i}, 0_{1\times 6}) \end{aligned}$$

in which

$$U_i = \begin{bmatrix} PM_{Ai} \\ 0_{4\times 1} \\ -E_j^T PM_{Ai} \\ PM_{Ai} \end{bmatrix}$$

$$V_i = \begin{bmatrix} PM_{A\tau i} \\ 0_{4\times 1} \\ -E_j^T PM_{A\tau i} \\ PM_{A\tau i} \end{bmatrix}$$

then the fuzzy Fast Adaptive Fault Estimation (FAFE) algorithm (5) can realize $e_x(t)$ and $e_f(t)$ uniformly ultimately bounded,

In this case, the L_i are given by (6).

Proof:

In the case with uncertainty, we obtain theorem (2) in which Ξij is replaced by $\bar{\Xi} ij$ such that

$$\bar{\Xi}_{ij} = \Xi_{ij} + \Delta\Xi_{ij}$$

The uncertain part is given by

$$\Delta\Xi_{ij} = \begin{bmatrix} \Delta\Xi_{ij}^{11} & 0 & P\Delta A_{\tau i} & 0_{1\times 2} & -\Delta A_i^T PE_j & \Delta A_i^T P \\ & 0 & 0 & 0_{1\times 2} & 0 & 0 \\ & * & 0 & 0_{1\times 2} & -\Delta A_{\tau i}^T PE_j & \Delta A_{\tau i}^T P \\ & * & * & 0_{1\times 2} & 0 & 0 \\ & * & * & 0_{1\times 2} & 0 & 0 \\ & * & * & 0_{1\times 2} & 0 & 0 \\ & * & * & 0_{1\times 2} & 0 & 0 \end{bmatrix}$$

in which

$$\Delta\Xi_{ij}^{11} = P\Delta A_i + \Delta A_i^T P$$

$$\begin{aligned} \Delta\Xi_{ij} &= U_i F(t) \begin{bmatrix} E_{Ai} & 0_{1\times 6} \end{bmatrix} + (*) \\ &\quad +V_i F(t) \begin{bmatrix} 0_{1\times 2} & E_{A\tau i} & 0_{1\times 4} \end{bmatrix} + (*) \quad (15) \end{aligned}$$

By applying lemma 3 and schur complement, we obtain theorem 3.

Remark 1 It is easy to solve inequality (3) and (14) by using LMI Toolbox. For equations (4), we can make a transform into the following optimization problem:

Minimize $\rho > 0$ subject to

$$\begin{bmatrix} \rho I & E_i^T P - F_i C \\ * & \rho I \end{bmatrix} > 0, i = 1, \cdots, r \qquad (16)$$

Remark 2 Compared with theorem (1), theorem 2 contains some new improvements as follows:

(i) The result of theorem (2) is less conservative than that of theorem (1). This is because the conditions (3) is recovered by setting $Q_1 = Q_2 = Q_3 = Q_5 = R_1 = R_2 = R_3 = R_4 = 0$, $\tau(t) = \tau$, $\beta = 0$ in conditions (14).

(ii) Theorem 1 consider an interval time varying delay which is more general than constant time delay.

Furthermore, the uncertain case has been considered in theorem (3).

Remark 3 Based on the on-line fault estimate, an observer-based fast active fault tolerant controller can be designed to compensate for the effects of faults. This design is presented in ([4]) by using the basic concept of generalized inverse.

IV. Simulation Result

Consider the following T-S fuzzy model

$$\dot{x}(t) = \sum_{i=1}^{2} h_i[A_i x(t) + A_{\tau i} x(t - \tau(t)) + B_i u(t)] \qquad (17)$$

The membership functions for rules 1 and 2 are:

$$\begin{aligned} h_1(x_2(t)) &= 1 - \frac{x_2(t)^2}{2.25} \\ h_2(x_2(t)) &= 1 - h_1(x_2(t)) \end{aligned} \qquad (18)$$

where

$$A_1 = \begin{bmatrix} -0.1125 & -0.0200 \\ 1 & 0 \end{bmatrix}, A_2 = \begin{bmatrix} -0.1125 & -1.5270 \\ 1 & \end{bmatrix}$$

$$A_{\tau 1} = \begin{bmatrix} -0.0125 & -0.0050 \\ 0 & 0 \end{bmatrix}, A_{\tau 2} = \begin{bmatrix} -0.0125 & -0.2300 \\ 0 & 0 \end{bmatrix}$$

$$B_1 = B_2 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}, C = \begin{bmatrix} 0 & 1 \end{bmatrix}$$

Assume that time varying fault $f(t)$ is created as

$$\begin{aligned} f(t) &= 0, \qquad 0 \le t < 3 \\ &= 0.7 + 0.15\sin(t), 3 \le t \le 10 \end{aligned} \qquad (19)$$

By using theorem 2 for $\tau(t) = 0.2 + 0.1\sin(t)(\tau_m = 0.1; \tau_M = 0.3, \beta = 0.1)$ with the choice of $\lambda = 5$, we can obtain the following feasible solution:

$$P = 10^3 \times \begin{bmatrix} 1.5409 & -1.5409 \\ -1.5409 & 3.3868 \end{bmatrix}$$

$$F = 10^3 \times 1.8459$$

$$L_1 = \begin{bmatrix} 1.7056 \\ 2.1581 \end{bmatrix}, L_2 = \begin{bmatrix} 0.1081 \\ 2.1555 \end{bmatrix}$$

The simulation result is shown in figure 1.

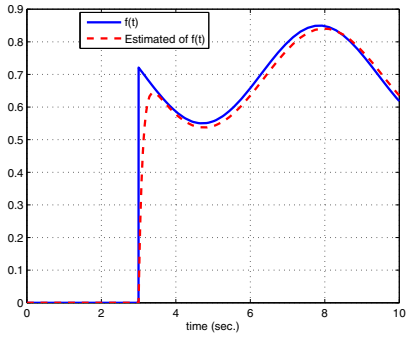

Fig. 1. Fault $f(t)$ and its estimated

V. Conclusion

The problem of delay dependent AFDO design to a class of T-S fuzzy systems with interval time varying delay has been investigated. Based on improved Lyapunov function, a delay dependent conditions for the existence of the fault estimator are given in terms of linear matrix inequalities. This result overcomes the drawbacks of delay independent results. An illustrative example has been presented to demonstrate the potential of the method.

Abstract—**This study presents the technology to combine the remote sensing image of SPOT and FORMOSAT-2 satellite image by Fuzzy theory and case base reasoning. This method adopt three experience identify factors of NDVI, shape, and color to establish the membership function. The Fuzzy theory was applied to estimate the process of thinking as the human brain; while the Case Base Reasoning method was used to increase the capability of self-loop learning and support its consistency with the real nature. The results show that the successful rate of identification was between 90 percent. The Case Base Reasoning results show that the two data similarity was between 46 percent. The Fuzzy and Case Base Reasoning difference factor was (satellite sensors, inclination, date, shadowing, etc.). The rate can be increase if there is enough experienced data. It reveal that fuzzy theory with case base reasoning indeed can rapid screen the change area from remote sensing image in before and after the disaster event.**

Keywords: fuzzy theory, case base reasoning, image extraction, image variation

I. INTRODUCTION

The objective of monitoring the change of catchment area is to avoid the damage from the nature disaster or excessive development. Previous method uses the software to identify the build the land category, and followed by the human experience to check it one by one. However, it has to spend a lot of time to identify the image from the remote sensing images. If it is possible to automatically study and train the capability of selection system, then the time of distinguish can be effectively reduced.

Using image segmentation software to produce the image segmentation vector and extract the variation region is a common practice for remote sensing technique in the past. The process is: select image to segment, output the segmentation vector file, use the software to extract the vector layer, and screen for variation area. The work was done by the accumulation of human experience. The memory capability of human can accumulate the previous experience, and it can compile the things touched to the rules of information.

Human brain can trigger the corresponding rules to the next move. If there were no corresponding rules, it can also trigger the fuzzy space for self-learning and reasoning. This capability can be simulated by the case base reasoning with fuzzy theory. Therefore, we use the fuzzy theory and case base reasoning to construct a quantitative fuzzy space structure to learn the human brain logic and estimate the variation region in the remote sensing image.

II. METHODOLOGY

Jose et al.[3]using Case Base Reasoning design remote sensing search system. Every image have severl classify index in database. The user can use these index combination search any image conform their demand. All user need not understand any programming language or Structured Query Language (SQL) in search process. Hsu and Hong[2]research typhoon remote sensing image classified according Wavelet Transform and Fuzzy Neural Network. They used Case Base Reasoning and Fuzzy damage estimated agricultural products and inhabitants damage. The experiment shows that their method can fast estimate typhoon damage area.

A. Set the membership function and numerical value of prediction indexes

Three indexes were adopted in this study as the experience rules for quick discrimination, which were: NDVI value difference, shape ratio, and color difference ratio (TABLE 1).

1) NDVI.

The meaning of NDVI value difference is to compare the ratio of red light absorption and near-infrared light reflection by green plant in the remote sensing image. The numerical value of NDVI difference is the difference of the early image and late image. Its value was ranged between -2～2.

- Define the NDVI value of previous image is a, and the value of post-image is b. The range of a single NDVI value is between -1 to 1.
- Let f(a) = {1,-1} f(b)= {-1,1} ,then f(b)-f(a) = -2 and 2 , so the maximum threshold value is between -2~2.

- The different value of NDVI is in the range between -2 to 2. According to the induction of manual experience, if the difference values of NDVI lower than 0.3, it could be regarded as no change.
- Let f(a)= {0.2,0.5} f(b)= {0.5,0.2} , we set the range as.
- If the value is between -0.3 to 0.3, then there is no change. If the value is between 02 to -0.3, then there is change exists.

The function of NDVI is to rapidly analyze the plant growth rate in the variation region. Otsu have proposed a rule for plant in the remote sensing image in 1979.[4]The color value of image was divided into two area as vegetation and non-vegetation.

2) Shape ratio

The definition of shape ratio is the ratio of post stage area to the previous stage area. It has to be assigned with the value accordant to the error factors of location, shape, and twist, etc. If the values lower than 1, then it is the reduction change. If the value is 1 to 1.5, then there is no change. If the value is greater than 1.5, then it is the diffusion change.

The shape ratio is not applicable to the land use type as: from never to have, from having to no, and the simplest change of type. The shape ratio is applicable to the condition when the land use types have no change, and only the area shape changes. The shape ratio is also applicable to the area which has been labeled as the variable region.

3) Color difference value

The color difference value is the total post RGB value minus the previous value of previous RGB in the same area. The total RGB value in the remote sensing image should nor over 255+255+255=765. So the category range for the index is:

- Set the total RGB for the previous image is a, and for the post image is b. Then b-a = 765 or-765.
- Therefore, the range of the maximum threshold value is between -765 to 765.

According to the induction of manual experience, the value of RGB difference lower than 30 is an acceptable value. Therefore, the membership function value of the fuzzy interval is defined as the following. If the value is lower than 30, than it is similar. If the value is between 30 to 765 or 765 to 30, then it is not similar.

B. Construct fuzzy and case base reasoning

The MATLAB fuzzy toolbox was used to construct a structure of rapid extraction. Three groups of indicators were identified. The functional forms and membership function value were shown as Figure1. to Figure 4..

Since, every index has three attribute of fuzzy interval. So,every index has four critical range. Kaufmann,Gupta[1] induced several kinds type of membership function. Most suitable for all index are trapezoidal fuzzy number. As in（1）:

$$f(x,a,b,c,d)=\begin{cases} 0 & x \le a \\ \dfrac{x-a}{b-a} & a \le x \le b \\ 1 & b \le x \le c \\ \dfrac{d-x}{d-c} & c \le x \le d \\ 0 & x \ge d \end{cases} \quad (1)$$

$a \le b, c \le d$

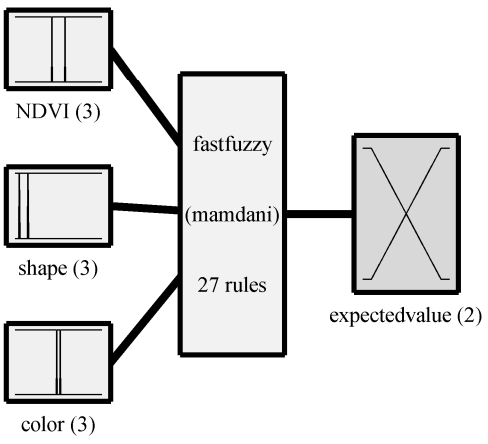
The trapezoidal function was chosen in this study because the interval of threshold value for the three indexes in this study is relatively fixed. Twenty seven rules of < IF…THEN > were formulating as the following:

1. If (NDVI is nochange) and (shape is nochange) and (color is Similar) then (expectedvalue is nochange)
2. If (NDVI is nochange) and (shape is nochange) and (color is Dissimilar) then (expectedvalue is yeschange)
3. If (NDVI is nochange) and (shape is nochange) and (color is Dissimilar) then (expectedvalue is yeschange)
4. If (NDVI is nochange) and (shape is Reduction) and (color is Similar) then (expectedvalue is yeschange)
5. If (NDVI is nochange) and (shape is Reduction) and (color is Dissimilar) then (expectedvalue is yeschange)
6. If (NDVI is nochange) and (shape is Reduction) and (color is Dissimilar) then (expectedvalue is yeschange)
7. If (NDVI is nochange) and (shape is Diffusion) and (color is Similar) then (expectedvalue is yeschange)
8. If (NDVI is nochange) and (shape is Diffusion) and (color is Dissimilar) then (expectedvalue is yeschange)
9. If (NDVI is nochange) and (shape is Diffusion) and (color is Dissimilar) then (expectedvalue is yeschange)
10. If (NDVI is negative) and (shape is nochange) and (color is Similar) then (expectedvalue is yeschange)
11. If (NDVI is negative) and (shape is nochange) and (color is Dissimilar) then (expectedvalue is yeschange)
12. If (NDVI is negative) and (shape is nochange) and (color is Dissimilar) then (expectedvalue is yeschange)
13. If (NDVI is negative) and (shape is Reduction) and (color is Similar) then (expectedvalue is yeschange)
14. If (NDVI is negative) and (shape is Reduction) and (color is Dissimilar) then (expectedvalue is yeschange)
15. If (NDVI is negative) and (shape is Reduction) and (color is Dissimilar) then (expectedvalue is yeschange)
16. If (NDVI is negative) and (shape is Diffusion) and (color is Similar) then (expectedvalue is yeschange)
17. If (NDVI is negative) and (shape is Diffusion) and (color is Dissimilar) then (expectedvalue is yeschange)
18. If (NDVI is negative) and (shape is Diffusion) and (color is Dissimilar) then (expectedvalue is yeschange)
19. If (NDVI is positive) and (shape is nochange) and (color is Similar) then (expectedvalue is yeschange)
20. If (NDVI is positive) and (shape is nochange) and (color is Dissimilar) then (expectedvalue is yeschange)
21. If (NDVI is positive) and (shape is nochange) and (color is Dissimilar) then (expectedvalue is yeschange)
22. If (NDVI is positive) and (shape is Reduction) and (color is Similar) then (expectedvalue is yeschange)
23. If (NDVI is positive) and (shape is Reduction) and

(color is Dissimilar) then (expectedvalue is yeschange)
24. If (NDVI is positive) and (shape is Reduction) and (color is Dissimilar) then (expectedvalue is yeschange)
25. If (NDVI is positive) and (shape is Diffusion) and (color is Similar) then (expectedvalue is yeschange)
26. If (NDVI is positive) and (shape is Diffusion) and (color is Dissimilar) then (expectedvalue is yeschange)
27. If (NDVI is positive) and (shape is Diffusion) and (color is Dissimilar) then (expectedvalue is yeschange) .

TABLE 1. MEMBERSHIP FUNCTION AND NUMERICAL VALUE OF THE THREE EVALUATION INDEXES

evaluation index of Variation regional	Type of membership function	Attribute of fuzzy interval	Membership function value
Differences in NDVI values	Trapezoidal	*NDVI ddifferences values is positive*	0.3 ~ 2
		NDVI no change	-0.3 ~ 0.3
		NDVI differences values is negative	-2 ~ -0.3
Shape ratio	Trapezoidal	*No change*	1 to 1.5 times
		Diffusion change	1.5 times to 10 times
		Reduction change	0 ~ 1 time
Color difference value	Trapezoidal	*Similar*	-30 ~ 30
		Dissimilar, positive value	30 ~ 765
		Dissimilar, negative value	-765 ~ -30



System fastfuzzy: 3 inputs, 1 outputs, 27 rules

III. RESULTS AND DISCUSSION

The study area was Shihmen Reservoir in Taoyuan County, Taiwan (Figure 6). The area of orchard planting showed rapid growth in the catchment area, according to the third stage governance planning of Shihmen Dam by Water Resource Agency, Ministry of Economic Affairs, Taiwan. These area were distributed in the slope place above 800 meters. It is more suitable for the planting of temperate fruit trees such as honey peach. And the low attitude area is more suitable for the planting of citrus trees. It shows that the land use was influenced by the demand of tourism and economic effect. There is a substantial degree of change comparing to the types of agriculture crop planting in earlier stage.

The forth stage investigation data from the project of SWCB-97-157 in 2008 were taken as the experience cases. Using four FORMOSAT-2 and SPOT panchromatic (pan) and multispectral (MS) images. The results were further verified by the three indexes. The expected value of variations was calculated by the module and obtains the value of 0.67, as shown in Figure 5. It means that if there is a possibility of change, its value will be greater than 0.67. Otherwise, the value of change will be lower than 0.67. The results of experience cases were shown in TABLE 2.

From the above TABLE 2 results, there are three cases with the expected value of variance lower than 0.67 among the thirty two cases. So the success rate of distinguish is 33-3/33=0.90. The recognition rate is about 90%.

From the above TABLE 3 ~TABLE 6 results, using fourth contrast third case data and count total mean similarity. The total mean similarity is about 46 %(Figure 7).

IV. CONCLUSION

It is necessary to appropriately monitor the environment according to the characteristic of land use in the watershed. If it was done by human observation to understand the hillside use condition, then it will take more time and more cost consuming. Remote sensing technology helps to provide the real time data, and can quickly glimpse the land picture status of watershed. This technology enforce the capability of variation region monitoring, and could save the time and cost. How to use this technology in the conservation of hillside deserves our attention.

***Abstract*—In this paper, we present a weights-learning algorithm based on the CHC algorithm, which is a specialization of traditional genetic algorithms, to automatically learn the optimal weights of the antecedent variables of the fuzzy rules for the proposed weighted fuzzy interpolative reasoning method based on bell-shaped membership functions. We also apply the proposed method to deal with the truck backer-upper control problem. The experimental results show that the proposed method using the optimally learned weights gets better accuracy rates than the existing methods for dealing with the truck backer-upper control problem.**

Keywords-Fuzzy interpolative reasoning; sparse fuzzy rule-based systems; weighted antecedent variables; genetic algorithms

I. INTRODUCTION

Sparse fuzzy rule bases contain blank areas uncovered by fuzzy rules in the universe of discourse with respect to the input variables. When the observation occurs in these blank areas, traditional fuzzy rule-based systems may get improper fuzzy reasoning results. Because fuzzy interpolation techniques can make inferences with sparse fuzzy rule bases effectively, fuzzy interpolation is an essential solution for inference in sparse fuzzy rule-based systems. Some fuzzy interpolative reasoning methods have been presented for sparse fuzzy rule-based systems [1]-[7], [10], [11], [13], [14], [17], [18].

In this paper, we present a weights-learning algorithm based on the CHC algorithm [8], which is a specialization of traditional genetic algorithms (GAs) [12], to automatically learn the optimal weights of the antecedent variables of the fuzzy rules for the proposed weighted fuzzy interpolative reasoning method, based on bell-shaped membership functions. We also apply the proposed method to deal with the truck backer-upper control problem. The experimental results show that the proposed method using the optimally learned weights gets smaller error rates than the existing methods [1], [6], [7], [11], [15].

II. PRELIMINARIES

A bell-shaped fuzzy set A in the universe of discourse U can be represented by $e^{-\left(\frac{x-c}{a}\right)^{2b}}$, where the parameters a and b alter the width of the membership function curve of A, the parameter c denotes the mean (i.e., the center) of the membership function of A and $b \geq 0$. For simplicity, a bell-shaped fuzzy set A can be represented by (a, b, c). For example, Figure 2 shows a bell-shaped fuzzy set A, where $A = (2, 2, 5)$. The representative value "$Rep(A)$" of a bell-shaped fuzzy set A is defined as follows:

$$Rep(A) = c. \tag{1}$$

Let c_A and c_B be the representative values of two bell-shaped fuzzy sets A and B, respectively. If $c_A \leq c_B$, then A is at the left-hand side of B and the total ordering relationship between A and B is denoted by "$A \prec B$". Otherwise, A is at the right-hand side of B and the total ordering relationship between A and B is denoted by "$B \prec A$".

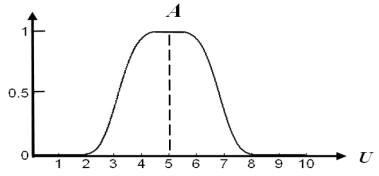

Figure 1. Bell-shaped fuzzy set $A = (2, 2, 5)$.

Generally speaking, the larger the values of the parameters a_A and b_A of the bell-shaped fuzzy set A, the larger the fuzziness of the fuzzy set A. Let A and B be two bell-shaped fuzzy sets, where $A = (a_A, b_A, c_A)$ and $B = (a_B, b_B, c_B)$. The ratios of the fuzziness $RF_a(A, B)$ and $RF_b(A, B)$ of the bell-shaped fuzzy set A to the fuzziness of the bell-shaped fuzzy set B with respect to the parameters a and b, respectively, are defined as follow:

$$RF_a(A, B) = \frac{a_A}{a_B}, \tag{2}$$

$$RF_b(A, B) = \frac{b_A}{b_B}. \tag{3}$$

III. A WEIGHTED FUZZY INTERPOLATIVE REASONING METHOD FOR SPARSE FUZZY RULE-BASED SYSTEMS USING BELL-SHAPED MEMBERSHIP FUNCTIONS

In this section, we present a weighted fuzzy interpolative reasoning method for sparse fuzzy rule-based systems using bell-shaped membership functions. Consider the following weighted multiple fuzzy rules interpolation scheme using bell-shaped membership functions:

***Rule* 1: If** X_1 is A_{11} (w_1) **and** X_2 is A_{12} (w_2) **and** ...**and** X_m is A_{1m} (w_m) **Then** Y is B_1
***Rule* 2: If** X_1 is A_{21} (w_1) **and** X_2 is A_{22} (w_2) **and** ...**and** X_m is A_{2m} (w_m) **Then** Y is B_2
⋮
***Rule n*: If** X_1 is A_{n1} (w_1) **and** X_2 is A_{n2} (w_2) **and** ...**and** X_m is A_{nm} (w_m) **Then** Y is B_n
***Observation*:** X_1 is A_1^* **and** X_2 is A_2^* **and** ...**and** X_m is A_m^*

***Conclusion*:** Y is B^*

where X_j denotes the jth antecedent variable, Y denotes the consequence variable, the antecedent fuzzy set A_{ij} of *Rule i* is represented by $(a_{A_{ij}}, b_{A_{ij}}, c_{A_{ij}})$, the consequence fuzzy set B_i of *Rule i* is represented by $(a_{B_i}, b_{B_i}, c_{B_i})$, the jth observation fuzzy set A_j^* is represented by $(a_{A_j^*}, b_{A_j^*}, c_{A_j^*})$, the interpolated consequence fuzzy set B^* is represented by $(a_{B^*}, b_{B^*}, c_{B^*})$, w_j denotes the weight of the antecedent variable X_j, $0 \le w_j \le 1$, $1 \le j \le m$, m denotes the number of antecedent variables appearing in the fuzzy rules and n denotes the number of fuzzy rules. Based on the weighted multiple fuzzy rules interpolation scheme, the proposed method for fuzzy rule interpolation using bell-shaped membership functions is now presented as follows:

Step 1: Choose p neighboring fuzzy rules *Rule* 1, *Rule* 2, …, and *Rule p* with respect to the observation as the closest fuzzy rules [5] with respect to the observation, where each antecedent fuzzy set A_{ij} of the closest fuzzy rule *Rule i* is either the left nearest fuzzy set or the right nearest fuzzy set of the observation fuzzy set A_j^*, $1 \le j \le m$ and $1 \le p \le n$.

Step 2: Based on [5], calculate the weight W_i of *Rule i*, where $1 \le i \le p$. Assume that $A_{l_j j}$ and $A_{r_j j}$ are the left nearest antecedent fuzzy set and the right nearest antecedent fuzzy set with respect to the observation fuzzy set A_j^*, respectively, where $1 \le l_j \le p$ and $1 \le r_j \le p$. Let

$$\lambda_{l_j j} = \begin{cases} \left(1 - \dfrac{\left|c_{A_j^*} - c_{A_{l_j j}}\right|}{\left|c_{A_{r_j j}} - c_{A_{l_j j}}\right|}\right), & \text{if } A_{l_j j} \prec A_j^* \prec A_{r_j j}, \\ 1, & \text{if } A_{ij} \prec A_j^*, \text{ where } 1 \le i \le p, \end{cases} \tag{4}$$

$$\lambda_{r_j j} = \begin{cases} \left(1 - \dfrac{\left|c_{A_{r_j j}} - c_{A_j^*}\right|}{\left|c_{A_{r_j j}} - c_{A_{l_j j}}\right|}\right), & \text{if } A_{l_j j} \prec A_j^* \prec A_{r_j j}, \\ 1, & \text{if } A_j^* \prec A_{ij}, \text{ where } 1 \le i \le p, \end{cases} \tag{5}$$

where $1 \le j \le m$. Let

$$W_i = \frac{\underset{1 \le j \le m}{\text{Min}}\, w_j \lambda_{ij}}{\sum_{q=1}^{p} \underset{1 \le j \le m}{\text{Min}}\, w_j \lambda_{qj}}, \tag{6}$$

where W_i denotes the weight of the fuzzy rule *Rule i*, $0 \le W_i \le 1$, $\sum_{i=1}^{p} W_i = 1$ and $1 \le i \le p$.

Step 3: Calculate the mean c_{B^*} of the interpolated consequence fuzzy set B^*, shown as follows:

$$c_{B^*} = \sum_{i=1}^{p} W_i \times c_{B_i}, \tag{7}$$

where $0 \le W_i \le 1$, $\sum_{i=1}^{p} W_i = 1$ and $1 \le i \le p$.

Step 4: Calculate the ratio RF_b of the composite fuzziness of the observation fuzzy sets to the composite fuzziness of the antecedent fuzzy sets with respect to the parameter b, shown as follows:

$$CF_b^* = \sum_{j=1}^{m} w_j \times b_{A_j^*}, \tag{8}$$

$$CF_{b,i} = \sum_{j=1}^{m} w_j \times b_{A_{ij}}, \quad \text{where } 1 \le i \le p \tag{9}$$

$$RF_b = \frac{RF_b^*}{\sum_{i=1}^{p} W_i \times RF_{b,i}}, \tag{10}$$

where CF_b^* denotes the composite fuzziness of the observation fuzzy sets A_1^*, A_2^*, …, and A_m^* with respect to the parameter b, $CF_{b,i}$ denotes the composite fuzziness of the antecedent fuzzy sets A_{i1}, A_{i2}, …, and A_{im} of the fuzzy rule *Rule i* with respect to the parameter b, RF_b denotes the ratio of the composite fuzziness of the observation fuzzy sets to the composite fuzziness of the antecedent fuzzy sets A_{ij} with respect to the parameter b, $RF_b \ge 0$, $0 \le W_i \le 1$, $\sum_{i=1}^{p} W_i = 1$, $1 \le j \le m$ and $1 \le i \le p$. Calculate the value of b_{B^*} of the interpolated consequence fuzzy set $B^* = (a_{B^*}, b_{B^*}, c_{B^*})$, shown as follows:

$$b_{B^*} = RF_b \times \left(\sum_{i=1}^{p} W_i \times b_{B_i}\right), \tag{11}$$

where $0 \le W_i \le 1$, $\sum_{i=1}^{p} W_i = 1$ and $1 \le i \le p$.

Step 5: Calculate the ratio RF_a of the composite fuzziness of the observation fuzzy sets to the composite fuzziness of the antecedent fuzzy sets with respect to the parameter a, shown as follows:

$$CF_a^* = \sum_{j=1}^{m} w_j \times a_{A_j^*}, \tag{12}$$

$$CF_{a,i} = \sum_{j=1}^{m} w_j \times a_{A_{ij}}, \tag{13}$$

$$RF_a = \frac{CF_a^*}{\sum_{i=1}^{p} W_i \times CF_{a,i}}, \tag{14}$$

where CF_a^* denotes the composite fuzziness of the observation fuzzy sets A_1^*, A_2^*, … and A_m^* with respect to the parameter a, $CF_{a,i}$ denotes the composite fuzziness of the antecedent fuzzy sets A_{i1}, A_{i2}, …, and A_{im} of the fuzzy rule *Rule i* with respect to the parameter a, RF_a denotes the ratio of the composite fuzziness of the observation fuzzy sets A_j^* to the composite fuzziness of the antecedent fuzzy sets A_{ij} with respect to the parameter a, $RF_a \ge 0$, $0 \le W_i \le 1$, $\sum_{i=1}^{p} W_i = 1$, $1 \le j \le m$ and $1 \le i \le p$. Calculate the value of a_{B^*} of the interpolated consequence fuzzy set $B^* = (a_{B^*}, b_{B^*}, c_{B^*})$, where

$$a_{B^*} = RF_a \times \left(\sum_{i=1}^{p} W_i \times a_{B_i} \right), \quad (15)$$

$0 \le W_i \le 1$, $\sum_{i=1}^{p} W_i = 1$ and $1 \le i \le p$. Therefore, we can get the interpolated consequence fuzzy set B^*, where $B^* = (a_{B^*}, b_{B^*}, c_{B^*})$.

IV. A Weights-Learning Algorithm to Automatically Learn the Optimal Weights of the Antecedent Variables of the Fuzzy Rules

In this section, we present a weights-learning algorithm based on the CHC algorithm [8], which is a specialization of traditional genetic algorithms (GAs) [12], to automatically learn the optimal weights of the antecedent variables of the fuzzy rules for the weighted fuzzy interpolative reasoning method. The CHC algorithm [8] uses the crossover generation, elitist selection, heterogeneous recombination and cataclysmic mutation for evolution. Assume that a fuzzy rule-based system has a knowledge base consisting of n fuzzy rules, where X_1, X_2, …, and X_m denote the antecedent variables of the fuzzy rules with respect to the inputs x_1, x_2, …, and x_m, respectively, and Y denotes the consequence variable of the fuzzy rules with respect to the output. Let W_{X_j} denote the weight of the antecedent variable X_j, where $1 \le j \le m$. Given a set S of training samples, where $S = \{S_1, S_2, \ldots, S_P\}$, the input values of each training sample S_i are represented by $(x_{i1}, x_{i2}, \ldots, x_{im})$, the target output of training sample S_i is represented by y_i, $1 \le i \le P$ and P denotes the number of training samples. In the proposed weights-learning algorithm, a population consists of l chromosomes and each chromosome consists of m genes, where the value g_j of the jth gene denotes the weight W_{Xj} of the antecedent variable X_j of the fuzzy rules, $0 \le g_j \le 1$ and $1 \le j \le m$, as shown in Figure 2. Assume that h denotes the heterogeneous recombination threshold for incest prevention.

Chromosome	g_1	g_2	g_3	…	g_{m-1}	g_m

Figure 2. Encoding the weights of the antecedent variables into a chromosome.

The proposed weights-learning algorithm is now presented as follows:

Step 1: Initialize two chromosomes, where one chromosome has the weights 0, 1, 0, 1, …, 0, 1 and the other chromosome has the weights 1, 0, 1, 0, …, 1, 0. Then, the system randomly generates the remaining l - 2 chromosomes to form the initial population. Let $h = \left\lceil \frac{m}{4} \right\rceil$.

Step 2: For each chromosome in the current population, decode the chromosome into the weight W_{X_j} of each antecedent variable X_j of the fuzzy rules, where $1 \le j \le m$. Based on the weighted fuzzy rules interpolation scheme, let the input values $x_{i1}, x_{i2}, \ldots$, and x_{im} of each training sample S_i $(x_{i1}, x_{i2}, \ldots, x_{im}, y_i)$ be the input observation "$X_1 = x_{i1}$, $X_2 = x_{i2}$, …, and $X_m = x_{im}$", where $1 \le i \le P$ and y_i denotes the target output of S_i. For each training sample $S_i = (x_{i1}, x_{i2}, \ldots, x_{im}, y_i)$, apply the proposed weighted fuzzy interpolative reasoning method to generate the fuzzy interpolated result B_i^* with respect to the input observation "$X_1 = x_{i1}$, $X_2 = x_{i2}$, …, $X_m = x_{im}$", where $1 \le i \le P$. For each B_i^*, if B_i^* is a fuzzy set, then use the center of gravity defuzzification method [16] to defuzzify B_i^* into a crisp-valued inferred output y_i^*, where $1 \le i \le P$. Based on a predefined fitness function, calculate the fitness value of each chromosome between the inferred outputs and the target outputs of the training samples.

Step 3: Select chromosomes from the current population based on the binary tournament selection method [9] to form a mating pool. The system repeatedly randomly selects two chromosomes from the current population and puts the chromosome having the larger fitness value into the mating pool and then puts the two selected chromosomes back into the current population. Repeatedly perform the above process until the number of chromosomes in the mating pool is equal to l, where l denotes the number of chromosomes of a population.

Step 4: Perform the blend crossover (BLX-α) method [8] with the chromosomes in the mating pool, where $0 \le \alpha < 1$ (Note: In this paper, we let $\alpha = 0.5$). For each chromosome C_i in the mating pool, the system randomly generates a real value between 0 and 1. If the randomly generated real value is smaller than a predefined crossover rate γ, where $\gamma \in [0, 1]$, then the system randomly chooses another chromosome C_j from the mating pool in which the number of distinct genes between C_i and C_j is larger than the value of h, and randomly chooses $\left\lceil \frac{m}{4} \right\rceil$ crossover points to perform the BLX-α crossover [8] with the selected chromosomes C_i and C_j. Figure 3 shows an example how the system updates the genes between the two selected chromosomes C_i and C_j, where the values of the genes g_2 and g_7 of C_i and C_j shown in Figure 3 are updated by the system, respectively.

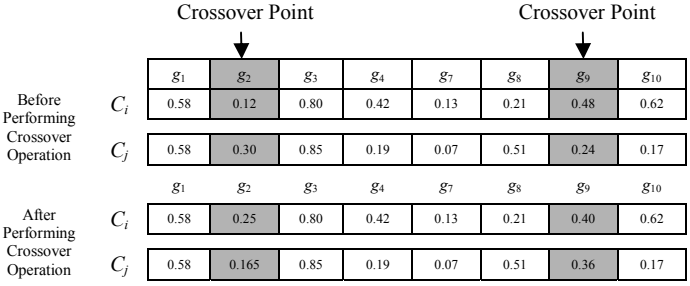

Figure 3. The system updates the genes between the two selected chromosomes.

Step 5: For each chromosome in the mating pool, decode the chromosome into the weight W_{X_j} of each antecedent variable X_j of the fuzzy rules, where $1 \le j \le m$. Based on the weighted fuzzy rules interpolation scheme, let the input values $x_{i1}, x_{i2}, \ldots$, and x_{im} of each training sample $S_i = (x_{i1}, x_{i2}, \ldots, x_{im}, y_i)$ be the input observation "$X_1 = x_{i1}$, $X_2 = x_{i2}$, …, and $X_m = x_{im}$", where $1 \le i \le P$ and y_i denotes the target output of S_i. For each training sample $S_i = (x_{i1}, x_{i2}, \ldots, x_{im}, y_i)$, apply the proposed weighted

fuzzy interpolative reasoning method to generate the fuzzy interpolated result B_i^* with respect to the input observation "$X_1 = x_{i1}, X_2 = x_{i2}, \ldots, X_m = x_{im}$", where $1 \le i \le P$. For each B_i^*, if B_i^* is a fuzzy set, then use the center of gravity defuzzification method [16] to defuzzify B_i^* into a crisp-valued inferred output y_i^*, where $1 \le i \le P$. Based on a predefined fitness function, calculate the fitness value of each chromosome between the inferred outputs and the target outputs of the training samples. Perform the elitist replacement to form the population of the next generation. The system selects chromosomes having the top l largest fitness values from the l chromosomes in the current population together with the l chromosomes in the mating pool to form the population of the next generation. If the number of selected chromosomes from the mating pool is equal to zero, then let $h = h - 1$. Otherwise, go to Step 6. If $h = 0$, then go to Step 7. Otherwise, go to Step 6.

Step 6: If the number of evolutions meets a predefined maximum number of evolutions, then let the chromosome, which has the largest fitness value be the optimal chromosome and go to Step 8. Otherwise, go to Step 2.

Step 7: Reinitialize the population using the cataclysmic mutation method [8]. The system puts the best chromosome having the largest fitness value in the current population into the population of the next generation and mutates the remaining l - 1 chromosomes of the current population to form the l - 1 chromosomes in the population of the next generation. For each gene of a mutated chromosome, the system randomly generates a real value between 0 and 1. If the generated real value is smaller than 0.5, then the system replaces the value of the gene with a randomly generated real value between 0 and 1. Let $h = \left\lceil \frac{m}{4} \right\rceil$, where m denotes the number of genes in a chromosome, and go to Step 2.

Step 8: Decode the chromosome having the largest fitness value into the weights W_{X_1}, W_{X_2}, …, and W_{X_m} to be used in the proposed weighted fuzzy interpolative reasoning method.

V. Experimental Results

In this section, we apply the proposed weights-learning algorithm to automatically learn the optimal weights of the antecedent variables of the fuzzy rules for the weighted fuzzy interpolative reasoning method to deal with the truck backer-upper control problem [15].

The goal of the truck backer-upper control problem [15] is to back up a truck to a loading dock as precisely as possible, where the behavior of the truck can be described by three state variables $x \in [0, 100]$, $y \in [0, 200]$ and $\phi \in [-90, 270]$, x denotes the horizontal axis, y denotes the vertical axis and ϕ denotes the azimuth angle. The truck starts from an initial state and should back up to the loading dock with the target state (50, 200, 90), i.e., $x = 50$, $y = 200$, and $\phi = 90$. In order to control the truck, the steering angle $\theta \in [-30, 30]$ is provided for each move of the truck. In general, it is assumed that the distance between the truck and the loading dock is quite large, and the state variable y can be ignored, so that the truck backer-upper control problem can be simplified into $\theta = f(x, \phi)$ [11]. In [11], Huang and Shen used a more compact fuzzy rule base of the six fuzzy rules shown in Figure 4 for truck backer-upper control. In this paper, we adopt the fuzzy rule base of the six fuzzy rules shown in Figure 4 for truck backer-upper control, where each row shown in Figure 4 denotes a fuzzy rule, shown as follows:

If x is A and ϕ is B **Then** θ is C,

where x and ϕ are the antecedent variables denoting the horizontal axis and the azimuth angle, respectively, θ is the consequence variable denoting the steering angle, and A, B and C are the possible fuzzy sets of x, ϕ and θ, respectively.

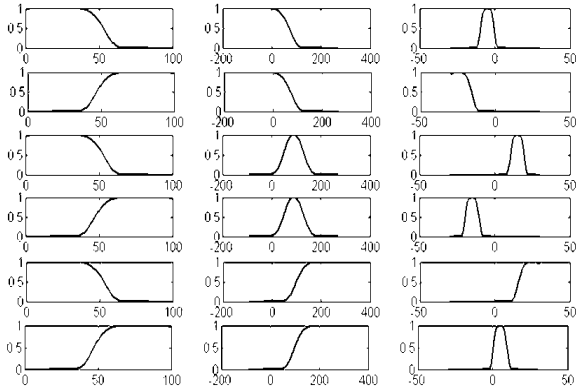

Figure 4. Membership functions of the six fuzzy rules [11].

Based on the weighted multiple fuzzy rules interpolation scheme, assume that each fuzzy rule of the six fuzzy rules for truck backer-upper control is represented as follows:

If x is A (w_x) and ϕ is B (w_ϕ) **Then** θ is C,

where x and ϕ are the antecedent variables denoting the horizontal axis and the azimuth angle, respectively, θ is the consequence variable denoting the steering angle, A, B and C are the possible fuzzy sets of x, ϕ and θ, respectively, and w_x and w_ϕ denote the weights of the antecedent variables x and ϕ, respectively. Let each chromosome have two genes g_1 and g_2 which denote the weights w_x and w_ϕ of the antecedent variables x and ϕ, respectively, where $0 \le g_1 \le 1$ and $0 \le g_2 \le 1$. Based on the fuzzy rule base shown in Figure 4 and the 64 initial states shown in Table I, we apply the proposed weights-learning algorithm for truck backer-upper control shown in Figure 5 to learn the optimal weights of w_x and w_ϕ for the proposed weighted fuzzy interpolative reasoning method, where the population size is 30, the crossover rate is 0.95 and the number of evolutions is 100. In this paper, we use the following fitness function to calculate the fitness value *Fitness* of each chromosome for truck backer-upper control:

$$Fitness = \left(\frac{1}{64} \sum_{i=1}^{64} \frac{|x_i^f - 50| + |\phi_i^f - 90|}{2} \right)^{-1}, \tag{16}$$

where $1 \le i \le 64$.

Based on the proposed weights-learning algorithm for truck backer-upper control shown in Figure 5, we can get the optimally learned weights $w_x = 0.55$ and $w_\phi = 0.70$ with respect to the antecedent variables x and ϕ, respectively. Table II shows a comparison of the reaching states of the four trajectories for different methods with respect to the target state (50, 200, 90). From Table II, we can see that the proposed method using the optimally learned weights $w_x = 0.55$ and $w_\phi = 0.70$ gets better truck backer-upper control results than the ones using the traditional fuzzy inference system [15], the CCL method [1], the CK method [6], the CKCP method [7] and the HS method [11].

TABLE II

VI. CONCLUSION

In this paper, we have presented a weights-learning algorithm based on the CHC algorithm to automatically learn the optimal weights of the antecedent variables of the fuzzy rules for the weighted fuzzy interpolative reasoning method. We also apply the proposed method to deal with the truck backer-upper control problem. The experimental results show that the proposed method using the optimally learned weights gets better accuracy than the existing methods [1], [6], [7], [11], [15] for dealing with the truck backer-upper control problem.

***Abstract*—Network lifetime is one of the most vital issues in wireless sensor network and is fundamental to any design and development effort. Extending the life time requires energy efficiency in every aspect. Besides, fuzziness, a feature of imperfect information was used to measure the distances between the sensed values. Involved with type-2 fuzzy sets, an effectively thresholding method is proposed and discussed in this study. Given an adaptive threshold value, the membership function of a sensed value is implemented, and the potential improvement gained by using our method is demonstrated by the simulated results presented.**

Keywords-type-2 fuzzy sets, entropy, measufes of fuzziness, wireless sensor network

I. INTRODUCTION

Over the last half a century, computers are becoming small and cheap, the single-purpose computers with embedded sensors are practical from both economical and theoretical points; the revolution has been taking place. Wireless sensor networks (WSNs), which combine wireless network and context aware computations as the next logical step, make the technology easy enough to be implemented by non-specialists [1]. Thought a range of impending applications are envisaged in the area of WSNs, which are categorized as event driven monitoring, continuous monitoring and hybrid methods.

In event driven monitoring application, sensors derived the data packet when events are triggered. On the other hand, in continuous monitoring approach, data was generated continuously with a predefined reporting frequency. The representativeness is to aggregate data in a cluster-based architecture with low energy adaptive clustering hierarchy (LEACH) [2]. The former approach reports time critical data reactively, however, the later reports the periodic data proactively. Thus, continuous monitoring approach would send data to the sink even if there is no significant importance of the sensed values; the result causes the wastage of resources. To resolve these problems, a hybrid protocol has been proposed by adapting the periodic threshold-sensitive time.

The main goals of this study are to reduce the power consumption of sensor nodes and to improve data quality received by the sink node in event driven monitoring application. However, the author assumes that different nodes detect different signal strength of the event, that is, the fault tolerances are distinct. Some sensor nodes may send packets to sink node when no event occurs due to the noise in the environment, and some sensor nodes may not send packets when an event occurs. A new thresholding technique will be introduced in this study.

Fuzziness, a feature of imperfect information, results from the lack of crisp distinction between the elements belonging and not belonging to a set. In 1969, Zadeh introduced the fuzziness/fuzzy-entropy for the first time [3], and in 1972 DE Luca and Termini introduced the axiom construction of entropy of fuzzy sets and referred to Shannon's probability entropy [4]. Due to intrinsic similarity to the equations in the Shannon entropy, fuzziness and entropy are significance of equality. It's very different from the classical entropy measure which measures probabilistic information. The index of fuzziness represents the average amount of fuzziness by measuring the distance between the sensed values. Accordingly, in this paper, based on the concept of type-2 fuzzy set, an effectively thresholding method is proposed. Given an adaptive threshold value, the membership function of a sensed value is defined by the absolute difference between the sensed value and average value. The larger the absolute difference is, the smaller the membership value becomes. In addition, the optimal threshold can then be effectively determined by minimizing the measure of fuzziness of nodes.

II. RELATED WORK

A. Event-Driven WSNs

Because the power consumption and data quality are usually the most important issues in WSNs, many research efforts have been proposed to find the best tradeoff between these two issues. Besides, in the event-driven WSNs, no event occurs at most of the time. Therefore, how to reduce the power consumption in the idle time is the another important aspect of energy saving. The authors in [5] proposed an energy efficient S-MAC protocol to arrange sensor nodes falling into sleep periodically. In [6], the authors propose an efficient sleep scheduling to exploit the timing semantics of WSNs. The proposed algorithm is light-weight because of no TDMA schedules or communication backbones needed, and the simulation results show the robust in the dynamic WSNs. In [7],

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

a distributed, cross layer scheduling scheme was proposed to communicate with its parent for transmission. The authors design an efficient schedule for the query processing with the following processing cycle, sampling, computing, communicating, and falling sleep. The experimental results show that the algorithm achieves the great power saving goal on the sensor nodes. In [8], the authors proposed an energy efficient protocol, multiple thresholds, and dynamic sampling/hop frequency to save energy when there is no event and wakes up the corresponding sensor nodes quickly when an event occurs.

B. Entropy and Measures of Fuzziness

The fuzziness of a fuzzy set, or entropy, tries to answer the following question: how fuzzy is a fuzzy set? Thus, De Luca and Termini first axiomatically proposed non-probabilistic entropy, they assume that E is a set-to-point mapping $E: F(2^x) \rightarrow [0,1]$, thus E is a fuzzy set defined on fuzzy universal sets [4]. Besides, if E is also satisfies the four DE Luca and Termini axioms, it is an entropy measure,

1. $E(A) = 0$ if $A \in 2^x$ $(A\ non-fuzzy)$,
2. $E(A) = 1$ if $\mu_A(x_i) = 0.5$ $for\ all\ i$,
3. $E(A) \leq E(B)$ if A is $less\ fuzzy\ than\ B, i.e.,$ if
   $\mu_A(x) \leq \mu_B(x)$ $when\ \mu_B(x) \leq 0.5$ and
   $\mu_A(x) \geq \mu_B(x)$ $when\ \mu_B(x) \geq 0.5$,
4. $E(A) = E(A^C)$.

Accordingly, there are several approaches of measuring fuzziness have been proposed, the most famous approaches are modified by Shannon's function and Yager's measuring functions [9][10]. According to the Shannon's function, De Luca and Termini defined the entropy of a fuzzy set X as

$$E(A) = \frac{1}{n\ln 2}\sum_i S\big(\mu_A(x_i)\big), \quad i = 1,2,\dots,n$$

With the Shannon's function

$$S(\mu_A(x_i)) = -\mu_A(x_i)\ln[\mu_A(x_i)] - [1-\mu_A(x_i)]\ln[1-\mu_A(x_i)].$$

Using the histogram information, the above equation can be revised as [11]

$$E(A) = \frac{1}{MN\ln 2}\sum_g S\big(\mu_A(g)\big)h(g), \quad g = 1,2,\dots,L,$$

where $h(g)$ denotes the number of occurrences at the data input level of g. On the other hand, Yager defines the major distinction between the fuzzy set and the traditional crisp set is on the discontent of the law of the excluded middle [9]. He argued that the measure of fuzziness should be dependent on the relationship between the fuzzy set A and its complement $\bar{A}$. Thus, he defined the distance between them as

$$D(A,\bar{A}) = [\sum_i |\mu_A(x_i) - \mu_{\bar{A}}(x_i)|^p]^{\frac{1}{p}}, \quad p = 1,2,\dots,$$

where $\mu_{\bar{A}}(x_i) = 1 - \mu_A(x_i)$. The measure of fuzziness of X is denoted as

$$\eta_p(A) = 1 - \frac{D(A,\bar{A})}{|A|^{1/p}}.$$

Accordingly, to compute $D(X,\bar{X})$ can be simplified by adding the histogram information as

$$D(A,\bar{A}) = [\sum_g |\mu_A(g) - \mu_{\bar{A}}(g)|^p]^{\frac{1}{p}} h(g)$$
$$g = 1,2,\dots,L.$$

Note that, for p=1, D(.) is called the Hamming metric, and for p=2, D(.) is called the Euclidean metric.

C. Type-2 Fuzzy Sets

Type-2 fuzzy sets are designed by making membership function in three dimensions where each element in type-2 fuzzy sets has membership value in range [0, 1]. The third dimension is an extension and adds degrees of freedom to get more information in represented fuzzy sets. Type-2 fuzzy sets are very useful when there is a difficulty in deciding appropriate membership function with ambiguity. Membership value in type-2 fuzzy sets can be any value in range [0, 1]. The based membership is called by primary membership, besides, related to the primary membership, there is a secondary membership by assigning possibility in range [0, 1] to the primary membership. To clarify statement, the fuzzy set 'tall' is represented as

$$tall = \frac{0.95}{\text{Michael}} + \frac{0.4}{\text{Danny}} + \frac{0.6}{\text{Robert}}.$$

Conversely, the interpretation by type-2 fuzzy set could be

$$tall = \frac{High}{\text{Michael}} + \frac{Low}{\text{Danny}} + \frac{Medium}{\text{Robert}},$$

where *High*, *Low* and *Medium* are themselves fuzzy sets. The previous set is measured by one condition for one element, on the contrary, the latter defined set is measured by several conditions for one element. Type-2 fuzzy sets are useful when the exact membership for a usual fuzzy set cannot be easily determined, and hence are advantageous for incorporating uncertainties.

D. Measure of Ultrafuzziness

Accordingly to [11], to measure the threshold value as type-2 fuzzy sets is what we called "how ultrafuzzy is a fuzzy set". If membership value degree in a fuzzy set can be decided clearly and without ambiguity, then ultrafuzzy value is zero. Whenever the membership value can only state as value interval, then its ultrafuzziness total value will be increased.

Measure of ultrafuzziness $\tilde{\gamma}$ with L level $g \in [0, L-1]$, the histogram $h(g)$ and the membership function $\mu(g)$ can be written as follows [11],

$$\tilde{\gamma} = \frac{1}{N}\sum_{g=0}^{L-1} h(g)\, x[\mu_U(g) - \mu_L(g)]$$

where

$\mu_U(g) = [\mu(g)]^{1/\alpha}$,

$\mu_L(g) = [\mu(g)]^{\alpha}, \alpha \in [1,2]$.

Note that $\mu_U(g)$ and $\mu_L(g)$ are the upper/lower bound of fuzzy set respectively.

III. Proposed Algorithm

In this study, the author employs the network environment as the static event-driven WSN, and the approach is based on the following observations;

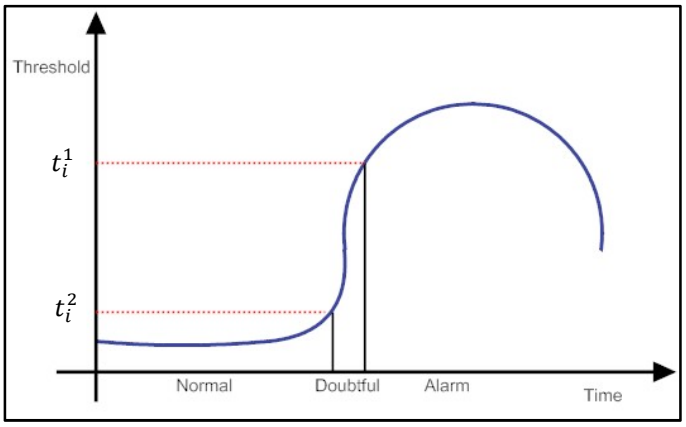

Figure 1. Multi-level thresholding

1. The sensor nodes have different quality with different signal-to-noise ratio and different memory capability, and all have limited processing and basic decision ability.
2. In some case, when an event occurs, several sensor nodes would be activated and deliver packets for response simultaneously. Thus, the network will leads to data implosion and redundancy. For the severely limited bandwidth, these nodes may have contention on the packet transmissions and ACKs overload.
3. Because of distinct signal-to-noise ratios, a sensor node with low signal-to-noise ratio may generate more irregularly data than those with high ratio when there is no event occurred.
4. With the same detected signal strength, the more sensor nodes can receive packets from sensor nodes with higher priority than ones with lower priority. In the meantime, most of retransmitted packets are redundant and useless.
5. The sink node has more resources, computation ability and memory capability.
6. For the purpose to reduce packet transmissions, each sensor node i have multiple threshold t_i^j to determine the packet need to be transmitted or not. That means that if there is no event occurred or only with noise interference, the packet don't need to be transmitted or are only transmitted to its neighbors within a small number of hops.
7. Based on the "positive feed-back" algorithm, when an event occurs, several nodes sense the varying of the environment, the transmission hops and frequency of these nodes are also increase. Then the frequency of received packets for nodes near these sensor nodes increases, and these neighbor nodes also increase the sensing frequency too.

In this study, because of the distinct noise tolerance for each node, the author attempts to develop multi-level thresholds in the histogram of a sensor node based on the fuzziness measure, please review Figure 1. Our proposed method performs an iterative operation for each node, and we assume the target histogram contains K different non-empty data levels. The method is listed as follows;

1. Choose type of membership function to determine membership value $\mu(g)$ and initialize value of α. In this paper, three membership functions derived as the normal, doubtful and alarm states respectively.
2. Compute the history data histogram.
3. Determine initial position location of membership functions.
4. Shift membership function along data range to calculate fuzziness total in each position as shown in Figure 2.
5. Compute upper membership value $\mu_U(g)$ and lower membership value $\mu_L(g)$ in each position.
6. Calculate ultrafuzziness value for each state.
7. Compute ultrafuzziness total value with the following equation:

$$\tilde{\Upsilon}_{total} = \tilde{\Upsilon}_{normal} \times \tilde{\Upsilon}_{doubtful} \times \tilde{\Upsilon}_{alarm}.$$

8. Find the optimum threshold positions with maximum ultrafuzziness total value.
9. Threshold data using this optimum value.

Using the above method, significant differences among different states are achieved. Therefore, optimal thresholding among them can be derived.

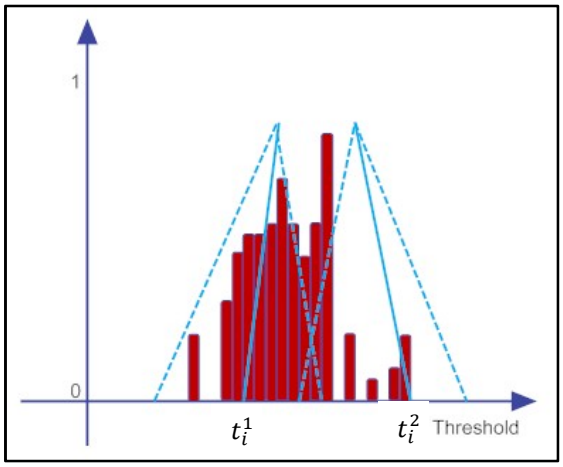

Figure 2. Shifting two membership functions

IV. RESUTL AND DISCUSSION

To evaluate the performance of our method, the author simulates the transmission by TinyOS simulator TOSSIM [12]. Here real data is used for the evaluation of the techniques (Intel lab data for both sensed and network connectivity data [13]). The comparison method is the general transmission protocol to flood sensing data when nodes sense the even occurred. Figure 3 shows the average energy consumptions of our proposed protocol and general protocol over the time (1200-4000 seconds) with 20 nodes deployments. The result shows our proposed method gains the better performance than the general case. Intuitively in this case the energy efficiency is achieved on the expense of loosing data accuracy.

V. CONCLUSIONS

Network lifetime is one of the most vital issues in WSNs and is fundamental to any design and development effort. Extending the lifetime of WSNs requires energy efficiency in every aspect of the utilized techniques such as energy efficient medium access control, energy efficient routing, aggregation and son on. This study presents a simple transmission technique that maintains the data accuracy while utilizing spatiotemporal correlation of data. The presented technique is to reduce the power consumption of sensor nodes and to improve data quality based on the type-2 fuzzy thresholding protocol. The potential improvement gained by using our method is demonstrated by the simulated results presented.

ACKNOWLEDGMENT

***Abstract*—λ-measure, P-measure, additive measure and B-measure are four well known fuzzy measure, all of them are univalent fuzzy measure with only one formulaic fuzzy measure solution. In this paper, first of all, it is proved that both λ-measure and additive measure are larger than P-measure and less than B-measure, in other words, both λ-measure and additive measure are never equal to the smallest fuzzy measure, P-measure and the largest fuzzy measure, B-measure. Furthermore, a novel multivalent fuzzy measure with infinitely many fuzzy measure solutions based on λ-measure, called a generalized λ-measure, is proposed. It is proved that the measure function of this new measure is continuous and increasing on λ, each different λ value corresponding different fuzzy measure, from the smallest fuzzy measure, P-measure to the largest fuzzy measure, B-measure, and containing λ-measure itself, in other words, all of above four univalent fuzzy measures are special cases of this new fuzzy measure. Moreover, this new generalized λ-measure is also satisfying the monotone condition rather than the old generalized λ-measure proposed by L.-Z. Yang, M.-H. Ha, X.-J. Wang and Z.-R. Zhang. However, the old one is just the λ-measure without the monotone condition. It is a generalized measure but no more a fuzzy measure. Hence, this new and true generalized fuzzy measure is called Liu's generalized λ-measure. Some properties about this new measure are also discussed.**

Keywords- λ-measure; P-measure; B-measure; L-measure; Liu's generalized λ-measure

I. INTRODUCTION

When interactions among independent variables exist in forecasting problems, the performances of the multiple linear regression models and ridge regression models [1] are not good enough. For improving this situation, G. Choquet proposed his fuzzy integral, called Choquet integral, in 1953 [2], M. Sugeno rediscovered the concepts of fuzzy integral and fuzzy measure and also proposed his λ-measure in 1974 [3], L. A. Zadeh's simple sub-additive fuzzy measure with closed form, P-measure, was proposed in 1978 [4], the author, H.-C. Liu, proved that the P-measure is the smallest fuzzy measure and proposed the largest fuzzy measure, B-measure in 2009 [6], all of above measures and traditional additive measure [5] are univalent fuzzy measure with only one formulaic fuzzy measure solution, the author, H.-C. Liu, proposed some multivalent fuzzy measures with infinitely many fuzzy measure solutions, called L-measure, completed L-measure, maximized L-measure, etc, [6-9]. It is showed that the interactions problem can be improved by using Choquet integral regression models with λ-measure and above multivalent fuzzy measures [6-9].

However, although all of L-measure, completed L-measure and maximized L-measure are multivalent fuzzy measures with infinitely many fuzzy measure solutions, but they do not contain λ-measure, in other words, λ-measure is not a special case of above multivalent fuzzy measures and all of the above multivalent fuzzy measures are not a generalized λ-measure.

L.-Z. Yang, M.-H. Ha, X.-J. Wang, and Z.-R. Zhang proposed a generalized λ-measure by deleting the monotone condition of λ-measure in 2008 [10], and then λ-measure is a a special case of their generalized λ-measure, but if the monotone condition is not satisfied, then this generalized λ-measure is not a fuzzy measure, in other words, this generalized λ-measure is a generalized measure of λ-measure, but not a generalized fuzzy measure of λ-measure, since a fuzzy measure must be a monotone measure.

In this paper, a novel multivalent fuzzy measure satisfying the monotone condition with infinitely many fuzzy measure solutions based on λ-measure also containing λ-measure itself and rather than the generalized λ-measure proposed by L.-Z. Yang, M.-H. Ha, X.-J. Wang, and Z.-R. Zhang, is considered. t. Some relative properties about this new generalized λ-measure are also considered.

II. FUZZY MEASURES

A. Fuzzy measures

Definition 1. [3,5] A measure μ on a finite set X is a fuzzy measure, if its measure function $g_\mu : 2^X \to [0,\infty)$ satisfying

(i) $g_\mu(\phi) = 0$ (vanishing at the empty set) (1)

(ii) $A \subseteq B \Rightarrow g_\mu(A) \le g_\mu(B)$ (monotonicity) (2)

B. Fuzzy support function, support

Definition 2. [6] A fuzzy support function of a fuzzy measure μ on a finite set X is a function $s : X \to [0,\infty)$ satisfying:

$$s(x)=\mu(\{x\}),\ x\in X \tag{3}$$

$s(x)$ is called the support value of singleton x.

C. Additive measure

Definition 3. [5] For a given fuzzy support function, $s(x)$ on a finite set X, a measure σ on X is an additive measure, if its measure function $g_\sigma : 2^X \to [0,\infty)$ satisfying :

(i) $g_\sigma(\phi)=0$ (vanishing at the empty set) (4)

(ii) $$\forall A\in 2^X \Rightarrow g_\sigma(A)=\sum_{x\in A}s(x)=\sum_{x\in A}g_\sigma(\{x\}) \tag{5}$$

Theorem 1. [5] An additive measure on a finite set X is a fuzzy measure on X satisfying

(i) $$A,B\in 2^X,\ A\cap B=\phi \Rightarrow g_\sigma(A\cup B)=g_\sigma(A)+g_\sigma(B) \tag{6}$$

(ii) $$A,B\in 2^X,\ A\subseteq B \Rightarrow g_\sigma(A)\le g_\sigma(B) \tag{7}$$

Proof:

(i) $A,B\in 2^X,\ A\cap B=\phi$

$$\Rightarrow g_\sigma(A\cup B)=\sum_{x\in A\cup B}g_\sigma(\{x\})=\sum_{x\in A}g_\sigma(\{x\})+\sum_{x\in B}g_\sigma(\{x\}) =g_\sigma(A)+g_\sigma(B) \tag{8}$$

(ii) $$A,B\in 2^X,\ A\subseteq B \Rightarrow g_\sigma(A)=\sum_{x\in A}g_\sigma(\{x\})\le\sum_{x\in B}g_\sigma(\{x\})=g_\sigma(B) \tag{9}$$

D. λ-measure [3]

Definition 4. [3] For a given fuzzy support function, $s(x)$, on a finite set X, a measure on X is a λ-measure, if its measure function $g_\lambda : 2^X \to [0,\infty)$ satisfying

(i) $g_\lambda(\phi)=0$ (Vanishing at the empty set) (10)

(ii) $$\lambda\in\left[-\frac{1}{\max_{A\subset X}\{g_\lambda(A)\}},\infty\right) \tag{11}$$

(iii) $A,B\in 2^X,\ A\cap B=\phi,\ A\cup B\ne X$

$$\Rightarrow g_\lambda(A\cup B)=g_\lambda(A)+g_\lambda(B)+\lambda g_\lambda(A)g_\lambda(B) \tag{12}$$

(iv) $$\forall A\subset X\Rightarrow g_\lambda(A)=\begin{cases}\frac{1}{\lambda}\left(-1+\prod_{x\in A}[1+\lambda s(x)]\right) & \lambda\ne 0\\ \sum_{x\in A}s(x) & \lambda=0\end{cases} \tag{13}$$

Note that

(i) Eq. (12) and Eq. (13) are called $\sigma-\lambda-$ rule of λ-measure.

(ii) Eq. (11) is the monotone condition of λ-measure.

E. P-measure

Definition 5. [4] For a given fuzzy support function, $s(x)$, on a finite set X, a measure is called P-measure, g_P, if its measure function $g_P : 2^X \to [0,\infty)$ satisfying

(i) $g_P(\phi)=0$ (vanishing at the empty set)

(ii) $$\forall A\in 2^X \Rightarrow g_P(A)=\max_{x\in A}\{s(x)\}=\max_{x\in A}g_P(\{x\}) \tag{14}$$

III. NORMALIZED FUZZY MEASURES

A. Normalized fuzzy measures [2,3]

Definition 6. [5,6] A fuzzy measure μ on a finite set X is a normalized fuzzy measure, if its measure function $g_\mu : 2^X \to [0,1]$ satisfying the following axioms:

(i) $g_\mu(\phi)=0,\ g_\mu(X)=1$ (normalized conditions) (15)

(ii) $A\subseteq B\Rightarrow g_\mu(A)\le g_\mu(B)$ (monotonicity) (16)

B. Fuzzy density function

Definition 7. A fuzzy density function of a normalized fuzzy measure μ on a finite set X is a function $d : X\to[0,1]$ satisfying:

$$s(x)=g_\mu(\{x\}),\ x\in X \tag{17}$$

$s(x)$ is called the density of singleton x.

C. Normalized additive measure

Definition 8. [5] For a given fuzzy density function, $d(x)$ on a finite set X, a measure σ on X is an normalized additive measure, if its measure function $g_\sigma : 2^X \to [0,1]$ satisfying :

(i) $g_\sigma(\phi)=0,\ g_\sigma(X)=1$ (Normalized conditions) (18)

(ii) $$\forall A\in 2^X \Rightarrow g_\sigma(A)=\sum_{x\in X}s(x)=\sum_{x\in X}g_\sigma(\{x\}) \tag{19}$$

Theorem 2. [5] An normalized additive measure on a finite set X is a fuzzy measure on X satisfying

(i) $$A,B\in 2^X,\ A\cap B=\phi \Rightarrow g_\sigma(A\cup B)=g_\sigma(A)+g_\sigma(B) \tag{20}$$

(ii) $$A,B\in 2^X,\ A\subseteq B \Rightarrow g_\sigma(A)\le g_\sigma(B) \tag{21}$$

(iii) $$\sum_{x\in X}g_\sigma(\{x\})=1 \tag{22}$$

D. Normalized λ-measure

Definition 9. [3] For a given fuzzy density function, $d(x)$, on a finite set x, a normalized fuzzy measure is called a normalized **λ**-measure, if its measure function $g_\lambda : 2^X \to [0,1]$ satisfying the following axioms:

(i) $g_\lambda(\phi)=0,\ g_\lambda(X)=1$ (normalized conditions) (23)

(ii) $$\lambda\in[-1,\infty) \tag{24}$$

(iii) $A,B\in 2^X,\ A\cap B=\phi,\ A\cup B\ne X$

$$\Rightarrow g_\lambda(A\cup B)=g_\lambda(A)+g_\lambda(B)+\lambda g_\lambda(A)g_\lambda(B) \tag{25}$$

(iv) $$\forall A\subset X\Rightarrow g_\lambda(A)=\begin{cases}\frac{1}{\lambda}\left(-1+\prod_{x\in A}[1+\lambda d(x)]\right) & \lambda\ne 0\\ \sum_{x\in A}d(x) & \lambda=0\end{cases} \tag{26}$$

(v) $$\prod_{x\in X}[1+\lambda d(x)]=1+\lambda>0,\ d(x)=g_\lambda(\{x\}) \tag{27}$$

Note that Eq. (27) is the upper bounded condition of Definition 9.

Theorem 3. [3] If $d(x)$ is the fuzzy density function of a normalized λ-measure on a finite set X, then normalized λ-measure is a normalized fuzzy measure on X with exact one solution of the value of λ satisfying

(i) $$\sum_{x\in X} d(x) > 1 \Rightarrow -1 \le \lambda < 0, \quad (28)$$

(ii) $$\sum_{x\in X} d(x) = 1 \Rightarrow \lambda = 0 \quad (29)$$

(iii) $$\sum_{x\in X} d(x) < 1 \Rightarrow \lambda > 0, \quad (30)$$

Definition 10. [3] Let μ be a normalized fuzzy measure, $g_\mu : 2^X \to [0,1]$ be its measure function

(i) If the formula (31) is satisfied, then μ is called a normalized sub-additive measure,

$$\forall A, B \in 2^X,\ A \cap B = \phi \Rightarrow g_\mu(A \cup B) < g_\mu(A) + g_\mu(B) \quad (31)$$

(ii) If the formula (32) is satisfied, then μ is called a normalized additive measure,

$$\forall A, B \in 2^X,\ A \cap B = \phi \Rightarrow g_\mu(A \cup B) = g_\mu(A) + g_\mu(B) \quad (32)$$

(iii) If the formula (33) is satisfied, then μ is called a normalized supper-additive measure,

$$\forall A, B \in 2^X,\ A \cap B = \phi \Rightarrow g_\mu(A \cup B) > g_\mu(A) + g_\mu(B) \quad (33)$$

Theorem 4. [3] Let $d(x)$ be the fuzzy density function of a normalized λ-measure on a finite set X,

(i) If $\sum_{x\in X} s(x) > 1$, then normalized λ-measure is a normalized sub-additive measure

(ii) If $\sum_{x\in X} s(x) = 1$, then normalized λ-measure is a normalized additive measure

(iii) If $\sum_{x\in X} s(x) < 1$, then normalized λ-measure is a normalized supper-additive measure

E. Normalized P-measure

Definition 11. [4] For a given fuzzy density function $d(x)$ on a finite set X, a normalized fuzzy measure is called a normalized P-measure, if its measure function $g_P : 2^X \to [0,1]$ satisfying

(i) $g_P(\phi) = 0$, $g_P(X) = 1$ (normalized conditions) (34)

(ii) $$\forall A \in 2^X \Rightarrow g_P(A) = \max_{x\in X}\{s(x)\} = \max_{x\in X}\{g_P(\{x\})\} \quad (35)$$

IV. Regular Fuzzy Measures

Definition 12. A fuzzy density function $d(x)$ of a normalized fuzzy measure μ on a finite set X is called a regular fuzzy density function, if it satisfies

$$\forall x \in X \Rightarrow d(x) = g_\mu(\{x\}) > 0 \quad (36)$$

Definition 13. Any normalized fuzzy measure is called a regular fuzzy measure, if its fuzzy density function is a regular fuzzy density function

Definition 14.

(i) A normalized additive measure is called a regular additive measure, if its fuzzy density function is a regular fuzzy density function

(ii) A normalized sub-additive measure is called a regular sub-additive measure, if its fuzzy density function is a regular fuzzy density function.

(iii) A normalized supper-additive measure is called a regular supper-additive measure, if its fuzzy density function is a regular fuzzy density function

(iv) A normalized λ-measure is called a regularλ-measure, if its fuzzy density function is a regular fuzzy density function

(v) A normalized P-measure is called a regular P-measure, if its fuzzy density function is a regular fuzzy density function.

V. Comparison between two measures

A. B-measure

Definition 15. [6] For any given fuzzy density function, $d(x)$, on a finite set, X, a normalized fuzzy measure is called a B-measure, if its measure function, $g_B : 2^X \to [0,1]$, satisfies

$$g_B(A) = \begin{cases} 0 & A = \phi \\ d(x) & A = \{x\}, x \in X \\ 1 & |A| > 1, A \subset X \end{cases} \quad (37)$$

Definition 16. A B-measure is called a regular B-measure, if its fuzzy density function is a regular fuzzy density function.

B. Definition of Comparisons of fuzzy measures

Definition 17. [6] Comparison of two fuzzy measure

For any given fuzzy density function, $d(x)$, on a finite set, X, let μ_1 and μ_2 be two normalized fuzzy measures on X,

(i) If $g_{\mu_1}(A) = g_{\mu_2}(A), \forall A \subset X,$, then we say that μ_1-measure is equal to μ_2-measure, denoted as

$$\mu_1 - measure = \mu_2 - masure. \quad (38)$$

(ii) If $g_{\mu_1}(A) < g_{\mu_2}(A), \forall A \subset X, 1 < |A| < |X|$ then we say that μ_1-measure is less than μ_2-measure, or μ_2-measure is larger than μ_1-measure, denoted as

$$\mu_1 - measure < \mu_2 - masure. \quad (39)$$

(iii) If $g_{\mu_1}(A) \le g_{\mu_2}(A), \forall A \subset X, 1 < |A| < |X|$, then we say that μ_1-measure is not larger than μ_2-measure, or μ_2-measure is not smaller than μ_1-measure, denoted as

$$\mu_1 - measure \le \mu_2 - masure . \quad (40)$$

C. Important properties for comparisons of fuzzy measures

Theorem 5. For any given fuzzy density function $d(x)$ on a finite set X, P-measure is not larger than any other fuzzy measure μ, that is

$$P - measure \le \mu - measure \quad (41)$$

Proof.

Let $\forall A \subset X$ and $1 < |A| < |X|$,

From the definition of monotonicity, we have

$$g_\mu(A) \ge g_\mu(\{x\}), \forall x \in A \quad (42)$$

And then

$$g_\mu(A) \ge \max_{x \in A}\{g_\mu(\{x\})\} \quad (43)$$

Since $g_\mu(\{x\}) = g_p(\{x\}) = d(x), \forall x \in A$ (44)

We can obtain

$$g_\mu(A) \ge \max_{x \in A}\{g_\mu(\{x\})\} = \max_{x \in A}\{g_p(\{x\})\} = g_P(A) \quad (45)$$

That is $g_P(A) \le g_\mu(A), \forall A \subset X$, the proof is completed.

Theorem 6. For any given fuzzy density function $d(x)$ on a finite set X, B-measure is not less than any other fuzzy measure μ, that is

$$\mu - measure \le B - measure \quad (46)$$

Proof.

Let $\forall A \subset X$ and $1 < |A| < |X|$,

From the definition of B-measure, we have

$$g_\mu(A) \le g_B(A) = 1, \forall x \in A \quad (47)$$

That is $g_\mu(A) \le g_B(A), \forall A \subset X$, the proof is completed

Theorem 7.

$$regular\ P - measure < regular\ \lambda - measure$$

Proof:

i) Let $\forall A \subset X$ and $1 < |A| < |X|$ (48)

Satisfy $A = B \cup C, B \ne \phi \ne C, B \cap C = \phi$ (49)

From the definition of regular fuzzy measure, we know that $d(x) > 0, \forall x \in X$ (50)

Since $B \ne \phi \ne C$, then $g_\lambda(B), g_\lambda(C), g_p(B), g_p(C) > 0$ (51)

ii) From the definition of regular λ- measure, we know that

$$\lambda > -1 \quad (52)$$

We can get $g_\lambda(C)[1 - \lambda g_\lambda(B)] > 0$ (53)

Then

$$\begin{aligned} g_\lambda(A) &= g_\lambda(B \cup C) = g_\lambda(B) + g_\lambda(C) - \lambda g_\lambda(B) g_\lambda(C) \\ &= g_\lambda(B) + g_\lambda(C)[1 - \lambda g_\lambda(B)] > g_\lambda(B), \end{aligned} \quad (54)$$

That is $g_\lambda(A) = g_\lambda(B \cup C) > g_\lambda(B)$, (55)

Similarly we have $g_\lambda(A) = g_\lambda(B \cup C) > g_\lambda(C)$, (56)

Then $g_\lambda(A) = g_\lambda(B \cup C) > \max[g_\lambda(B), g_\lambda(C)]$ (57)

In general, we can obtain

$$\begin{aligned} &g_\lambda(A) > \max_{x \in A}\{g_\lambda(\{x\})\} = \max_{x \in A}\{g_P(\{x\})\} = g_P(A) \\ &\Rightarrow g_\lambda(A) > g_P(A), \forall A \subset X, 1 < |A| < |X| \end{aligned} \quad (58)$$

Then $regular\ P - measure < regular\ \lambda - measure$.

Theorem 8.

$$regular\ \lambda - measure < B - measure$$

Proof:

(i) Suppose that $regular\ \lambda - measure < B - measure$ is not true, then there exist $A \subset X$ such that $1 < |A| < |X|$ satisfies

$$g_\lambda(A) = 1 \quad (59)$$

(ii) Since $1 < |A| < |X|$, then $A' = X - A \ne \phi$ (60)

and $A \ne \phi \ne A'$ (61)

From the definition of regular λ-measure, we know that $\lambda > -1$ and $g_\lambda(A') > 0$

then $g_\lambda(A')[1 + \lambda] > 0$ (62)

(iii) Since

$$\begin{aligned} g_\lambda(X) &= g_\lambda(A \cup A') \\ &= g_\lambda(A) + g_\lambda(A') + \lambda g_\lambda(A) g_\lambda(A') \\ &= g_\lambda(A) + g_\lambda(A')[1 + \lambda g_\lambda(A)] \\ &= 1 + g_\lambda(A')[1 + \lambda] > 1 \end{aligned} \quad (63)$$

But $g_\lambda(X) = 1$, it leads a contradiction,

hence $\lambda - measure < B - measure$.

Theorem 9.

$$regular\ P - measure < regular\ \lambda - measure < B - measure \quad (64)$$

Proof: It is trivial!

Theorem 10.

$$regular\ P - measure < regular\ additive\ measure$$

Proof:

(i) Let $\forall A \subset X$ and $1 < |A| < |X|$ (65)

Satisfy $A = B \cup C, B \ne \phi \ne C, B \cap C = \phi$ (66)

From the definition of regular fuzzy measure, we know that $d(x) > 0, \forall x \in X$ (67)

Since $B \ne \phi \ne C$, then $g_\sigma(B), g_\sigma(C) > 0$ (68)

ii) From the definition of regular additive measure, we know that

$$g_\sigma(A) = g_\sigma(B \cup C) = g_\sigma(B) + g_\sigma(C) \quad (69)$$

That is $g_\lambda(A) = g_\lambda(B \cup C) > g_\lambda(B)$, (70)

and $g_\lambda(A) = g_\lambda(B \cup C) > g_\lambda(C)$, (71)

Then $g_\lambda(A) = g_\lambda(B \cup C) > \max[g_\lambda(B), g_\lambda(C)]$ (72)

In general, we can obtain

$$g_\sigma(A) > \max_{x\in A}\{g_\sigma(\{x\})\} = \max_{x\in A}\{g_P(\{x\})\} = g_P(A)$$
$$\Rightarrow g_\sigma(A) > g_P(A), \forall A \subset X, 1 < |A| < |X| \quad (73)$$

Then *regular* $P-$*measure* < *regular additive measure* .

Theorem 11.

regular additive measure < $B-$*measure*

Proof:

(i) Suppose that *regular additive measure* < $B-$*measure* is not true,

then there exist $A \subset X$ such that $1 < |A| < |X|$ satisfies

$$g_\sigma(A) = 1 \quad (74)$$

(ii) Since $1 < |A| < |X|$, then $A' = X - A \neq \phi$ (75)

and $A \neq \phi \neq A'$ (76)

From the definition of regular additive measure, we know that $g_\sigma(A') > 0$ (77)

(iii) Since

$$g_\sigma(X) = g_\sigma(A \cup A') = g_\sigma(A) + g_\sigma(A') > g_\sigma(A) = 1 \Rightarrow g_\sigma(X) > 1 \quad (78)$$

But $g_\lambda(X) = 1$, it leads a contradiction,

Hence *regular additive measure* < $B-$*measure* .

Theorem 12.

regular $P-$*measure* < *regular additive measure* < $B-$*measure* (79)

Proof: It is trivial!.

Note that

(i) If there is no confusion, for brief, the regular fuzzy measure is also called fuzzy measure.

(ii) Both λ-measure and additive measure are larger than the smallest fuzzy measure, P-measure and less than the largest fuzzy measure, B-measure.

VI. YANG'S GENERALIZED LAMBDA MEASURE

Yang's generalized λ-measure was proposed by L.-Z. Yang, M.-H. Ha, X.-J. Wang and Z.-R. Zhang in 2008 [10], its formal definition is list as below'

Definition 18. [10] For a given fuzzy support function, $s(x)$, on a finite set X, a measure on X is a Yang's generalized λ-measure, if its measure function $g_\lambda : 2^X \to [0,\infty)$ satisfying

(i) $g_\lambda(\phi) = 0$ (Vanishing at the empty set) (80)

(ii) $$A, B \in 2^X, A \cap B = \phi, A \cup B \neq X$$
$$\Rightarrow g_\lambda(A \cup B) = g_\lambda(A) + g_\lambda(B) + \lambda g_\lambda(A) g_\lambda(B) \quad (81)$$

(iii) $$\forall A \subset X \Rightarrow g_\lambda(A) = \begin{cases} \frac{1}{\lambda}\left(-1 + \prod_{x\in A}\left[1+\lambda s(x)\right]\right) & \lambda \neq 0 \\ \sum_{x\in A} s(x) & \lambda = 0 \end{cases} \quad (82)$$

Note that

(i) Eq. (84) and Eq. (85) are called $\sigma - \lambda -$ rule of λ - measure.

(ii) To compare the definition of Yang's generalized λ-measure with the definition of λ -measure, we know that Yang's generalized λ-measure is just the λ -measure without the monotone condition $\lambda \in \left[-\frac{1}{\max_{A\subset X}\{g_\lambda(A)\}}, \infty\right)$, in other words, Yang's generalized λ-measure is a generalization of λ-measure not necessarily monotone,

(iii) Since a fuzzy measure must be a monotone measure. If a Yang's generalized λ-measure does not satisfy the monotone, condition, then it is not a fuzzy measure, hence Yang's generalized λ-measure is only a generalized measure of λ-measure, but not a generalized fuzzy measure of λ-measure

VII. LIU'S GENERALIZED LAMBDA FUZZY MEASURE

A. Definition of multivalent fuzzy measures

Definition 19. [6] Multivalent fuzzy measures

(i) A fuzzy measure is called a univalent fuzzy measure, if it has only one fuzzy measure solution.

(ii) A fuzzy measure is called a multivalent fuzzy measure, if its fuzzy measure solutions are more than one

(iii) A normalized fuzzy measure is called a univalent normalized fuzzy measure, if it has only one normalized fuzzy measure solution.

(iv) A normalized fuzzy measure is called a multivalent normalized fuzzy measure, if its normalized fuzzy measure solutions are more than one

(v) A regular fuzzy measure is called a univalent regular fuzzy measure, if it has only one regular fuzzy measure solution.

(vi) A regular fuzzy measure is called a multivalent regular fuzzy measure, if its regular fuzzy measure solutions are more than one

B. Definition of multivalentλ- measures

Definition 20. Multivalent λ- measures

For any $$\lambda \in \left[-\frac{1}{\max_{A\subset X}\{g_\lambda(A)\}}, \infty\right) \quad (83)$$

and a given fuzzy support function, $s(x)$ on a finite set X, a measure on X is a multivalent λ - measure, if its measure function $g_\lambda : 2^X \to [0,\infty)$ satisfying

(i) $g_\lambda(\phi) = 0$ (Vanishing at the empty set) (84)

(ii) $$\forall A, B \in 2^X, A \cap B = \phi$$
$$\Rightarrow g_\lambda(A \cup B) = g_\lambda(A) + g_\lambda(B) + \lambda g_\lambda(A) g_\lambda(B) \quad (85)$$

(iii) $$\forall A \subset X \Rightarrow g_\lambda(A) = \begin{cases} \frac{1}{\lambda}\left(-1 + \prod_{x\in A}\left[1+\lambda s(x)\right]\right) & \lambda \neq 0 \\ \sum_{x\in A} s(x) & \lambda = 0 \end{cases} \quad (86)$$

Note that multivalent λ - measure do not need the condition;

$$\prod_{x\in X}\left[1+\lambda s(x)\right]=1+\lambda>0,\ s(x)=g_\lambda(\{x\})$$

Theorem 13. Multivalent λ - measure is a multivalent fuzzy measure

Proof;

(I) For any $\lambda\in\left[-\frac{1}{\max\limits_{E\subset X}\{g_\lambda(E)\}},\infty\right)$, let $\forall A,B\in 2^X$, $A\subseteq B$,

to prove that $g_\lambda(A)\le g_\lambda(B)$ (87)

Since $\lambda\in\left[-\frac{1}{\max\limits_{E\subset X}\{g_\lambda(E)\}},\infty\right)$,

then $\lambda>-\frac{1}{\max\limits_{E\subset X}\{g_\lambda(E)\}}\Rightarrow 1+\lambda\max\limits_{E\subset X}\{g_\lambda(E)\}>0$ (88)

(i) if $-\frac{1}{\max\limits_{E\subset X}\{g_\lambda(E)\}}<\lambda<0$ (89)

Then $1+\lambda g_\lambda(A)\ge 1+\lambda\max\limits_{E\subset X}\{g_\lambda(E)\}>0$ (90)

$$\begin{aligned}g_\lambda(B)&=g_\lambda\left(A\cup(B-A)\right)\\&=g_\lambda(A)+g_\lambda(B-A)+\lambda g_\lambda(A)g_\lambda(B-A)\\&=g_\lambda(A)+g_\lambda(B-A)\left[1+\lambda g_\lambda(A)\right]\\&\ge g_\lambda(A)+g_\lambda(B-A)\left[1-\frac{g_\lambda(A)}{\max\limits_{E\subset X}\{g_\lambda(E)\}}\right]\\&\ge g_\lambda(A)\end{aligned}\quad(91)$$

(ii) if $\lambda\ge 0$ (92)

$$\begin{aligned}g_\lambda(B)&=g_\lambda\left(A\cup(B-A)\right)\\&=g_\lambda(A)+g_\lambda(B-A)+\lambda g_\lambda(A)g_\lambda(B-A)\\&\ge g_\lambda(A)\end{aligned}\quad(93)$$

(II) For any $\forall A\subset X$ to prove $g_\lambda(\phi)=0$

$$\begin{aligned}&g_\lambda(\phi)=g_\lambda(\phi\cup\phi)=g_\lambda(\phi)+g_\lambda(\phi)+\lambda g_\lambda(\phi)g_\lambda(\phi)\\&=2g_\lambda(\phi)+\lambda\left[g_\lambda(\phi)\right]^2\\&\Rightarrow g_\lambda(\phi)+\lambda\left[g_\lambda(\phi)\right]^2=g_\lambda(\phi)\left[1+\lambda g_\lambda(\phi)\right]=0\\&Since\quad\left[1+\lambda g_\lambda(\phi)\right]>0\\&\Rightarrow g_\lambda(\phi)=0\end{aligned}\quad(94)$$

The proof is completed.

Definition 21. Multivalent normalizedλ- measures

For any $\lambda\in[-1,\infty)$ (95)

and a given fuzzy density function $d(x)$ on a finite set X, a measure on X is a multivalent normalized λ - measure, if its measure function $g_\lambda:2^X\to[0,1]$ satisfying

(i) $g_\lambda(\phi)=0,\ g_\lambda(X)=1$ (normalized conditions) (96)

(ii) $\forall A,B\in 2^X,\ A\cap B=\phi$

$$\Rightarrow g_\lambda(A\cup B)=\left[g_\lambda(A)+g_\lambda(B)+\lambda g_\lambda(A)g_\lambda(B)\right]\wedge 1 \quad(97)$$

(iii) $\forall A\subset X\Rightarrow g_\lambda(A)=\begin{cases}\left[\frac{1}{\lambda}\left(-1+\prod\limits_{x\in A}\left[1+\lambda d(x)\right]\right)\right]\wedge 1 & \lambda\ne 0\\ \sum\limits_{x\in A}d(x) & \lambda=0\end{cases}$ (98)

Note that multivalent normalized λ - measure also do not need the condition; $\prod_{x\in X}\left[1+\lambda d(x)\right]=1+\lambda>0,\ d(x)=g_\lambda(\{x\})$.

Theorem 14. Multivalent normalized λ - measure is a multivalent normalized fuzzy measure

Proof;

(I) For any $\lambda\in[-1,\infty)$, let $\forall A,B\in 2^X$, $A\subseteq B$,

to prove that $g_\lambda(A)\le g_\lambda(B)$

(i) if $-1\le\lambda\le 0$ then $1+\lambda g_\lambda(A)\ge 1-g_\lambda(A)\ge 0$ (99)

$$\begin{aligned}g_\lambda(B)&=g_\lambda\left(A\cup(B-A)\right)\\&=g_\lambda(A)+g_\lambda(B-A)+\lambda g_\lambda(A)g_\lambda(B-A)\\&=g_\lambda(A)+g_\lambda(B-A)\left[1+\lambda g_\lambda(A)\right]\ge g_\lambda(A)\end{aligned}\quad(100)$$

(ii) if $\lambda>0$ then

$$\begin{aligned}g_\lambda(B)&=g_\lambda\left(A\cup(B-A)\right)\\&=g_\lambda(A)+g_\lambda(B-A)+\lambda g_\lambda(A)g_\lambda(B-A)\\&=g_\lambda(A)+g_\lambda(B-A)\left[1+\lambda g_\lambda(A)\right]\ge g_\lambda(A)\end{aligned}\quad(101)$$

(II) For any $\lambda\in[-1,\infty)$, and any $A\subset X$ to prove

$$0\le g_\lambda(A)\le 1 \quad(102)$$

From (I), we know that $0=g_\lambda(\phi)\le g_\lambda(A)\le g_\lambda(X)=1$

The proof is completed.

Definition 22. Multivalent regularλ- measures

For any $\lambda\in[-1,\infty)$ (103)

and a given fuzzy regular density function $d(x)$ on a finite set X, a measure on X is a multivalent regular λ - measure, if its measure function $g_\lambda:2^X\to[0,1]$ satisfying

(i) $g_\lambda(\phi)=0,\ g_\lambda(X)=1$ (Normalized conditions) (104)

(ii) $\forall A,B\in 2^X,\ A\cap B=\phi$

$$\Rightarrow g_\lambda(A\cup B)=\left[g_\lambda(A)+g_\lambda(B)+\lambda g_\lambda(A)g_\lambda(B)\right]\wedge 1 \quad(105)$$

(iii) $\forall A\subset X\Rightarrow g_\lambda(A)=\begin{cases}\left[\frac{1}{\lambda}\left(-1+\prod\limits_{x\in A}\left[1+\lambda d(x)\right]\right)\right]\wedge 1 & \lambda\ne 0\\ \sum\limits_{x\in A}d(x) & \lambda=0\end{cases}$ (106)

Theorem 15. Multivalent regular λ - measure is a multivalent regular fuzzy measure

Proof: it is trivial.

C. Completed measure

Definition 23 [6] **C**ompleted measure

For any given fuzzy density function, $d(x)$, on a finite set, X, a multivalent fuzzy measure,μ-measure, with determined coefficient, $\mu \in R$ it is called a completed fuzzy measure, if it satisfies

(i) $\forall \mu \in [a,b]$ ∋ μ-measure is a fuzzy measure

(ii) $\mu = a \Rightarrow g_\mu(A) = g_p(A), \forall A \subset X$ (107)

(iii) $\mu = b \Rightarrow g_\mu(A) = g_B(A), \forall A \subset X$ (108)

Note that all of regular λ-measure, multivalent λ - measure and multivalent normalized λ - measure are not completed fuzzy measure.

Definition 23 Liu's generalizedλ-measure

For any given fuzzy density function $d(x)$ on a finite set X,

$$\text{And} \quad \forall \lambda \in [a,b] = \left[\frac{-2}{\min\limits_{0 \neq x \in X} \{d(x)\}}, \frac{1}{\left[\min\limits_{0 \neq x \in X} \{d(x)\}\right]^2} \right] \tag{109}$$

a measure on X is called a Liu's generalized λ - measure, if its measure function $g_\lambda : 2^X \to [0,1]$ satisfying

(i) $g_\lambda(\phi) = 0, g_\lambda(X) = 1$ (Normalized conditions) (110)

(ii) $\forall A, B \in 2^X, A \cap B = \phi$

$$\Rightarrow g_\lambda(A \cup B) = \begin{cases} \frac{\lambda+1}{a+1} \max\limits_{x \in A \cup B} \{d(x)\} + \frac{a-\lambda}{a+1}\left[g_\lambda(A) + g_\lambda(B) - g_\lambda(A) g_\lambda(B)\right] & a \le \lambda < -1 \\ \left[g_\lambda(A) + g_\lambda(B) + \lambda g_\lambda(A) g_\lambda(B)\right] & -1 \le \lambda \le 0 \\ \left[g_\lambda(A) + g_\lambda(B) + \lambda g_\lambda(A) g_\lambda(B)\right] \wedge 1 & 0 < \lambda \le b \end{cases} \tag{111}$$

$$a = \frac{-2}{\min\limits_{0 \neq x \in X} \{d(x)\}} < -1, \quad b = \frac{1}{\left[\min\limits_{0 \neq x \in X} \{d(x)\}\right]^2} > 1 \tag{112}$$

(iii) $$\forall A \subset X \Rightarrow g_\lambda(A) = \begin{cases} \frac{\lambda+1}{a+1} \max\limits_{x \in A} \{d(x)\} + \frac{a-\lambda}{a+1} f_{-1}(A) & a \le \lambda < -1 \\ f_\lambda(A) & -1 \le \lambda < 0 \\ \sum\limits_{x \in A} s(x) & \lambda = 0 \\ \left[f_\lambda(A)\right] \wedge 1 & 0 < \lambda \le b \end{cases} \tag{113}$$

where $$f_\lambda(A) = \left[\frac{1}{\lambda} \left(-1 + \prod_{x \in A} \left[1 + \lambda d(x)\right] \right) \right] \tag{114}$$

Theorem 16. Liu's generalizedλ-measure is a **C**ompleted, continuous and increasing normalized fuzzy measure

Proof:

(I) Let $\forall A \in 2^X$ to prove that $0 \le g_\lambda(A) \le 1$,

From (113) and the definition of fuzzy density function we know that

If $A = \phi, or\ A = X, or\ |A| = 1 \Rightarrow 0 \le g_\lambda(A) \le 1$ (115)

If $|A| > 1,\ A = B \cup C, B \cap C = \phi, B \neq \phi \neq C$ (116)

From (113), we know that

$$0 \le \max_{x \in A}\{d(x)\} = \max_{x \in B \cup C}\{d(x)\} \le g_\lambda(B \cup C) = g_\lambda(A) \le 1 \tag{117}$$

(II) Let $\forall A, B \in 2^X, A \subseteq B$ to prove that $g_\lambda(A) \le g_\lambda(B)$

From (102) and (106), we can obtain that

$$\forall A \in 2^X \Rightarrow g_\lambda(A) \ge \max_{x \in A}\{d(x)\} = g_P(A) \tag{118}$$

Since $B = A \cup (B - A)$, then we have

$$g_\lambda(B) = g_\lambda(A \cup (B - A)) = \begin{cases} \frac{\lambda+1}{a+1} \max\limits_{x \in B}\{d(x)\} + \frac{a-\lambda}{a+1}\left[g_\lambda(A) + g_\lambda(B-A) - g_\lambda(A) g_\lambda(B-A)\right] & a \le \lambda < -1 \\ \left[g_\lambda(A) + g_\lambda(B-A) + \lambda g_\lambda(A) g_\lambda(B-A)\right] & -1 \le \lambda \le 0 \\ \left[g_\lambda(A) + g_\lambda(B-A) + \lambda g_\lambda(A) g_\lambda(B-A)\right] \wedge 1 & 0 < \lambda \le b \end{cases} \tag{119}$$

(i) if $0 < \lambda \le b$, then $g_\lambda(A) \le g_\lambda(B)$ is trivial.

(ii) if $-1 \le \lambda \le 0$, since $0 \le g_\lambda(A) \le 1$ then

$\lambda g_\lambda(A) \ge \lambda \ge -1$ and $\left[1 + \lambda g_\lambda(A)\right] \ge 0$ we can obtain

$$\begin{aligned} g_\lambda(B) &= g_\lambda(A) + g_\lambda(B - A) + \lambda g_\lambda(A) g_\lambda(B - A) \\ &= g_\lambda(A) + g_\lambda(B - A)\left[1 + \lambda g_\lambda(A)\right] \ge g_\lambda(A) \end{aligned} \tag{120}$$

That is $g_\lambda(A) \le g_\lambda(B)$

(iii) if $a \le \lambda < -1$ then $g_\lambda(B) = \frac{\lambda+1}{a+1} g_P(B) + \frac{a-\lambda}{a+1} f_{-1}(B)$ (121)

Where $g_P(A) \le g_P(B), f_{-1}(A) \le f_{-1}(B)$

We can obtain

$$g_\lambda(A) = \frac{\lambda+1}{a+1} g_P(A) + \frac{a-\lambda}{a+1} f_{-1}(A) \le \frac{\lambda+1}{a+1} g_P(B) + \frac{a-\lambda}{a+1} f_{-1}(B) = g_\lambda(B) \tag{122}$$

And we know that Liu's generalizedλ-measure is a fuzzy measure.

(II) Let $\lambda = a = \frac{-2}{\min\limits_{0 \neq x \in X}\{d(x)\}}$ to prove

$$g_\lambda(A) = g_a(A) = \max_{x \in A}\{d(x)\} = g_P(A) \tag{123}$$

Let $\forall A, B \subset X, A \cap B = \phi$, and $\lambda = a = \frac{-2}{\min\limits_{0 \neq x \in X}\{d(x)\}}$

then

$$\begin{aligned} & a \le -\left(\frac{1}{\min\limits_{0 \neq x \in A}\{d(x)\}} + \frac{1}{\min\limits_{0 \neq x \in B}\{d(x)\}} \right) \le -\left(\frac{1}{g_a(A)} + \frac{1}{g_a(B)} \right) \\ & \le \frac{-g_a(A) - g_a(B)}{g_a(A) g_a(B)} \le \frac{\max\limits_{x \in A \cup B}\{d(x)\} - g_a(A) - g_a(B)}{g_a(A) g_a(B)} \\ & \Rightarrow a g_a(A) g_a(B) \le \max_{x \in A \cup B}\{d(x)\} - g_a(A) - g_a(B), \forall A, B \subset X \\ & \Rightarrow \left[g_a(A) + g_a(B) + a g_a(A) g_a(B)\right] \le \max_{x \in A \cup B}\{d(x)\} \end{aligned} \tag{124}$$

Then we can obtain

$$g_a(A\cup B)$$
$$=\left[g_a(A)+g_a(B)+\alpha g_a(A)g_a(B)\right]\vee\max_{x\in A\cup B}\left\{d(x)\right\}=\max_{x\in A\cup B}\left\{d(x)\right\} \quad (125)$$
$$\Rightarrow g_a(A\cup B)=\max_{x\in A\cup B}\left\{d(x)\right\}$$

That is

$$g_\lambda(A)=g_a(A)=\max_{x\in A}\left\{d(x)\right\}=g_P(A),\forall A\subseteq X$$

(III) Let $$\lambda=b=\frac{1}{\left[\min_{0\neq x\in X}\left\{d(x)\right\}\right]^2} \quad (126)$$

to prove $$g_\lambda(A)=g_b(A)=g_B(A),\forall A\subseteq X,|A|>1 \quad (127)$$

let

$$\forall A,B\subset X, A\cap B=\phi, g_\lambda(A)g_\lambda(B)>0,,$$

$$|A\cup B|>1,\ \lambda=b=\frac{1}{\left[\min_{0\neq x\in X}\left\{d(x)\right\}\right]^2} \quad (128)$$

then $$\lambda=b=\frac{1}{\left[\min_{0\neq x\in X}\left\{d(x)\right\}\right]^2}\geq\frac{1}{\left[g_b(A)\wedge g_b(B)\right]^2} \quad (129)$$
$$\geq\frac{1}{g_b(A)g_b(B)}\geq\frac{1-g_b(A)-g_b(B)}{g_b(A)g_b(B)}$$

$$\Rightarrow g_b(A)+g_b(B)+bg_b(A)g_b(B)\geq 1,\forall A,B\subset X$$
$$\Rightarrow g_b(A\cup B)=\left[g_b(A)+g_b(B)+bg_b(A)g_b(B)\right]\wedge 1=1 \quad (130)$$

In other words, $$\forall A\subseteq X,|A|>1\Rightarrow g_b(A)=1$$

Then $$g_\lambda(A)=g_b(A)=g_B(A),\forall A\subseteq X,|A|>1$$

(IV) From above we know that Liu's generalizedλ-measure is a **C**ompleted normalized fuzzy measure

(V) It is trivial that the measure function of Liu's generalizedλ-measure is a continuous and increasing function on λvalue.

VIII. CONCLUSIONS AND FUTURE WORKS

In this paper, first of all, it is proved that both λ-measure and additive measure are never equal to the smallest fuzzy measure, P-measure and the largest fuzzy measure, B-measure.

Second, this paper pointed out that the generalized λ-measure proposed by L.-Z. Yang, M.-H. Ha, X.-J. Wang, and Z.-R. Zhang, is a generalized measure of λ-measure, but not a generalized fuzzy measure of λ-measure, since a fuzzy measure must be a monotone measure.

Furthermore, a novel multivalent fuzzy measure with infinitely many fuzzy measure solutions based on λ-measure, called Liu's generalized λ-measure, is proposed. It is proved that the measure function of this new measure is continuous and increasing on λ, each different λ value corresponding different fuzzy measure, from the smallest fuzzy measure, P-measure to the largest fuzzy measure, B-measure, and containing additive measure and λ-measure itself, Moreover, it is a generalize fuzzy measure of λ-measure satisfying the monotone condition, and rather than the old generalized λ-measure proposed by L.-Z. Yang, M.-H. Ha, X.-J. Wang, and Z.-R. Zhang. Some properties about this new measure are also discussed.

In the future, we can use Choquet integral with respect to this new fuzzy measure to analysis forecasting problem and multiple criterion decision making problem.

***Abstract*—This paper presents the conceptual framework of fuzzy intelligent decision support system for typhoon disaster management. The typhoon risk management pattern was mentioned in the first section. Several types of database should be established in the decision support system. There are three steps to predict the typhoon risk. The first one is the feature extraction of typhoon pattern. The second one is the damage estimation by case base reasoning method. And the third one is the linguistic estimation of typhoon risk. An example of risk evaluation from the experiment data shows that the decision supporting system can be further improved if there is a complete and accurate dataset in this system.**

Keywords-component; fuzzy theory, decision support system, disaster management, risk analysis

I. INTRODUCTION TO TYPHOON DISASTER MANAGEMENT

Typhoon is one of the most worrisome natural disasters in Taiwan. Its management is related to the location because typhoon is a variable vector in the space. The concept of geospatial information system helps us to construct the geographic database. However, the prediction of typhoon must have large amount of observational data. The choice of these data is a process worthy of careful condition.

Typhoon disaster is a decision analysis process under uncertain condition. We need to concern about the combination of information on human identification and instrumental observation to make consolidated conclusion.

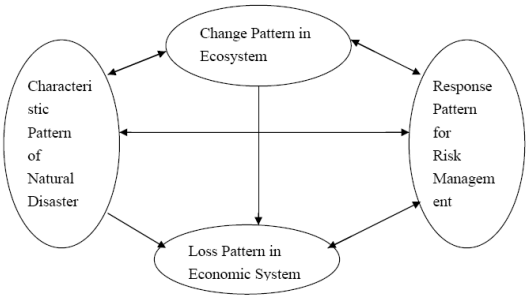
The aim of this study was to build a decision support system for typhoon mitigation. The system can provide the disaster prevention and rescue unit to temporary reduce risk and disaster preparedness. Besides, it can support the operations as decision making or disaster recovery. The system has to integrate with the function of geographical information system to incorporate the typhoon forecasting and analysis model. A model bank with the spatial decision support system was included in this system to obtain the necessary knowledge of typhoon risk management.

How to obtain the wisdom related to typhoon disaster management is an important issue in constructing the intelligent system. The theory of ontology can systematically organize the human knowledge.(Hadzic et al., 2009) Knowledge ontology allows us to share the wisdom and knowledge more easily. It can also quickly help us to find the required information and data. The knowledge ontology in this study also accumulates the technical results of typhoon risk prevention and assists the researchers to identify the topic worthy of further research. (Chang and Wang, 1996)

II. MATHEMATICAL MODEL

A. Feature extraction

Feature extraction of typhoon risk includes the image decomposition, pattern recognition and noise filtering. Many researchers have applied the Artificial Neural Network (ANN) model in feature extraction. ANN has capacity to simulate the brain's thinking process objectively and avoid the influence of the forecasters' subjective judgment.



Fug 1 the four types of pattern in the typhoon risk management system

Chen et al have used the multivariable method to clarify the relationship of typhoon pattern. (Chen et al, 2010) We may consider the feature of typhoon has the following four categories: (1) typhoon natural itself; (2) change in ecosystem; (3) loss in economic system; (4) response for risk management. (Chen, 2010) (Schuermann, 1996) (Richard et al, 2001)

B. Damage prediction

The typhoon damage can be estimated by the basic principle of case-based reasoning (CBR). CBR is one of the new reasoning methods of artificial intelligence, and it is the simplest way to perform fuzzy risk assessment and calculate the fuzzy expected value. Case base reasoning method can also convert the fuzzy risk into the non-fuzzy risk by converting it to a clear number. Decision support system of typhoon uses various risk factors of typhoon to analyze the damage by the case base reasoning method.

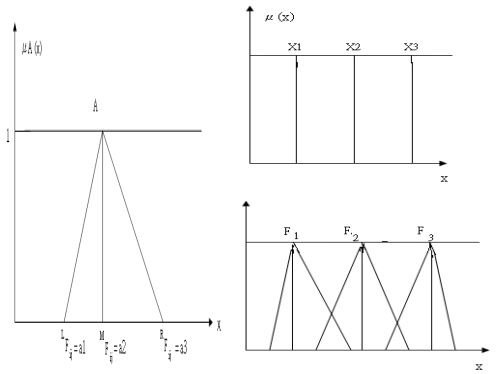
C. Risk analysis

Prediction of typhoon risk is difficult because the term "risk" is a very subjective work. Some people think that is very dangerous, but others believe that not dangerous. For example, if the damage of typhoon can be represented as: very safe, safe, medium, serious, very serious, then we can use fuzzy logic operation to convert it into an objective amount. The Triangle Fuzzy Number (TFN)r is often used in the representation of a vague amount. For example, the i^{th} damage of the j^{th} area, X_{ij}, the fuzzy equation can be written as $F_{ij} = (LF_{ij}, MF_{ij}, RFi_j)$, where F_{ij} is the characteristic value of X_{ij}, LF_{ij} is the lowest value of F_{ij}, RF_{ij} is the maximum value of F_{ij}, MF_{ij} is the most probable value of F_{ij}, and ${}^{L}F_{ij} < {}^{M}F_{ij} < {}^{R}F_{ij}$.(Figure 2a)

We can use the membership function $\mu_A(x)$ represented by (a_1, a_2, a_3) to express the triangular fuzzy number (TFN). Thus the characteristic number of the i^{th} damage of the j^{th} area is $a_1 = {}^{L}F_{ij}$, $a_2 = {}^{M}F_{ij}$, $a_3 = {}^{R}F_{ij}$. The membership function by TFN then becomes

$$\mu_A(x) = \begin{cases} 0 & , \quad x < a_1 \\ \dfrac{x - a_1}{a_2 - a_1} & , \quad a_1 \le x \le a_2 \\ \dfrac{a_3 - x}{a_3 - a_2} & , \quad a_2 \le x \le a_3 \\ 0 & , \quad x > a_3 \end{cases} \qquad (1)$$

Since the range of fuzzy interval for everyone is different, so the value of TFN is not the same. Figure 2b describe that there are various TFN value from different observer.



(a) (b)

Fig 2 (a) Membership function of the triangular fuzzy numbers (TFN) (b) Converting the original results into a normalized fuzzy number

III. System Description

The knowledge bank of typhoon disaster management is shown as figure 3.

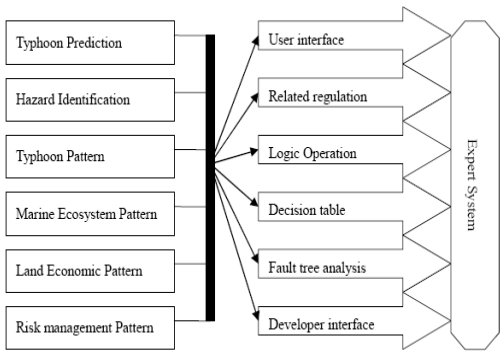


Fig 3 Intelligent knowledge-based expert system

A. Knowledge bank and data base design

The input data of typhoon disaster decision support system includes the following: real- time meteorological data, forecast typhoon data, historical typhoon data, and other basic typhoon information. There are two types of real time data, the real-time meteorological data and the forecast typhoon data. Therefore the system must have the real-time data loading capability in order to meet the "real time" feature.

The real-time meteorological data can be obtained from the government. The typhoon forecast data is also real-time information; however, it may not so complete as the general meteorological data. Most of this information is image base, such as satellite image, typhoon forecasting, or typhoon path map, etc.

B. Real-time and historical information query

The real-time information of typhoon includes the real-tine trend of typhoon. These includes typhoon the previous typhoon path and forecast typhoon path, satellite images, and related descriptive statistics information.

The historical information of typhoon provides the function of query. The query is through the configuration condition by name, landing time, landing location, and generating location, etc. the information available in this system are: landing data, landing time, generating location, generating time, typhoon grade, cumulative rainfall, total rainfall, satellite image, and disaster description.

C. Typhoon damage prediction

Typhoon damage prediction can be performed by the case base reasoning method as described in section 2.3. The major disaster of typhoon is flooding and landslides which were caused by the precipitation due to typhoon. The major function of typhoon damage prediction is to provide the real time rainfall data as for the risk analysis. It includes the spatial and temporal distribution of real time rainfall and accumulates rainfall.

D. Typhoon risk analysis

The results of risk analysis provide the decision maker the information about the loss of life and property. Typhoon risk prediction can be performed by the linguistic risk analysis as described in section 2.3. In this study, we selected five

grades of typhoons in this system: 1.very strong; 2. strong; 3. medium; 4. weak; 5.very weak.

There are many variable for describing the degree of risk. These include: extent of flooding, number of death, number of disappear, number of injury, housing collapse(all), housing collapse(half), housing loss, and agriculture loss.

E. Scenario simulation and information display

The scenario simulation and information display of typhoon should consider the space and time characteristic of typhoon. Since the typhoon disaster is a space-time event, we define the event by the same equation. The scenario simulation was based on the historical typhoon information. The case base reasoning can help us to simulate the possible damage in order to prevent the disaster.

Typhoon can be represented by a mathematical vector. The space geographical information can be represented by the following equation:

$$I = \sum_{i=1}^{m} \left[\sum_{j=1}^{n} \begin{bmatrix} S_{ij}(T_{ij}) \\ A_{ij}(T_{ij}) \\ T_{ij} \end{bmatrix} \right] \quad T_{ij}(t_b, t_e)_{ij} \qquad (2)$$

Where I is the collection of space geographical information; i is the individual vector for the i^{th} item, j is the state of this item; $S_{ij}(T_{ij})$ and $A_{ij}(T_{ij})$ represent the characteristics of this item in time t_b to t_e.

Because the decision support system is based on the core concept of geographical information system, therefore the information should fully demonstrate the characteristic of spatial information. It has to show the relationship between the space and spatial distribution. In addition, it has to integrate the traditional text, statistics, reports, and display mode.

F. Intelligent decision support system

Spatial Decision Support Systems is one of the major development item of Geographic Information Science. (Goodchild, 2005;Sengupta and Bennett , 2003;) The development of intelligent decision support system should include the intelligence and knowledge for this kind of decision making.

In this system, the database includes the real-time meteorological data, with this information and other data; it can provide the related table and figure for the decision maker.

To solve the decision making problem of typhoon disaster management, we need to utilize our information technology. Intelligent spatial decision support system (ISDSS), which is now the major research direction in geographic information science and decision makers, can help us integrate the data base in various types of information and knowledge.

IV. EXAMPLE AND DISCUSSION

An example of risk analysis was presented in this section to explain the importance of database. The prediction of typhoon risk has to use the available data. There are three different types of data for the prediction of typhoon risk. The first one is the value with definite quantity; the second one is the value with fuzzy interval, and the third one is the linguistic expression.

In order to compare the different types of data, we have to adjust these data into the same type. **W**e use three types of fuzzy degree to calculate the fuzzified number, 20%, 10%, and 5%. The fuzzified results were shown in figure 4. Then, the normalized risk was calculated and the aggregate results of total risk were shown in figure 5.

In figure 5, there are different fuzzy degree ranges with different type of typhoon, from very strong to very weak. If it is twenty percent fuzzy degree as figure 5(a), then there is a very wide range of risk interval; however, if the fuzzy degree is low, such as figure 5(c), then the range of risk interval will be decreased.

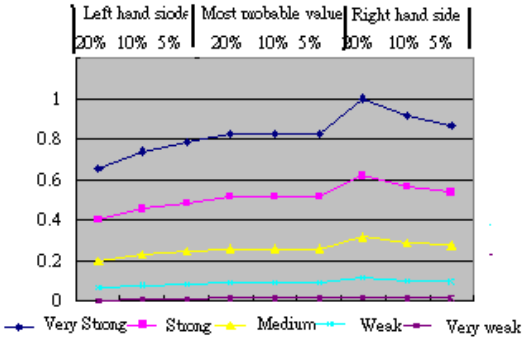

Figure 4 the evaluation results of the typhoon risk

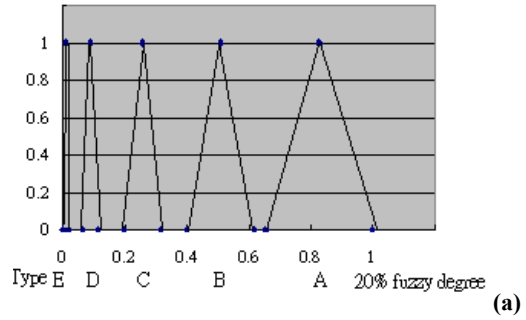

(a)

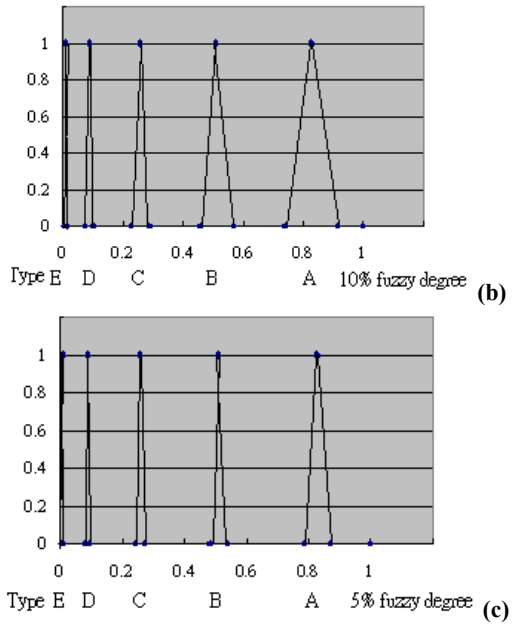

Figure 5 Different fuzzy degree range with different type of typhoon, A: very strong B: strong C: medium D: weak E: very weak

The reasons for the discrepancy of these results were due to the reliable extent of information. The damage prediction need adequate data to support the decision making process. However, the determination of the availability of information is very cumbersome. The decision maker does not have enough time to determine. Therefore, more unreliable information cause more credible decision-making. The best way to improve the efficiency of this decision support system is to increase the reliability completeness of the database.

The feature extraction and damage prediction help us to confirm the extent of harm by typhoon. In this article, there is not enough space to elaborate. Hope there will have more research appeared in this area.

V. CONCLUSION

This paper describes the framework of a fuzzy intelligent decision support system for typhoon disaster management. The development of spatial decision support system was introduced in this article. The mathematical model of the intelligent system includes the feature extraction by artificial neural network, damage estimation by case base reasoning, and risk prediction by fuzzy linguistic transformation. An example of the typhoon risk analysis show that the improvement of this system is depends upon the accuracy and completeness of its knowledge. And the development of feature extraction and damage estimation will be of great benefit of these results.

Abstract—**An H_∞ fuzzy trajectory estimation is proposed for robust tracking guidance and early warning in antitactical ballistic missile systems with model uncertainties and external disturbances. In order to avoid solving the nonlinear Hamilton-Jacobi-Isaac(H-J-I) partial differential equation for H_∞ trajectory estimation of the nonlinear reentry vehicle (RV) dynamic equation, the Takagi and Sugeno fuzzy linear model is employed to interpolate piecewise to approximate the RV nonlinear dynamic equation. Then, from the fuzzy linear model, a fuzzy H_∞ state estimator is developed for robust trajectory estimation of RV with optimal attenuation of the worst-case effect of system uncertainties such as approximation error, external disturbance, maneuver and unpredictable external forces in flight and other sources. The proposed method parameterizes the H_∞ trajectory estimation problem in terms of an eigenvalue problem (EVP), so that the worst-case effect of system uncertainties on the trajectory estimation error is minimized in the robust trajectory estimation design subject to certain linear matrix inequality (LMI) constraints. Convex optimization techniques are employed to solve the EVP of the H_∞ fuzzy trajectory estimation in antitactical ballistic missile systems. Simulation results indicate that the proposed method possesses a satisfactory performance.**

Keywords-Tactical ballistic missile; H_∞ Trajectory estimation

I. INTRODUCTION

In antitactical ballistic missile (ATBM) systems, trajectory estimation of a reentry vehicle from a single radar plays an important role in radar tracking, missile guidance, and early-warning systems. Trajectory estimation of the reentry vehicle in the terminal phase is typically investigated in postflight analysis to identify state variables and key parameters from available flight data measured by radar, satellite, and on-board sensor [1]-[4]. Since the ATBM system is uncertain and nonlinear, one of the major topics behind trajectory estimation problems is related to model uncertainties, which are normally induced by simplification of assumptions, parameter uncertainty, maneuver and unpredictable external forces in flight, and other sources.

In general, an on-line optimal trajectory estimation in ATBM warfare is more difficult because one needs to solve a nonlinear partial differential Hamilton Jacobi (H-J) equation and all mathematical model quantities to be identified must be measurable by radar [1]. Therefore, a simplified model is desired, but this may induce a more serious model uncertainty problem. Klein et al. have introduced an important stepwise regression method in the determination of air plane model structure with both model orders and control derivatives [5]. However, it is too complex to be implemented in on-line trajectory estimations. Furthermore, the on-line trajectory estimation only operates well with a simplified model and needs to maintain a low sensitivity in order to avoid uncertainties.

In recent years, trajectory estimation of a RV in antitactical missile systems has received more attention. A filtering algorithm for state and parameter estimation has been developed by Chang et al. for a maneuvering RV subject to a simplified dynamic model with maneuver forces in terms of related coefficients like drag force [7]. They proposed an augmented state vector which contains position, velocity, and corresponding parameters to drag and maneuver forces in their filter. In order to avoid solving the nonlinear estimation problem by H-J equation, the extended Kalman filter was employed to perform the trajectory estimation work. The trajectory estimation performance, however, is degraded if the maneuvering forces are absent. Furthermore, the simplified dynamic model also confines the applications to maneuvering cases and is rarely applied to real flight. Manohar and Krishnan have proposed a trajectory reconstruction algorithm for a rocket system by using a differential correction method [8]. The dynamic equations for trajectory construction contain an unmodeled acceleration term to take care of all the forces acting on the vehicle other than those from aerodynamic, propulsive, and gravitational sources. In their trajectory algorithm, trajectory states and unmodeled acceleration values are estimated simultaneously. However, the required data are beyond what a simple radar can provide.

In the past two decades, input estimation methods have been successfully applied to tracking problems and initial leveling of strapdown inertial navigation system. A trajectory estimation algorithm using input estimation technique has recently been proposed for a RV via an extended Kalman filter to provide accuracy and fast trajectory estimation with low sensitivities. Since the estimation algorithm is developed from the linearized dynamic model on the present estimated state vector, the estimation errors may propagate with increasing

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

estimation steps. Furthermore, input estimation needs a large amount of computations and precise statistic knowledge of external noises, which may confine its practical applications. H_∞ filter has been employed for state estimation of nonlinear systems with uncertain external noises by minimizing the worst-case effect of external noises. However, a nonlinear partial H-J-I equation needs to be solved. At present, an effective method for treating the H-J-I equation has not been found.

Recently, fuzzy techniques have been effectively used to approximate nonlinear dynamics and successfully applied to control system design. In this study, a fuzzy nonlinear H_∞ filter based on Takagi-Sugeno fuzzy is proposed. At first, the three-dimensional (3D) RV dynamic system is approximated by a fuzzy system motivated by a Takagi-Sugeno fuzzy model, which is obtained by interpolating several linearized systems at different operation points through the smoothing of fuzzy basis functions. Then, the nonlinear H_∞ estimation problem of RV systems is solved by fuzzy interpolation filtering method via an eigenvalue technique. For the convenience of design, the nonlinear H_∞ trajectory estimation problem via the fuzzy filtering approach is characterized in terms of an EVP, i.e., the worst-case effect of external disturbances on the estimation error is minimized subject to certain LMI constraints. The EVP or LMIP is to be solved via convex optimization techniques with the help of LMI optimization toolbox of Matlab. Finally, a simulation example is given to illustrate the design procedure and to confirm the estimation performance of our proposed method.

II. System Description and Problem Formulation

Consider the RV along a ballistic trajectory. For trajectory estimation and analysis, a mathematical model of ballistic missile system must be constructed first with some simplified assumptions to describe its motion. Fig. 1 shows a vehicle in the reentry phase over a flat, nonrotating earth with constant gravity. Since the RV has flown over several hundred kilometers along a ballistic trajectory above the rotating earth, the distance that the RV travels in this phase is shorter than the distance traveled before reentry. The RV can be considered as a point mass with constant weight following a ballistic trajectory in which two types of significant forces, i.e., drag and gravity, act on the RV. Extra forces induced by model uncertainties or disturbances must be considered when assumptions on the system are violated or the RV undertakes a maneuver. These effects can be grouped as uncertain accelerations in each axis. Suppose the RV system model in radar coordinates *(O, X, Y, Z) centered at radar site can be expressed as,*

$$\begin{aligned}
\dot{v}_x(t) &= -\frac{\rho v^2(t)}{2\beta} g\cos\gamma_1(t)\sin\gamma_2(t) + a_x(t) \\
\dot{v}_y(t) &= -\frac{\rho v^2(t)}{2\beta} g\cos\gamma_1(t)\cos\gamma_2(t) + a_y(t) \\
\dot{v}_z(t) &= -\frac{\rho v^2(t)}{2\beta} g\sin\gamma_1(t) - g + a_z(t)
\end{aligned} \tag{1}$$

Where v_x, v_y, and v_z denote the velocity components along *X*, *Y*, and *Z*, respectively, $a_x(t)$, $a_y(t)$ and $a_z(t)$ are uncertain accelerations due to model uncertainties and RV's maneuvering along *X*, *Y*, and *Z*, respectively, ρ stands for the air density. γ_1, γ_2 and the ballistic coefficient β are defined as,

$$\begin{aligned}
\gamma_1(t) &= \tan^{-1}\left(-\frac{v_z(t)}{\sqrt{v_x^2(t)+v_y^2(t)+v_z^2(t)}}\right) \\
\gamma_2(t) &= \tan^{-1}\left(\frac{v_x(t)}{v_y(t)}\right) \\
\beta &= \frac{W}{sC_{D0}}
\end{aligned} \tag{2}$$

where *s*, *W*, and C_{D0} represent the reference area, weight, and zero-lift drag coefficient, respectively. (1) can be translated into the following equations,

$$\begin{aligned}
\dot{v}_x(t) &= -\frac{\rho}{2\beta} g\left(\sqrt{v_x^2(t)+v_y^2(t)+v_z^2(t)}\cdot v_x(t)\right) + a_x(t) \\
\dot{v}_y(t) &= -\frac{\rho}{2\beta} g\left(\sqrt{v_x^2(t)+v_y^2(t)+v_z^2(t)}\cdot v_y(t)\right) + a_y(t) \\
\dot{v}_z(t) &= -\frac{\rho}{2\beta} g\left(\sqrt{v_x^2(t)+v_y^2(t)+v_z^2(t)}\cdot v_z(t)\right) - g + a_z(t)
\end{aligned} \tag{3}$$

Let us denote the state vector as,

$$\begin{aligned}
x(t) &= \left[x_1(t)\,x_2(t)\,x_3(t)\,x_4(t)\,x_5(t)\,x_6(t)\right]^T \\
&= \left[x_m(t) \quad y_m(t) \quad z_m(t) \quad v_x(t) \quad v_y(t) \quad v_z(t)\right]^T
\end{aligned} \tag{4}$$

where $x_m(t)$, $y_m(t)$, and $z_m(t)$ are the RV positions in *X*, *Y*, and *Z*, respectively; $v_x(t)$, $v_y(t)$ and $v_z(t)$ are the RV velocities along *X*, *Y*, and *Z*, respectively. Then, we get the nonlinear state equation for RV trajectories as follows:

$$\dot{x}(t) = F\left(x(t)\right) + Dw(t) \tag{5}$$

where,

$$F\left(x(t)\right) = \begin{bmatrix}
x_4(t) \\
x_5(t) \\
x_6(t) \\
-\left(\frac{\rho}{2\beta}\right)\left(\sqrt{x_4^2(t)+x_5^2(t)+x_6^2(t)}\cdot x_4\right)\cdot g \\
-\left(\frac{\rho}{2\beta}\right)\left(\sqrt{x_4^2(t)+x_5^2(t)+x_6^2(t)}\cdot x_5\right)\cdot g \\
-\left(\frac{\rho}{2\beta}\right)\left(\sqrt{x_4^2(t)+x_5^2(t)+x_6^2(t)}\cdot x_6\right)\cdot g - g
\end{bmatrix}$$

$$D = \begin{bmatrix} 0_{3\times3} & 0_{3\times3} \\ 0_{3\times3} & I_{3\times3} \end{bmatrix}$$

$$w(t) = \begin{bmatrix} 0\ 0\ 0\ a_x(t)\ a_y(t)\ a_z(t) \end{bmatrix}$$

(6)

The air density ρ in (3) is a function of altitude and the altitude dramatically changes as RV flies over 44 km. An

approximate model of air density ρ in g/cm3 is given as follows:

$$\rho = 0.12492((1-0.0000225577\cdot z_m(t))^{4.2561} \quad (7)$$

for $z_m(t) < 44332m$

For conventional air defense missile systems, the ground radar is the major instrument for detecting the RV. The measurement equation is then,

$$y(t) = Cx(t) + n(t) \quad (8)$$

where $n(t)$ denotes the measurement noise vector, and $C = I_{6\times 6}$ denotes the response distribution matrix.

Suppose the following fuzzy system is employed to approximate the nonlinear RV system in (5) and (8), the *ith* rule of this fuzzy model for the nonlinear RV system (5) is of the following form;

System Rule i:

If $a_1(t)$ is G_{i1} and …and $a_g(t)$ is G_{ig},

Then $\dot{x}(t) = A_i x(t) + Dw(t)$

$y(t) = Cx(t) + n(t)$, for $i = 1, 2, ..., l$ (9)

where, G_{ij} is the fuzzy set, $A_i \in R^{6\times 6}$, $D \in R^{6\times 6}$, l is the number of If-Then rules, and $a_1(t)$, ..., $a_g(t)$ are the premise variables.

The overall fuzzy RV system is inferred as follows :

$$\dot{x}(t) = \frac{\sum_{i=1}^{l}\mu_i(a(t))(A_i x(t))}{\sum_{i=1}^{l}\mu_i(a(t))} + Dw(t)$$
$$y(t) = Cx(t) + n(t) \quad (10)$$

or,

$$\dot{x}(t) = \sum_{i=1}^{l} h_i(a(t))(A_i x(t)) + Dw(t)$$
$$y(t) = Cx(t) + n(t) \quad (11)$$

where,

$$\mu_i(a(t)) = \prod_{j=1}^{g} G_{ij}(a_j(t))$$

$$h_i(a(t)) = \frac{\mu_i(a(t))}{\sum_{i=1}^{l}\mu_i(a(t))}$$

$$a(t) = [a_1(t),\ a_2(t),\ ...,\ a_g(t),]$$

and $G_{ij}(a_j(t))$ is the grade of membership of $a_j(t)$ in G_{ij}.

In this study, we assume

$\mu_i(a(t)) \geq 0$,for $i = 1, 2, \ldots, l$

and

$$\sum_{i=1}^{l}\mu_i(a(t)) > 0$$

for all *t*. Therefore, we get the certainty functions,

$h_i(a(t)) \geq 0$

(12)

for $i = 1, 2, \ldots, l$ and

$$\sum_{i=1}^{l} h_i(a(t)) > 1$$

(13)

The physical meaning of the fuzzy system in (11) is that the local linearized systems $\dot{x}(t) = A_i x(t) + Dw(t)$ at different operation regions (different fuzzy set G_{ij}) are interpolated via the fuzzy basis functions $h_i(a(t))$ to approximate the nonlinear RV system in (6).

Therefore, form (9), we get,

$$\begin{aligned}\dot{x}(t) &= F(x(t)) + Dw(t)\\ &= \sum_{i=1}^{l} h_i(a(t))(A_i x(t)) + Dw(t)\\ &+ \left\{F(x(t)) - \sum_{i=1}^{l} h_i(a(t))(A_i x(t))\right\}\end{aligned} \quad (14)$$

where $\left\{F(x(t)) - \sum_{i=1}^{l} h_i(a(t))(A_i x(t))\right\}$ and $h_i(a(t)) \geq 0$ denotes the approximation error and interpolation function between the nonlinear RV system (6) and the fuzzy RV model (9). Let us denote the sum of approximation error and external disturbance as the following uncertain disturbance,

$$\xi(t) = \left[F(x(t)) - \sum_{i=1}^{l} h_i(a(t))(A_i x(t))\right] + Dw(t)$$

Then, we get the fuzzy RV system in the following equivalent form,

$$\dot{x}(t) = \sum_{i=1}^{l} h_i(a(t))(A_i x(t)) + \xi(t)$$
$$y(t) = Cx(t) + n(t) \quad (15)$$

This study proposes using the following fuzzy trajectory estimator to deal with the state estimation of nonlinear RV system in (6) and (8) or the fuzzy equivalent system in (11), on Rule i:

If $a_1(t)$ is G_{i1} and …and $a_g(t)$ is G_{ig}

Then $\hat{x}(t) = A_i\hat{x}(t) + L_i\left(y(t) - \hat{y}(t)\right)$ (16)

where L_i is the estimator parameter to be designed for $i = 1, ..., l$. The overall fuzzy trajectory estimator in (16) is equivalent to,

$$\dot{\hat{x}}(t) = \sum_{i=1}^{l} h_i\left(a(t)\right)\left\{A_i\hat{x}(t) + L_i\left(y(t) - C\hat{x}(t)\right)\right\} \quad (17)$$

Now let us denote the estimation error as

$$\tilde{x}(t) = x(t) - \hat{x}(t) \quad (18)$$

By differentiating (18), and from (11) and (17), it is seen,

$$\dot{\tilde{x}}(t) = \sum_{i=1}^{l} h_i\left(a(t)\right)\left\{\left(A_i - L_iC\right)\tilde{x}(t) - L_in(t)\right\} + \xi(t) \quad (19)$$

After some manipulations, (19) can be expressed in a compact form:

$$\dot{\tilde{x}}(t) = \sum_{i=1}^{l} h_i\left(a(t)\right)\left\{\tilde{A}_i\tilde{x}(t) + \tilde{E}_i\tilde{w}(t)\right\} \quad (20)$$

Where

$$\tilde{A}_i = \left[A_i - L_iC\right],\ \tilde{E}_i = \left[-L_i \quad I\right],\ \tilde{w}(t) = \begin{bmatrix} n(t) \\ \xi(t) \end{bmatrix} \quad (21)$$

In order to attenuate the effect of uncertain disturbance $\tilde{w}(t)$ resulting form the uncertain target accelerations, approximation error and measurement noise $n(t)$ on the performance of the above estimation error dynamics, the H_∞ estimation performance is proposed to attenuate the worst-case effect of $\tilde{w}(t)$ on $\tilde{x}(t)$ as follows;

$$\frac{\int_0^{t_f} \tilde{x}^T(t)Q\tilde{x}(t)}{\int_0^{t_f} \tilde{w}^T(t)\tilde{w}(t)\,dt} \le \gamma^2,\ \forall\tilde{w}(t) \in L_2\left[0, t_f\right] \quad (22)$$

where Q is a weighting matrix with $Q^T = Q \ge 0$ and γ^2 denotes a prescribed attenuation level which is always chosen to be less than 1. The above equation is equivalent to

$$\int_0^{t_f} \tilde{x}^T(t)Q\tilde{x}(t)\,dt \le \gamma^2 \int_0^{t_f} \tilde{w}^T(t)\tilde{w}(t)\,dt,\ \forall\tilde{w}(t) \in L_2\left[0, t_f\right]$$

Theorem 1: *Suppose the fuzzy estimator in (17) is employed in the nonlinear trajectory estimation of RV dynamic system in (6) and (8), and P=P^T > 0 is the common solution of the following Riccati-like inequalities,*

$$\tilde{A}_i^T P + PA_i + P\left(\frac{1}{\gamma^2}\tilde{E}_i\tilde{E}_i^T\right)P + Q < 0, \text{ for, } i = 1, 2, ..., l \quad (23)$$

the H_∞ estimation performance in (22) is guaranteed for the fuzzy trajectory estimator in (17) with a prescribed γ^2 in presence of external uncertain disturbance $\tilde{w}(t)$.

III. Simulation Results

To demonstrate the performance robustness of the proposed estimation method, the following case of initial condition is considered in the simulation example.

*Case*1 : the reentry target is with $\beta = 2400$ (kg/m^2) and maneuvering accelerations of $4g$ and $-4g$ in X and Y, respectively, during $14(\text{sec}) \le t \le 18(\text{sec})$ and $7(\text{sec}) \le t \le 9(\text{sec})$ as figure 2, respectively as Fig. 2. The following is the initial condition of the high speed reentry target:

$$x_m(0) = 4km,\quad y_m(0) = 4km,\quad z_m(0) = 55km,$$
$$v_x(0) = -550m/s,\quad v_y(0) = -650m/s,\quad v_z(0) = -1800m/s.$$

and the initial condition for the estimation system is set up as follows:

$$\hat{x}_m(0) = 6km,\quad \hat{y}_m(0) = 6km,\quad \hat{z}_m(0) = 70km,$$
$$\hat{v}_x(0) = -900m/s,\quad \hat{v}_y(0) = -800m/s,\quad \hat{v}_z(0) = -1900m/s.$$

As seen in Figs 3-6, the proposed nonlinear H_∞ fuzzy tilter yields satisfactory estimation results under ballistic coefficient $\beta = 2400$ (kg/m^2) and the strong effect of a maneuvering acceleration: step maneuver as shown in Fig. 2. Figs. 3 show the 3D profiles of the true trajectory of RV systems and their estimation result by the proposed trajectory estimation method corresponding to the above high differentiation in initial conditions between high speed reentry target and the estimator. These results imply that the proposed method is robust in overriding the effect of modeling uncertainties: modeling uncertainties of reentry targets in our design procedures include 1. model approximation errors, 2. unpredictable accelerations of targets and 3. measurement noise. Since, the proposed method has minimized the worst-case effect of modeling uncertainties in advance; the superior performance of proposed fuzzy H_∞ filter is predictable. This is reasonable because several linearized models around different operation points of the nonlinear system were first obtained by the ANFIS algorithm, hence, the interpolation model of the local linear models by the fuzzy basis function are very similar to that of the nonlinear RV system, i.e., the nonlinear RV systems are approximated piecewise by the fuzzy-interpolated local linear models with small approximation errors, and then the worst-case effect of the proposed method has been eliminated with a systematic analysis. From simulation results, it is obvious that the state trajectories of the RV system can be efficiently estimated by the proposed fuzzy H_∞ filter.

IV. Conclusions

In this study, a nonlinear fuzzy H_∞ filter is successfully developed for the state estimation of high speed reentry vehicles. In general, it needs to solve the Hamilton-Jacobi-Isaac equation for obtaining a robust filter with noise reduction and modeling uncertainty elimination ability. To

avoid solving the complicated Hamilton-Jacobi-Isaac equation in the conventional H_∞ filter design, the robust fuzzy H_∞ filter design problem is first transformed to an eigenvalue problem with the fuzzy approximation technology and then formulates it as a solvable LMI so that the trajectory estimation problem of reentry vehicles could be efficiently solved with the available computer software. The simulation results reveal that the proposed method yield accurate and satisfactory estimation ability. Simulation results also show that the proposed H_∞ filter offers the potential application in the precise trajectory estimation of RV systems.

***Abstract*—Three-dimensional fuzzy logic controller (3-D FLC) is a novel FLC developed for spatially distributed parameter systems. In this study, we are concerned with data-based 3-D FLC design. A nearest neighborhood clustering algorithm is employed to extract fuzzy rules from input-output data pairs, and then an optimization algorithm based on geometric similarity measure is used to reduce the obtained rule base. The consequent parameters are estimated using linear support vector regression. Finally, a catalytic packed-bed reactor is taken as an application to demonstrate the effectiveness of the 3-D FLC.**

Keywords-3-D fuzzy set; three-dimensional fuzzy logic controller; nearest neighborhood clustering; linear support vector regression

I. INTRODUCTION

In the real world, many physical processes and systems have the characteristics of spatial distribution, and are usually called spatially distributed systems. Recently, A novel three-dimensional fuzzy logic controller (3-D FLC) [1] has been developed for the control of such systems. 3-D FLC employs 3-D fuzzy sets [1], which is composed of the traditional fuzzy set plus a third dimension for the spatial information, and carries out 3-D rule inference engine. It has an inherent capability to express and process spatial information. The design of 3-D FLC is usually divided into two different approaches: expert experience based approach and data-driven based approach. When much domain knowledge from human experts or operators is obtained, a satisfied 3-D FLC can be designed by expert experience such as in [1]. On the other hands, if the domain knowledge is not available, or the domain knowledge is very hard to be extracted or described by human's words, but effective input-output data is available, the 3-D FLC can also be designed using the data information such as in [2].

In [2], a table look-up scheme that took into account the tempo-spatial nature sufficiently was applied to the 3-D FLC design. Each input-output data pair generates one rule; as a result, the number of rules is very large. To reduce the number of rules, a degree is assigned to a rule, and then only the rule with maximum degree from a conflict group is accepted. However, it is equal to the number of boxes of the base when the fuzzy rule base is complete, and then, it increases exponentially as the dimension of the input space increases. Instead of the most direct way to partition the input space, fuzzy clustering algorithms provide a more flexible partition, such as the nearest neighborhood clustering in [3]. In this study, we adopt the Frobenius norm as a distance measurement, instead of the Euclidean norm in the traditional counterpart. Via comparing the inverse of sum of unit and distance with a given threshold, a new fuzzy rule is determined whether to be generated. To simplify the redundancy fuzzy sets in the input space partition, similarity measures techniques are usually used, such as in [4]- [6], which can be divided into two categories [6]: geometric similarity measures and set-theoretic similarity measures. For the 3-D fuzzy set, a distance-based similarity measure [4], as a special geometric similarity measures method, is employed to combine similar fuzzy sets. After constructing the antecedent parts, the linear support vector regression (SVR, i.e. ε-linear support vector regression) will be used to determine the parameters in consequent parts.

The paper is divided into five sections. In Section II, preliminaries on 3-D FLC and SVR are described. In Section III, the proposed data-based 3-D FLC design is presented in detail. Application to the catalytic packed-bed reactor and experimental results are given in Section IV. Finally, conclusions and future works are given in Section V.

II. PRELIMINARIES

A. *Three-dimensional fuzzy logic controller*

The 3-D FLC is designed to have the inherent capability to deal with spatial information and its basic structure is shown in Fig. 3. It has a similar functional structure similar to the traditional FLC, which consists of three basic blocks: fuzzification, rule inference, and defuzzification. However, it will differ in the detailed operations because of the spatial processing requirement [1]. Generally, the 3-D FLC will be involved with the following basic designs: 3-D membership function (MF), 3-D fuzzification, 3-D rule base, 3-D rule inference, and defuzzification. One can refer to [1] for detailed description. In this study, we consider the multi-input single-output (MISO) cases where the finite sensors are employed; extensions to general multi-input multi-output (MIMO) cases are straightforward. Given N fuzzy rules with the following form

$$\bar{R}^l\text{: IF } x_1(z) \text{ is } \bar{C}_1^l \text{ and..and } x_s(z) \text{ is } \bar{C}_s^l, \text{THEN } u \text{ is } B^l \quad (1)$$

where $x_i(z)\,(i=1,...,s)$ denotes the ith spatial input variable; $z \in Z$ is a point in one-dimensional space Z; In discrete space, Z can be represented by $Z=\{z_1,z_2,...,z_p\}$, $z_1,z_2,...,z_p$ denote the discrete space positions; $\bar{C}_i^l$ denotes a 3-D fuzzy set; u denotes output variable (the control action). B^l denotes a traditional fuzzy set; $l=1,...,N$.

To design a 3-D fuzzy set, for instance $\bar{C}_i^l$ $(i=1,...,s,$ $l=1,...,N)$ in (1), one simple method is to decompose the 3-D fuzzy set into the multiple 2-D fuzzy sets. As a result, the design method from the traditional 2-D fuzzy sets can be used. Similarly, the 3-D fuzzification can be regarded as the assembly of the traditional 2-D fuzzification at each sensing location. When the Gaussian type fuzzy set is chosen for 3-D fuzzy set, it means that MF of the ith spatial input variable $x_i(z)$ at the sensing location $z=z_j$ is Gaussian MF, which can be written as

$$\mu_{Gij}(x_i(z_j))=\exp\left(-(x_i(z_j)-v_{ij}^l)^2/(\sigma_{ij}^l)^2\right) \quad (i=1,...,s,\ j=1,...,p,\ l=1,...,N) \quad (2)$$

where v_{ij}^l and σ_{ij}^l are center and width of the Gaussian MF, respectively.

If we choose singleton fuzzification, product for the spatial information fusion operation, the centroid approach for the dimension reduction, product inference, center-of-sets defuzzification, and Gaussian MF in (2), then the input-output mapping of the 3-D FLC, $u: R^{p\times s} \to R$, is given by

$$u(x_z)=\frac{\sum_{l=1}^N u^l \sum_{j=1}^p a_j^l \prod_{i=1}^s \mu_{Gij}(x_i(z_j))}{\sum_{l=1}^N \sum_{j=1}^p a_j^l \prod_{i=1}^s \mu_{Gij}(x_i(z_j))} \quad (3)$$

where u^l is the centroid of the consequent set, i.e. the center of Gaussian MF, such that $\mu(u^l)=1$; a_j^l denotes the time-variant weight with the following form

$$\begin{cases} a_1^l=\Delta\theta_1^l/\left(2\sum_{k=1}^{p-1}\Delta\theta_k^l\right) \\ a_j^l=\left(\Delta\theta_{j-1}^l+\Delta\theta_j^l\right)/\left(2\sum_{k=1}^{p-1}\Delta\theta_k^l\right) \quad j=2,...,p-1 \\ a_p^l=\Delta\theta_{p-1}^l/\left(2\sum_{k=1}^{p-1}\Delta\theta_k^l\right) \\ \Delta\theta_k^l=\sqrt{\left(\mu_{W^l}(z_{k+1})-\mu_{W^l}(z_k)\right)^2+\left(z_{k+1}-z_k\right)^2} \\ \mu_{W^l}(z_k)=\prod_{i=1}^s \mu_{Gik}(x_i(z_k)) \end{cases} \quad (4)$$

Let

$$\phi^l(x_z)=\frac{\sum_{j=1}^p a_j^l \prod_{i=1}^s \mu_{Gij}(x_i(z_j))}{\sum_{l=1}^N \sum_{j=1}^p a_j^l \prod_{i=1}^s \mu_{Gij}(x_i(z_j))} \quad l=1,...,N \quad (5)$$

be the fuzzy basis functions (FBF) of 3-D FLC and u^l be constants, then (3) can be viewed as a linear combination of fuzzy basis functions.

$$u(x_z)=\sum_{l=1}^N \phi^l(x_z)\theta^l \quad (6)$$

where $\theta^l \in R$ are constants, i.e. $\theta^l=u^l$.

From (1) and (5), we can see that each FBF corresponds to a fuzzy IF-THEN rule.

B. *Linear support vector regression*

In this subsection, we will briefly introduce the basic theory of linear SVR (i.e. ε-linear support vector regression) [7].

Suppose there is a set T composed of n input-output training data pairs

$$T=\{(x_i,y_i)\big|x_i\in R^s, y_i\in R, i=1,...,n\} \tag{7}$$

In ε-linear SVR, the aim is to find a decision function $f(x)$ that has at most ε deviation from the actually obtained targets y_i for all the training data pairs, and at the same time is as flat as possible. $f(x)$ has the following form

$$f(x)=\langle w,x\rangle+b \text{ with } w\in R^s, b\in R \tag{8}$$

where $\langle\cdot,\cdot\rangle$ denotes the dot product in R^s; w is a high-dimensional weight vector, and b is a bias term. Flatness in the case of (8) means that one seeks a small w. One way to ensure this is to minimize $\|w\|^2=\langle w,w\rangle$.

If the considered problem is infeasible or some errors are allowed, then the task is to minimize the following convex optimization problem by introducing slack variables ξ_i,ξ_i^*.

$$\begin{aligned}&\min_{w,b,\xi^{(*)}} \quad \frac{1}{2}\|w\|^2+C\sum_{i=1}^{n}(\xi_i+\xi_i^*)\\ &s.t. \quad \begin{cases} y_i-(w\cdot x_i+b)\le\varepsilon+\xi_i\\ (w\cdot x_i+b)-y_i\le\varepsilon+\xi_i^*\\ \xi_i,\xi_i^*\ge 0,\ i=1,...,n\end{cases}\end{aligned} \tag{9}$$

where constant C determines the trade-off between the flatness of f and the amount up to which deviations larger than ε are tolerated. This corresponds to dealing with a so called ε-insensitive loss function $|\xi|_\varepsilon$ described by

$$|\xi|_\varepsilon:=\begin{cases}0 & \text{if } |\xi|\le\varepsilon\\ |\xi|-\varepsilon & \text{otherwise.}\end{cases}$$

The corresponding dual optimization problem of convex optimization problem in (9) is given by

$$\begin{aligned}&\max_{\alpha^{(*)}\in R^{2l}} \quad \begin{cases}-\frac{1}{2}\sum_{i,j=1}^{n}(\alpha_i-\alpha_i^*)(\alpha_j-\alpha_j^*)\langle x_i,x_j\rangle\\ -\varepsilon\sum_{i=1}^{n}(\alpha_i+\alpha_i^*)+\sum_{i=1}^{n}y_i(\alpha_i-\alpha_i^*)\end{cases}\\ &s.t. \quad \sum_{i=1}^{n}(\alpha_i-\alpha_i^*)=0 \text{ and } \alpha_i,\alpha_i^*\in[0,C]\end{aligned} \tag{10}$$

The vector w has the form: $w=\sum_{i=1}^{n}(\alpha_i-\alpha_i^*)x_i$ and therefore

$$f(x)=\sum_{i=1}^{n}(\alpha_i-\alpha_i^*)\langle x_i,x\rangle+b \tag{11}$$

The points with $(\alpha_i-\alpha_i^*)\neq 0$ are defined as support vectors.

III. Data-Based 3-D FLC Design

The design of 3-D FLC includes two steps: structure learning and parameter learning. In structure learning, the nearest neighborhood clustering is employed to mine the underlying knowledge of the data set S such that fuzzy rules and Gaussian 3-D MFs in the antecedent part are constructed, and then an optimization algorithm based on similarity measure is utilized to combine similar MFs and then simplify the rule base. In parameter learning, the linear SVR algorithm is used to estimate the parameters of the traditional Gaussian-type fuzzy sets in the consequent part.

Firstly, the concerned 3-D FLC can be defined as follows.

Definition 1: The set of 3-D FLC with fuzzy rule base in (1), singleton fuzzification, product inference, center-of-sets defuzzification, and Gaussian MF can be described mathematically in (12)

$$u(x_z)=\frac{\sum_{l=1}^{N}u^l\sum_{j=1}^{p}a_j^l\prod_{i=1}^{s}\mu_{Gij}(x_i(z_j))}{\sum_{l=1}^{N}\sum_{j=1}^{p}a_j^l\prod_{i=1}^{s}\mu_{Gij}(x_i(z_j))}+b \tag{12}$$

From (12), we can see that each 3-D FLC in the set combines a 3-D FLC in (3) and a constant b. b is included for the bias term in the linear SVR. The motivation of this study is to determine a mapping u in (12) using the fuzzy rules generated from a set S represented by (13), which consists of input-output data pairs from a spatially distributed system.

$$S=\{(x_z^k,u^k)\big|x_z^k\in R^{p\times s}, u^k\in R, k=1,...,n\} \tag{13}$$

where $x_z^k=(x_1^k(z),...,x_s^k(z))$ denotes the value of all s spatial input variables at the kth sampling time, $x_i^k(z)=(x_i^k(z_1),...,x_i^k(z_p))^T$ $(i=1,...,s)$, u^k denotes the output value at the kth sampling time, n denotes the number of sampling time, and p denotes sensor number.

A. Structure Learning

Define abbreviations and acronyms the first time they are used in the text, even after they have been defined in the abstract. Abbreviations such as IEEE, SI, MKS, CGS, sc, dc, and rms do not have to be defined. Do not use abbreviations in the title or heads unless they are unavoidable.

1) Nearest neighborhood clustering: Different from the traditional vector input-output data pairs, the input-output data pairs S in (13) are of matrix form. Therefore, the Frobenius norm will be used for defining the distance in a nearest neighborhood clustering algorithm [3]. By comparing the inverse of sum of unit and distance with a given threshold, we can determine whether to add a new fuzzy rule. The nearest neighborhood clustering algorithm is summarized as follows:

Step 1: Begin from the first input-output data pair x_z^1. Let the first cluster center c_z^1 be x_z^1, the number of data pairs m_1 be 1 in this cluster, and the threshold be ρ_0 for generating new fuzzy rules.

Step 2: Suppose that the kth input-output data pair $x_z^k(k=2,...,n)$ is considered, when N clusters have been generated and their centers are $c_z^1,...,$and c_z^N, respectively. Firstly, the distance between x_z^k and each center of N clusters is computed using $\|x_z^k-c_z^l\|_F$ $(l=1,...,N)$, where $\|\cdot\|_F$ denotes the Frobenius norm, $\|X\|_F=\sqrt{tr(X^TX)}$ $(X\in R^{p\times s})$. Then, threshold ρ is given by (14)

$$\rho=\max_{l=1,...,N}\left(1\Big/\left(1+\|x_z^k-c_z^l\|_F\right)\right) \tag{14}$$

Hence, the corresponding cluster center $c_z^{l_k}$ is taken as the nearest neighborhood cluster of x_z^k.

Step 3: If $\rho < \rho_0$, then x_z^k is taken as the new cluster center. Let $N = N+1$, $m_N = 1$, and $c_z^N = x_z^k$. Otherwise, x_z^k belongs to the cluster $c_z^{l_k}$, by introducing a learning rate $\eta = \eta_0/(m_{l_k}+1)$ ($\eta_0 \in [0,1]$) [1] described by (15) for tuning the center of l_kth cluster;

$$c_z^{l_k} = c_z^{l_k} + \eta(x_z^k - c_z^{l_k});\ m_{l_k} = m_{l_k} + 1 \tag{15}$$

Step 4: Let $k = k+1$. If $k \geq n+1$, then quit; otherwise, back to Step 2.

2) Rule extraction and 3-D MF construction: After clustering learning, we can obtain a input space partition with N cluster centers $c_z^1, c_z^2, ..., c_z^N$. Then, we will produce antecedent part of rule base and construct 3-D MF in terms of the partition. Each cluster corresponds to a fuzzy rule, and the cluster center corresponds to the center of Gaussian 3-D MFs in the antecedent part. Thus, the number of fuzzy rules is equal to the number of clusters N. Finally, let the width of 3-D Gaussian MFs have the same value as in (16) [1] at each sensing location.

$$\sigma(z_j) \approx \max_{1 \leq i \leq s} \left((x_i^{\max}(z_j) - x_i^{\min}(z_j))/10 \right) \tag{16}$$

where $x_i^{\max}(z_j)$ and $x_i^{\min}(z_j)$ are the maximum and the minimum bound value of the ith spatial input in S, respectively. Similarly, the width of traditional Gaussian MF in the consequent part is given as

$$\sigma_B \approx (\max(u) - \min(u))/10 \tag{17}$$

where $\max(u)$ and $\min(u)$ are the maximum and the minimum bound value of the output in S, respectively.

3) Optimization algorithm: The obtained input space partition may have redundancy in terms of highly overlapping membership functions. It is necessary to optimize the above obtained fuzzy partition. The optimization task includes: removing 3-D fuzzy sets similar to the universal set or the singleton set, and merging some similar 3-D fuzzy sets and some rules with similar antecedent part.

Firstly, the definition of the similarity of two 3-D fuzzy sets is given as follows.

Definition 2: Define the similarity of two 3-D fuzzy sets $\overline{A}$ and $\overline{B}$ as

$$\overline{S}(\overline{A}, \overline{B}) = \frac{1}{1 + d(\overline{A}, \overline{B})} \quad \overline{S}(\cdot) \in (0,1] \tag{18}$$

where $d(\overline{A}, \overline{B})$ is the distance between $\overline{A}$ and $\overline{B}$. Since Gaussian type membership functions are chosen, the following simple expression can be used to approximate the distance.

$$d(\overline{A}, \overline{B}) = \left\| \begin{bmatrix} c_{\overline{A}(z_1)} & \sigma_{\overline{A}(z_1)} \\ \vdots & \vdots \\ c_{\overline{A}(z_p)} & \sigma_{\overline{A}(z_p)} \end{bmatrix} - \begin{bmatrix} c_{\overline{B}(z_1)} & \sigma_{\overline{B}(z_1)} \\ \vdots & \vdots \\ c_{\overline{B}(z_p)} & \sigma_{\overline{B}(z_p)} \end{bmatrix} \right\|_F \tag{19}$$

where $c_{\overline{A}(z_j)}(c_{\overline{B}(z_j)})$ and $\sigma_{\overline{A}(z_j)}(\sigma_{\overline{B}(z_j)})$ are center and width of Gaussian MF at sensing location $z = z_j$ $(j = 1, ..., p)$ respectively.

If 3-D fuzzy sets $\overline{A}$ and $\overline{B}$ are similar, then they will be merged into a new spatial fuzzy set $\overline{C}$, the center and width of which are viewed as the average value of the two original 3-D fuzzy sets, i.e. $c_{\overline{C}(z_j)} = (c_{\overline{A}(z_j)} + c_{\overline{B}(z_j)})/2, \sigma_{\overline{C}(z_j)} = (\sigma_{\overline{A}(z_j)} + \sigma_{\overline{B}(z_j)})/2$.

The similarity of fuzzy rules only measures their similarity in antecedent part. Therefore, the similarity between two fuzzy rules $\overline{R}^{l_1}$ and $\overline{R}^{l_2}$ can be computed by (20).

$$\overline{S}_{rule}(\overline{R}^{l_1}, \overline{R}^{l_2}) = \min_{1 \leq i \leq s} \left\{ \overline{S}(\overline{C}_i^{l_1}, \overline{C}_i^{l_2}) \right\} \tag{20}$$

The rule base simplification algorithm in [1] can be extended to this study only for antecedent part, where the similarity measure is replaced by (18) and two thresholds γ (for removing fuzzy sets similar to the universal set) and λ (for merging two similar fuzzy sets) are required. In this study, we choose $\gamma \in (\lambda, 1]$ and $\lambda \in [0.6, 0.9]$.

B. Parameter Learning

For a complete rule base, the rest task is to determine the consequent part parameters. In this subsection, a linear SVR algorithm is applied to estimate the consequent part parameter b^l $(l = 1, ..., N)$ in the 3-D FLC. Each input x_z^k $(k = 1, ..., n)$ in S is transformed into a corresponding FBF $\phi(x_z^k) = (\phi^1(x_z^k), \phi^2(x_z^k), ..., \phi^N(x_z^k))$. Hence, the original data set S in (13) can be represented by (21)

$$S = \{(\phi(x_z^k), u^k) \,|\, \phi(x_z^k) \in R^N, u^k \in R, k = 1, ..., n\} \tag{21}$$

From (13), the final decision function $f(\phi(x_z^k))$ can be described in the following form

$$f(\phi(x_z^k)) = \sum_{k=1}^n (\alpha_k - \alpha_k^*) \langle \phi(x_z^k), \phi(x_z) \rangle + b \tag{22}$$

where α_k^* and α_k are obtained by solving the dual optimization problem in (10). Then (22) can further be expressed as follows

$$\begin{aligned} u(x_z) &= \sum_{k=1}^n (\alpha_k - \alpha_k^*) \sum_{l=1}^N \phi^l(x_z^k) \phi^l(x_z) + b \\ &= \sum_{l=1}^N \left(\sum_{k=1}^n (\alpha_k - \alpha_k^*) \phi^l(x_z^k) \right) \phi^l(x_z) + b \\ &= \sum_{l=1}^N u^l \phi^l(x_z) + b \end{aligned} \tag{23}$$

We can see that (23) is equal to (12), namely, $u^l = \sum_{k=1}^n (\alpha_k - \alpha_k^*) \phi^l(x_z^k)$. Thus, the parameters u^l $(l = 1, ..., N)$ in consequent parts are obtained, which can be modified as follows.

$$u^l = \sum_{k \in SV} (\alpha_k - \alpha_k^*) \phi^l(x_z^k) \tag{24}$$

where SV denotes the support vectors of linear SVR. It is noted that C in (9) is an adjustable parameter. In this study, we choose a better one through several turns of simulation."

IV. Application To Catalytic Packed-bed Reactor

We take a catalytic packed-bed reactor [1] [10] as an example. A reaction of the form $C \rightarrow D$ takes place on the catalyst. The reaction is endothermic and a jacket is used to

heat the reactor. A dimensionless model that describes this nonlinear tubular chemical reactor is provided as follows:

$$\varepsilon_p \frac{\partial T_g}{\partial t} = -\frac{\partial T_g}{\partial z} + \alpha_c (T_s - T_g) - \alpha_g (T_g - u)$$
$$\frac{\partial T_s}{\partial t} = \frac{\partial^2 T_s}{\partial z^2} + B_0 \exp\left(\frac{\gamma T_s}{1+T_s}\right) - \beta_c (T_s - T_g) - \beta_p (T_s - b(z)u) \quad (25)$$

Subject to the boundary conditions

$$z = 0, T_g = 0, \frac{\partial T_s}{\partial z} = 0; z = 1, \frac{\partial T_s}{\partial z} = 0 \quad (26)$$

where T_g, T_s, and u denote the dimensionless temperature of the gas, the catalyst, and jacket, respectively. The values of the process parameters are given as follows:

$\varepsilon_p = 0.01, \gamma = 21.14, \beta_c = 1.0, \beta_p = 15.62, B_0 = -0.003, \alpha_c = 0.5, \alpha_g = 0.5$

A sin distribution heat source is used with $b(z) = 1 - \cos(\pi z)$, $0 \le z \le 1$. The spatial reference profile is given as $T_{sd}(z) = 0.42 - 0.2\cos(\pi z)$.

Five point sensors are uniformly located along the length of the reactor with $z = (0, 0.25, 0.5, 0.75, 1)^T$ for collecting the spatial distribution of the temperature T_s. Two spatial inputs are error $e^*(z) = [e_1^*, ..., e_5^*]^T$ and error in change $r^*(z) = [r_1^*, ..., r_5^*]^T$, where $e_i^* = T_s(z_i, q) - T_{sd}(z_i)$ $r_i^* = e_i^*(q) - e_i^*(q-1)$; q and $q-1$ denotes the qth and q-1th sampling time, respectively. Δu^* denotes the incremental output at the qth sampling time.

It should be noted that the model represented by (25)-(26) is just used to unveil the system dynamics and is employed as the simulated model by the method of lines [11] to evaluate the control scheme. The only information we can utilize is the measured input-output data pairs.

Two groups data set are obtained from [1] by adding Pseudo-Random Quinary Sequence (PRQS) signal [12] with different amplitude (i.e. 0.447 and 0.1) to the control input. The scaling factors of 3-D FLC in [1] are set as 2.0, 0.001 and 0.8716 respectively. Each group has 150 data pairs composed of $e^*(z), r^*(z)$ and Δu^* with the sampling time 0.2s. The group generated from the control input with amplitude 0.447 is taken as the training data set, while the other group is taken as the test data set. The design process of data-based 3-D FLC is given as follows:

- Apply the nearest neighborhood clustering algorithm to partition the input space. Let $\rho_0 = 0.7$ and $\eta_0 = 0$. Then 16 fuzzy rules were generated, where the width of 3-D MF was $\sigma_z \approx [0.0620, 0.0902, 0.1518, 0.2008, 0.2175]^T$ as in (16).
- Optimization algorithm with $\gamma = 0.95$ and $\lambda = 0.9$ was used to simplify the obtained fuzzy rules and 3-D fuzzy sets.
- The linear SVR algorithm was used to obtain optimal consequent part parameters, where the width of Gaussian MF is set as $\sigma_B \approx 0.1247$ by (17). Let ε be 0.01, and C be a real number in [10, 10^7]. Root Mean-Squared Error (RMSE) defined in (27) was chosen as the quantitative performance to select the best approximated 3-D FLC, and then the *RMSEs* of the training data set and the test data set under different parameter C were listed in the Table I. From Table I, we can find that when $C = 10^7$, *RMSE* has a minimal value. Therefore, we choose $C = 10^7$ in this study. The extracted 3-D rule base and the related MFs were depicted in Fig. 4.

The proposed data-based 3-D FLC is applied to the control of catalytic packed-bed reactor, where simulation time is 10s. We select the same quantitative performance criteria as in [1]: steady-state error (SSE), integral of the absolute error (IAE), and integral of time multiplied by absolute error (ITAE). The control performance is given in Table II, and the control profile is given in Fig. 5. We can find that the data-based 3-D FLC has comparable control performance with the expert experience based 3-D FLC in [1] both in ideal condition and in disturbed condition.

V. CONCLUSION

In this paper, a new data-based 3-D FLC is designed by using a nearest neighborhood clustering algorithm, fuzzy similarity measurement techniques, and a linear SVR algorithm. Firstly, the nearest neighborhood clustering algorithm is used to partition the input space and construct 3-D rule base and 3-D MFs. Then, geometric similarity measure is employed to reduce the rule base. Finally, a linear SVR algorithm is used to estimate the optimal consequent part parameters. The proposed 3-D FLC was applied to the control of catalytic packed-bed reactor. The simulation results show that the designed 3-D FLC had a satisfied control performance compared with the expert experience based 3-D FLC.

***Abstract*—The method of kernel data analysis is now a standard tool in modern data mining. An implicit mapping into a high-dimensional feature space is assumed in this method, in other words, an explicit form of the mapping is unknown but their inner product should be known instead. Contrary to this common assumption, we propose a method of explicit mappings. The reason why we use explicit mappings is as follows. (1) The use of these mappings does not lose any fundamental information in kernel data analysis. (2) We have the same formulas in kernel methods with and without the explicit mappings. (2) Usually the derivation becomes simpler by using these mappings. (3) New applications of the kernel methods become possible using these mappings. Two types of the mappings are proposed, one of which uses $\Phi(x_k) = \boldsymbol{e}_k$ $(k = 1, \ldots, N)$ while the second type uses $\Phi(x_k) = K^{\frac{1}{2}}\boldsymbol{e}_k$, where $K = (K(x_i, x_j))$ is $N \times N$ matrix. As an application we consider L_1 space fuzzy c-means clustering and lower dimensional approximation of kernel K. The effectiveness of the proposed method is shown by numerical examples.**

Keywords-data mining; kernel function; explicit mapping; clustering.

I. Introduction

Kernel functions [7] have been used in support vector machines [8] and are now becoming a standard tool in many applications of data mining. The *kernel trick* is commonly used in this method which means that we consider a mapping, e.g. $\Phi(x)$, from a data space into a high-dimensional feature space of which an explicit form is unknown, but we know the explicit functional form of their inner product $K(x, y) = \langle \Phi(x), \Phi(y) \rangle$ in the feature space. The function $K(x, y)$ is called a kernel function. Hence formulas in data analysis should be described in terms of the inner product of $\Phi(x)$, since the functional form of $\Phi(x)$ is unknown.

Kernel functions are known to be useful in many applications, but the derivations are generally complicated, since original formulas should be rewritten by the inner product forms. A typical example is kernel fuzzy c-means clustering [4] and kernel VQ clustering [5].

Contrary to this common understanding, we propose a method of kernel functions using explicit mappings. The idea is simple: the original idea is to assume a mapping $\Phi\colon \boldsymbol{R}^p \to H$, where $\boldsymbol{R}^p$ is the data space and H is the feature space. Instead, we assume $\Phi\colon \{x_1, \ldots, x_N\} \to \boldsymbol{R}^p$, where $\{x_1, \ldots, x_N\}$ is the set of objects to be analyzed. As a result we do not need to have the full functional form of $K(x, y)$; it is sufficient to know $K(x_i, x_j)$ $(1 \le i, j \le N)$. However, we do not know the actual form of $\Phi(x_k)$ but we know only $K = (K(x_i, x_j))$. How to handle $\Phi(x_k)$? The answer is simple: we consider two mappings:

1) $\Phi(x_k) = \boldsymbol{e}_k$;
2) $\Phi(x_k) = K^{\frac{1}{2}}\boldsymbol{e}_k$.

By these mappings the derivation of a kernel method becomes simpler, and some new techniques can be developed, as we will see later.

To illustrate the effectiveness of the present method, a typical result of kernel fuzzy c-means clustering with L_2 and L_1 norms will be shown. Further, a low dimensional approximation of a kernel is shown.

II. Explicit Mappings for Kernel Functions

A. Preliminary consideration

A set of objects $X = \{x_1, \ldots, x_N\} \subset \boldsymbol{R}^p$ is assumed to be given. They are points in the p-dimensional real space: $x_k = (x_k^1, \ldots, x_k^p)^\top \in \boldsymbol{R}^p$. We consider a mapping into a high-dimensional feature space $\Phi\colon \boldsymbol{R}^p \to H$ and associated kernel function as usual:

$$K(x, y) = \langle \Phi(x), \Phi(y) \rangle$$

where $\langle \cdot, \cdot \rangle$ is the inner product of H. We also assume $\| \cdot \|_H$ is the norm of H.

In this section we first suppose, as usual, we do not know an explicit form of function $\Phi(\cdot)$ but we know $K(x, y)$. Specifically, the Gaussian kernel is frequently used:

$$K(x, y) = \exp(-\lambda \|x - y\|^2),$$

where $\lambda > 0$ and $\|x\|$ is the norm of $\boldsymbol{R}^p$.

1) Kernel-based fuzzy c-means clustering: Let us review the method of kernel-based fuzzy c-means clustering [4], [5]. In this section we do not use an explicit mapping.

An objective function of fuzzy c-means using the feature space H is the following.

$$J_H(U, W) = \sum_{i=1}^{c} \sum_{k=1}^{N} (u_{ki})^m \|\Phi(x_k) - W_i\|_H^2, \quad (m > 1)$$

where $U = (u_{ki})$ is $n \times c$ membership matrix of x_k to cluster i. U has the next constraint when it is optimized.

$$M = \{U = (u_{ki}) : \sum_{i=1}^{c} u_{ki} = 1,\ u_{\ell j} \geq 0, \forall \ell, j\},$$

while $W = (W_1, \ldots, W_c)$ is a collection of cluster centers in H.

The iterative algorithm of fuzzy c-means clustering [1] is basically an alternative minimization of $J_H(U, W)$ with respect to U and W until convergence. We have the next solutions [5]:

$$u_{ki} = \left[\sum_{j=1}^{c} \left(\frac{D(x_k, W_i)}{D(x_k, W_j)} \right)^{\frac{1}{m-1}} \right]^{-1}, \tag{1}$$

$$W_i = \frac{\sum_{k=1}^{N} (u_{ki})^m \Phi(x_k)}{\sum_{k=1}^{N} (u_{ki})^m}, \tag{2}$$

where we put

$$D(x_k, W_i) = \|\Phi(x_k) - W_i\|_H^2. \tag{3}$$

Equations (1) and (2) should be repeated until convergence, but since $\Phi(x_k)$ is unknown, we use another formula for kernel fuzzy c-means clustering.

The formula is derived by eliminating (2) from iteration, i.e., we substitute (2) into (3) to have an updating formula for $D(x_k, W_i)$ [4]:

$$D(x_k, W_i) = K(x_k, x_k) - \frac{2}{\sum_{k=1}^{N} (u_{ki})^m} \sum_{j=1}^{N} (u_{ji})^m K(x_j, x_k) + \frac{1}{\{\sum_{k=1}^{N} (u_{ki})^m\}^2} \sum_{j=1}^{N} \sum_{\ell=1}^{N} (u_{ji} u_{\ell i})^m K(x_j, x_\ell). \tag{4}$$

We thus repeat (1) and (4) until convergence in kernel-based fuzzy c-means clustering.

B. Two explicit mappings

The above derivation needs transformation of an original algorithm into another one, due to the fact that no explicit mapping is available.

In contrast, if we have an explicit mapping, then no additional derivation is needed and we can use an existing algorithm.

We show two explicit mappings. First mapping is very simple:

$$\Phi_1(x_k) = \boldsymbol{e}_k \quad (k = 1, 2, \ldots, N) \tag{5}$$

where $H = \boldsymbol{R}^N$ and $\boldsymbol{e}_k$ is the k-th unit vector that has unity as ith component and all other components are zero. Note that $\Phi_1 \colon X \to \boldsymbol{R}^N$, i.e., $\Phi(\cdot)$ is not defined on $\boldsymbol{R}^p$ but is limited to the finite set X. We also assume that the inner product of $\boldsymbol{R}^N$ is

$$\langle \boldsymbol{e}_k, \boldsymbol{e}_\ell \rangle = K(x_k, x_\ell) \tag{6}$$

instead of the standard inner product $\langle \boldsymbol{e}_k, \boldsymbol{e}_\ell \rangle = \delta_{k\ell}$ ($\delta_{k\ell}$ is the Kronecker delta).

We have the next proposition.

Proposition 1: If kernel function $K(x, y)$ is positive-definite, $\langle \boldsymbol{e}_k, \boldsymbol{e}_\ell \rangle$ defined by (6) satisfy the axioms of the inner product of $\boldsymbol{R}^N$, that is, $\boldsymbol{R}^N$ with (6) is an inner product space.

(*Proof*) The detailed proof is given in standard textbooks [7]. As a rough sketch of the proof, note that the Mercer condition [8]

$$\int \int K(x, y) \eta(x) \eta(y) dx dy \geq 0$$

for all $\eta(x)$ guarantees

$$\sum_{i,j} K(x_i, x_j) \zeta_i \zeta_j \geq 0$$

$\forall \zeta_i \in \boldsymbol{R}$, by putting $\eta(x) = \sum_i \zeta_i \delta(x - x_i)$. Thus the matrix $K = (K(x_i, x_j))$ is positive semi-definite. (*QED*)

We introduce second explicit mapping that may be more time consuming in calculation but useful in applications. Note that a positive definite matrix K can be divided into $K = K^{\frac{1}{2}} K^{\frac{1}{2}}$. We thus define the second mapping:

$$\Phi_2(x_k) = K^{\frac{1}{2}} \boldsymbol{e}_k \quad (k = 1, 2, \ldots, N) \tag{7}$$

In this case, $\Phi_2 \colon X \to \boldsymbol{R}^N$, i.e., the domain and the codomain are the same as Φ_1, but now the inner product of $\boldsymbol{R}^N$ is standard:

$$\langle \boldsymbol{e}_k, \boldsymbol{e}_\ell \rangle = \delta_{k\ell}. \tag{8}$$

We now apply mappings Φ_i ($i = 1, 2$) to fuzzy c-means clustering. It is sufficient to show the optimal solution of W_i.

Proposition 2: For all positive semi-definite kernel $K(x, y)$ and mapping Φ_1 by (5), the cluster centers are given by

$$W_i = \left(\frac{(u_{1i})^m}{\sum_{k=1}^{N} (u_{ki})^m}, \ldots, \frac{(u_{ni})^m}{\sum_{k=1}^{N} (u_{ki})^m} \right)^T, \quad i = 1, \ldots, c \tag{9}$$

When Φ_2 by (7) is used, the cluster centers are given by

$$W_i = K^{\frac{1}{2}} \left(\frac{(u_{1i})^m}{\sum_{k=1}^{N} (u_{ki})^m}, \ldots, \frac{(u_{ni})^m}{\sum_{k=1}^{N} (u_{ki})^m} \right)^T, \quad i = 1, \ldots, c \tag{10}$$

(*Proof*) The proof of this proposition is not difficult by observing closely (2). Note that W_i given by (2) is the solution of

$$\min_{W_i} \sum_{k} (u_{ki})^m \|x_k - W_i\|^2$$

where the space can be an arbitrary inner product space, since the derivation of (2) uses a general variational principle valid for any Hilbert space. Note moreover that we substitute (9) into (1) to have the optimal solution of U. It should be noted that although optimal W_i is the same for all positive definite

kernel, optimal U differs because (6) give different values for different kernels. (*QED*)

The proof of the next proposition is almost trivial and is omitted.

Proposition 3: Substituting (9) or (10) into (3), we have (4).

That is, (9) (or (10)) derived from mapping (5) (or (7)) has all necessary and sufficient information for kernel fuzzy c-means clustering.

The mappings (5) and (7) are moreover useful for application to SOM [3] and VQ clustering [5], where vectors for updating quantization vectors should be based on learning. The explicit mappings enable vector representations in $\boldsymbol{R}^N$, and hence we can use every formulas in VQ and SOM.

C. L_1 space fuzzy c-means

Let us consider a method specific to an explicit mapping. Although kernel-based methods assume Euclidean spaces, we use an L_1 space clustering [5], which may be useful in applications. The L_1 space fuzzy c-means clustering uses

$$J_H(U,W) = \sum_{i=1}^{c}\sum_{k=1}^{N}(u_{ki})^m \|\Phi(x_k) - W_i\|_{L_1}, \quad (m>1),$$

where we assume the second mapping: $\Phi(x_k) = K^{\frac{1}{2}}\boldsymbol{e}_k$. Hence

$$\|\Phi(x_k) - W_i\|_{L_1} = \sum_{j=1}^{N} |(K^{\frac{1}{2}}\boldsymbol{e}_k)^j - W_i^j|$$

where $\boldsymbol{z}^j$ is j-th component of $\boldsymbol{z}$.

Accordingly the solution is

$$u_{ki} = \left[\sum_{j=1}^{c}\left(\frac{\|\Phi(x_k) - W_i\|_{L_1}}{\|\Phi(x_k) - W_j\|_{L_1}}\right)^{\frac{1}{m-1}}\right]^{-1},$$

while calculation of W_i needs an algorithm of an weighted median [5] of which the details are omitted for simplicity. We note, however, that calculation of an weighted median is frequently faster than the weighted centroid in the ordinary L_2-space based method.

Note also that this algorithm is valid only for the explicit mapping, since it does not assume an Euclidean feature space.

D. Low dimensional approximation of kernels

Another method specific to the explicit mapping is a low dimensional approximation of kernels. As we will see in the next section of numerical examples, the effectiveness of a kernel data analysis frequently depends on a small dimension of those subspaces of a few top eigenvalues of the kernel matrix. This means that a low dimensional approximation of the kernel simplifies the analysis and yet preserves its effectiveness. Such approximation is also suitable when an original kernel matrix is not known to be positive-definite. Then we can take a subspace of a number of top positive eigenvalues.

Let us assume that the original $N \times N$ kernel matrix K is decomposed into

$$K = T^\top \Lambda T,$$

where T is an orthogonal matrix which is composed of eigenvectors, and

$$\Lambda = diag(\lambda_1, \lambda_2, \ldots, \lambda_N)$$

is the diagonal matrix of eigenvalues with $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_N$. Let us consider D-dimensional approximation by taking

$$\hat{\Lambda} = diag(\lambda_1, \lambda_2, \ldots, \lambda_D, 0, \ldots, 0),$$

where $D < N$ and $\lambda_D > 0$. Accordingly we put

$$\hat{K} = T^\top \hat{\Lambda} T,$$

and use $\hat{K}$ instead of K. We thus assume $\Phi_2(x_k) = \hat{K}^{\frac{1}{2}}\boldsymbol{e}_k$, where

$$\begin{aligned}\hat{K} &= T^\top \hat{\Lambda}^{\frac{1}{2}} T \\ &= T^\top diag(\sqrt{\lambda_1}, \sqrt{\lambda_2}, \ldots, \sqrt{\lambda_D}, 0, \ldots, 0)T.\end{aligned}$$

It is easily seen that the feature space is now D-dimensional and when $D << N$, we have a low-dimensional approximation of the kernel space.

Note 1: This approximation appears similar to the kernel principal component analysis, but the concepts and the derivations are different. The method herein is an approximation of kernel K, while the kernel principal component analysis is approximation of a covariance matrix. Note also that, when D is two or three, we can visualize the 'principal part' of a kernel feature space. Thus the low dimensional approximation is useful as a visualization method for the feature space.

III. Numerical Examples

A set of data shown in Fig. 1 was used to show the effectiveness of the proposed method. This example is well-known in the sense that a usual fuzzy c-means (abbreviated as FCM) algorithm cannot separate the outer circle and the inner ball, while a kernel-based c-means algorithm can. Figure 2 depicts the result of an ordinary FCM, while Fig. 3 with the kernel-based FCM with the explicit mappings of the Gaussian kernel successfully separated the two groups.

Moreover Fig. 4 shows two major principal components with mapping Φ_2, where the method of the ordinary principal component analysis has been applied. In contrast, Figure 5 shows the two-dimensional approximation ($D = 2$) of the Gaussian kernel, which shows a similar, yet different configuration of the points.

The same result of perfect separation in Fig. 2 was obtained by the L_1-based method with an L_1 exponential kernel:

$$K(x,y) = \exp(-const\|x - y\|_{L_1})$$

which has been proved to be a kernel function [8], [2]. The two-dimensional approximation with this kernel is shown in Fig. 6.

Note that both Φ_1 and Φ_2 give the successful separation in Fig. 2 because they are equivalent to (4), while Φ_1 cannot

be used for the principal component analysis, since the coordinates for Φ_1 does not satisfy $\langle \boldsymbol{e}_k, \boldsymbol{e}_\ell \rangle = \delta_{k\ell}$ which is necessary in the principal component analysis.

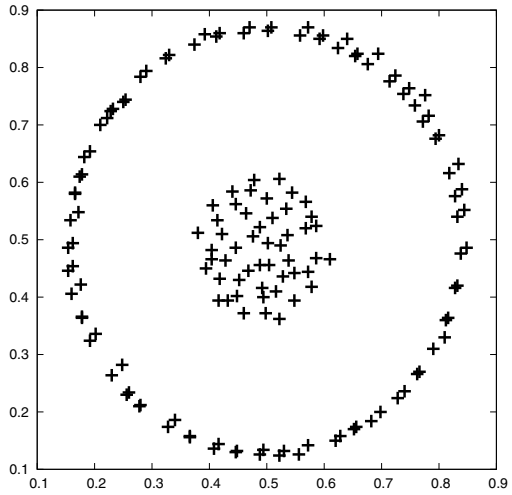

Fig. 1. A ball in a circle with 150 data points.

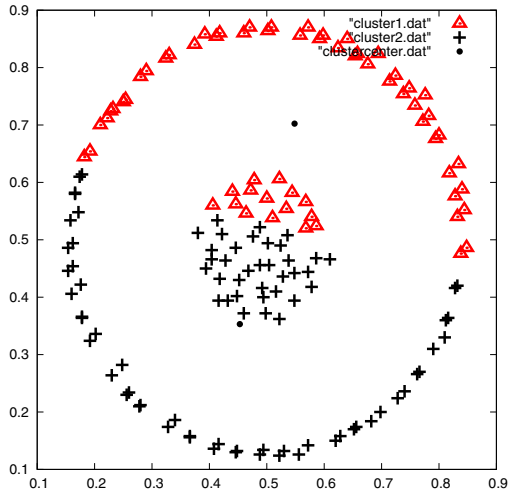

Fig. 2. The result of ordinary FCM applied to data in Fig. 1.

IV. Conclusions

We have proposed the method of explicit mappings for kernel based data analysis. Either one of Φ_1 and Φ_2 can be used, as there is no fundamental difference between the two, but the second mapping seems to be more useful in applications. Indeed, the L_1-based method and the low dimensional approximation of kernels has been developed for the second mapping. The low dimensional approximation is also useful when we do not know whether a kernel function is positive-definite or not, since it may be difficult to prove positive-definiteness in real applications.

In summary, we note the following advantages of the present method.

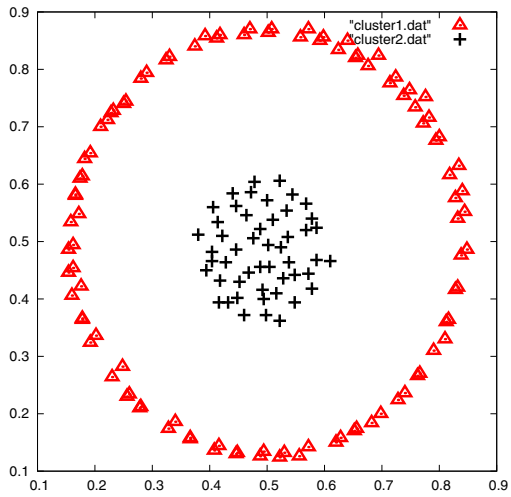

Fig. 3. The result of kernel-based FCM applied to data in Fig. 1.

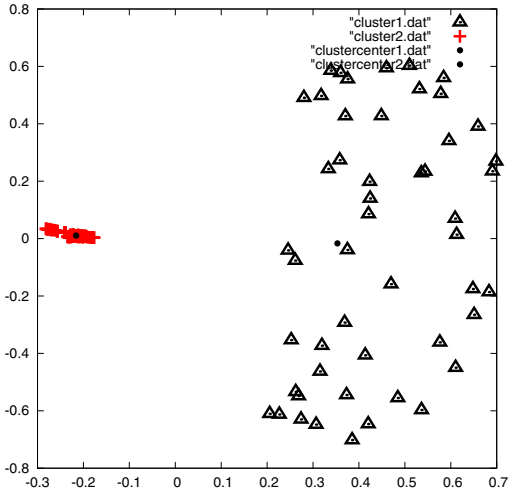

Fig. 4. The display of two major principal components to data in Fig. 1 with mapping $\Phi_2(x_k)$.

1) Using this mapping, we do not lose any fundamental information in kernel data analysis.
2) Generally the derivation becomes simpler using this mapping.
3) New applications of the kernel methods become possible using this mapping.

The last statement should be further studied. In relation to fuzzy clustering, the method of fuzzy c-varieties [1] should be considered. We also have many research possibilities related to SOM and LVQ [3].

Moreover we have other possibility to use nonlinear methods of data analysis such as LLE [6] to the transformed data, where the above explicit mapping is essential. Without such a mapping, we cannot apply a nonlinear tool of data analysis.

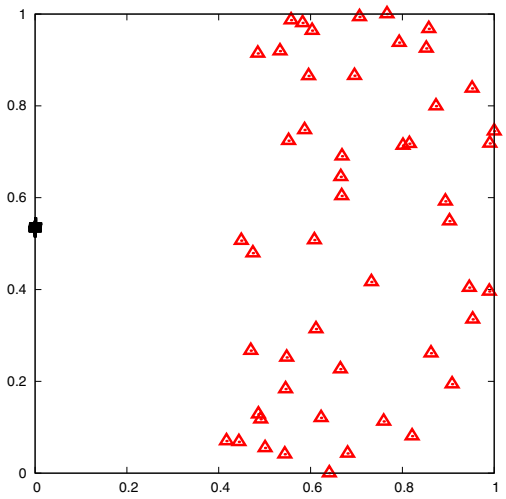

Fig. 5. The display of the low dimensional approximation to data in Fig. 1 with mapping $\Phi_2(x_k)$.

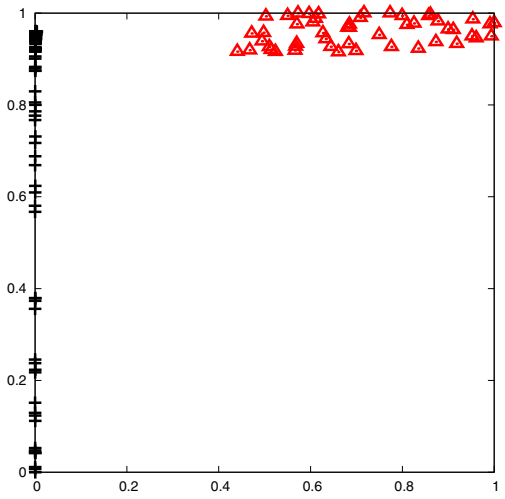

Fig. 6. The display of the low dimensional approximation to data in Fig. 1 with mapping $\Phi_2(x_k)$. L_1-based FCM with L_1-exponential kernel was applied.

Comparison of Scaling Behavior Between Fuzzy c-Means Based Classifier with Many Parameters and LibSVM

Hidetomo Ichihashi, Katsuhiro Honda, Akira Notsu

***Abstract*—This paper reports the scaling behavior of the fuzzy c-means based classifier (FCMC) with many parameters. FCMC is a classifier based on clustering approaches. The classification accuracy on test sets (i.e., the generalization capability) is not necessarily improved by increasing the number of clusters. Especially when the number of training samples is relatively small, not only the classification boundary over-fits the data, but also covariance matrices and cluster centers are computed incorrectly, since the number of samples in each cluster becomes smaller. Hence, the test set accuracy deteriorates.**

The performance of FCMC with two clusters in each class and the number of training samples less than 1000, was reported in the literature. This paper reports the scaling behavior of FCMC by testing with variously-sized training samples. The number of clusters of FCMC is increased up to eight. The number of clusters used in this paper is not very large but the number of parameters is relatively large. So, the parameters are optimized to training sets.

LibSVM is one of the widely known state of the art tools for support vector machines (SVM). The test set accuracy, training time and testing time (i.e., the detection time) of FCMC are compared with LibSVM by varying the size of training sets. FCMC shows a good generalization capability, though the parameters are optimized to training sets. When the number of training samples is increased by 10 times, the training time of FCMC increases by 10 times, but that of LibSVM increases by a factor of 100. The testing time is also much shorter than LibSVM when the size of the training set is large.

***Index Terms*—classifier, clustering, large data set, scaling behavior.**

I. Introduction

Fuzzy c-means based classifier (FCMC) [1], [2], [3], [4] is a classifier based on clustering approaches. We put FCMC in practical use for the vehicle detection system at several parking lots in Japan [4].

In this paper, for testing scaling behaviors of FCMC, the number of clusters is increased up to 8 for each class. Large-sized training sets with samples from 100,000 to 1,000,000 are used and the size of the training set is variously varied. Mixing proportions of clusters are parameterized. So, FCMC has many parameters, though the number of clusters is not very large. The parameters are optimized to training sets and the test set accuracy is evaluated on the test set.

When the number of training samples is relatively small, the classifier tends to over-fits the data. The obtained covariance matrices and cluster centers become incorrect, because the number of samples in each cluster is small.

For parameter optimization, PSO [5], [6], [7] is implemented just because PSO is as simple as the random search method. The selection of the optimization method is not essential because small improvement in training time on average is not significant in practice.

Support vector machines (SVMs) deliver superb performance in many real-world applications. SVMs are the standard tools for machine learning and data mining. We also give results with LibSVM: a library for support vector machines by Chang and Lin [8] for the sake of comparison. LibSVM incorporates SMO [9], which is a standard in SVM resolution for large size data sets and LibSVM is a state-of-the-art approach to SVM.

We need to compare the performance of FCMC from the following two points of view.

1) Comparison of scaling behaviors by varying the number of training samples. The number of clusters in each class is increased up to 8, and the mixing proportions of clusters are parameterized for FCMC. The parameters are optimized to training sets and are not regarded as free parameters.

2) Comparison of classification performances on very large datasets, when the number of clusters in each class is increased as many as possible for FCMC. The number of free parameters is set to less than or equal to 3 and the rage for parameter search is limited for both FCMC and LibSVM.

This paper reports the results of 1). Free parameters (hyper-parameters) of LibSVM and FCMC, which are optimized to test sets or validation sets, are assumed to be known from the knowledge about the given set of data. Our results indicate that FCMC surpasses LibSVM with properly chosen parameters in classification accuracy when the size of training set is reduced by sampling. So, we can reduce the training time by a simple sampling of training data. For FCMC, the training time and the testing time are proportional to the size of training set and the size of testing set respectively.

The choice of the free parameters of SVM does not only

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

influence greatly the accuracy but also the training and testing time. These computation times are usually difficult to estimate in advance because the time largely depends on the number of support vectors, which is not known in advance. Our experiments on LibSVM show similar behaviors as those reported in the literature concerning training size and performance.

The advantages of FCMC with many parameters are the high generalization capability and the fast testing time.

II. Fuzzy c-Means Based Classifier

The first phase of FCMC is clustering or partitioning, which is modified from [10], [11]. See [3] for details of the derivation of the algorithm. The objective function of FCM with regularization by Kullback-Leibler divergence (KLFCM) [12], [10] is linearized and the update rules are derived by using Lagrangian multiplier method. Let $x_k \in \mathcal{R}^p$ be a feature vector and

$$D(x_k, v_i; S_i) = (x_k - v_i)^\top S_i^{-1}(x_k - v_i) \tag{1}$$

be squared Mahalanobis distance from x_k to $v_i \in \mathcal{R}^p$. S_i is a covariance matrix of data samples of the i-th cluster written as:

$$S_i = \frac{\sum_{k=1}^N u_{ki}(x_k - v_i)(x_k - v_i)^\top}{\sum_{k=1}^N u_{ki}}. \tag{2}$$

$$v_i = \frac{\sum_{k=1}^N u_{ki} x_k}{\sum_{k=1}^N u_{ki}} \tag{3}$$

is a cluster center and the mixing proportion of i-th cluster is

$$\alpha_i = \frac{\sum_{k=1}^N u_{ki}}{\sum_{j=1}^c \sum_{k=1}^N u_{kj}} = \frac{1}{N}\sum_{k=1}^N u_{ki}. \tag{4}$$

c denotes the number of clusters and N denotes the number of samples. The above updating rule is repeated and called as the generalized hard c-means [12], [11].

Initial locations of cluster centers or membership values are usually given randomly in the clustering approach. Since the classification performance is sensitive to the initialization, our approach does not use random initializations and use the principal component analysis (PCA) instead. Let $f_k, k = 1, ..., N$ be PCA scores of the data set $X = (x_1, ..., x_N)^\top$ of a class. f_k are associated with the largest singular value of mean corrected X. First, initial membership values of the two clusters of a class are given by

$$\begin{aligned} u_{k1} &= \begin{cases} 1 & (f_k \le 0) \\ 0 & (\text{otherwise}) \end{cases} \\ u_{k2} &= \begin{cases} 0 & (f_k \le 0) \\ 1 & (\text{otherwise}). \end{cases} \end{aligned} \tag{5}$$

This bisection method is repeated on each cluster, and the number of clusters (c) is increased. The resultant leaf nodes of the binary tree are the clusters. In this paper, the number of clusters is less than or equal to 8 for each class. The number of parameters to be optimized by PSO increases with the number of clusters (c). Moreover, when c is large, the number of training samples in each cluster becomes small, and covariance matrices and cluster centers become inaccurate. This leads to the deterioration of classification accuracy. We can not use many more clusters for testing scaling behaviors.

One of the impediments for FCMC is the singularity of covariance matrices, which frequently occurs when feature dimension is relatively high and the number of samples in each cluster is small. So, the low-rank approximation of covariance matrices in the mixture of probabilistic principal component analysis (MPCA) [13] and the character recognition [14] is applied. By reducing the number r of basis vectors in the approximation of S_i, the algorithm becomes stably convergent. When r=0, S_i is a diagonal matrix, hence is non-singular, and $D(x_k, v_j; S_j)$ is reduced to Euclidean distance. The clustering is done on a per class bases.

The classification (i.e., the second phase) is performed by computing fuzzy memberships. Let π_q denote the mixing proportion of class q, i.e., the $a\ priori$ probability of class q. Let α_{qj} be α_i in (4) for cluster j of class q. The class membership of k-th data x_k to class q is computed as:

$$u^*_{qjk} = \alpha_{qj}|S_{qj}|^{-\frac{1}{\gamma}}(D(x_k, v_{qj}; S_{qj}) + \nu)^{-\frac{1}{m}}, \tag{6}$$

$$\tilde{u}_{qk} = \frac{\pi_q \sum_{j=1}^c u^*_{qjk}}{\sum_{s=1}^Q \pi_s \sum_{j=1}^c u^*_{sjk}}, \tag{7}$$

where c denotes the number of clusters of each class and Q denotes the number of classes. We selected the functional form of u^* based on the membership functions derived from the generalized FCM objective function [12] and that of FCM with regularization by Kullback-Leibler divergence [12], [10].

At the completion of clustering for all classes in the first phase of FCMC, we then compute Mahalanobis distances by (1) for all the samples in the training sets. The second phase of FCMC is the supervised classification and the parameters, i.e., $m \in [0, 2], \gamma \in [0, 20], \nu \in [0, 200]$ and the change rates of $\alpha_{qj} \in [-0.5, 0.5]$ (see [3]), are selected to minimize error rate on the training sets. Since we have Q classes and c clusters for each class, the number of α_{qj} is $Q \times c$. The distances by (1) for all the samples in the training set are fixed and the best setting of the parameters are searched by PSO [5], [6], [7]. The free parameters (C, γ) of LibSVM in Section III are chosen to fit the given test set. But, the parameters $(m, \gamma, \nu, \alpha_{qj})$ of FCMC are optimized to training set since the number of parameters is much larger than LibSVM. After the optimization, the test set accuracy on the test set is evaluated.

III. Experiments

In this Section, we implement FCMC and LibSVM, and illustrate the scaling behavior of FCMC on several benchmark data sets. Table I summarizes the characteristics of the data sets used. The parking lot image data were used for the vehicle detection system in [4]. Checkerboard data are artificial data. Other data sets are downloaded from http://www.cse.ust.hk/~ivor/cvm.html (Ivor W. Tsang, Andras Kocsor, James T. Kwok [15]). FCMC is implemented in

Matlab. FCMC has several to dozens of parameters, which are optimized by PSO. But FCMC has other parameters that are not automatically optimized. They are the number c of clusters and the number r of basis vectors for the low-rank approximation of covariance matrices. c is chosen from $\{2, 4, 8\}$ and $r \in \{0, 2, 5, 20, 40, 30\}$ and they also need to be selected. But in this paper, we assume that these two parameters are the free parameters and their optimum values are known from the knowledge about the given data sets. The free parameters (C, γ) of LibSVM are also assumed to be known. We use the Gaussian kernel $k(x, y) = \exp(-\gamma|x-y|^2)$ for nonlinear classification. The kernel parameter γ and the regularization parameter C are the free parameters of LibSVM.

For medium-sized problems, cross validation might be the most reliable way for parameter selection. But, for large-sized problems as in Table I, it is hard to implement cross validation procedure since it takes very long computation time. Therefore, in this paper PSO in FCMC is used for optimizing training accuracy on training set. Then, we evaluate the accuracy on the given test set. The free parameters of LibSVM are also chosen manually. We tested various parameter values including those reported in the literatures of SVM, and we report the best results.

Experiments are performed on DELL T5400 3.16GHz, 4GB. Each experiment reports the error rate on test set, the training time on training set, and the testing time (i.e., the detection time).

TABLE I
DATA SETS USED FOR PERFORMANCE COMPARISON

data	features	training	testing
Parking lot image	50 (1,024)	135,000	135,000
USPS zero-one	50 (676)	266,079	75,383
Checkerboard	2 (2)	1,000,000	2000
KDD-CUP 1999	5 (127)	2,449,216 (4,989,431)	311,029
MNIST	50 (576)	60,000	10,000

Parking Lot Image Data

First, we use the set of image data with 50 feature dimensions. The image data are used for the vehicle detection system in [4]. The camera images of a parking lot are first stored in JPEG format of 704 × 576. Vehicle/parking space sub-windows are cropped from each picture. Each RGB image of the sub-windows is thinned as 32×32×3 and transformed into HSV and then into gray scale image of 32×32 (=1,024). 50 PCA (principal component analysis) basis vectors were computed using a subset of sample images. PCA for image compression is also know as the Hotelling, or Karhunen and Leove (KL), transform. All the collected gray scale image data were compressed by multiplying PCA basis vectors (i.e., inner product). The obtained 270,000 vectors with 50 feature dimensions were used. The first half (135,000 image data) is used for training and the latter half (135,000) is used for testing. The best accuracy by LibSVM is obtained with $C = 1.0$ and $\gamma = 5.0$. We found this parameter values by testing many times. We make the training size varies. Fig. 1 shows the results for experiments where the training size is growing. The error rate of FCMC on the test set is smaller than LibSVM as shown in Fig. 1, though the training time (dashed line) is slightly longer than LibSVM with the proper values of C and γ. The straight line with circles show the result of FCMC with the best settings of the parameters, while the dashed line shows the result by PSO for each reduced set of training samples. It should be noted that to increase the numbers of iterations and particles of PSO does not necessarily improve the testing accuracy, since PSO optimize the parameters to training sets. The straight line with circles shows the results when the parameters are fixed to the best setting, i.e., the change rate of α_{qj}= (0.2035, 0.7642, 0.3540, 0.1885, 0.7342, 0.7632, 0.4914, -0.1085, 0.6106, 0.1501, 0.7356, 0.5202, 0.4685, 0.9049, 0.2748, 1.1440), m=0.1143, γ=8.2049, and ν=173.8178. The testing time of LibSVM is much longer than that of FCMC when the size of training set is large as shown in Fig. 3. For FCMC, we set as c=8, and r=30. The number of particles in PSO is 50 and the number of iterations is 10 (denoted as 50×10).

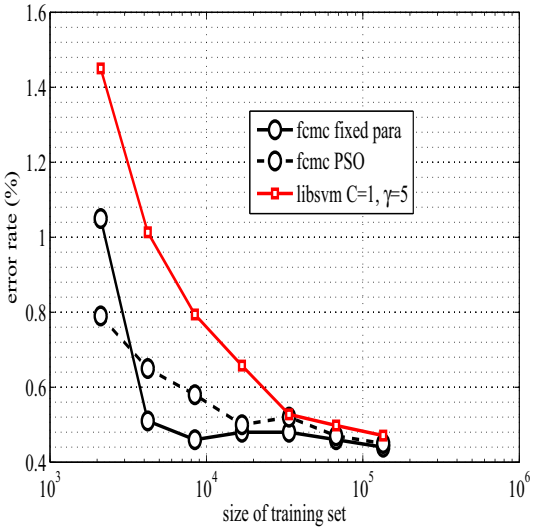

Fig. 1. Error rates (%) on the test sets of the parking lot image data (FCMC: PSO 50×10, c=8, r=30). Note that the size of the training set is in log scale.

Extended USPS Zero-one Data

In this experiment, our task is to classify digits zero from one in an extended version of the USPS data set. The original training set has 1,005 zeros and 1,194 ones, while the test set has 359 zeros and 264 ones. To better study the scaling behavior, Tsang, Kwok and Cheung [15] extend this data set by first converting the resolution from 16×16 to 26×26, and then generate new images by shifting the original ones in all directions for up to

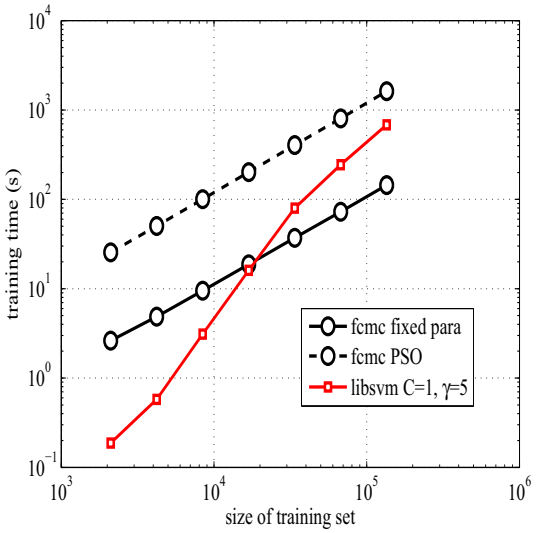

Fig. 2. Training time (s) on the parking lot image data (FCMC: PSO 50×10, c=8, r=30). Note that the training time is also in log scale.

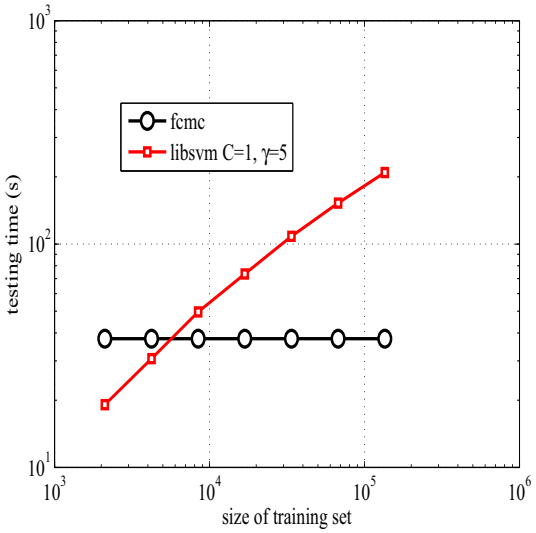

Fig. 3. Testing time (s) on the test sets of the parking lot image data (FCMC: PSO 50×10, c=8, r=30)

five pixels. Thus, the resultant training set has a total of (1005+1194)×112 =266,079 samples while the extended test set has (359+264)×112 = 75,383 samples (http://www.kernel-machines.org/data/usps.mat.gz). 50 PCA basis vectors were computed using a subset of image data. All the image data were compressed by multiplying PCA basis vectors. The obtained training and testing samples with 50 feature dimensions were used. As shown in Fig. 4, the accuracy of LibSVM deteriorates with the decreasing number of training samples. The straight line with circles show the result of FCMC with the best settings of the parameters, while the dashed line shows the result by a single trial of PSO (20×10) for each reduced set of training samples. Therefore, the training time can not be reduced for LibSVM by a simple sampling of the training data, though FCMC's accuracy is high for a wide range of training set sizes. When the size of training set is larger than 30,000, the best set of the parameters in terms of testing accuracy is $C = 1, \gamma = 0.03$ for LibSVM, and the training time is nearly equal to FCMC with $c = 8$, and $r = 5$. This, however, is true only when we know the best parameter values. If we test LibSVM with $C = 1, \gamma = 0.1$, it takes 10 times longer than FCMC as shown in Fig. 5. So, the total training time including parameter search may become extremely long for LibSVM. And, the testing time is longer than that of FCMC by more than an order of magnitude as shown in Fig. 6.

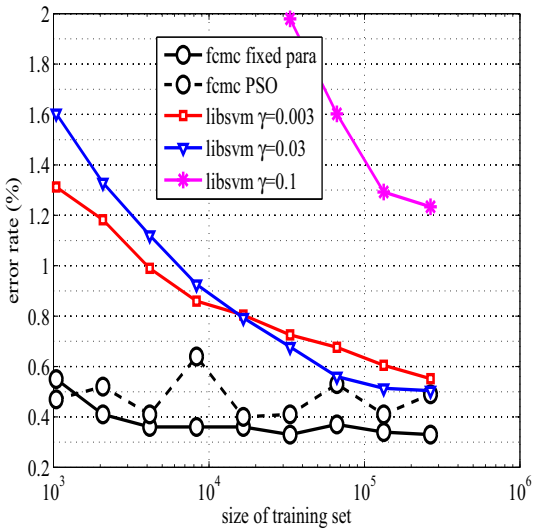

Fig. 4. Error rates (%) on the test sets of the extended USPS digits data (LibSVM: C=1, FCMC: PSO 20×10, c=8, r=5).

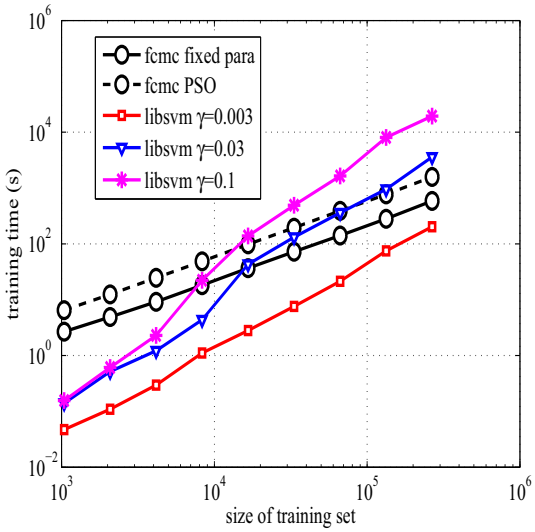

Fig. 5. Training time (s) on the extended USPS digits data (LibSVM: C=1, FCMC: PSO 20×10, c=8, r=5)

Checkerboard Data

We experiment on the 4×4 checkerboard data commonly

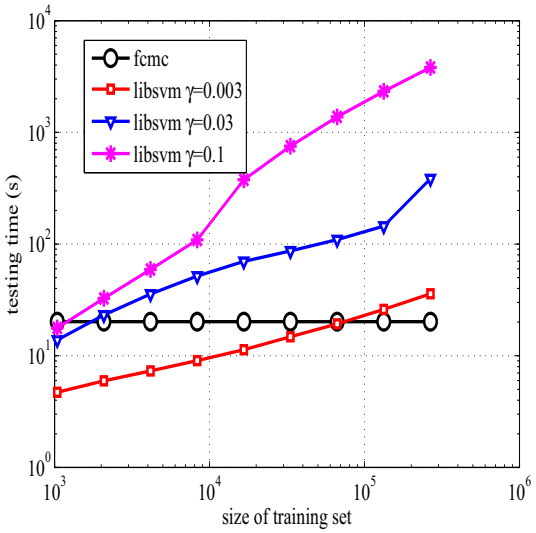

Fig. 6. Testing time (s) on the test sets of the extended USPS digits data (LibSVM: C=1, FCMC: PSO 20×10, c=8, r=5)

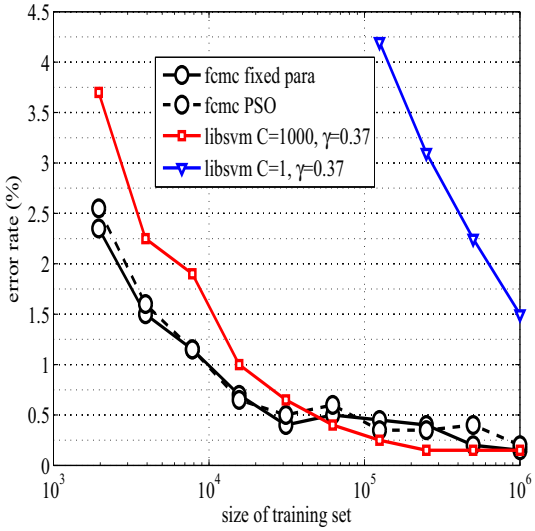

Fig. 7. Error rates (%) on the test sets of the checkerboard data (FCMC: PSO 50×10, c=8, r=0)

used for evaluating large-scale non-linear SVM implementations [15], [16]. We use training sets with a maximum of 1 million points and 2,000 independent points for testing.

Fig. 7 shows that the accuracy of both approaches deteriorates as the training samples are reduced by sampling. For relatively small training sets, with less than 100,000 samples, the error rate of LibSVM is twice larger than FCMC. But, LibSVM is faster as shown in Fig. 8. When the number of training samples is 1,000,000, the training time is nearly the same. This, however, is true when we know the best parameter values of LibSVM. If we test LibSVM with $C = 10, \gamma = 0.001$, it takes 10 times longer than FCMC. So, the total training time of LibSVM for parameter search may become extremely long. The testing time for LibSVM with the best parameter setting is 10 times longer than FCMC as shown in Fig. 9. As we know the clusters are all squares of the same size on the checker board and the number of clusters is 8 for each class. we set as $c = 8, r = 0$

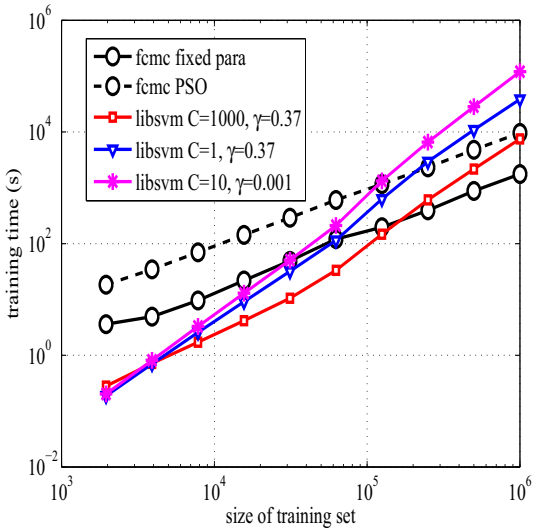

Fig. 8. Training time (s) on the checkerboard data (FCMC: PSO 50×10, c=8, r=0)

KDDCUP-99 Intrusion Detection Data

This intrusion detection data set has been used for the Third International Knowledge Discovery and Data Mining Tools Competition, which was held in conjunction with KDD-99. Each original sample has 34 continuous features and 7 symbolic features (http://kdd.ics.uci.edu/databases/kddcup99/kddcup99.html). The original training set contains 4,898,431 connection records, which are processed from about four gigabytes of compressed binary TCP dump data from seven weeks of network traffic. Another two weeks of data produced the test data with 311,029 samples. The data set includes a wide variety of intrusions simulated in a military network environment. There are a total of 24 training attack types, and an additional 14 types that appear in the test data only. The task is to separate normal connections from attacks. We used 2 million samples for training. Each sample is compressed with PCA and has only 5 feature (PCA score) dimensions because of not enough memory. As the test results show, the accuracy does not deteriorate by the significant reduction of the feature dimensionality. This is the case only for the KDD data. We computed 5 PCA basis vectors by using first 300,000 training samples and then multiply them with all training and testing samples. We used the compressed data for both FCMC and LibSVM.

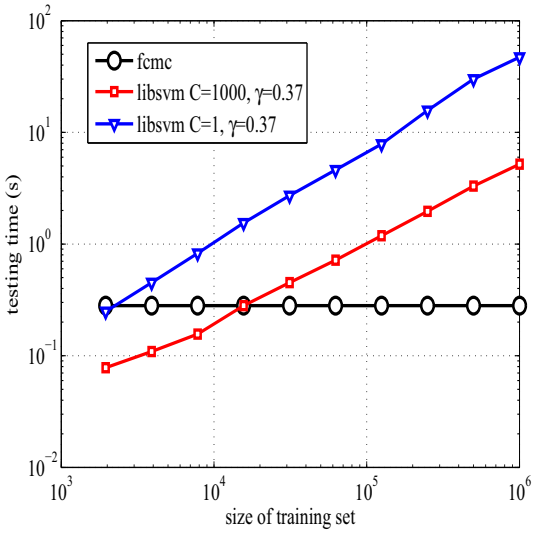

Fig. 9. Testing time (s) on the test sets of the checkerboard (FCMC: PSO 50×10, c=8, r=0)

When $C = 1,000,000$ and $\gamma = 0.1$, LibSVM attains the best accuracy, but the differences between LibSVM with some other parameter settings and FCMC are slight for a wide range of sizes of training samples as shown in 10. The training time for FCMC is shorter than LibSVM when the size is larger than 1,000,000 as shown in Fig. 11. The testing time is shorter than LibSVM with $C = 1, \gamma = 0.0001$ by two orders of magnitude as shown in Fig. 12.

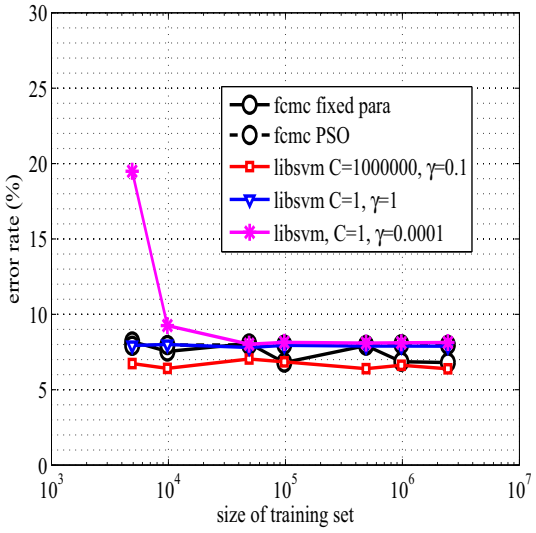

Fig. 10. Error rates (%) on the test sets of the KDD data (FCMC: PSO 20×10, c=2, r=2)

MNIST Data

The MNIST database of handwritten digits (10-class problem), has a training set of 60,000 samples, and a test set of 10,000 samples. It is a subset of a larger set available from NIST by LeCun research group at AT&T lab [17]. A 576-dimensional directional feature based

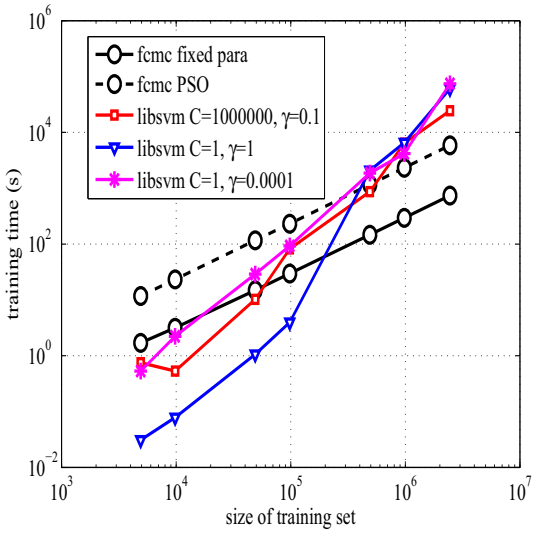

Fig. 11. Training time (s) on the KDD data with (FCMC: PSO 20×10, c=2, r=2)

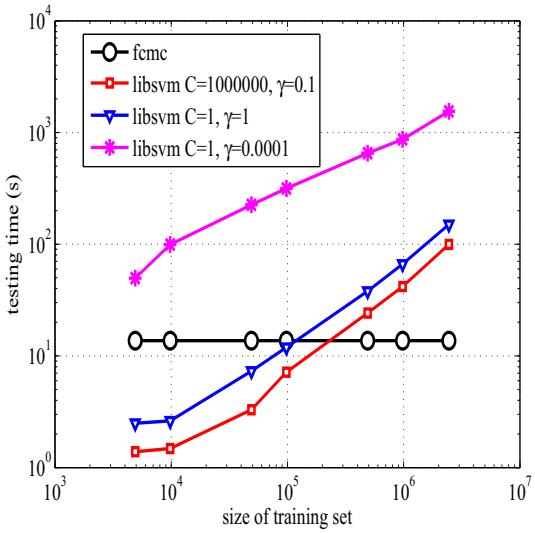

Fig. 12. Testing time (s) on the test sets of the KDD data (FCMC: PSO 20×10, c=2, r=2)

on gradient of gray-level image was extracted by using Robert edge operator. The data set is available from http://www.cenparmi.concordia.ca/~jdong/HeroSvm.html.

Results are shown in Figs. 13-15. When the number of training samples is smaller, the accuracy of FCMC is better for $c = 2$, but when the number is larger than 20,000, $c = 8$ is better. LibSVM use the "one-against-one" approach in which $Q(Q-1)/2$ classifiers are constructed and each one trains data from two different classes. In classification a voting strategy is used: each binary classification is considered to be a voting where votes can be cast for all data points x - in the end point is designated to be in a class with maximum number of votes. LibSVM's training time and testing time is short, since the number of training samples handled by each classifier is small. We used the same data set of 50 dimensional feature vectors for

both LibSVM and FCMC. It should be noted that the training time does not include the time for parameter search, hence in practice a long computation time is indispensable for LibSVM.

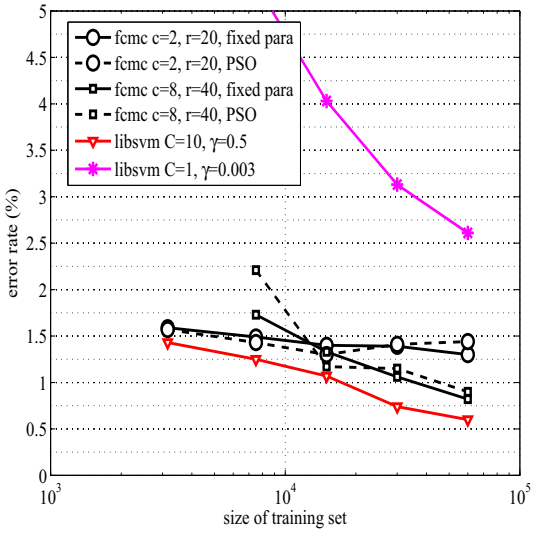

Fig. 13. Error rates (%) on the test sets of the MNIST 10-class data (FCMC: PSO 20×10)

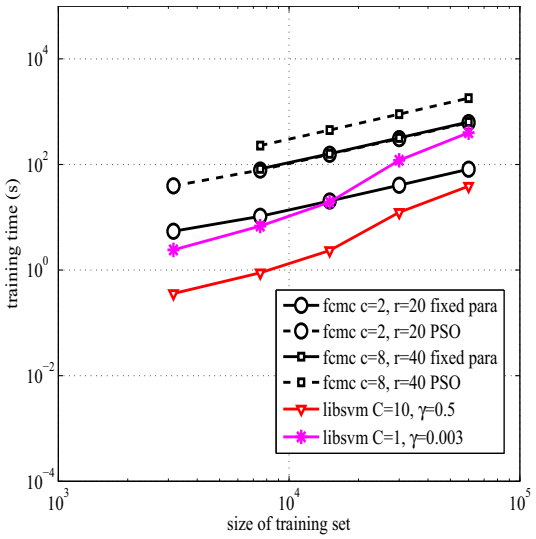

Fig. 14. Training time (s) on the MNIST 10-class data with (FCMC: PSO 20×10)

IV. Conclusion

We have demonstrated the performance of FCMC by comparing with LibSVM. We used five large sized data sets whose feature values are mainly continuous real numbers.

When the number of clusters of FCMC is increased, in order for cluster covariance matrices and cluster centers to be correctly estimated, a very large-sized training set is necessary. Therefore, we tested the performance with the number of clusters less than or equal to 8, and the number of parameters $c \times Q + 3$. The results are summarized as follows:

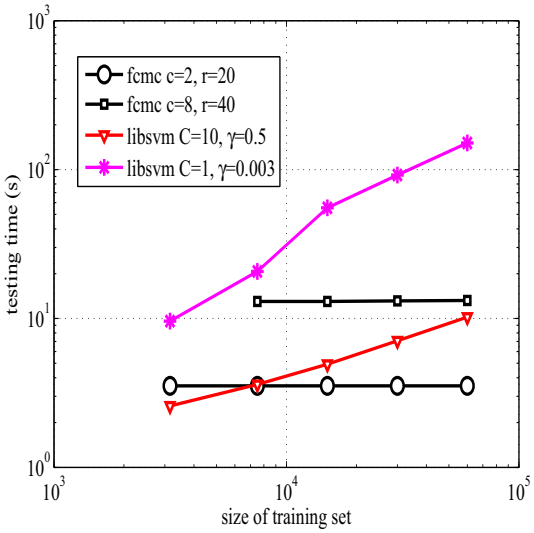

Fig. 15. Testing time (s) on the test sets of the MNIST 10-class data (FCMC: PSO 20×10)

1) When the number of training samples is large, the difference in the test set accuracy (i.e., the generalization capability) between FCMC and LibSVM is slight.

2) When the size of training set is reduced, the test set accuracy of FCMC surpasses LibSVM in many data sets.

3) Training time of FCMC proportionally increases with the size of training set (i.e., $O(N)$). But, the time needed for LibSVM increases more rapidly than FCMC (i.e., $O(N^2)$ for LibSVM). Thus, the training is faster than LibSVM, when the size of training set is large.

4) The testing time (detection time) is faster than LibSVM by an order of magnitude, when the size of training set is large.

There may be other types of benchmark data such as those with many categorical features. To confirm the discriminative power on various benchmark data is left for our future work.

***Abstract*—Shell clustering methods partition data sets into several shell-shape clusters by extracting local circles or ellipses as prototypes of clusters. This paper proposes hard c-regression models (HCRMs) for shell clustering. The procedure is a defuzzified switching regression models. HCRMs successfully detect ellipses by using random initializations. We report the performance using 20 data sets each of which consists of two ellipses. The detection time on average is 14 milliseconds on DELL PRECISION T5400 3.16GHz.**

***Index Terms*—ellipse detection, clustering, switching regression, random initializations.**

I. Introduction

Figs. 1-2 illustrates an application of ellipse detection, where a robot grasps a saucer placed upside-down. First, Sobel edge detection method is applied on the gray scale image. Then the coordinate of pixels on the edges are picked by thresholding the gray scale values and thinned by sampling every 10 points. The data set consisted of the coordinate of points on edge is used for ellipse detection. The robot can know the relative position of the saucer precisely and can grasp it correctly, since the mathematical formula of the ellipses are obtained.

A standard method of detecting ellipses is the Hough transform (HT). The Hough transform extracts geometrical parameters of an image and maps them into the Hough domain. Standard HT, however, is not really used for fast ellipse detection since it requires a lot of computational processing. An ellipse has five parameters and requires intensive memory.

The 5-dimensional parameter space is decomposed into several subspaces of fewer dimensions via parallel edge points in [3]. A multistage HT approach using the polar and pole definition of ellipses has been proposed in [4]. Ellipses were extracted by relating local geometric features of a parametric representation to the local features in an image in [5]. In [6] a global geometric symmetry method was utilized to locate the centers of ellipses and circles and then used the accumulative concept of the Hough transform to extract all ellipses and circles in an image. Another HT variant is the Randomized Hough Transform (RHT) [7] which is well-suited to ellipse detection due to its lessened usage of memory and fast processing characteristic as proposed in [8].

Some non-Hough transform methods were also proposed for detecting ellipses. Dave [9] used the fuzzy c-shells to detect circles and ellipses. Shell clustering methods divide data into clusters, each one representing a circle or an ellipse. Fuzzy c-Shells (FCS) [9] and Adaptive Fuzzy c-Shells (AFCS) [10] are represented by a prototype of nonlinear function; FCS is effective for dividing data into circle clusters and into ellipse clusters. However for each iteration, it is necessary to solve a set of nonlinear equations, so there is a problem in terms of complexity. R. Krishnapuram's Fuzzy c-Spherical

Shells (FCSS) [11] improves the computational efficiency by calculating prototypes analytically with "algebraical" distance. Fuzzy c-Quadratic Shells (FCQS) adopts quadratic polynomial as a distance function, and extracts clusters in the shape of ellipsoid, hyperbola, and parabola. Probabilistic approach for FCQS and robust FCQS which are less affected by noise also have been studied [12], [13], [14]. FCV-based robust shell clustering is proposed but there are problems in terms of computational time [15].

For improving computational time and detection accuracy, we defuzzify fuzzy c-regression models (FCRM) [16] and formulate hard c-regression models (HCRMs). Hence, the first half of our approach can be regarded as one of the switching regression models [1], [2] on an extended high dimensional space. The approach is based on an objective function. The procedure is repetitive and the termination condition by using another error evaluation function is adopted.

HCRMs quickly extract circles or ellipses by repeating random initializations. We test the performance using 20 data sets and report that the detection time on average is 14 milliseconds.

II. Shell clustering with hard c-regression models

Fuzzy c-regression models (FCRM) regards c-regression equations as clustering prototypes. In this section, we formulate the methods which capture nonlinear structures of data sets efficiently by applying hard clustering to FCRM.

Two dimensional data (i.e., points on a plane), each of which is written as $\mathbf{x}_k = (x_{k1}, x_{k2})^\top$, are extended as:

$$\mathbf{x}_k^* = (x_{k1}, x_{k2}, {x_{k1}}^2, {x_{k2}}^2, x_{k1}x_{k2})^\top \quad k = 1, \cdots, n, \tag{1}$$

where $\mathbf{x}_k^*$ denotes the vector of dependent variables. We minimize the squared errors of the following regression equation so that z_{ki} is as close to 1 as possible.

$$\begin{aligned} z_{ki} &= a_{i1}x_{k1} + a_{i2}x_{k2} + a_{i3}{x_{k1}}^2 \\ &+ a_{i4}{x_{k2}}^2 + a_{i5}x_{k1}x_{k2} \\ &= \mathbf{x}_k^{*\top}\mathbf{a}_i \\ \mathbf{a}_i &= (a_{i1}, a_{i2}, a_{i3}, a_{i4}, a_{i5})^\top, \end{aligned} \tag{2}$$

where i denotes the cluster number ($i = 1, \cdots, c$). (2) represents an ellipse when z_{ki} is a positive constant. We choose $\mathbf{a}_i$ such that z_{ki} are all close to a constant value. The constant value can be 1, and the squared error between 1 and z_{ki} is defined as:

$$\begin{aligned} d_{ki}^2 &= (a_{i1}x_{k1} + a_{i2}x_{k2} + a_{i3}{x_{k1}}^2 \\ &+ a_{i4}{x_{k2}}^2 + a_{i5}x_{k1}x_{k2} - 1)^2 \\ &= (\mathbf{x}_k^*\mathbf{a}_i - 1)^2 \end{aligned} \tag{3}$$

and the objective function is defined as:

$$L = \sum_{i=1}^{c}\sum_{k=1}^{n} u_{ki}d_{ki}^2. \tag{4}$$

$u_{ki} \in [0,\ 1]$ is the membership and 1 or 0 is assigned to u_{ki}, since L is linear with respect to u_{ki}. For updating u_{ki}, following rule is adopted.

$$u_{ki} = \begin{cases} 1 & (i = \arg\min_{1\le j\le c} d_{kj}^2), \\ 0 & (\text{otherwise}). \end{cases} \tag{5}$$

Regression coefficient $\mathbf{a}_i$ is the least squares estimator of the following simultaneous equations.

$$\begin{bmatrix} u_{1i}\mathbf{x}_1^{*\top}\mathbf{a}_i \\ u_{2i}\mathbf{x}_2^{*\top}\mathbf{a}_i \\ \vdots \\ u_{ni}\mathbf{x}_n^{*\top}\mathbf{a}_i \end{bmatrix} = \begin{bmatrix} u_{1i} \\ u_{2i} \\ \vdots \\ u_{ni} \end{bmatrix}. \tag{6}$$

Let us rewrite (6) as:

$$X\mathbf{a}_i = \mathbf{u}_i. \tag{7}$$

Then, $\mathbf{a}_i$ is computed with singular value decomposition

$$X = Z\Lambda P^\top, \tag{8}$$

where Z is an n $\times$ 5 matrix, Λ is the diagonal matrix of singular values $\lambda_j, j = 1, ..., 5$, and $P^\top$ denotes the transpose of P, an 5 $\times$ 5 matrix. Column vectors of Z and P are all length 1.

By using the pseudoinverse, the solution becomes:

$$\mathbf{a}_i = P\Lambda^+ Z^\top \mathbf{u}_i, \tag{9}$$

where Λ^+ is a inverse of Λ and $1/\lambda_j$ is replaced by zero when $\lambda_j = 0$. This solution procedure is embedded by certain programming languages, such as Matlab.

As $\mathbf{a}_i$ and u_{ki} are updated repeatedly, the above mentioned regression method can be seen as one of the switching regression models [1], [2]. In our proposed method, initial values of $\mathbf{a}_i$ are given randomly and then the initial membership values are calculated. We choose $\mathbf{a}_i$ which minimize the objective

function L. But, for example, for data set 4 in Fig. 3, L often becomes smaller when the detection is false than when the detection is correct. So, we repeatedly change initial values until the following evaluation function E becomes less than a given threshold e.

$$E = \sum_{i=1}^{c} \left(\sum_{k=1}^{n} u_{ki}\beta_{ki} \mid \mathbf{x}_k - \mathbf{v}_i \mid / \sum_{k=1}^{n} u_{ki} \right) \tag{10}$$

$\mathbf{v}_i$ is a center and $\mid \cdot \mid$ denotes the Euclidean distance. β_{ki} is calculated such that $\mathbf{y}_k$ is the projection of $\mathbf{x}_k$ on the oval.

$$\begin{gathered} \mathbf{y}_k = \mathbf{x}_k + \beta_{ki}(\mathbf{x}_k - \mathbf{v}_i) \\ \mathbf{y}_k^{*\top} \mathbf{a}_i = 1, \end{gathered} \tag{11}$$

where $\mathbf{y}_k^*$ are extended 5 dimensional data of $\mathbf{y}_k$. The smallest absolute value of β_{ki} is chosen.

The procedure is repeated to a maximum of r-times if the condition $E < e$ is not met, then $\mathbf{a}_i$ which minimizes E is chosen.

The detection algorithm using the above mentioned update rules is as follows.

1. Extend $\mathbf{x}_k$ to $\mathbf{x}_k^*$.
2. Initialize regression coefficients $\mathbf{a}_i$ randomly.
3. Compute the errors by (3).
4. Update the membership value u_{ki} by (5).
5. Update $\mathbf{a}_i$ by (6).
6. If the change in the objective function values (4) becomes small enough ($|L^{old} - L^{new}| < 10^{-7}$), then go to 7, else go to 3.
7. Compute evaluation function (10) for detecting ellipses.
8. If repetition time is less than r and $E > e$, then go to 2, else go to 9.
9. Select $\mathbf{a}_i$ which minimizes the evaluation function (10).

In the next section we set as $r = 200$ and $e = 0.02$.

III. Detection Performance

To evaluate the effectiveness of the proposed method, experiments were conducted using the 20 different data sets shown in Figs. 3-4. Table II-I shows the results. Initial values of $\mathbf{a}_i$ are given as:

$$\begin{aligned} \mathbf{a}_1 &= (2.10561.3352 - 1.6725 - 1.6585 - 0.1724) \times 1.1 \\ &+ (rand - 0.5) \times 2 \\ \mathbf{a}_2 &= (2.10561.3352 - 1.6725 - 1.6585 - 0.1724) \times 1.8 \\ &+ (rand - 0.5) \times 2 \end{aligned}$$

where $rand$ denotes a vector of uniform random numbers $rand \in [0, 1]$. The program stops when E in (10) is less than 0.02.

Each data set is tested 10 times and values of E, detection times and the number of repetitions (i.e., the numbers of initializations of $\mathbf{a}_i$ until $E < 0.02$ is satisfied) are given in Tables II-III. In all cases, the algorithm terminated before reaching the final termination condition ($r = 200$). For Data set 1, E=0.0107 is attained in 18 milliseconds on average. The detected ellipses are shown in Fig. 3 upper left. For example, the maximum detection time for Data set 10 is 6 milliseconds, the mean time is 4 milliseconds and the minimum time is 3 milliseconds. Table I shows the results on all data sets. The mean detection time on all the data sets is 14 milliseconds. Experiments are performed on DELL PRECISION T5400 3.16GHz 4GB.

TABLE I
DETECTION TIME ON ALL DATA SET

	E	time (s)	repetitions (initializations)
Max	0.0197	0.155	155
Mean	0.0139	**0.014**	11.2
Min	0.0075	0.002	1

The methods based on Hough transform are most popular for ellipse detection. By comparison, the time for detecting two ellipses by Hough-based ellipse detection algorithm is about 1500 seconds and that of Randomized Hough Transform is about 15 seconds [8]. 10% detection error at minimum is reported in [8].

IV. Conclusion

The shell clustering method in this paper is based on the hard c-regression models with random initializations. An additional evaluation function is used for terminating the repetitive algorithm. With this enhancement, HCRM accurately detects circles or ellipses very quickly.

Our possible future work includes setting more effective initial random values, coping with a large number of clusters, and robustizing the method by using the noise clustering approach [17].

***Abstract*—In a world of constant technological evolution, the expansion of location tracking technologies is a fact. Most of us may have a device which can tell us our location with more or less accuracy. Most of those devices collect our location information and, usually, the trajectories we make. Publishing this information is essential for companies to improve their marketing strategies, for the traffic department in order to have some control about the traffic, and for many other entities. With the publishment of this information an important problem arises, the privacy. On the literature, many approaches to trajectory protection are provided. We contribute to the scene providing a framework with a protection method and measures for both the computation of the perturbation added to the data, and the risk of linking a protected trajectory to its original.**

***Index Terms*—Trajectory anonymization, location privacy, information loss, disclosure risk.**

I. Introduction

Nowadays, it is very common to have devices equiped with technologies that can localize you, such as smartphones, GPS navigators, etc. Those devices can store data about the trajectories you made. Those trajectories might be very useful for companies, e.g. they can know which are the most common places that people visit, the most transited roads, etc. The problem here is that this data can easily compromise your privacy. If this data falls in the hands of the wrong person, he could identify an individual and have the information about all their moves, which can be highly dangerous. The rationale, in order to avoid this, is to protect the data. There are many approaches in the literature for this purpose such as [1], [2], [3], and [4] between others. Some of them, for example [1], [2], and [3], only focus on protecting the data. Others, like [4], prevent the disclosure and try to preserve the data utility as high as possible. There is literature that focus on using generalization as a protection method, like in [1]. Generalization receives n trajectories and it returns n undistinguishable trajectories. Therefore, the re-identification of an individual becomes more difficult. In this paper, we focus on using microaggregation as a protection method, like in [4], and we provide a framework to evaluate the information loss (i.e. the amount of perturbation added to the data) and the disclosure risk. In contrast to [4], our work aims to be as generic as possible for the information loss calculation. This is specially important as there is a wide range of uses that this data can be given. This paper is organized as follows. In Section 2 we present some preliminar information that will be used across all the text. In Section 3 we talk about protection methods and we present our approach. In Section 4, the information loss measures are presented. In Section 5, we explain the disclosure risk measure we use. In Section 6, we present the experiments made in order to validate our framework and we present the results. Finally, Section 7 concludes and give some directions for future research.

II. Preliminaries

In this section we review several definitions on trajectories that are needed in the rest of the paper.

A. Trajectories

A trajectory can be defined as a sequence of places or spots that a given object or person has gone through. We will define each place or spot with their coordinates x and y and a timestamp t that determines the time when the object or person was there. Therefore, we can define formally a trajectory as:

$$\{(x_1, y_1, t_1), (x_2, y_2, t_2), \ldots, (x_n, y_n, t_n)\} \text{ where } n \in \mathbb{N}$$

In this way, we can observe a trajectory as numerical data that varies over time, and thus we can find similarities with the definition of time series. Recall that they are defined as:

$$\{(x_1, t_1), (x_2, t_2), \ldots, (x_n, t_n)\} \text{ where } n \in \mathbb{N}$$

Given this, we can easily adapt distances and statistics from time series to trajectories. The first part of this section includes a section for distances and another for the autocorrelation function. The original distances were taken from [5].

B. Distances between trajectories

As we have already pointed out, there is a similarity between trajectories and time series. Due to this, we take two distance functions from time series and adapt them to trajectories. Trajectories can be totally overlapped over time, partially overlapped over time, or non overlapped at all. The distances adapted should take into account all those cases. It is important, though, that when we apply a distance to a pair of trajectories, the two trajectories have the same number of points.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

1) Adapted Euclidean Distance: The common Euclidean distance does not take into account the time. As the distance between two trajectories partially overlapped over time should be less than the distance between two trajectories non overlapped, we need to include the time factor in the distance calculation.

Given two time series r and s as follows

$$r = \{p_1, p_2, \ldots, p_n\}$$
$$s = \{q_1, q_2, \ldots, q_n\}$$

with their elements p_i and q_i represented as

$$p = (p_x, p_y, p_t)$$
$$q = (q_x, q_y, q_t)$$

we can define the Adapted Euclidean Distance between r and s as:

$$d_{EU}(r, s) = \sqrt{\sum_{i=1}^{n} d_e(r_i, s_i)}$$

where

$$d_e(p, q) = (1 + (p_t - q_t)^2) \cdot ((p_x - q_x)^2 + (p_y - q_y)^2)$$

2) Adapted Short Time Series Distance: Adapting the Short Time Series distance to trajectories is quite straightforward. It is enough to add the y coordinate to the distance formula. Therefore, we can define the Adapted Short Time Series Distance as:

$$d_{STS_A}(r, s) = \sqrt{\sum_{i=1}^{n} d_s(r_i, s_i)}$$

where

$$d_s(p, q) = \left[\left(\frac{q_{x_{i+1}} - q_{x_i}}{q_{t_{i+1}} - q_{t_i}} - \frac{p_{x_{i+1}} - p_{x_i}}{q_{t_{i+1}} - q_{t_i}}\right)^2\right] + \left[\left(\frac{q_{y_{i+1}} - q_{y_i}}{p_{t_{i+1}} - p_{t_i}} - \frac{p_{y_{i+1}} - p_{y_i}}{p_{t_{i+1}} - p_{t_i}}\right)^2\right]$$

C. Adapted Autocorrelation Function

The Autocorrelation function applied to time series is used in [5] as part of the computation of data utility. In the same way as the distances, we adapt this function to work with trajectories. Again, it is quite straightforward. It is enough to add the y coordinate to the formula.

Given the time series r represented by

$$r = \{p_1, p_2, \ldots, p_n\}$$

with the elements p_i with the following components

$$p = (p_x, p_y, p_t)$$

we can define the Adapted Autocorrelation Function as:

$$\rho(h) = \frac{\gamma'_A(h)}{\gamma'_A(0)}$$

where

$$\gamma'_A(h) = n^{-1} \cdot \sum_{i=1}^{n-|h|} \left(p_{x_{t+|h|}} - \mu_x\right) \cdot \left(p_{x_t} - \mu_x\right) + \left(p_{y_{t+|h|}} - \mu_y\right) \cdot \left(p_{y_t} - \mu_y\right)$$

and

$$\mu_x = \frac{1}{n} \sum_{i=1}^{n} p_x$$
$$\mu_y = \frac{1}{n} \sum_{i=1}^{n} p_y$$

III. Protection Methods

As stated before, the objective of trajectory anonymization is to preserve the privacy of the individuals whose trajectory data has been collected. In order to achieve this, we need a protection method.

Given a data set X a protection method transforms X into a protected data set X'. In general, X can be seen as a matrix with n rows (records) and m columns (attributes). We can classify the attributes in two types: identifiers and quasi-identifiers. A given attribute is considered an identifier when it unambiguously identifies an individual (e.g the social security number), in contrast an attribute is considered a quasi-identifier when it can not identify an individual by itself but a set of them can. Note that a concrete group of quasi-identifier attributes can identify an individual depending on the scenario. E.g. age and sex can be quasi-identifiers in a small company but not in a class. Quasi-identifier attributes can be divided in two classes: confidential and non-confidential depending on whether they contain private information. For instance, let us imagine that an attacker A has some quasi-identifier attributes of an individual, as e.g age, birth place, sex and medical history. The first three attributes are non-confidential while the last one is confidential. In a very large database those attributes would not give the attacker the necessary information to identify an individual as lots of people of the same sex may have been born in the very same place at the same year. But if we have a different scenario, e.g. a database with the employees of a company, where those quasi-identifier attributes are unique in the whole data set, the attacker could clearly identify the individual.

Our scenario is the same as the scenario presented in [5]. In the standard scenario (see eg. [6] [7] [8] [9] [10] [11]) before releasing a data set X with confidential attributes, a protection method ρ is applied, leading to a protected data set X'. Indeed, we will assume the following: (i) identifier attributes in X are either removed or encrypted, therefore we will write $X = X_{nc}||X_c$; (ii) confidential quasi-identifier attributes X_c are not modified, so we have $X'_c = X_c$; (iii) the protection method itself is applied to non-confidential quasi-identifier

attributes in order to preserve the privacy of the individuals whose confidential data is being released. Therefore, we have $X'_{nc} = \rho(X_{nc})$.

In the remaining part of this section we discuss microaggregation, one of the most effective data protection methods. We describe our approach for applying microaggregation to trajectories.

A. Microaggregation

Microaggregation is a protection method that ensures k-anonymity by building small clusters of at least k elements and replacing the original values with the centroid of the cluster to which the record belongs to.

In order to solve the information loss problem of the basic microaggregation method, multivariate microaggregation is used at the cost of increasing the disclosure risk. Specifically, after dividing attributes into different blocks and applying the basic microaggregation technique to each block separately. This means that the k records which fall in the same cluster for the first block of attributes, may fall in a different cluster for any of the other block of attributes. So, the resulting protected records will not be equal and no k-anonymity is ensured.

In order to preserve information loss as low as possible, microaggregation methods try to minimize the total sum of distances between all the elements to be protected and the centroid of the cluster where an element belongs to, i.e. to minimize the total Sum of Square Errors (SSE):

$$SSE = \sum_{i=1}^{C} \sum_{x_{ij} \in C_i} (X_{ij} - \bar{X}_i)^T (X_{ij} - \bar{X}_i),$$

where c is the total number of clusters, C_i is the ith cluster and $\bar{x}_i$ is the centroid of C_i. The restriction is $|C_i| \geq k$, for all $i = 1, \ldots, c$. In general, the larger the value of k the lower the disclosure risk. Therefore, in order to parametrize microaggregation methods, k has to be large enough to ensure confidentiality but not too large to compromise the statistical utility of the protected information.

The rationale of this process is to make the protected data as similar as possible to the original one. In any case, methods should provide clusters with at least k elements. Finding the optimal multivariate microaggregation has been proven to be an NP-Hard problem. For this reason, heuristic methods have been proposed in the literature.

In our work, we will adapt for trajectories one of the most used methods for heuristic multivariate microaggregation: the MDAV (Maximum Distance to Average Vector) algorithm.

B. MDAV microaggregation

The *MDAV (Maximum Distance to Average Vector)* algorithm is an heuristic algorithm for clustering records in a data set X so that each cluster is constrained to contain at least k records. You can see the *MDAV* algorithm description in Algorithm 1.

The generic *MDAV* algorithm can be used for different data types, but then it requires the appropiate definitions for distance and average. When we want to apply the *MDAV* algorithm to a particular type of data, we need to define what the most distant record means, which the closest records of a given record are, and the average record of a set of records. The average vector will be used in step (3) and to mask the original data in steps (4) and (8).

Algorithm 1: MDAV

Input: X: original microdata, k: integer
Output: X': protected microdata
1: **while** $|X| > k$ **do**
2: Compute the average record $\bar{x}$ of all records X
3: Consider the most distant record x_r to the average record $\bar{x}$
4: Form a cluster around x_r. The cluster contains x_r together with the $k-1$ closest records to x_r
5: Remove these records from microdata file X
6: **if** $|X| > k$ **then**
7: Find the most distant record x_s from record x_r
8: Form a cluster around x_s. The cluster contains x_s together with the $k-1$ closest records to x_s
9: Remove these records from microdata file X
10: **end if**
11: **end while**
12: Form a cluster with the remaining records

C. Trajectory microaggregation

In order to apply the *MDAV* algorithm to trajectories we need to determine which distance and which average functions we are going to use in order to implement the general *MDAV* algorithm described in Algorithm 1.

- **Distance functions.** We use our *Adapted Euclidean Distance* and our *Adapted Short Time Series Distance*, which were already explained in section 2.
- **Average.** As we are working with trajectories, using an average function would not give realistic results. Given a cluster, when doing the aggregation process, that is, the step when you replace the original values with the centroid of the cluster, if the centroid is computed with an average function, the microaggregated trajectories could have points that fall inside a building, which would be correct if the individual is a pedestrian, but not if it is an automobile. In the latter case, the trajectory would not have any utility. We assume that there can not be points inside a building. In order to avoid that, we propose two approaches based on the median function.
  - The first approach, which we call *(X median, Y median)*, is to calculate the median for the X coordinate of points of different trajectories that have the same timestamp t and fall into the same cluser. Then, do the same with the Y coordinate, so you end up having a trajectory that represents all the trajectories in that cluster.
    E.g. Given the trajectories r, s and u defined as

$$r = (r_1, r_2, r_3)$$
$$s = (s_1, s_2, s_3)$$
$$u = (u_1, u_2, u_3)$$

    where

$$r_1 = (3, 6, 1), r_2 = (1, 7, 2), r_3 = (8, 5, 3)$$
$$s_1 = (2, 9, 1), s_2 = (7, 8, 2), s_3 = (2, 4, 3)$$
$$u_1 = (0, 3, 1), u_2, = (6, 2, 2), u_3 = (9, 2, 3)$$

we calculate the median for the X and Y coordinate of the points with the same timestamp t, resulting in a single trajectory v. That is,

$$v = (v_1, v_2, v_3)$$

where

$$v_1 = (2, 6, 1), v_2 = (6, 7, 2), v_3 = (8, 4, 3)$$

– The second approach, which we call *(X median, Y)* is not very different. Again, calculate the median for the X coordinate of the same points of the different trajectories that fall into the same cluster. Then instead of doing the same with the Y coordinate, search through all the trajectories in the same cluster for that X value, and get the corresponding Y value. This gives a trajectory with real points (i.e. points that will not fall inside a building), that represents all the trajectories in that cluster.
E.g. Given the trajectories r, s and u that fall into the same cluster, defined as

$$r = (r_1, r_2, r_3)$$
$$s = (s_1, s_2, s_3)$$
$$u = (u_1, u_2, u_3)$$

where

$$r_1 = (3, 6, 1), r_2 = (1, 7, 2), r_3 = (8, 5, 3)$$
$$s_1 = (2, 9, 1), s_2 = (7, 8, 2), s_3 = (2, 4, 3)$$
$$u_1 = (0, 3, 1), u_2, = (6, 2, 2), u_3 = (9, 2, 3)$$

we calculate the median for the X coordinate of the points with the same timestamp t and get the Y coordinate corresponding to that X value, resulting in a single trajectory v. That is,

$$v = (v_1, v_2, v_3)$$

where

$$v_1 = (2, 9, 1), v_2 = (6, 2, 2), v_3 = (8, 5, 3)$$

In section 6 we show how one approach or the other, affect the results.

IV. Information Loss measures

Trajectories information can have a wide range of uses. It can be used by companies to improve their advertisement strategy, for marketing purposes, for traffic control, etc. In our scenario, we assume no concrete use can be specified before its protection.

When applying any perturbative methods to protect a data set, there is always some kind of information loss. I.e, the perturbation inflicted to the data decreases their utility. As we would like to minimize this loss, we need a measure to compare different perturbations due to different parameters within a method or even different methods.

Information loss clearly depends on the uses that will be given to the protected data. Nervertheless, as stated above we focus on generic uses. In this case, it is desirable to have a generic way to measure this information loss. It should reflect the amount of perturbation that is being added with a given protection method and the decay of data utility for a range of data uses.

In order to achieve this goal, we define information loss in terms of three components: IL_1, IL_2, IL_3. They are partial information loss measures described below.

- IL_1. It is defined as the average value of the measures $IL_{1.1}$ and $IL_{1.2}$ which are defined below. That is,

  $$IL_1 = \frac{IL_{1.1} + IL_{1.2}}{2}$$

  $IL_{1.1}$ is the average of the difference between the means of both original and protected trajectories, and $IL_{1.2}$ is the average of the difference between the autocorrelation functions of both original and protected trajectories. They are defined by:

  $$IL_{1.1} = \frac{1}{2s}\left(\sum_{i=1}^{s} \frac{|\mu_{x_i} - \mu'_{x_i}|}{Max(|\mu_{x_i}|, |\mu'_{x_i}|)} + \frac{|\mu_{y_i} - \mu'_{y_i}|}{Max(|\mu_{y_i}|, |\mu'_{y_i}|)}\right)$$

  $$IL_{1.2} = \frac{1}{4}\sum_{h=0,n/4,n/2,3n/4}\left(\frac{1}{s}\sum_{i=1}^{s} \frac{|\rho_i(h) - \rho_i(h)'|}{Max(|\rho_i(h)|, |\rho_i(h)'|)}\right)$$

  where s is the number of trajectories in the given data set, μ_x the average of the X coordinate, μ_y the average of the Y coordinate, and the $\rho_i(h)$ is the *Adapted Autocorrelation Function* explained on the preliminaries.
- IL_2. It is defined as the absolute differences between original and protected data. That is,

  $$IL_2 = \frac{1}{2 \times s \times n}\sum_{i=1}^{s \times n}\left(\frac{||x_i| - |x'_i||}{Max(|x_i|, |x'_i|)} + \frac{||y_i| - |y'_i||}{Max(|y_i|, |y'_i|)}\right)$$

  where s is the number of trajectories in the given data set, n the number of points of a trajectory (i.e. its length), x and y the coordinates of a point that belongs to a non protected trajectory and x' and y' the coordinates of a point that belongs to a protected trajectory. Each pair of x, y - x', y' has the same timestamp t.

- IL_3. This measure was taken from [4] and is called *Space Distortion*. The aim of this measure is to capture the distortion of the shape of an anonymized trajectory. The definition on [4], takes into account that the distances used for the protection process are not defined for all kind of trajectories (i.e. totally overlapped over time, partially overlapped over time or non overlapped over time). As our distances can be applied to all of those trajectories we can simplify the Space Distortion measure presented in [4]. The *Simplified Space Distortion measure (SSD)* is defined as

$$SSD = \sum_{i=1}^{s} \sqrt{(x_i - x'_i)^2 + (y_i - y'_i)^2}$$

where s is the number of trajectories of a given data set, x and y the coordinates of a point that belongs to a non protected trajectory and x' and y' the coordinates of a point that belongs to a protected trajectory. Each pair of x, y - x', y' has the same timestamp t.
After the SSD calculation, a min-max range normalization is applied as it is desirable to have this value in the range $[0, 1]$.

V. Disclosure risk measure

When protecting trajectories or any data in general, the main goal is to maintain the privacy of the individuals. As it is desirable to keep the data useful, the protection method has to try to achieve a minimum information loss. The problem is that while the information loss decreases, it resembles more the original data and, therefore, the disclosure risk increases. Then a way to measure this disclosure risk is needed.

A. Record Linkage method

One direct approach to measure the disclosure risk is to get both the original and protected data and try to establish some links between the individuals in both data sets. That is what an attacker would do in case he gets the original and protected data sets. This method is based on the standard *Distance Based Record Linkage (DB-RL)* which can only be applied when a distance measure exists between a pair of records. This method links every protected record to the closest original one. Here, we use two different distances. Those distances are the same that were used in the microaggregation process, i.e. *Adapted Euclidean Distance* and *Adapted Short Time Series Distance*. Consider *AEULD (Adapted Euclidean distance Linkage Disclosure)* and *ASTSLD (Adapted Short Time Series distance Linkage Disclosure)*, then, we compute the disclosure risk (DR) as

$$DR = Max(AEULD, ASTSLD)$$

The DB-RL process for trajectories is detailed below, in Algorithm 2.

Algorithm 2: Trajectory Record Linkage

Input: X: original data set, k: protected data set
Output: X': LP: linked pairs
1: **foreach** $a \in X$ **do**
2: $b' = arg_min_{b \in X'} d_{tr}(a, b)$
3: $LP = LP \cup (a, b')$
4: **end foreach**

VI. Experiments

In this section we present the experiments we made, in order to empirically analyze our framework. The experiments consist in applying our protection method to some data sets (those data sets are explained in detail later in this section). Once the data sets are protected, the information loss and the disclosure risk is computed. As stated before, as information loss decreases, disclosure risk increases, and viceversa. Due to this, a trade-off between the two measures is needed to evaluate the method. There are several approaches in the literature, some of them use a graphical representation, for instance R-U maps [12], others are analytical. For example, in [13] , the authors use a combination of both information loss and disclosure risk, which they call *Score*, using the arithmetic mean between these two values. In this way, we can have a numerical value to determine the effectiveness of the method in different scenarios. The score is defined as

$$score = \frac{IL + DR}{2}$$

where IL is the information loss measure and DR the disclosure risk measure. Note that the lower the score, the best is the protection method.

A detailed explanation of the data sets we used as well as the process applied for the experiments and the commented results are found below.

A. Data sets

When doing experiments it is desirable that the data sets are real data from the real world instead of random generated data. In our case, in order to get data sets as real as possible, we used Brinkhoff's generator [14] to obtain trajectories of moving entities. The trajectories generated this way, have the same behaviour that would have real trajectories. That is because moving objects in a city usually follow a network (e.g. the street map) made of interconnected nodes (e.g. cross-streets), and also because of the large ammount of trajectories generated as well as their variable length. The synthetic trajectories are precisely generated this way. This generator has also been used for evaluation of approaches like [15] and [16]. We generated 1049 trajectories separated in 10 different data sets. The generated trajectories are over the map of Oldenburg in Germany, with 5 moving entities (object classes). As the object classes can represent different moving entities such pedestrians or automobiles, the microaggregation process is applied to each object class separately.

B. Process

In the clustering part of the microaggregation process, there is a parameter k that constraints each cluster to have at least k trajectories. Due to this, varying this parameter affects the final results as the microaggregated trajectories will not be the same for different values of k. Therefore, in our experiments, we considered applying the protection process for different values of k to each data set. That is, $k \in \{2, 3, 6, 9, 12, 14\}$. As we stated before, in the microaggregation we have two ways of doing the aggregation process. Recall that *(X median, Y median)* is the process where the median for the X coordinate and the median for the Y coordinate is calculated, and *(X median, Y)* the process where the median for the X coordinate is calculated and its corresponding Y coordinate is taken. We also stated before that we use two different distances, the *AEUD (Adapted Euclidean Distance)* and the *ASTSD (Adapted Short Time Series Distance)*. This gives us two more ways of applying the microaggregation. The experiments take into account those two distances as well as the *(X median, Y median)* and *(X median, Y)* methods for doing the aggregation process.

C. Results

This section presents the results on our experiments. In order to present them as clearly as possible, we only present the common behaviours detected from the analyzed results.

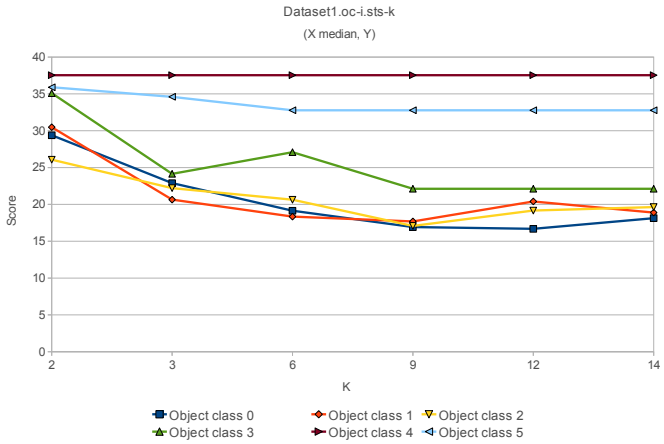
Figures 1(a) - 1(b) and 2(a) - 2(b) present four graphics as a representation of all the results. The graphics for the other data sets have a similar behaviour so we omit them.

In these figures, in the X axis we have the different values for the k parameter, on the Y axis we have the *Score* value (the lower, the better). Each graphic represents the *Score* for each k value, for the different object classes.

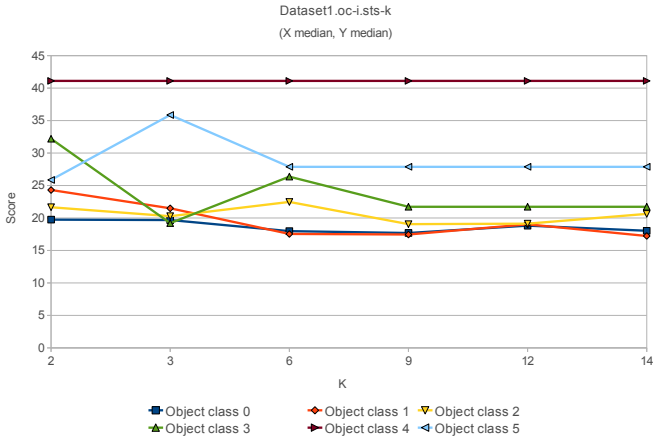
In general all the graphics have a similar shape. The *Score* value starts decreasing until it reaches a minimum value and then, they increase or they keep equal. The common behaviour of the *Score* value is precisely this. We stated that information loss and disclosure risk are contrary measures (i.e. when one increases the other decreases) and they both have the same relevance when computing the *Score*. This means that the best result for a given k value will be the one that has the lower *Score*. Thinking in this way, we observe that, among the different object classes, the lowest values for the *Score* are at $k = 9$, Except for the case of Figure 1(b) where the best k value is $k = 12$.

In all the results there are two object classes (4 and 5) that stand out of the others, not for they high *Score* values but for they shape: The *Score* is monotonically stable. This is because the information loss and the disclosure risk measures have the same relevance on the *Score* computation so, when they equilibrate each other, the *Score* does not change.

We stated before that we use two different distances for the microaggregation process as well as two different ways of doing the aggregation process, so it is interesting to compare the obtained results. Focusing at the k value that gives, in general, the best result (i.e. $k = 9$) and comparing the



(a) *AdaptedEuclidean distance, X median - Y*



(b) *Adapted Euclidean distance, X median - Y median*

Fig. 1. *Adapted Euclidean distance results*

AEUD microaggregation with the *ASTSD* microaggregation in combination of the two different aggregation methods the *(X median, Y median)* and the *(X median, Y)*, the differences between them are not remarkable but the combination of the *ASTSD* microaggregation with the *(X median, Y)* aggregation process seems to be the best. That is because the value of the *Score* is the lowest at each object class, except for the object class 5. This behaviour is due to a high value of the information loss measure for the *ASTSD* microaggregation with the *(X median, Y)* aggregation process, which come from the microaggregation process, where, in this case, the anonymity achieved is not high enough to equilibrate the information loss. Therefore, the *Score* value is higher for this object class. This can be appreciated on Figure 3.

Figure 4 represents the *Disclosure Risk* and *Information Loss* measures for each pair consisting of the microaggregation of an object class using a particular aggregation process. In the figure, the nearer a pair to $(0, 0)$, the better. Note that $(0, 0)$ stands for data with no information loss and no disclosure risk. Also, the exceptional cases commented above can be appreciated.

VII. Conclusions and Further Work

In this paper, we have presented a new framework for trajectory anonymization. We adapted the microaggregation protection method in order to apply it to trajectory anonymization. We have introduced a set of information loss measures which try to cover the general uses of trajectories. We adapted the distance based record linkage for trajectories. We adapted

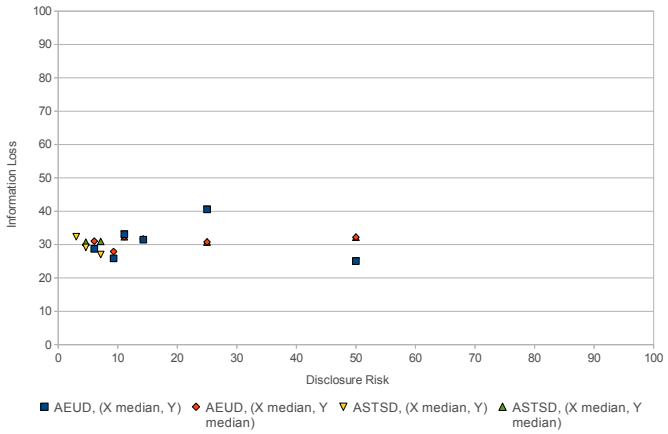

Fig. 4. *R-U Map for $k = 9$*

a couple of existing distances so that they can be applied to trajectories, no matter what their overlapping degree is. Finally, we have presented some results from applying the microaggregation method to different data sets in order to get the best parameter combination for this method when working with trajectories.

As future work, new protection methods can be found or adapted as well as new information loss and disclosure risk measures.

***Abstract*—In this paper we discuss some tools for graph perturbation with applications to data privacy. We present and analyse two different approaches. One is based on matrix decomposition and the other on graph partitioning. We discuss these methods and show that they belong to two traditions in data protection: noise addition/microaggregation and k-anonymity.**

***Index Terms*—Data privacy, clustering, k-anonymity, microaggregation, graph**

I. Introduction

Graphs are useful mathematical structures for representing a large variety of data. In particular, they can be used to represent social networks and other kind of data where elements establish relationships with other elements.

In this paper we discuss methods for protection of data represented in terms of a graph. More specifically, we focus on problems in which the graph can be represented in an explicit way in terms of an adjacency matrix of manageable size.

The interest of this work is twofold. First, it is useful for protection of social networks with a limited number of nodes, as e.g. the data from a company or a university department. Naturally, this approach can be adapted to subsets of larger networks. Second, as these methods can be applied to a network that can be expressed in its entirety in a compact way, they permit us to analyse with some detail their effect as well as the effect of their parameterizations. In particular, we can study their effectiveness with respect to disclosure risk and information loss.

A. Our scenario in data privacy

We discuss in this section the scenario of data privacy we are considering in this paper. The scenario is basically the same as in previous research in the area of data privacy (see e.g. [1], [2]), although those papers focus on standard databases and not on relational data representable as graphs.

Scenario 1.1: A company or a national office wants to release data to a third party for doing some kind of analysis. Nevertheless, confidentiality should be ensured and so, no confidential information should be inferred by this third party from the data received.

In the framework of this scenario, existing tools for data privacy can be roughly classified in two broad classes:

- Cryptographic or computation oriented methods. They are methods based on cryptographic tools which try to avoid any disclosure at all. These methods are developed ad hoc for a particular analysis. That is, given a particular computation – a function of the data, a particular protocol is built which computes the function without giving to the data suppliers more information than the result of the function. As such, these methods are computation oriented, as they need to know and are based on the function to be computed.
- Perturbative or data oriented methods. These methods try to avoid disclosure manipulating the original data set and introducing some noise into the set. Then the perturbated data is released to the third party who can apply any analysis to the data. In this way, there is no need of knowing the function to be computed. That is why these methods are data oriented. Disclosure is (partially) avoided because of the perturbation inflicted to the data. Nevertheless, some disclosure risk is inherent in the data and, therefore, needs to be quantified. At the same time, the perturbation modifies the data and some information loss occurs. So, information loss also needs to be quantified.

Following [1], [3], we focus on the data oriented approach. That is, we focus on perturbative methods that add some kind of noise to the data. As stated above, the evaluation of these methods requires the quantification of information loss and disclosure risk. Then, we consider that a method has a good performance (i.e., it is a good data protection method) if for a particular type of data it achieves a good compromise between disclosure risk (i.e., the risk of disclosing sensitive information) and information loss (i.e., the amount of *data utility* that is lost when data is perturbated).

Among all possible data types, this paper focus on data protection tools for data representable in terms of graphs. The literature already presents some tools for data protection of graph structures. See e.g. the survey in [4]. There are tools [5] for graph perturbation based on random addition and deletion of nodes, and others [6] based on k-anonymity.

In this paper we focus on tools for small graphs. More specifically, in tools for graphs that can be representable in their entirety by a adjacency matrix or an equivalent structure and small enough to be stored and operated in memory. That is, we focus on tools for graph perturbation to be applied to

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

graphs of limited size. Then, we develop methods based on the decomposition of the matrix and on similarities between the nodes of the graph. This diverges from previous works.

The goal of this paper is to present a set of tools for data privacy that will be further studied in detail for analysing its effectiveness. We discuss the appropriateness of our approach and illustrate it with some examples. Then, in a further research, we can develop approximate solutions for larger datasets, or apply them to subsets of larger sets.

The structure of the paper is as follows. In Section II we review some basic concepts that are needed in the rest of the paper. Then, in Section III we present some approaches for graph perturbation. The paper finishes with some conclusions.

II. Preliminaries

In this section we review some concepts that are needed later on in this paper. We focus on some tools we use later for operating with graphs. In particular, in methods of matrix decomposition.

A. Matrix decomposition

We will denote by U^H the conjugate transpose of U. That is, U^H is the transpose of the conjugate matrix. Recall that the conjugate of the complex number $a + bi$ is $a - bi$. When U only contains real numbers, U^H is the standard transpose of U.

A matrix M is said to be unitary when $MM^T = I_n$. Here I_n stands for the diagonal matrix of dimension n.

The singular value decomposition of a matrix M consists of a factorization of M in three matrices U, D and V as follows:

$$M = UDV^H$$

where U and V are unitary matrices and where D is a nonnegative diagonal matrix.

Here, if M is an $m \times n$ matrix, then U is an $m \times m$ matrix, D is an $m \times n$ matrix, and V is an $n \times n$ matrix.

The eigendecomposition or spectral decomposition of a square matrix M of dimension n consists of the factorization of M in terms of two matrices V and D as follows:

$$M = VDV^{-1}$$

where V is an $n \times n$ matrix with the eigenvalues of M, and D is an $n \times n$ diagonal matrix with the eigenvalues of M on the diagonal.

Both decompositions are related for some particular matrices. In particular, if M is symmetric and positive definite, then the spectral decomposition corresponds to a singular value decomposition.

III. Graph perturbation

In this section we discuss two different approaches for graph perturbation. One is based on matrix decomposition, and the other on graph partitioning. Both follow the tradition of perturbation methods. Nevertheless, they can be seen as belonging to two different *traditions*. We will discuss this later in Section III-C.

A. Methods based on matrix decomposition

In statistics a dimension reduction is a reduction of the number of random variables under consideration. The dimension reduction can be performed using the spectral decomposition or the singular value decomposition (SVD) of the matrix representing the data. If we apply the same methods to the adjacency matrix of a graph, then we accomplish a perturbation of the matrix. Appropriate selection of the eigenvalues in the spectral method and of the singular values in the SVD method will reduce the *complexity* of the matrix so that the most significant features of the structure is kept. In this way it is possible to perturbate the graph while keeping its most significative edges.

The rationale of the approach is to perform a transformation similar to random addition and deletion of edges (as in e.g. [5]) but in a more learned way. We define the approach below. We start with the method based on the spectral decomposition.

Definition 3.1: Let $G = (V, E)$ be a graph and let M be its adjacency matrix, let p be a parameter such that $0 \leq p \leq |V|$. Then, the SD-graph protection method consists in (i) computing the spectral decomposition of M: let $M = UDU^{-1}$ be the spectral decomposition of M; (ii) returning $M' = UD'U^{-1}$ where D' includes only the first p eigenvalues of D.

Here, as usual in spectral decomposition, we assume that the eigenvalues of D are arranged in descending order with respect to the size of their absolute value.

We now define the method based on singular value decomposition.

Definition 3.2: Let $G = (V, E)$ be a graph and let M be its adjacency matrix, let p be a parameter such that $0 \leq p \leq |V|$. Then, the SVD-graph protection method consists in (i) computing the singular value decomposition of M: let $M = U\Sigma W^H$ be the singular value decomposition of M; (ii) returning $M' = U\Sigma' W^H$ where Σ' includes only the first p values of the diagonal of Σ, where these are arranged in descending order.

As we saw in the introduction, the SVD and the spectral decomposition are related. For undirected graphs we get the following proposition.

Proposition 3.3: For undirected graphs the methods defined in Definition 3.1 and Definition 3.2 are equivalent.

Proof: The adjacency matrix of an undirected graph is symmetric and real, but in general not positive definite. The singular values of the matrix are the absolute values of its eigenvalues. This implies that for undirected graphs the two methods are equivalent. ■

For both methods, the smaller the number p, the larger the distortion inflicted to the graph. Naturally, when p equals the dimension of the matrix (i.e., $p = |V|$), data protection methods cause no distortion to the graph; in contrast, when $p = 0$, the distortion is maximal as the graph is completely distorted. Note that for $p = 0$, all edges are lost.

Therefore, the parameter p controls the degree of noise. This is in line of most perturbative data protection methods for databases. Note that e.g. the parameter k in microaggregation [7] permits the user a rank of results from maximal

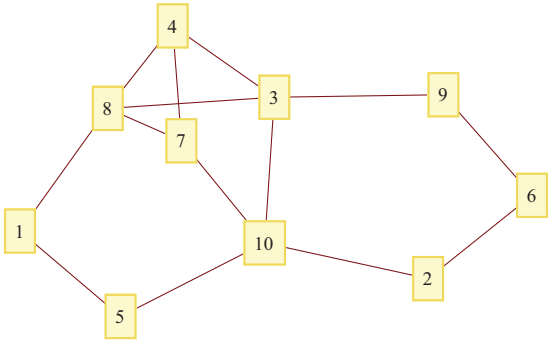
distortion (all records are replaced by the same value) to no distortion at all (all records are published as they are). Similar situation occurs with the different variants of rank swapping [8].

Although both methods are a natural way to implement a perturbation that introduces noise to the original data, they have two drawbacks.

The first one is that while the original matrix M contains only binary values to represent presence or absence of an edge, the matrix obtained as output from the method has coefficients with values in the real numbers. They are not restricted to [0,1] and can even be negative. This requires to develop a post processing in which the resulting matrix is transformed into a proper graph. For example, this binarization process could consist in transforming M' into a set of probabilities, and then using these probabilities for building a new matrix $\tilde{M}'$. Another approach for binarization consists in assigning zero or one according to a threshold. This latter approach has been applied in Example 3.4.

The second one is that, once the binarization process is applied, the *graph* represented by M' is quite similar to M for several of the parameterizations of the methods. That is, although M' is no longer a binary matrix, zero values in M result into values near zero in M', and unitary values in M result into values near one in M'. For example, for the matrix in Example 3.4, using a binarization with a threshold of 0.5, we have that we have to perform a dimension reduction of at least 6 ($p = 4$) in order to obtain a graph which is different from the original one. With $p = 4$ we remove two edges, with $p = 3$ we remove 8 edges and with $p = 2$ we remove 16 edges. With $p = 1$, 23 edges are changed (7 added and 16 removed) and, of course, all 28 edges are removed taking $p = 0$.

Example 3.4: This is a graph on 10 vertices with 14 edges:



This is the adjacency matrix of the graph:

$$\begin{pmatrix} 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 \end{pmatrix}$$

The singular values of this matrix are approximately

$$\{3.16, 2.52, 1.83, 1.63, 1.56, 1.28, 0.83, 0.77, 0.41, 0.31\}.$$

We applied first dimension reduction using SVD on the adjacency matrix of the graph. All values of p between 0 and 10 were considered. Below we list the correlations between the original matrix and the result as a function of p, using the function implemented in R [9].

dimensionality reduction$(1-p)$	*correlation*
0	1
1	0.4283313
2	0.475191
3	0.3822435
4	0.4283313
5	0.3360108
6	0.3822435
7	0.28843
8	0.2375955

Then we applied a binarization process to the result with a threshold of 0.5. Below we list the correlations between the original matrix and the binarized matrix as a function of p. For $p = 10$ no correlation can be computed because the perturbated graph has no edge.

dimensionality reduction$(1-p)$	*correlation*
0	1
1	1
2	1
3	1
4	1
5	1
6	0.948448
7	0.7953949
8	0.4516129
9	0.5663766
10	$--$

The selection of the threshold was done heuristically, defined as the mid point between 0 and 1 with respect to the perturbation of the matrix. This selection results into a rather conservative selection. For $p = 2$, except a threshold of 0.4 that leads to 13 changes in the matrix, all other thresholds lead to the same or more changes (with maximums of 49 and 20 changes for thresholds of 0.1 and 0.9).

When constructing a method for data perturbation with the ambition to obtain data privacy it is important to verify that the perturbation is hard to reverse, since otherwise the method implies no privacy, or at most limited privacy. The following arguments are made under the assumption that the graphs are undirected and simple (i.e. without multiedges and loops). Research on spectral graph theory has shown that 'almost all' graphs are uniquely determined by their spectra [10], so that in many cases given a sequence of eigenvalues, there is only one graph which has an adjacency matrix with these

eigenvalues. This is so due to the difficulties to find a set of eigenvectors which brings the diagonal matrix to a space where the matrix is symmetric, with entries either 0 or 1 and with the diagonal all 0. Suppose that we apply to a graph one of the methods for graph perturbation defined above. Before applying the binarization process, the result is a matrix M with p of the eigenvalues equal to the largest p eigenvalues of the original adjacency matrix A, ordered by their absolute value. The rest of the eigenvalues of M are all 0. The eigenvectors of M are the same as the eigenvectors of A. Counting the number of the eigenvectors of M which are 0, we can bound the number of removed eigenvectors. The absolute value of a removed eigenvalue (i.e. any eigenvalues of A which is not an eigenvalue of M) is smaller than the smallest absolute value of all the eigenvalues of M. Given M this significantly restrict the possible choices of A. If we also remember that since the diagonal of an adjacency matrix of a simple undirected graph is always 0, so is its trace, then it is clear that in some cases it is very easy to given M deduce A. For example when only one eigenvalue is removed, the missing eigenvalue is minus the sum of the other eigenvalues.

This observation highlights the importance of binarization process. Indeed, through the binarization process perturbations are introduced into the *eigenvectors* of the graph. This destroys the possibility to easily reverse the perturbation process. Important aspects of the privacy therefore relies on the binarization process, implying that the choice of binarization process could be most significant for the degree of privacy supplied by the method. Since the information loss of course also depends on the binarization process, the choice of the binarization process should be further investigated in the future.

B. Methods based on graph partitioning

The literature for database protection includes a large number of methods for achieving k-anonymity [2], [11], [12]. A file is said to be compliant with k-anonymity if for each record there are other $k-1$ indistinguishable records.

k-anonymity is used for data protection based on the following rationale:

> No disclosure takes place when any individual is indistinguishable of $k-1$ other different individuals.

Then, methods transform the original data file so that only sets of k-indistinguishable records are found in the data. Naturally, all such methods use k as one of the parameters. These methods act by means of clustering, generalizations and suppressions.

In the framework of k-anonymity, disclosure risk is usually not analysed but taken for granted once k is settled. This is so because the parameter k is assumed to be a threshold of the satisfactory disclosure risk. So, only information loss is evaluated here.

Methods for graph partitioning can be used for achieving protection following the idea of k-anonymity. In its simplest form, graph partitioning divides the vertices in two sets of equal size such that the number of edges between these two parts is minimized. In a more general formulation, the vertices are divided in p disjoint subsets of equal size.

Therefore, we can conceive a kind of k-anonymity from the results of graph partitioning. Let $G = (V, E)$ represent a graph, and let $\Pi_V = \{V_1, \ldots, V_p\}$ represent a partition of the edges of this graph into p clusters. Then, we consider the vertices of each cluster V_i as indistinguishable. So, given p, this results in $k = |V|/p$-anonymity. At this point, two alternatives can be foreseen.

1) Direct partitioning: In this case, we apply a partitioning algorithm to the original graph (i.e., to the original matrix). This causes clusters to be built on the basis of good connectivity. That is, the method detects sets of vertices that are well connected among themselves but with a low connectivity with the other ones.

This approach has an inconvenience. The partitioning algorithm does not distinguish between the different roles that vertices might have in well connected regions. To illustrate this point, let us consider the following example.

Let $G = (V, E)$ be a graph representing the relationships among members of a university. Let the vertices V represent the staff of the university and edges E represent mails and other types of communication among staff members. In this case, for an appropriate value of p, a graph partitioning algorithm will form p clusters. Such clusters shall roughly correspond to departments. Note that communication links between department members is likely to be more intense than communication links between members belonging to different departments.

So, in general, this approach is unable to detect and distinguish that within the department, some of the members might be administrative staff, other senior research staff, and other students. The approach proposed in the next section focuses on the detection of such roles.

2) Indirect partitioning: In this case, the partitioning algorithm is applied to a similarity matrix computed from the graph. Therefore, this is a two step process.

- First, we define a matrix $S : V \times V \to [0, 1]$ representing the edge similarity between the pairs of vertices in the graph with $|V| = n$.

  $$S(v_i, v_j) = \text{similarity}(v_i, v_j)$$

  where the similarity function should be selected in order to give a satisfactory clusterization.
- Second, we apply a graph partitioning algorithm to the matrix S.

While in the direct approach the algorithm clusters together well connected vertices, in the indirect approach we cluster vertices with a similar role in the graph. In some sense, this is similar to the approach in [6] which discusses the isomorphism between edges in the graph.

We have considered two distinct definitions of similarity between vertices: one based on the l_1 or Manhattan distance and the other based on which neighbors the vertices have in common. We define these two similarities below and discuss their properties. We represent the edges of a vertex v_i by the

row vector $A(i)$ of the adjacency matrix A (or equivalently, the column vector $A(j)$) corresponding to the vector.

Definition 3.5: Using the Manhattan or the l_1 distance, the similarity between two vertices v_i and v_j with edges $A(i)$ and $A(j)$ in a graph on n vertices is defined as

$$\text{similarity}_{l_1}(v_i, v_j) = n - \sum_{k=1}^{n} |A(i,k) - A(j,k)|$$

$$= \sum_{k=1}^{n} (1 - |A(i,k) - A(j,k)|) .$$

Definition 3.6: The 2-path similarity between two vertices v_i and v_j with edges $A(i)$ and $A(j)$ in a graph on n vertices is defined as

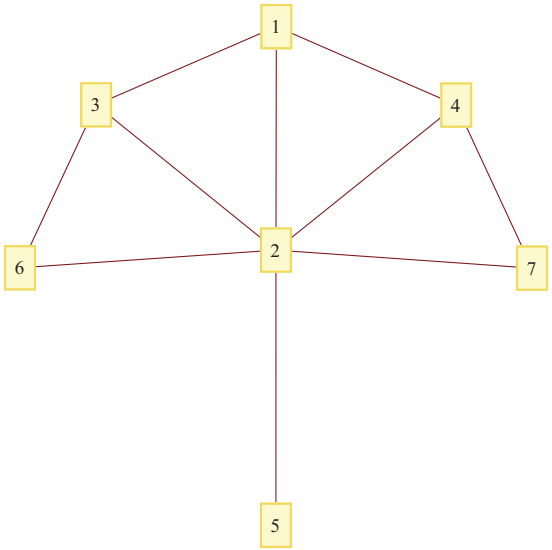
$$\text{similarity}_{2-path}(v_i, v_j) = \sum_{k=1}^{n} A(i,k)A(j,k).$$

Observe that since an adjacency matrix of an undirected graph is symmetric, the ith row is the ith column transposed.

The 2-path similarity is augmented with one for every neighbor the two vertices have in common. The similarity based on the Manhattan distance is also augmented with one for every neighbor the two vertices have in common, but it is augmented with one for every non-neighbor they have in common as well.

The 2-path similarity highlights the fact that similarity between vertices is based on the existing edges, and not on the missing edges. The following example illustrates this point.

Example 3.7: This is a graph with 7 vertices and 10 edges:



This is the adjacency matrix of the graph:

$$\begin{pmatrix} 0 & 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 & 0 \\ 1 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 & 0 \end{pmatrix}$$

The distance from vertex 1 to the other vertices is listed below.

vertex	similarity$_{l_1}$	similarity$_{2-path}$
2	2	2
3	3	1
4	3	1
5	5	1
6	6	2
7	6	2

The example illustrates the differences between the two similarities. It can be seen that while the similarity between vertex 1 and vertex 5 is much larger for the Manhattan distance than the similarity between vertex 1 and 2, in the 2-step similarity we have the reversal.

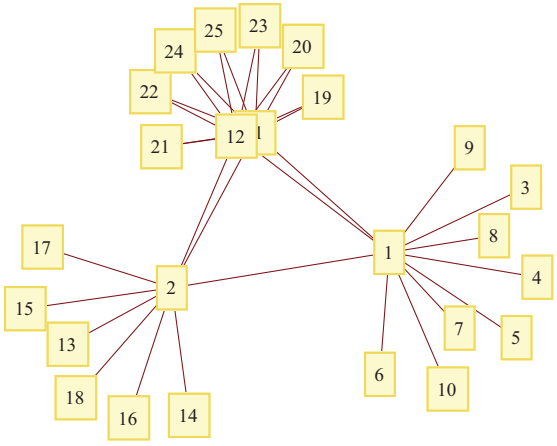
This is due to the fact that vertices 1 and 5 share four non-neighbours, while 1 and 2 do not share any of them. In contrast, vertices 1 and 2 share two neighbors and vertices 1 and 5 share only one. The 2-step similarity focuses on the common neighbors.

In relation to the interest of the approach of indirect partitioning with respect to the one of direct partitioning, let us consider the following scenario.

Example 3.8: Let us consider a social network where vertices can either represent individuals or mass media. While in the direct approach, individuals and media might be clustered together according to communities of news producers and consumers, in the indirect approach, producers and consumers can be kept disaggregated. That is, consumers with similar interests (reading newspaper n_1, n_2 and listening radios r_1, r_2) will be aggregated together in the same cluster. At the same time, media with a similar audience will also be clustered together (n_1, n_2, r_1 and r_2 will form a cluster).

We include below an example that illustrates this situation with a graph, and showing the results of the approach for indirect partitioning.

Example 3.9: This is a graph on 25 vertices with 33 edges:



In this example vertices 1, 2, 11, and 12 represent the mass media and the rest of the vertices represent individuals. Edges from individuals to mass media represent that the individuals access/use the mass media while edges between pairs of mass media represent interactions among them. Graph partitioning

using the similarity based on the Manhattan distance results in the following partition:

$$\{1, 2, 3, 4, 5, 6, 11, 12\}$$

$$\{8, 9, 10, 13, 14, 15, 16, 17, 18\}$$

$$\{7, 19, 20, 21, 22, 23, 24, 25\}$$

and graph partitioning using the 2-path similarity results in the following partition:

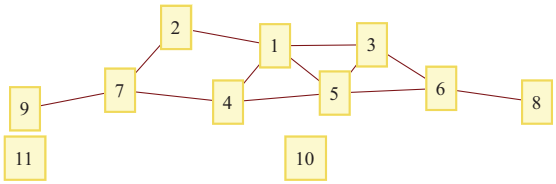
$$\{1, 2, 19, 20, 21, 22, 23, 24, 25\}$$

$$\{11, 12, 13, 14, 15, 16, 17, 18\}$$

$$\{3, 4, 5, 6, 7, 8, 9, 10\}$$

It can be seen that this partition includes in the partition elements the consumers of a (group) of media while the media themselves are disaggregated from the individuals. In contrast, graph partitioning using Manhattan distance does not show this behaviour as the media are clustered with their individuals. For example, the partition of the Manhattan distance contains 1, 2, 3, 4, 5, 6, 11, 12 but the 2-path distance contains 3, 4, 5, 6, 7, 8, 9, 10. Note that this latter cluster contains all vertices related to 2, but not the vertice 2. In contrast, the former contains a mix of nodes connected to 2, with node 2.

Example 3.10: In the graph below there are two leafs, the vertices 8 and 9. We want the vertices of the graph to be clusterized so that vertices with a similar role in the graph end up in the same cluster. What we mean with this depends on what we mean when we say that two vertices play a similar role. In this case, if the role is to be a leaf, then we probably want 8 and 9 to go together. However, if the role is to be connected to more or less the same vertices, then vertices 8 and 9 should be in different clusters.



Clustering the graph with respect to the Manhattan distance using the partition algorithm in METIS we obtain the partition

$$\{1, 5, 7\} \quad \{2, 8, 9, 10, 11\} \quad \{3, 4, 6\}$$

and if the clusterization is performed with respect to the 2-path distance, then the same partition algorithm gives us

$$\{8, 10, 11\} \quad \{2, 3, 4, 9\} \quad \{1, 5, 6, 7\}.$$

If we use the partition algorithm from Mathematica instead, in the last case we obtain

$$\{1, 7, 5, 6, 3, 8\} \quad \{2, 4, 9\} \quad \{10\} \quad \{11\}.$$

This illustrates that if the partition algorithm is calibrated in an adequate way (in this case it means that the number of partitions should be adequate), then the 2-path similarity creates clusters which collect vertices which more or less are connected to the same vertices, while the similarity based on the Manhattan distance rather tends to cluster vertexes together which are similar also in their non-existing edges, like for example two leafs or two isolated vertices like vertices 10 and 11. Indeed it is clear that the similarity based on the Manhattan distance considers similarity with respect to non-existing edges equally important as similarity with respect to existing edges.

Graph partitioning does not fully define a method compliant with k-anonymity. The correct application of this approach to a graph requires that the resulting partition satisfies two requirements: (i) that the number of vertices in a cluster is large enough; (ii) that the edges between vertices are reconstructed.

For solving the first issue, we propose the use of graph partitioning algorithms that lead to solutions with a similar number of vertices in all partitions. Then, if we require at least k vertices in each partition element, we should select a number of clusters less than $|V|/k$. The algorithm for graph partitioning implemented in METIS [13], [14] proceeds in this way.

As forcing solutions of this form might result into unnatural clusters for large graphs, an alternative approach is to proceed in a two step process. First, partitioning the vertices without any constraint (or a loose constraint) on the number of vertices in each cluster (the clustering algorithm in Mathematica proceeds in this way), and, then, refine the largest clusters applying a more constrained clustering algorithm.

The second element to be considered is about edge reconstruction. Once clusters are defined, the original edges have to be updated. First, vertices within the cluster are connected among themselves according to a pre-specified algorithm. Then, vertices should be connected to the other clusters, and all vertices from one cluster should be connected in the same way to vertices in another cluster. The decision of a connection can be done according to the majority of presence or absence of edges between the corresponding vertices.

The following proposition is crucial for how to choose the connections for the reconstruction between vertices in the same cluster.

Proposition 3.11: We call a cycle of length 3 a triangle. If the original graph is triangle-free, then the 2-path distance will cluster the graph so that the vertices in the same cluster are not connected.

Proof: We may suppose that two vertices a and b in the same cluster have at least one neighbor c in common, making a and b similar. Suppose that there is an edge between a and b. Then, since we have the path bca, there is the cycle $abca$ of length 3, that is, a triangle. This implies that in triangle-free graphs there are no edges between the vertices in the same cluster if the cluster was made using 2-path similarity. ■

The proposition implies that whenever the graph is triangle-free, assuming that it is desirable to preserve this property, the reconstruction of the graph from the clusters should be such that vertices in the same cluster are not connected.

Observe that if we cluster with respect to the similarity based on the Manhattan distance, Proposition 3.11 does not

apply, since two vertices in the same cluster not necessarily have any neighbors in common. Indeed, the similarity based on the Manhattan distance groups all isolated vertices together.

C. Discussion on graph perturbation

We have introduced two different families of methods for graph perturbation. One family consists on methods based on matrix decomposition, and the second one consists on methods based on graph partitioning.

While both methods perturbate the original graph resulting into a new graph with changes on the edges, they can be seen as belonging to two different traditions of perturbative approaches.

Methods based on matrix decomposition, with the parameter p, result into methods which try to find a good trade-off between information loss and disclosure risk. That is, on the tradition of noise addition and microaggregation. In contrast, methods based on graph partitioning follow the tradition of k-anonymity.

IV. Concluding remarks

In this paper we have presented some perturbation methods for graphs of limited size. We have discussed briefly some of the properties of the approaches, and we have given some examples of their behaviour. Further research should concentrate on analysing the properties of these methods further, and it is necessary to perform additional experiments for graphs of larger sizes. Future research should also include a comparative study of the results obtained by applying the different methods.

***Abstract*—FCM clustering is a fundamental technique for capturing intrinsic cluster structures of multivariate data sets. This paper presents a comparative study on the regularization effects of Fuzzy c-Means memberships estimated by two different fuzzification approaches: standard approach and entropy regularization approach. In this paper, the characteristics of the two fuzzification approaches are also discussed in noise fuzzy clustering (NFC) and it is revealed that the noise rejection mechanism of NFC can contribute to weakening the influence of initialization problems in entropy regularization approach although the approach is generally more sensitive to initial partition than the standard approach.**

***Keywords*—fuzzy clustering, regularization, noise clustering.**

I. Introduction

Fuzzy c-Means (FCM) [1] is a basic method for estimating fuzzy c-partitions and is a fuzzy variant of k-Means clustering model [2], in which bivariate cluster indicators of k-Means are fuzzified so that they represent the relative typicalities of degree of belongingness to clusters. In order to estimate "fuzzy memberships" drawn from the interval $[0, 1]$, the linear programming problem of k-Means is transformed into a non-linear one by introducing an additional weighting exponent.

Entropy regularization [3] is another approach to fuzzification of k-Means cluster memberships, in which a non-linear penalty term (regularization term) is added to the k-Means objective function so that the full objective function is non-linear with respect to memberships. Using an entropy-like penalty term, the FCM model has close relation to Gaussian mixture models (GMMs) with Expectation-Maximization (EM) algorithm [4], in which the weight for the penalty term corresponds to the variance parameter in GMMs [5]. Besides the entropy term, other non-linear penalty terms such as a quadratic term [6] and a K-L information term [7] were also proved to be useful in fuzzification of memberships [8].

Although the FCM models with various fuzzification approaches derive similar clustering results in many cases, an important difference between the standard fuzzification approach and the regularization approach is seen in their classification functions [9]. The classification function of the standard approach has the maximum value of "1" on cluster centers and has the "fuzziest" value in the area far distant from all cluster centers. On the other hand, the classification function of the entropy regularization approach does not have the maximum value on cluster centers and the value becomes large as a point goes away from all cluster centers.

This work was funded in part by the Ministry of Education, Culture, Sports, Science and Technology, Japan, under Grant-in-Aid for Scientific Research (20700214).

In this paper, the regularization effects of the standard fuzzification and entropy regularization are compared. It has been known that regularization of objective functions contributes to avoiding singular solutions. In the FCM clustering, we can expect that the fuzzified objective functions improve the possibility of avoiding local minima. Additionally, in this paper, the regularization effects are also compared in a robust clustering context. Noise fuzzy clustering [10], [11] is a robust clustering model, in which noise samples that are far distant from all cluster centers are dumped into an additional "noise cluster" in order to robustly estimate cluster centers. If we consider the noise rejection situation, the entropy regularization approach may have a similar classification function to the standard approach.

The remainder of this paper is organized as follows: Section II briefly reviews fuzzification approaches in the FCM clustering and noise fuzzy clustering. Section III considers the regularization effects of fuzzified objective function through a toy example. Section IV presents several experimental results to compare the characteristic features of the fuzzification approaches. Section V summarizes the conclusions of this paper.

II. Membership Fuzzification in FCM and Noise Rejection

A. Standard FCM

Let $\boldsymbol{x}_i = (x_{i1}, \cdots, x_{im})^\top$, $i = 1, \cdots, n$ denote m dimensional observations of n samples and the goal be to partition the sample into C clusters, in which samples belonging to same clusters are mutually similar. k-Means clustering [2] uses mean vector $\boldsymbol{b}_c$ as the prototype of cluster c and estimates cluster indicators (membership of each sample) by minimizing the following within-group-sum-of-errors.

$$L_{km} = \sum_{c=1}^{C}\sum_{i=1}^{n} u_{ci} d_{ci} = \sum_{c=1}^{C}\sum_{i=1}^{n} u_{ci}(\boldsymbol{x}_i - \boldsymbol{b}_c)^\top(\boldsymbol{x}_i - \boldsymbol{b}_c), \quad (1)$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

where u_{ci} represents the membership of data point $\boldsymbol{x}_i$ to cluster c and is given based on the nearest prototype principle as

$$u_{ci} = \begin{cases} 1; & \boldsymbol{x}_i \text{ belongs to cluster } c \\ 0; & \text{otherwise} \end{cases}$$

and

$$\sum_{c=1}^{C} u_{ci} = 1, \qquad i = 1, \cdots, n. \tag{2}$$

The clustering algorithm is a 2-step iterative procedure of calculation of memberships u_{ci} and mean vectors $\boldsymbol{b}_c$ [2].

In fuzzy clustering, memberships are generalized to $u_{ci} \in [0, 1]$ so that membership matrix $U = (u_{ci})$ represents a fuzzy partition composed of relative typicalities of belongingness to clusters. Equation (1) is, however, a linear function with respect to memberships and the optimal memberships are given in the extremal points ($u_{ci} \in \{0, 1\}$). Then, Standard Fuzzy c-Means (FCM^s) algorithm [1] introduced an additional weighting exponent into the linear objective function so that it becomes non-linear with respect to u_{ci}.

$$L^s_{fcm} = \sum_{c=1}^{C} \sum_{i=1}^{n} u_{ci}^{\theta} d_{ci}, \tag{3}$$

where $\theta (\theta > 1)$ is the additional weighting exponent of "fuzzifier". If $\theta = 1$, the clustering model is reduced to the (hard) k-Means model. The larger the θ, the fuzzier the memberships. θ is often set as $\theta = 2$ or sometime $\theta = 1.5$ in real applications. The clustering algorithm has similar formula to that of k-Means. New prototypes are derived as the weighted centers of clusters (mean vectors). Memberships are calculated under the constraint of Eq.(2) called "probabilistic constraint" [12]. The constraint forces memberships to have similar meaning to posterior probabilities in the EM algorithm [4] with probabilistic mixture models so that they represent the relative typicalities in clusters.

The FCM algorithm with standard fuzzification approach is summarized as follows:

Algorithm: Standard Fuzzy c-Means (FCM^s)

Step 1 Initialize memberships $u_{ci}, c = 1, \cdots, C, i = 1, \cdots, n$ randomly, and normalize the memberships so that they satisfy the probabilistic constraint. Choose termination threshold ε.

Step 2 Update $\boldsymbol{b}_c, c = 1, \cdots, C$ as

$$\boldsymbol{b}_c = \frac{\sum_{i=1}^{n} u_{ci}^{\theta} \boldsymbol{x}_i}{\sum_{i=1}^{n} u_{ci}^{\theta}}. \tag{4}$$

Step 3 Update $u_{ci}, c = 1, \cdots, C, i = 1, \cdots, n$ as

$$u_{ci} = \begin{cases} \left[\sum_{l=1}^{C} \left(\frac{d_{ci}}{d_{li}} \right)^{\frac{1}{\theta - 1}} \right]^{-1} & ; I_i = \emptyset \\ 1/|I_i| & ; I_i \neq \emptyset, c \in I_i \\ 0 & ; I_i \neq \emptyset, c \notin I_i \end{cases} \tag{5}$$

where I_i is the set of indices such that d_{ci} is zero, i.e., $I_i = \{c : d_{ci} = 0\}$.

Step 4 If

$$\max_{c,i} \mid u_{ci}^{NEW} - u_{ci}^{OLD} \mid < \varepsilon,$$

then stop. Otherwise, return to Step 2.

This standard FCM algorithm has the following characteristics [9]: If we use the membership calculation rules of Eq.(5) as fuzzy classification rules u_c, the maximum value $(u_c = 1)$ is given on the cluster center, and u_c moves toward $1/C$ as $||\boldsymbol{x}|| \to \infty$.

B. Fuzzy Clustering with Regularized Objective Function

If the goal is to fuzzify memberships in k-Means clustering, we can add a non-linear penalty term in order to make the objective function non-linear with respect to memberships. Miyamoto and Mukaidono [3] introduced a regularization term with a positive parameter λ into the objective function based on the regularization concept. Adding an entropy term, the objective function of FCM with regularization by entropy (FCM^e) is defined as

$$L^e_{fcm} = \sum_{c=1}^{C} \sum_{i=1}^{n} u_{ci} d_{ci} + \lambda \sum_{c=1}^{C} \sum_{i=1}^{n} u_{ci} \log u_{ci}, \tag{6}$$

where the entropy term works like the weighting exponent in the standard FCM algorithm and the parameter λ plays a role for tuning the degree of fuzziness of membership values. The larger the λ, the fuzzier the memberships.

This objective function has similar formulation to the negative log-likelihood in the EM algorithm with GMMs, in which λ correspond to the variance parameter of Gaussian distributions [5].

The clustering algorithm is also composed of the 2-step procedure, in which the updating rules for memberships and cluster centers are derived as follows:

$$u_{ci} = \frac{\exp(-\frac{1}{\lambda} d_{ci})}{\sum_{l=1}^{c} \exp(-\frac{1}{\lambda} d_{li})}, \tag{7}$$

$$\boldsymbol{b}_c = \frac{\sum_{i=1}^{n} u_{ci} \boldsymbol{x}_i}{\sum_{i=1}^{n} u_{ci}}. \tag{8}$$

From the classification viewpoint, the fuzzy classification function have different features from that of FCM^s [9]. u_c does NOT have the maximum value $(u_c = 1)$ on the cluster center and u_c moves toward 1 as $||\boldsymbol{x}|| \to \infty$. So, a data point that is far distant from all clusters may have a very large membership value.

The regularization approach can also be performed by using other regularization terms [6], [7], [13].

C. Noise Fuzzy Clustering

Noise fuzzy clustering [10], [11] introduced an additional noise cluster in order to damp noise samples into the noise cluster with the goal being to estimate robust cluster centers. In the noise clustering model, it is assumed that all samples have a constant (same) distance to the noise cluster, and that all samples, whose distance to all real cluster centers are greater

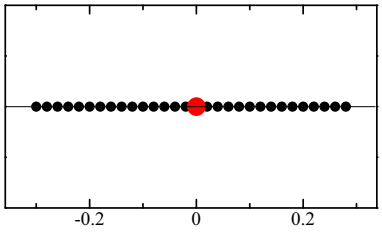

Fig. 1. an 1-D artificial data

than the constant distance, should be assigned to the noise cluster. In the FCM^s formulation, the objective function is given as

$$L^s_{nfc} = \sum_{c=1}^{C}\sum_{i=1}^{n} u_{ci}^{\theta} d_{ci} + \sum_{i=1}^{n} \delta \left(1 - \sum_{c=1}^{C} u_{ci}\right)^{\theta}, \quad (9)$$

where $1 - \sum_{c=1}^{C} u_{ci}$ represent the membership degree to the noise cluster and δ is the weight parameter that is identified with the distance to noise cluster. So, the conventional probabilistic constraint is redefined as

$$\sum_{c=1}^{C} u_{ci} \leq 1. \quad (10)$$

The membership updating rule of Eq.(5) (case of $I_i = \emptyset$) is modified as

$$u_{ci} = \left[\sum_{l=1}^{C} \left(\frac{d_{ci}}{d_{li}}\right)^{\frac{1}{\theta-1}} + \left(\frac{d_{ci}}{\delta}\right)^{\frac{1}{\theta-1}}\right]^{-1}. \quad (11)$$

In the same way, for the FCM^e formulation, Eq.(7) is modified as

$$u_{ci} = \frac{\exp(-\frac{1}{\lambda} d_{ci})}{\sum_{l=1}^{c} \exp(-\frac{1}{\lambda} d_{li}) + \exp(-\frac{1}{\lambda}\delta)}, \quad (12)$$

III. Consideration on Regularization Effects of Fuzzified Objective Functions

In this section, a toy example is shown in order to demonstrate the regularization effects of fuzzified objective functions. Figure 1 shows an 1-D artificial data composed of 30 samples uniformly distributed in a 1-D space.

Assume that we partition the samples into 3 clusters and the third cluster center ($\boldsymbol{b}_3$) is fixed on the center (red circle). Figure 2 shows the 3D contour surface of the k-Means objective function Eq.(1) calculated by changing $\boldsymbol{b}_1$ and $\boldsymbol{b}_2$ in the interval $[-0.35, 0.35]$. Local minima are shown by red marks. The figure indicates that we have the optimal (global) solution of $(\boldsymbol{b}_1, \boldsymbol{b}_2) = (0.21, -0.21)$ or $(\boldsymbol{b}_1, \boldsymbol{b}_2) = (-0.21, 0.21)$ and that we also have several other local minima. So, k-Means is severely influenced by initial partitions and is often trapped in local minima.

Figure 3 shows the 3D contour surfaces of the FCM objective functions Eqs.(3) and (6). The fuzzification coefficients were set as $\theta = 2$ and $\lambda = 0.05$, respectively. In the fuzzified objective functions, the contour surfaces were smoothened

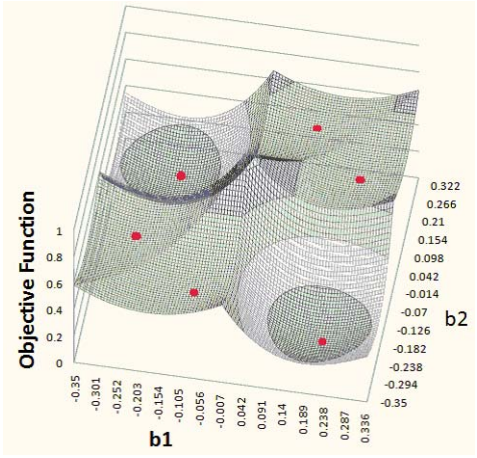

Fig. 2. Objective function of k-Means in toy example

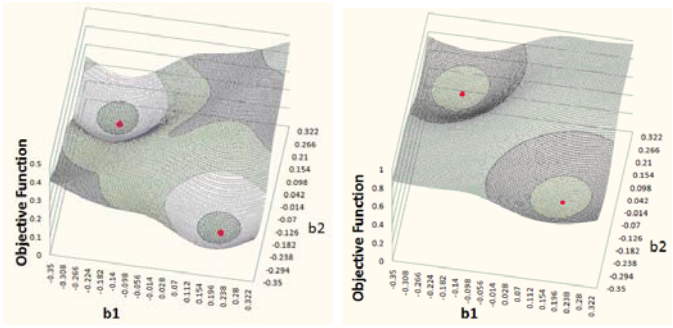

(a) standard fuzzification (b) entropy regularization

Fig. 3. Objective function of FCM in toy example

and the possibility of being trapped into local minima was weakened. In this way, both fuzzification approaches have the regularization effects in k-Means clustering.

IV. Numerical Experiments

In this section, several experimental results are shown in order to compare the regularization effects of fuzzification approaches.

A. Artificial data Set

The first experiment was performed with a 2-D ($m = 2$) artificially generated data set shown in Fig. 4, in which 200 samples ($n = 200$) were drawn from one of 4 Gaussian distributions (50 samples each) with unit variances whose mean vectors were (-1,-1), (-1,1), (1,-1) and (1,1), respectively. In order to compare the possibilities of being trapped into local minima, the samples were partitioned into 4 clusters with various initial partitions.

Applying the k-Means algorithm, 2 different partitions shown in Fig. 5 were derived. Figure 5-(a) is the optimal k-Means partition having the smallest objective function value and was given in 62% trials. On the other hand, another local optimal solution shown in Fig. 5-(b) was also derive in the remaining trials. The result implies that the (hard) k-Means

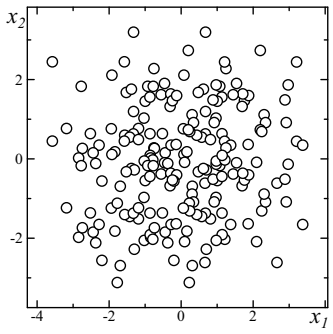

Fig. 4. 2-D artificial data set

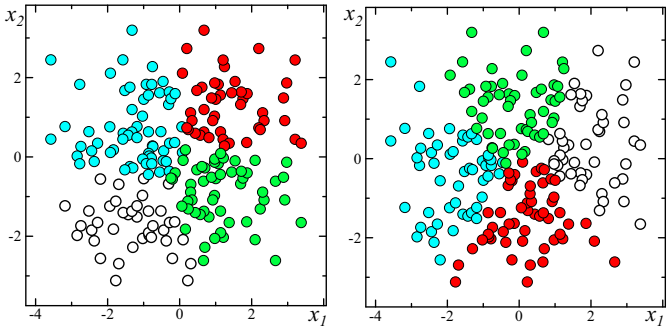

(a) partition a (b) partition b

Fig. 5. Derived partitions with 2-D artificial data set

algorithm is very sensitive to initial partitions and is often trapped into local minima.

Next, fuzzy c-partitions were estimated by the standard fuzzification approach and the entropy regularization approach comparing the regularization effects. Tables I and tab: Comparison of local solution FCM-e compare the frequencies of the local solutions (LS(%)) in 1820 trials, in which the initial cluster centers were located on $b_{cj} = \{x_{ij}^{\min}, \frac{1}{3}x_{ij}^{\min} + \frac{2}{3}x_{ij}^{\max}, \frac{2}{3}x_{ij}^{\max} + \frac{1}{3}x_{ij}^{\min}, x_{ij}^{\max}\}$ for each coordinate without duplication. The local solutions mean the case where the clustering algorithm failed to capture the c-partition of Fig. 5-(a). The tables imply that both fuzzification approach have regularization effects and contribute to avoiding being trapped into local minima as the weight parameters were increased.

Here, the fuzzy c-partitions derived by the two fuzzification approaches are compared using several clustering criteria. Partition coefficient (PC) and partition entropy (average entropy: AE) [1] are the average values of squared membership values u_{ci} and entropy of fuzzy memberships $-u_{ki}\log u_{ki}$. The criteria are used for evaluating the degree of fuzziness of fuzzy c-partition. A small PC and a large AE values imply a fuzzier partition with overlapping clusters. Xie-Beni index (XB) [14] is a cluster criterion considering the geometric features of FCM partitions:

$$XB = \frac{\sum_{c=1}^{C}\sum_{i=1}^{n} u_{ci}||\boldsymbol{x}_i - \boldsymbol{b}_c||^2}{n(\underbrace{\min}_{c\neq j}||\boldsymbol{b}_c - \boldsymbol{b}_j||^2)}. \quad (13)$$

TABLE I
COMPARISON OF FREQUENCIES OF LOCAL SOLUTIONS AND CLUSTER CRITERIA WITH 2-D ARTIFICIAL DATA SET (FCM^s)

θ	LS(%)	PC	AE	XB
1.01	62.4	1.000	0.000	0.274
1.05	21.5	0.987	0.006	0.269
1.1	12.1	0.968	0.014	0.257
1.15	12.1	0.948	0.023	0.245
1.17	11.8	0.940	0.026	0.241
1.18	11.8	0.936	0.028	0.239
1.19	0.0	0.932	0.030	0.237

TABLE II
COMPARISON OF FREQUENCIES OF LOCAL SOLUTIONS AND CLUSTER CRITERIA WITH 2-D ARTIFICIAL DATA SET (FCM^e)

λ	LS(%)	PC	AE	XB
0.05	23.6	0.997	0.000	0.273
0.1	22.5	0.988	0.005	0.272
0.2	11.9	0.971	0.012	0.263
0.4	11.7	0.934	0.028	0.250
0.45	11.3	0.925	0.032	0.248
0.49	10.9	0.917	0.036	0.247
0.5	0.0	0.915	0.037	0.246

A small XB value implies compact-separated clusters.

Comparing the cluster criteria in the situation where the local solutions were disappeared, the entropy regularization approach needs a "fuzzier" memberships than the standard approach in order to avoid local solutions and the derived fuzzy c-partition is more compact and separated.

It may be because FCM^e can assign larger memberships to samples that are far distant from all cluster centers as mentioned in Section II-2. If we gave a bad initial partition, some "noisy" samples having large memberships may illegally pull cluster centers.

B. Iris Data Set

A similar experiment was performed with Iris data set that is downloadable from UCI Machine Learning Repository [15]. In this experiment, 150 instances ($n = 150$) with 4 dimensional observation ($m = 4$) drawn from 3 classes were partitioned into 3 clusters without using the class label.

Tables III and IV compare the clustering performance with various fuzzification parameters. In this experiment, the cluster partition corresponding to the 3 Iris classes were regarded as the optimal solution. The frequencies and the average values were calculated after 85320 trials with a similar initialization strategy to the previous experiment in 4-D data space. In the same way with the previous experiment, FCM^s successfully derived a stable solution by using a suitable fuzzification weight. On the other hand, FCM^e was still trapped into local minima using larger fuzzification weights. Especially, when $\lambda \geq 1.0$, Xie-Beni index significantly increased, i.e. some clusters might be severely overlapping.

In this sense, FCM^s seems to work better than FCM^e from the viewpoint of regularization of k-Means objective function.

TABLE III
COMPARISON OF FREQUENCIES OF LOCAL SOLUTIONS AND CLUSTER CRITERIA WITH IRIS DATA SET (FCM^s)

1.5	15.1	0.777	0.114	0.323

C. Combination With Noise Fuzzy Clustering

Finally, the regularization effects of membership fuzzification are also compared in a robust clustering context using the 2-D data set shown in Fig. 4. Additional noise cluster adopted in noise fuzzy clustering [10] contributes to decreasing the membership degree of samples that are far distant from all cluster centers. We can expect that the robust feature may improve the effect of bad initial partitions in the entropy regularization approach by assigning smaller memberships to noisy samples. In noise fuzzy clustering, initial partitions are often given by FCM without noise rejection mechanism. In this experiment, however, the initial partition was given in the same initialization strategy with Section IV-A.

Table V compares the partition performance, in which the number of samples assigned to noise cluster "noise" was also shown with various noise weights δ. The fuzzification weights were set as $\theta = 1.19$ in order to consider the situation where the local solutions were first disappeared in Section IV-A. In this experiment, when $\delta \leq 1.5$, more than 30 out of 200 samples were regarded as noise and the plausible cluster centers could not be estimated. The table implies that the noise rejection mechanism increases the possibility of being trapped into local minima in FCM^s. In this sense, the FCM-guided initialization in noise fuzzy clustering seems to be plausible.

Next, Table VI shows the results given by FCM^e. The fuzzification paramter was set as $\lambda = 0.49$ where local solutions were still remained in Section IV-A. The table indicates that the noise rejection mechanism with large δ did not increase local solutions. Especially, when $\delta = 3.0$, the clustering performances were almost equivalent to those of $\lambda = 0.5$ in Table II, i.e., the noise rejection mechanism contributed to avoiding being trapped into local minima. It may be bacause the noise cluster plays a role for decreasing the membership values of samples far distant from all clusters, which would illegally draw in some cluster centers.

TABLE V
COMPARISON OF FREQUENCIES OF LOCAL SOLUTIONS AND CLUSTER CRITERIA WITH NOISE REJECTION (FCM^s)

δ	LS(%)	PC	XB	noise
1.0	–	0.451	0.078	97
1.25	–	0.570	0.132	72
1.5	–	0.727	0.124	33
1.75	28.8	0.788	0.160	25
2.0	16.3	0.852	0.172	12
2.25	20.5	0.887	0.193	4
2.5	16.6	0.908	0.209	2
2.75	15.8	0.919	0.219	1
3.0	14.9	0.925	0.227	0

TABLE VI
COMPARISON OF FREQUENCIES OF LOCAL SOLUTIONS AND CLUSTER CRITERIA WITH NOISE REJECTION (FCM^e)

δ	LS(%)	PC	XB	noise
1.0	–	0.311	0.042	90
1.25	–	0.472	0.070	66
1.5	–	0.637	0.107	37
1.75	25.1	0.748	0.139	27
2.0	17.6	0.828	0.172	13
2.25	19.0	0.878	0.204	5
2.5	0.0	0.905	0.223	2
2.75	0.0	0.913	0.234	1
3.0	0.0	0.915	0.242	0

The result implies that the noise rejection mechanism may have another role for tackling initialization problems in the regularized objective functions of FCM.

V. CONCLUSION

This paper discussed the effects of fuzzified memberships of k-Means clustering from the view point of the regularization of objective functions. Several experimental results revealed that the standard fuzzification approach is more useful for decreasing the effects of bad initial partitions than the entropy regularization approach, which can be identified with a sort of GMMs. In this paper, the regularization effects were also compared in the robust clustering context. An experimental result implied that the noise fuzzy clustering mechanism can also contribute to decreasing the effects of noisy samples in bad initial partitions by assigning smaller memberships in the entropy regularization approach.

Comparative study with other fuzzification approaches is remained in future work.

***Abstract*—Semi-supervised clustering with constraints has widely been studied, but there are few studies on constrained agglomerative hierarchical algorithms. We have shown modified kernel algorithms of agglomerative hierarchical clustering, but there is a drawback that the modified kernels are not positive-definite in general. In this paper we consider another idea of agglomerative hierarchical algorithms with pairwise constraints. That is, merging of clusters is with penalties. The centroid method and the Ward method with and without a kernel are considered. Typical numerical examples show effectiveness of the proposed algorithms in generating clusters with nonlinear cluster boundaries. We also compare the results with those by COP K-means, showing that the proposed algorithms outperform the COP K-means.**

Keywords-semi-supervised clustering; pairwise constraints; agglomerative hierarchical clustering.

I. Introduction

As cluster analysis is becoming a standard tool for data mining, various techniques have been developed and at the same time fundamental problems to be solved are addressed; three of them are as follows:

1) how traditional methods of agglomerative hierarchical clustering [6], [9], [10] should be used;
2) how clusters with nonlinear boundaries [11] should be generated;
3) how to semi-supervised clustering should be handled.

These three problems have sound reasons why they are important. First, agglomerative hierarchical clustering is frequently used for application to many contemporary problems including bioinformatics. Second, the theory of positive-definite kernels [1], [13] has been found to be useful to have nonlinearity in classification and clustering. Third, there are many studies in semi-supervised clustering using different ideas [4]. As to the last problem, various researches have been revealed that clustering with pairwise constraint is useful as a technique to handle semi-supervised classification [15], [2], [3], [8].

This paper concerns all these three problems and intends to give partial solutions to them. First, it proposes a constrained centroid method and a constrained Ward method of agglomerative hierarchical clustering. In contrast to our former paper [12] which uses a modified kernel function, the method herein does not use any kernel function and yet generates clusters with nonlinear boundaries, using a simple method of penalties in merging clusters. This paper also shows that the standard method of COP K-means [15] with pairwise constraint cannot generate clusters with nonlinear boundaries without a kernel function, while the present method can do this.

There are well-known typical examples with nonlinear boundaries that we can handle by the present method. We show the effectiveness of the proposed method and moreover compare performances of the proposed method and the COP K-means which shows the usefulness of the proposed method.

II. Agglomerative Clustering with Penalties

Let the set of objects for clustering be $X = \{x_1, \ldots, x_N\}$. We assume that object x_k $(k = 1, \ldots, N)$ is a point of a Euclidean space $\boldsymbol{R}^p$ with the Euclidean norm $\|\cdot\|$.

Generally a hard cluster denoted by G_i is a subset of X. The family of clusters is denoted by $\mathcal{G} = \{G_1, G_2, \ldots, G_K\}$, where the clusters form a crisp partition of X:

$$\bigcup_{i=1}^{K} G_i = X, \qquad G_i \cap G_j = \emptyset \quad (i \neq j).$$

Agglomerative hierarchical clustering uses a dissimilarity measure, frequently called a distance, between two clusters $d(G, G')$ $(G, G' \in \mathcal{G})$ which also is called an inter-cluster dissimilarity. In the following we sometimes write $d_{cn}(G, G')$ which means that the centroid method is used. Moreover, $d_{wm}(G, G')$ means that the Ward method is used. The two methods use the following definitions of the inter-cluster dissimilarity:

Centroid method:

Let the centroid of a cluster G be

$$M(G) = \frac{1}{|G|} \sum_{x_k \in G} x_k, \tag{1}$$

and let

$$d_{cn}(G, G') = \|M(G) - M(G')\|^2. \tag{2}$$

Ward method:

Assume $M(G)$ is the centroid as above, and let

$$E(G) = \sum_{x_i \in G} \|x_i - M(G)\|^2. \tag{3}$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Define

$$d_{wm}(G, G') = E(G \cup G') - E(G) - E(G'). \quad (4)$$

Although there are other three methods of the single linkage, complete linkage, and average linkage are often used, they are not studied in this paper.

Let us first describe a general procedure of agglomerative hierarchical clustering [9], [10] with a variation that a term $\mathcal{P}(G, G')$ is attached in the merging step, which is called **AHCP** (Agglomerative Hierarchical Clustering with Penalties) here. The definition of this term is described after the procedure.

AHCP Algorithm:

AHCP1: Assume that initial clusters are given by
$\mathcal{G} = \{\hat{G}_1, \hat{G}_2, \ldots, \hat{G}_{N_0}\}$.
Set $K = N_0$.
(K is the number of clusters and N_0 is the initial number of clusters)
$G_i = \hat{G}_i$ $(i = 1, \ldots, K)$.
Calculate $d(G, G')$ for all pairs $G, G' \in \mathcal{G}$.

AHCP2: Search the pair of minimum dissimilarity:

$$(G_p, G_q) = \arg \min_{G, G' \in \mathcal{G}} \{d(G, G') + \mathcal{P}(G, G')\}. \quad (5)$$

Merge: $G_r = G_p \cup G_q$.
Add G_r to $\mathcal{G}$ and delete G_p, G_q from $\mathcal{G}$.
$K = K - 1$.
if $K = 1$ then stop and output the dendrogram.

AHCP3: Update dissimilarity $d(G_r, G'')$ for all $G'' \in \mathcal{G}$.
Go to **AHCP2**.

End AHCP.

Assume that K_0 is given and it is necessary to have K_0 clusters, then we stop **AHCP** algorithm when K_0 clusters are obtained in **AHCP2**.

A. Pairwise constraints and penalties

A set $ML = \{(x_i, x_j)\} \subset X \times X$ consists of *must-link* pairs so that x_i and x_j should be in a same cluster, while another set $CL = \{(x_k, x_l)\} \subset X \times X$ consists of *cannot-link* pairs so that x_i and x_j should be in different clusters. ML and CL are assumed to be symmetric in the sense that if $(x_i, x_j) \in ML$ then $(x_j, x_i) \in ML$, and if $(x_k, x_l) \in CL$ then $(x_l, x_k) \in CL$.

Note that ML is regarded as an undirected graph in which nodes are objects appeared in ML, and an undirected edge is $(x_i, x_j) \in ML$. Accordingly, $V(ML)$ is the set of objects in graph ML. The connected components of graph ML is denoted by $ML_1, \ldots, ML_\ell$. Moreover the constraints are assumed to be consistent in the sense that if $(x_k, x_l) \in CL$, x_k and x_l are in different components of graph ML.

The must-link constraints are realized in **AHCP** algorithm by putting the initial clusters $\mathcal{G} = \{\hat{G}_1, \hat{G}_2, \ldots, \hat{G}_{N_0}\}$ to be the connected components $ML_1, \ldots, ML_\ell$.

In contrast, the following penalty term realizes the cannot-link constraints in **AHCP**:

$$\mathcal{P}(G, G') = W_{CL} \sum_{x \in G, x' \in G', (x, x') \in CL} \quad (6)$$

where W_{CL} is a positive constant. If W_{CL} is sufficiently large, the cannot-link constraints will never be broken.

Note: We handle ML to be hard constraints, while CL is treated to be *soft* constraints in (6). It is, however, straightforward to treat ML as soft constraints as well. For this purpose we modify (6) as follows:

$$\mathcal{P}(G, G') = W_{CL} \sum_{x \in G, x' \in G', (x, x') \in CL} - W_{ML} \sum_{x \in G, x' \in G', (x, x') \in ML} \quad (7)$$

Note also that the CL constraints become hard when W_{CL} is sufficiently large, which we assume later for the examples herein.

B. Positive-definite kernels in agglomerative clustering

It has been known that a high-dimensional mapping with a kernel function which is used in support vector machines [14], [13], [1] is also useful in agglomerative hierarchical clustering [5]. That is, regardless whether a high-dimensional mapping is used or not, the updating formulas for merging clusters remain the same in the centroid method and the Ward method [5]:

$$\begin{aligned} d_{cm}(G_r, G'') = & \frac{|G_p|}{|G_p| + |G_q|} d_{cm}(G_p, G'') \\ & + \frac{|G_q|}{|G_p| + |G_q|} d_{cm}(G_q, G'') \\ & - \frac{|G_p||G_q|}{(|G_p| + |G_q|)^2} d_{cm}(G_p, G_q), \end{aligned} \quad (8)$$

$$\begin{aligned} d_{wm}(G_r, G'') = & \frac{1}{|G_p| + |G_q| + |G''|} \Big[\\ & (|G_p| + |G''|) d_{wm}(G_p, G'') \\ & + (|G_q| + |G|) d_{wm}(G_q, G'') \\ & - |G''| d_{wm}(G_p, G_q) \Big]. \end{aligned} \quad (9)$$

except that the initial dissimilarities are different:

$$d_{cm}(x, y) = \|x - y\|^2 = K(x, x) + K(y, y) - 2K(x, y),$$
$$d_{wm}(x, y) = \frac{1}{2}\|x - y\|^2 = \frac{1}{2}\{K(x, x) + K(y, y) - 2K(x, y)\}.$$

for two objects $x, y \in X$ from which $d_{cm}(\hat{G}, \hat{G}')$ and $d_{wm}(\hat{G}, \hat{G}')$ are easily calculated.

We compare the results from the centroid method and the Ward method with and without the Gaussian kernel:

$$K(x, y) = \exp(-const. \|x - y\|^2).$$

III. Numerical Examples

Three illustrative examples are shown, in which cluster boundaries are nonlinear. First set of data is shown in Fig. 1 which has two obvious clusters of "double circles"; the outer circle has 100 objects while the inner has 50. Second data set in Fig. 2 has a ball inside a shape like a crescent, which is called " a moon and a ball." Third set of data in Fig. 3 is called "two moons" which also cannot be separated by a line. Each "moon" has 150 objects.

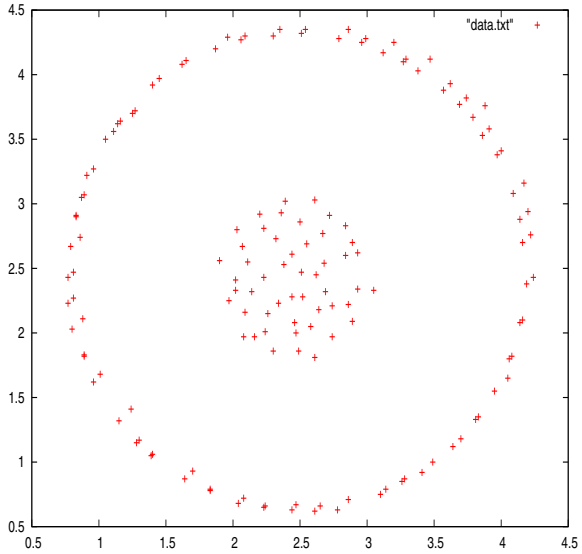

Fig. 1. First data set: double circles

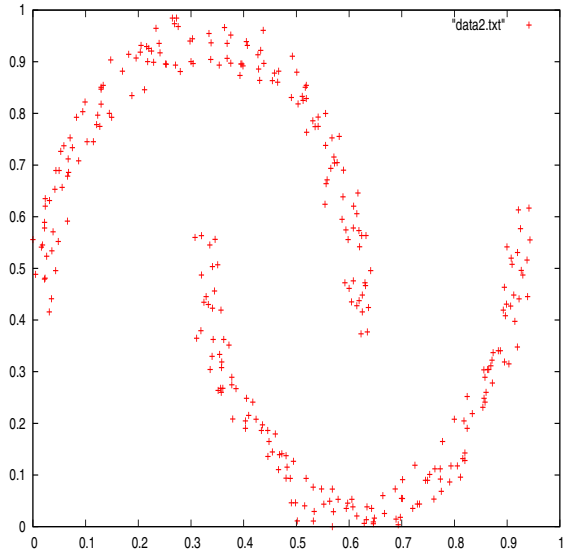

Fig. 3. Third data set: two moons

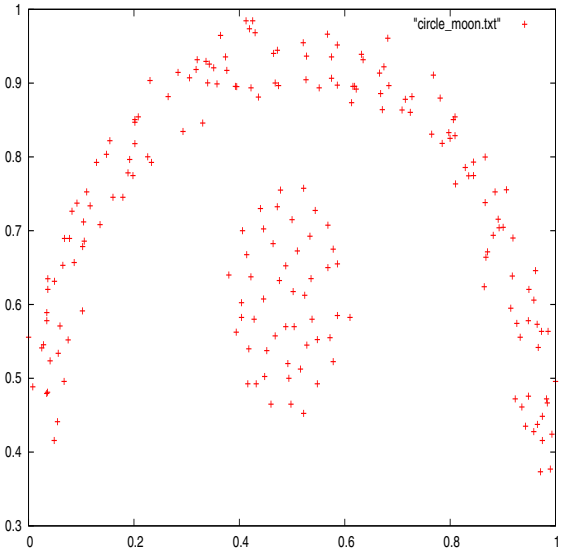

Fig. 2. Second data set: A moon and a ball

We generated ML and CL randomly, with the obvious restriction that ML are in the same (correct) cluster and CL connects two objects in different clusters. The penalty W_{CL} was sufficiently large so that CL pair did not be in a same cluster. Thus CL was handled as a hard constraint.

The numbers of constraints in ML and CL were changed in the numerical experiment and the ratios of correct results were evaluated as follows.

The Rand index which is one of the standard evaluation criteria was used:

$$Rand(a,b) = \frac{a+b}{N(N-1)/2}, \tag{10}$$

where a is the number of pairs that has to be in the same cluster and actually in the same cluster in the result, and b is the number of pairs that has to be in different clusters and actually in different clusters in the results. In short, $Rand(a,b)$ is the ratio of correct pairs in the whole number of pairs. Hence if the result is perfect, $Rand(a,b) = 1$.

The proposed method was compared with the COP K-means [15] with $K = 2$ in both examples.

We fixed the number of constraints and then generated the constraints randomly 1000 times, then generated clusters by the proposed method and the COP K-means. Then the averages of the rand index were calculated.

The number of constraints were then changed from 0 to 50 shown on the horizontal axis in Figs. 4–9.

In the following six kinds of results are compared; we did not mix ML and CL but included ML or CL alone:

1) results of the centroid method with ML (and no CL), shown by red line with $+$ in Figs. 4–9;
2) results of the centroid method with CL (and no ML) shown by green line with $\times$;
3) results of the Ward method with ML (and no CL) shown by blue line with $*$;
4) results of the Ward method with CL (and no ML) shown by pink line with $\square$;
5) results of the COP K-means with ML (and no CL) shown by light blue line with $\blacksquare$;
6) results of the COP K-means with CL (and no ML) shown by black line with $\bullet$.

Figures 4 and 5 respectively show the results without a kernel and those with the Gaussian kernel applied to the data set of the double circles. The all results from the COP K-means was without a kernel. Note that it has been known that K-means with the Gaussian kernel can separate the two clusters of the two circles.

It is observed that the centroid and the Ward methods with

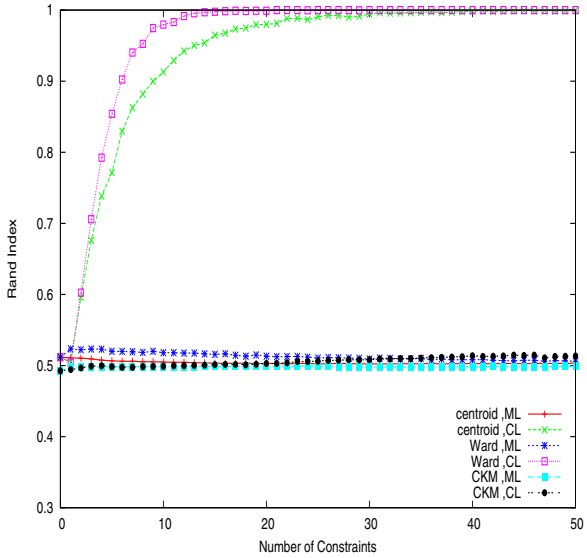

Fig. 4. The ratios of $Rand(a, b)$ by the proposed method without a kernel and the COP K-means applied to the double circle data set

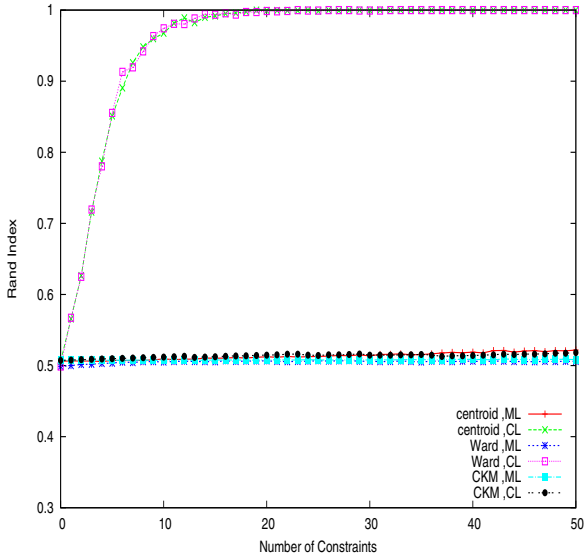

Fig. 6. The ratios of $Rand(a, b)$ by the proposed method without a kernel and the COP K-means applied to the moon and ball data set

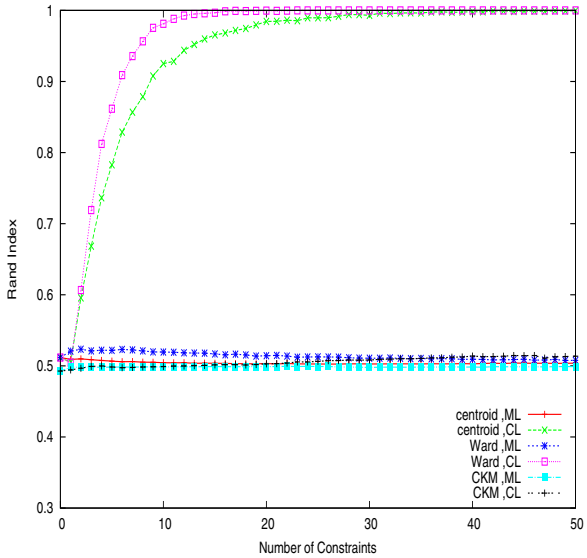

Fig. 5. The ratios of $Rand(a, b)$ by the proposed method with the Gaussian kernel ($const. = 0.01$) and the COP K-means applied to the double circle data set

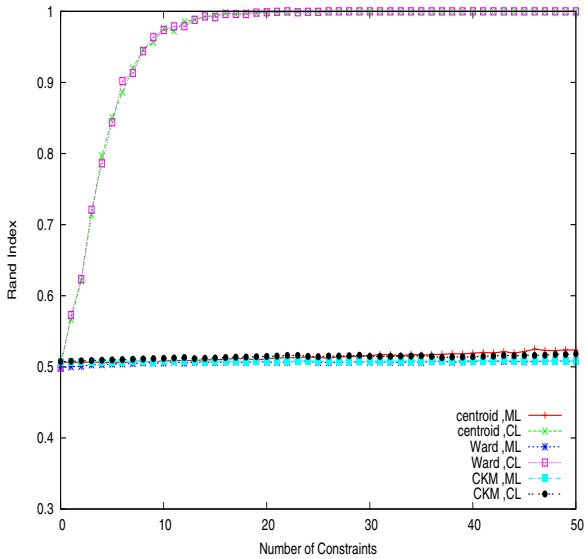

Fig. 7. The ratios of $Rand(a, b)$ by the proposed method with the Gaussian kernel ($const. = 0.01$) and the COP K-means applied to the moon and ball data set

CL better separated the two clusters as the number of the cannot-link constraints increase, while the other methods could not separate these two.

Figures 6 and 7 respectively show the results without a kernel and those with the Gaussian kernel applied to the data set of the "moon and ball." The same tendency as the first example is observed: the centroid and the Ward methods with CL better separated the two clusters as the number of the cannot-link constraints increase, whereas the other methods could not separate the moon and the ball.

Figures 8 and 9 respectively show the results without a kernel and those with the Gaussian kernel applied to the data set of the two moons. The COP K-means was used again without a kernel function. Note that in this case it is generally difficult to separate the two clusters using K-means, even with the Gaussian kernel.

It is observed again that the centroid and Ward methods with CL separated the two moons as the number of the cannot-link constraints increase, while the other methods could not separate the two clusters. It is moreover seen that the Gaussian kernel improved the performance in the second example when compared with the centroid and the Ward methods without a

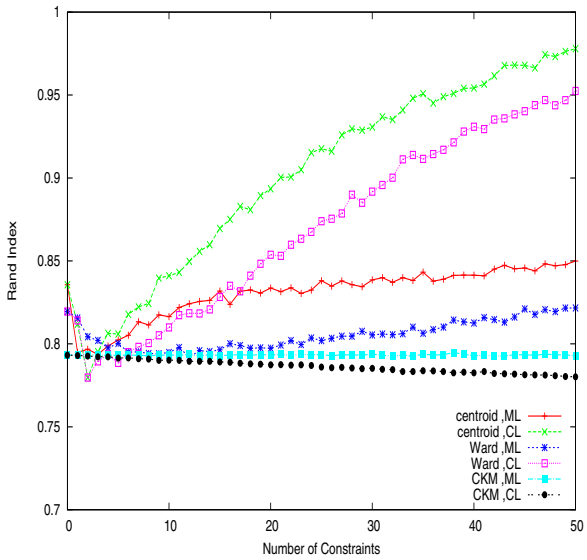

Fig. 8. The ratios of $Rand(a, b)$ by the proposed method without a kernel and the COP K-means applied to the two moons data set

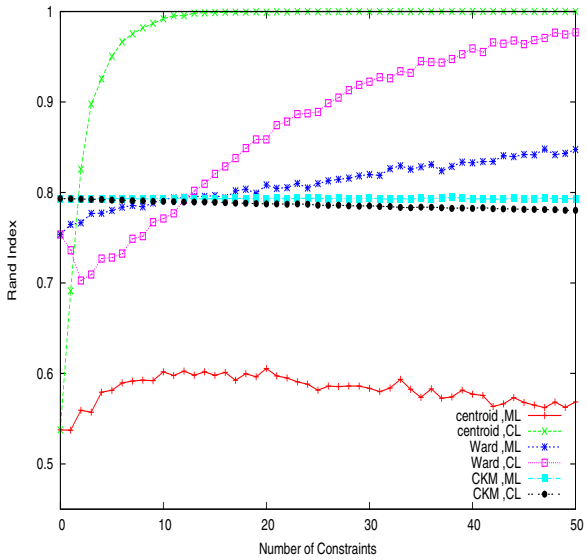

Fig. 9. The ratios of $Rand(a, b)$ by the proposed method with the Gaussian kernel ($const. = 10$) and the COP K-means applied to the two moons data set

kernel.

A. Discussion

The three illustrative examples show that the proposed method with CL outperforms other methods. It is also observed that the two clusters in the first and the second examples were separated without the use of a kernel function. This contrasts the general understanding that K-means type methods including fuzzy c-means without a kernel cannot separate clusters with nonlinear boundaries. Even if we use the COP K-means, the cluster boundaries remained the same with the exception of the pairwise constraints, and hence no perfect separation of the two clusters was observed for the COP K-means.

In contrast, the third data set of two moons could perfectly be separated with the use of the Gaussian kernel, which shows the effectiveness of a kernel function, as it generally is more difficult to separate the two moons than the two circles.

The three examples moreover show the generalization ability of the CL constraints especially in the first two examples, since the two clusters were almost perfectly classified when the number of CL constraints is 10, where the complete cannot links should have 50 constraints.

In contrast, we observed ML was not so effective as CL. Why ML was not so effective in agglomerative algorithms should be further investigated. We also observed that the increase in the number in ML did not result in the improvement of the rand index. The reason is unknown but similar tendency has also been observed in other studies (e.g. [7]).

IV. Conclusion

We have proposed the centroid method and the Ward method of agglomerative hierarchical clustering with penalties of the pairwise constraints. The three illustrative examples showed their effectiveness in extracting clusters with nonlinear boundaries. The idea herein is simple and can be implemented without difficulty. Note that agglomerative hierarchical clustering is frequently used in a variety of applications. We thus showed that the proposed method enhances the usefulness of the agglomerative algorithms.

When compared with our former proposal which uses modification of a kernel function [12], the present method is better in the sense that a kernel function is unnecessary and it does not have a drawback of indeterminate kernel which the former method of us has.

Future studies include testing its effectiveness in real examples and dendrogram output showing pairwise penalties. Comparison with fuzzy c-means with semi-supervision [16] which is not yet an established technique should also be considered.

***Abstract*—Adaptive fuzzy interpolation strengthens the potential of fuzzy interpolative reasoning. It first identifies all possible sets of faulty fuzzy reasoning components, termed the candidates, each of which may have led to all the contradictory interpolations. It then tries to modify one selected candidate in an effort to remove all the contradictions and thus restore interpolative consistency. This approach assumes that all the candidates are equally likely to be the real culprit. However, this may not be the case in real situations as certain identified reasoning components may be more liable to resulting in inconsistencies than others. This paper extends the adaptive approach by prioritizing all the generated candidates. This is achieved by exploiting the certainty degrees of fuzzy reasoning components and hence of derived propositions. From this, the candidate with the highest priority is modified first. This extension helps to quickly spot the real culprit and thus considerably improves the approach in terms of efficiency.**

***Index Terms*—Adaptive fuzzy interpolation, assumption-based truth maintenance systems, reliability-based general diagnostic engine.**

I. Introduction

Fuzzy rule interpolation enhances the robustness of fuzzy reasoning. When given observations have no overlap with any antecedent values, no rule can be fired in classical inference. However, interpolative reasoning through a sparse rule base may still obtain certain conclusions and thus improve the applicability of fuzzy models. Also, with the help of fuzzy interpolation, the complexity of a rule base can be reduced by omitting those fuzzy rules which may be approximated from their neighboring ones. A number of important interpolation approaches have been presented in the literature, including [1], [2], [3], [4], [7], [8], [9], [10], [11], [12], [13], [14]. In particular, the scale and move transformation-based approach can handle both interpolation and extrapolation, which involve multiple fuzzy rules, with each rule consisting of multiple antecedents. This approach also guarantees the uniqueness as well as normality and convexity of the resulting interpolated fuzzy sets. Yet, it is possible that more than one object value of a single variable may be derived in fuzzy interpolation. This implies that certain inconsistencies may have resulted.

To address this problem, *adaptive fuzzy interpolation* has recently been proposed [15]. This approach is capable of efficiently detecting inconsistencies, locating possible fault candidates and modifying the candidates in an effort to remove all the inconsistencies. It works by viewing the interpolative inference procedures as artificial system components, and then utilizing an assumption-based truth maintenance system (ATMS) [5] to record the dependencies between an interpolated value and its proceeding interpolation components. From this, the classical algorithm of general diagnostic engine (GDE) [6] is employed to manipulate the sets of dependent components of contradictions to hypothesize all possible candidates of defective rules.

The adaptive approach of [15] assumes that all the component candidates are equally reliable, but this may not be true in reality. This is because: i) two derived object values for a common variable which have led to a contradiction may not be equally reliable (moreover, one may be correct and the other wrong); and ii) all the interpolation components that jointly entail one of the two contradictory object values may not be equally reliable. Given information on such differences, all the generated component candidates may be prioritized. This is achieved by firstly extending the traditional ATMS not only to record dependencies, but also to record how reliable these dependencies are. Then GDE is modified in an effort to prioritize all the component candidates. The prioritization of candidates will inevitably help the modification procedure to quickly arrive at a consistent solution and thus save computational effort.

The rest of this paper is structured as follows. Sec. II reviews the adaptive fuzzy interpolation approach. Sec. III presents the extension that shows how component candidates can be efficiently prioritized. Sec. IV reconsiders the example given in [15] to illustrate how this extension can improve the original approach. Sec. V concludes the paper and points out important future research directions.

II. Adaptive Fuzzy Interpolation

Adaptive interpolative reasoning [15] provides a way to ensure that inference results remain consistent throughout the fuzzy interpolative process. The degree of consistency is typically expressed as the degree of matching. In particular, the matching degree between two fuzzy sets A_{ij} and A_{ik}, denoted as $M(A_{ij}, A_{ik})$, in the domain D_{x_i} of variable x_i is defined as follows, which is used to evaluate consistency efficiently (though distance-based measure may also be used for this):

$$M(A_{ij}, A_{ik}) = \sup_{x \in D_{x_i}} [\min(\mu_{A_{ij}}(x), \mu_{A_{ik}}(x))]. \quad (1)$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Then, the degree β of a contradiction with respect to two propositions P (x_i is A_{ij}) and P'(x_i is A_{ik}) is defined by:

$$\beta = 1 - M(A_{ij}, A_{ik}). \tag{2}$$

A predefined threshold β_0 ($0 \leq \beta_0 \leq 1$) is adopted in order to determine those values assigned to a common variable with an unacceptable contradictory degree. A contradiction is called a β_0-*contradiction* if the corresponding degree of contradiction $\beta > \beta_0$.

In implementing fuzzy interpolation, each pair of neighboring rules is defined as a *fuzzy reasoning component*. Such a component takes an input, an observation or a previously interpolated result, including that obtained by extrapolation (which are all hereafter referred to as an observation for simplicity), and produces another (the consequent of the interpolated rule) as output. The process of adaptive interpolation is summarized in Fig. 1. Firstly, the interpolator carries out interpolation and passes the interpolated results to the ATMS for dependency-recording. Then, the ATMS relays any β_0-*contradictions* as well as their dependent fuzzy reasoning components to the GDE which diagnoses the problem and generates all possible component candidates. After that, a modification process takes place to correct a certain candidate to restore consistency. A brief description of each of these key methods is given below.

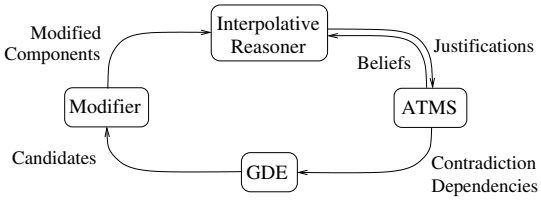

Fig. 1. Adaptive interpolative reasoning

A. Truth maintenance

ATMS is utilized to record the dependency of the interpolated results and that of contradictions, upon the fuzzy reasoning components from which they are inferred. Thus, propositions, contradictions and fuzzy interpolative reasoning components are all represented as ATMS nodes. In addition to the so-called datum field, which trivially denotes the actual meaning of the node, an ATMS node has two other fields: justification and label.

1) Justification: Briefly, a justification describes how a node is derivable from other nodes. Any ATMS node with an inferred proposition is represented by an ATMS justification as:

$$O, R_i R_j \Rightarrow C, \tag{3}$$

where $R_i R_j$ stands for the fuzzy reasoning component containing the two neighboring rules R_i and R_j ($i \neq j$) that have been used to infer the outcome C from the observation O.

According to the definition of contradiction above, any two propositions P (x_i is A_{ij}) and P'(x_i is A_{ik}) concerning the same variable x_i are contradictory to a certain degree β. When β is not higher than β_0, the contradictory degree is acceptable and the two considered propositions are treated as being consistent in ATMS. Otherwise, a β_0-$contradiction$ is deduced, which can be represented as:

$$P, P' \Rightarrow_{\beta_0} \perp. \tag{4}$$

2) Label and label-updating: A label is a set of environments, each of which supports the associated node. In particular, an environment is a minimal set of fuzzy reasoning components that jointly entail the supported node, thereby describing how the node ultimately depends on those fuzzy reasoning components. An environment is said to be β_0-*inconsistent* if β_0-contradiction is derivable propositionally by the environment and a given justification. An environment is said to be $(1-\beta_0)$-*consistent* if it is not β_0-inconsistent.

The label of each node is guaranteed to be $(1-\beta_0)$-consistent, sound, minimal and complete by the label updating algorithm, except that the label of the special "false" node is guaranteed to be β_0-inconsistent rather than $(1-\beta_0)$-consistent. In particular, the label of the special "false" node gathers all minimal β_0-inconsistent environments. Its corresponding label-updating process is given as follows. Whenever a β_0-contradiction is detected, each environment in its label is added into the label of "false" node and all such environments and their supersets are removed from the label of every other node. Also, any such environment which is a superset of another is removed from the label of the node "false".

B. Candidate generation

GDE [6] generates minimal candidates by manipulating the label of the specific "false" node. A candidate is a particular set of nodes or fuzzy reasoning components which may be responsible for the whole set of current contradictions. Because a β_0-inconsistent environment indicates that at least one of its elements is faulty, a candidate must have a non-empty intersection with each β_0-inconsistent environment. Thus, each candidate is constructed by taking one fuzzy reasoning component from each environment in the label of "false" node. Supersets removal then ensures such generated candidates to be minimal. In light of this, a successful correction of any single candidate will remove all the contradictions.

C. Candidate modification

Consistency can be restored by successfully correcting any single candidate because each single candidate explains the entire set of current contradictions. Given a set of candidates, the modification procedure is shown in Fig. 2.

For convenience, in the rest of this paper, A^*_{ij} is used to denote the modified consequence of a culprit interpolated rule whose consequent value is A_{ij}, and $A^*_{ij}{}'$ and λ^*_{ij} are used to denote the corresponding modified intermediate rule consequence and the *relative placement factor* [15] of A^*_{ij}, respectively. Also, for simplicity, only rules with a single antecedent are considered here, through extension to multi-antecedent rules is straightforward. Suppose that the neighboring rules $A_{11} \Rightarrow A_{21}$ and $A_{1n} \Rightarrow A_{2n}$ are the two rules used

Fig. 2. The CONSISTENCYRESTORING procedure

for interpolation by a defective fuzzy reasoning component, that $A_{12}, A_{13}, ..., A_{1(n-1)}$ are observations or previously interpolated results located in between A_{11} and A_{1n}, and that A_{1j} $(2 \leq j \leq n-1)$ is the middle most observation. The modification procedure for single fuzzy reasoning component can then be summarized as follows:

1. Find the rule $(A_{1j} \Rightarrow A_{2j})$ whose antecedent is located in the middle most of the neighborhood of the antecedents of any two rules that may be used for interpolation, with respect to their representative values. Assume that the *relative placement factor* of its consequence λ_{2j} is modified to λ^*_{2j}.

2. Calculate the *correction rate pair* according to the *relative placement factor* modification of rule $A_{1j} \Rightarrow A_{2j}$:

$$\begin{cases} c^- = \frac{\lambda^*_{2j}}{\lambda_{2j}} \\ c^+ = \frac{1-\lambda^*_{2j}}{1-\lambda_{2j}}. \end{cases} \tag{5}$$

3. Calculate the modified *relative placement factors* of consequences of all other interpolated rules which are generated from the same defective fuzzy reasoning component as per the *correction rate pair* computed above, where $i \in \{2, 3, ..., j-1\}$ and $k \in \{j+1, j+2, ..., n-1\}$:

$$\begin{cases} \lambda^*_{2i} = \lambda_{2i} \cdot c^- \\ 1 - \lambda^*_{2k} = (1 - \lambda_{2k}) \cdot c^+. \end{cases} \tag{6}$$

4. Calculate the modified consequences of all interpolated rules which are generated from the same defective fuzzy reasoning component in accordance with their modified *relative placement factors*:

$$\begin{cases} {A^*_{2x}}' = (1 - \lambda^*_{2x})A_{21} + \lambda^*_{2x}A_{2n} \\ T(A_{1x}', A_{1x}) = T(A^*_{2x}', A^*_{2x}), \end{cases} \tag{7}$$

where $x \in \{2, 3, ..., n-1\}$, and $T(A', A)$ represents the scale and move transformations [7], [8] from fuzzy set A' to A.

5. Restrict the modified consequence so that it is consistent with the context. Suppose that m object values $A_{i1}, A_{i2}, ..., A_{im}$ are obtained for variable x_i. If they are $(1-\beta_0)$-consistent, they must satisfy:

$$\bigcap_{j=1}^{m} (A_{ij})_{\beta_0} \neq \varnothing, \tag{8}$$

where $(A_{ij})_{\beta_0}$ denotes the β_0-*cut* of fuzzy set A_{ij}.

6. Restrict the propagations of all modified consequences so that they are consistent with the context. For simplicity, let function $I(A_{ij}, R_l R_r) = A_{kj}$ denote the standard interpolation from the antecedent fuzzy set A_{ij} to the consequent value A_{kj}, through fuzzy reasoning component $R_l R_r$. Suppose that m object values $A_{i1}, A_{i2}, ..., A_{im}$ of variable x_i, located between the antecedent values of rules R_l and R_r, are modified, that the corresponding modified object values of variable x_k are A^*_{kj}, $j \in \{1, 2, ..., m\}$, and that n object values A_{kl}, $l \in \{1, 2, ..., n\}$, of variable x_k are already derived previously. If the modified consequences A^*_{kj} are all $(1-\beta_0)$-consistent, then they must satisfy:

$$\begin{cases} A^*_{kl} = I(A^*_{ij}, R_l R_r) \\ \left(\bigcap_{j=1}^{m} (A^*_{kj})_{\beta_0} \right) \bigcap \left(\bigcap_{l=1}^{n} (A_{kl})_{\beta_0} \right) \neq \varnothing. \end{cases} \tag{9}$$

7. Solve all these simultaneous equations. The result is the modified solution which ensures inconsistency-free.

III. THE EXTENSION

The approach described above assumes that each candidate is equally likely to be the real culprit and naturally the candidate with the smallest cardinality is always tentatively modified first. However, this may not be true in real-world problems and, as argued earlier, differences exist amongst such candidates. In order to prioritize all the generated candidates, fuzzy reasoning components and derived propositions need to be ranked first in accordance with their certainty or reliability degrees.

A. Certainty degrees of fuzzy reasoning components

In this work, a fuzzy reasoning component composed by a pair of neighboring rules is used to represent the fuzzy interpolation mechanism which uses these two rules. In particular, the approach is based on the use of the scale and move transformation-based fuzzy interpolation techniques. Essentially, it is a fuzzy extension of classical linear interpolation. Thus, it is expected that such an artificial component will be more appropriate to represent those pairs of neighboring rules where relative distance between the two antecedents is closer to the corresponding relative distance between the two consequences than otherwise. In other words, the fuzzy reasoning components which are defined on such pairs of neighboring rules are more certain to derive correct interpolated results than the others, under the linearity assumption.

Suppose that fuzzy reasoning component $R_i R_j$ is composed by the following two rules:

$$\begin{array}{l} R_i: \text{ If } x_1 \text{ is } A_{1i}, \text{ then } x_2 \text{ is } A_{2i}; \\ R_j: \text{ If } x_1 \text{ is } A_{1j}, \text{ then } x_2 \text{ is } A_{2j}. \end{array} \tag{10}$$

Inspired by the above observation, the certainty degree $c_{R_iR_j}$ of fuzzy reasoning component R_iR_j can therefore be defined by:

$$c_{R_iR_j} = 1 - \left| \frac{d(A_{1i}, A_{1j})}{max_1 - min_1} - \frac{d(A_{2i}, A_{2j})}{max_2 - min_2} \right|, \quad (11)$$

where $d(A_{ki}, A_{kj})$, $k \in \{1, 2\}$, is the distance between fuzzy sets A_{ki} and A_{kj} (given a certain distance metric); max_k and min_k are the maximum and minimum of the domain values of variable x_k, respectively. Obviously, $c_{R_iR_j} \in [0, 1]$.

B. Certainty degree of an interpolated result

Given an observation or previously inferred result O and a fuzzy reasoning component R_iR_j which is composed by two rules R_i and R_j that flank the given observation O, a logical consequence C can be generated by the scale and move transformation-based fuzzy interpolation approach. The certainty degree c_C of the conclusion C is then calculated by:

$$c_C = c_O \otimes c_{R_iR_j}, \quad (12)$$

where the composition operator $\otimes$ can be minimum, algebraic product or any other T-norm operator. If O is an observation, it is regarded fully certain in this research and hence, c_O is assumed to be 1. Otherwise, c_O is calculated from a previous interpolation.

In general, the certainty degree of an interpolated result should also depend on the certainty degree (reliability) of the two rules used for interpolation. However, in this research, as with its preceding work, all given rules are presumed to be fixed and true. That is, the certainty degree of any rule in the rule base is 1. Therefore, the contribution of any rule's certainty degree can be ignored in the calculation of the certainty degree of an interpolated result.

Note that two different applications of interpolation procedures may result in the same interpolated result C, but with two different certainty degrees associated, say c_C and $c_{C'}$. Then the overall certainty degree of C, denoted as c is updated such that

$$c = c_C \oplus c_{C'}, \quad (13)$$

where $\oplus$ is the maximum operator, or any other S-norm operator.

C. Reliability-based ATMS

Having introduced the certainty degrees of fuzzy reasoning components and those of the interpolated results, ATMS needs to be extended accordingly in order to represent such information within the ATMS network. For this purpose, an extra filed, termed certainty degree, is introduced to each ATMS node, which measures to what extent the corresponding node can be (logically disjunctively) derived from all the label environments according to the entire set of current justifications. Each extended ATMS node is therefore of the following form:

$$\langle N, c, \{E_1, E_2, ..., E_n\}, \{J_1, J_2, ..., J_m\} \rangle, \quad (14)$$

where N is the underlying meaning of the node, c is the certainty degree of N, $\{E_1, E_2, ..., E_n\}$ is the ATMS label and $J_1, J_2, ..., J_m$ are the justifications. In addition, each label environment E_i $(1 \leq i \leq n)$ is of the form:

$$E_i = \{N_{11}, N_{12}, ..., N_{1k_i}\}, \quad (15)$$

where N_{ij}, $j \in \{1, 2, ..., k_i\}$, are those ATMS nodes which jointly support N.

1) Justification: A justification within this extended ATMS conveys two types of information: i) how the present node is derived from other nodes; and ii) to what extent the node is derivable from the other nodes. The first type of information is the same as that conveyed by the classical ATMS. For all nodes but the special "false" node, any justification is of the form of Eq. 3. Thus, the second type of information can be calculated with respect to Eq. 12.

Note that, for the special "false" node, the justifications are of the form of Eq. 4. However, in this research, no direct use of such justifications is required. Hence, any calculation involving the second type of information for this node is omitted.

2) Label and label-updating: In the extended ATMS, the set of fuzzy reasoning components that compose a label environment not only jointly entails their supported node, but also determines how certain the supported node can be logically derived from that environment. From this, the overall certainty degree of the supported node can be determined by the entire set of label environments. Without losing generality, suppose that node N can be derived by n different environments and that the kth $(1 \leq k \leq n)$ environment consists of m_k fuzzy reasoning components $F_{k1}, F_{k2}, ..., F_{km_k}$. Then the node N can be derived through the kth environment to the degree:

$$c_{N_k} = c_{F_{k1}} \otimes c_{F_{k2}} \otimes ... \otimes c_{F_{Km_k}}. \quad (16)$$

This is simply the generalized case of Eq. 12 by multiple applications of Eq. 12. By applying Eq. 13, the overall certainty degree c_N of the node N can be calculated such that

$$\begin{aligned} c_N &= c_{F_1} \oplus c_{F_2} \oplus ... \oplus c_{F_n} \\ &= (c_{F_{11}} \otimes c_{F_{12}} \otimes ... \otimes c_{F_{1m_1}}) \\ &\quad \oplus (c_{F_{21}} \otimes c_{F_{22}} \otimes ... \otimes c_{F_{2m_2}}) \\ &\quad \oplus ... \\ &\quad \oplus (c_{F_{n1}} \otimes c_{F_{n2}} \otimes ... \otimes c_{F_{nm_n}}). \end{aligned} \quad (17)$$

In general, to update the overall certainty degree of a given node, the label-updating algorithm needs to be applied. Hence, when a new justification is present, the extended label-updating algorithm not only updates the label of the node in question in exactly the same way as that of the classical ATMS, but also updates the overall certainty degree of this node according to Eq. 17.

D. Reliability-based GDE

In this work, a β_0-contradiction appears when two object values are derived for a common variable and the contradictory degree of the two object values is greater than a given threshold β_0. A contradiction indicates that at least one of the two derived object values is faulty. In earlier work such as [15], due to lack of information, both derived object values are supposed to be equally faulty. With additional information on certainty

degrees, and with the assistance of reliability-based ATMS, any two object values for a common variable can be distinguished. In effect, given a β_0-contradiction, the real defective fuzzy reasoning components which have caused this contradiction are more likely within the label environments of the less certain object value. Note that there may be more than one defective fuzzy reasoning component for a certain contradiction because there may be multiple environments each supporting the same contradiction. Amongst each label environment of one of the two object values which has caused the contradiction, the fuzzy reasoning component with the smallest certainty degree is intuitively regarded as the most likely to be the real culprit.

In the same way, all the components in each label environment of the special "false" node can be ranked. For this, a ranking value r is attached to every component of each of such label environments. The ranking value of each of those components which are in a label environment of the less certain object value, is set to its certainty degree. The ranking value of any other component in the label environments of the special "false" node is then set to its original certainty degree plus 1. Note that the range of a certainty degree is $[0, 1]$. Thus, the integer part of a ranking value indicates whether the environment that contains the given component entails a more certain object value, whilst the decimal part of the ranking value simply denotes the certainty degree of that component.

Example 3.1: Assume that a contradiction is derived from propositions P_1 and P_2, that the label of P_1 is $\{\{F_1, F_2\}, \{F_3\}\}$, and that the label of P_2 is $\{\{F_4\}\}$. Then the label of the contradiction is $\{\{F_1, F_2, F_4\}, \{F_3, F_4\}\}$ as illustrated in Fig. 3.

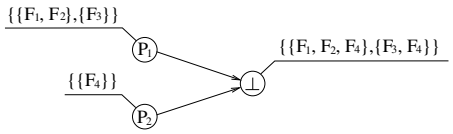

Fig. 3. The contradiction and its dependencies

Suppose that the certainty degrees of F_i, $i \in \{1, 2, 3, 4\}$, are: $c_{F_1} = 0.80$, $c_{F_2} = 0.40$, $c_{F_3} = 0.70$, $c_{F_4} = 0.50$. The certainty degrees of propositions P_1 and P_2 can be calculated with respect to Eq. 17. If the maximum and algebraic product operators are used to implement $\oplus$ and $\otimes$, respectively, then:

$$\begin{aligned} c_{P_1} &= \max\{c_{F_1} \times c_{F_2}, c_{F_3}\} \\ &= \max\{0.80 \times 0.40, 0.70\} \\ &= 0.70. \end{aligned}$$

Similarly, c_{P_2} can be calculated and the result is: $c_{P_2} = 0.50$. For label environment $\{F_1, F_2, F_4\}$ of the "false" node, because $c_{P_1} > c_{P_2}$ and F_4 is an element of the label environment of node P_2, the ranking value of F_4 is set to itself, i.e. $r_{F_4} = 0.50$, and the ranking values of F_1 and F_2 are set to their original certainty degrees plus 1, i.e. $r_{F_1} = 1.80$ and $r_{F_2} = 1.40$. In the same way, the ranking values of components in the label environment $\{F_3, F_4\}$ are set as: $r_{F_3} = 1.70$ and $r_{F_4} = 0.50$.

Without losing generality, suppose that $E_\perp$ is one of the label environments of the "false" node and it is deduced by two contradictory propositions P and P', represented by ATMS nodes N_P and $N_{P'}$ respectively. Then there must exist environments $E = \{F_1, F_2, ..., F_m\}$ and $E' = \{F'_1, F'_2, ..., F'_n\}$ which entail nodes N_P and $N_{P'}$ respectively such that $E \cup E' = E_\perp$. Suppose that the certainty degrees of propositions P and P' are c and c', respectively. Note that c is not necessarily equal to the certainty degree of which the environment E entails node N_P. The same holds for c' and $N_{p'}$. This is because: (1) an object value may be supported by more than one environment (or derived by more than one inference path), and (2) the certainty degree of the object value indicates the overall extent to which this object value may be supported by all its environments (or derived by all possible inference paths). Of course, certain elements in E may be identical to some in E'. In this case, the ranking value of each of those elements will take the less value (i.e. the one with higher priority). The procedure of attaching a ranking value to each element of $E_\perp$ is outlined in Fig. 4.

COMPONENTRANKING(E,E',c,c')

```
(1)  E⊥ = E ∪ E'
(2)  foreach F ∈ E⊥
(3)      if (c ≤ c' && F ∈ E)
(4)          r_F = c_F
(5)      else
(6)          if (c ≥ c' && F ∈ E')
(7)              r_F = c_F
(8)          else
(9)              r_F = c_F + 1
```

Fig. 4. The COMPONENTRANKING procedure

Each label environment of the special "false" node entails a contradiction and each candidate is formed by taking one element from each environment of the special "false" node. Therefore, if all the duplications are deliberately kept, all the candidates have the same cardinality which is equal to the number of label environments in the special "false" node. From this, all candidates can be prioritized according to the ranking values of their components. This is achieved by two steps of sorting as outlined in Fig. 5. In this figure, $\mathbb{S}$ is the generated candidate set and each candidate C is itself a set of fuzzy reasoning components. SORT(C) can be any standard sorting procedure, which sorts the fuzzy reasoning components in a given candidate C in an ascending order with respect to their ranking values. STABLESORT($\mathbb{S}, i$) is any stable sorting algorithm which ranks all the candidates in the candidate set $\mathbb{S}$ in an ascending order by the ranking value of the ith reasoning component. Since each candidate is a set of components, any duplication needs to be removed. Also, in order to generate only a minimal candidate set, all those candidates which are a superset of one other candidate are removed. Of course, such removals do not affect the overall ranking of the remaining candidates.

Example 3.2: Continue Ex. 3.1. Suppose that the contradiction in question is the only one in the system. Therefore,

TABLE I
THE CANDIDATES SORTING PROGRESS

Candidates with duplications	Every candidate sorted	Stable-sorted (2nd elements)	Stable-sorted (1st elements)
$C_1 = [(F_1, 1.80), (F_3, 1.70)]$	$C_1 = [(F_3, 1.70), (F_1, 1.80)]$	$C_6 = [(F_4, 0.50), (F_4, 0.50)]$	$C_6 = [(F_4, 0.50), (F_4, 0.50)]$
$C_2 = [(F_1, 1.80), (F_4, 0.50)]$	$C_2 = [(F_4, 0.50), (F_1, 1.80)]$	$C_4 = [(F_4, 0.50), (F_2, 1.40)]$	$C_4 = [(F_4, 0.50), (F_2, 1.40)]$
$C_3 = [(F_2, 1.40), (F_3, 1.70)]$	$C_3 = [(F_2, 1.40), (F_3, 1.70)]$	$C_3 = [(F_2, 1.40), (F_3, 1.70)]$	$C_5 = [(F_4, 0.50), (F_3, 1.70)]$
$C_4 = [(F_2, 1.40), (F_4, 0.50)]$	$C_4 = [(F_4, 0.50), (F_2, 1.40)]$	$C_5 = [(F_4, 0.50), (F_3, 1.70)]$	$C_2 = [(F_4, 0.50), (F_1, 1.80)]$
$C_5 = [(F_4, 0.50), (F_3, 1.70)]$	$C_5 = [(F_4, 0.50), (F_3, 1.70)]$	$C_1 = [(F_3, 1.70), (F_1, 1.80)]$	$C_3 = [(F_2, 1.40), (F_3, 1.70)]$
$C_6 = [(F_4, 0.50), (F_4, 0.50)]$	$C_6 = [(F_4, 0.50), (F_4, 0.50)]$	$C_2 = [(F_4, 0.50), (F_1, 1.80)]$	$C_1 = [(F_3, 1.70), (F_1, 1.80)]$

CANDIDATESORTING($\mathbb{S}$)

(1) **foreach** $C \in \mathbb{S}$
(2) SORT (C)
(3) **foreach** $i = |C| : 1$
(4) STABLESORT$(\mathbb{S}, i)$

Fig. 5. The CANDIDATESORTING procedure

the label of this contradiction is the same as that of the special "false" node. By deliberately keeping all the duplications, six candidates are generated as illustrated in the first column of Tab. I. The second column of this table is the result of sorting all the components of each candidate. Because the cardinality of these candidates are 2, the stable sorting subroutine will be invoked twice. The third column is the result of the first calling which is carried out by comparing the second elements of these candidates. The last column is the result of the second calling (and also the final result) achieved by comparing the first elements of all the candidates based on the previous sorting result. After removing all element duplications in each candidate and all the candidate duplications, there are three candidates remaining, which (in ascending order of priority) are: $C_6 = [(F_4, 0.50)]$, $C_3 = [(F_2, 1.40), (F_3, 1.70)]$, $C_1 = [(F_3, 1.70), (F_1, 1.80)]$.

Having generated the set of prioritized candidates, the next step is to correct a single candidate in order to remove all the contradictions and thus restore system consistency. By the ranking procedure, the higher priority a candidate has, the more likely the candidate is to be the real culprit. Therefore, the tentative modification always starts from the candidate with the highest priority. If the tentative modification succeeds, the algorithm terminates. Otherwise, the candidate will be removed from the candidate set and the candidate with the next highest priority in the current set will be tried, and so on.

IV. AN ILLUSTRATIVE EXAMPLE

To illustrate the potential of this extended adaptive approach, the problem given in [15] is reconsidered. The rule base is given as follows:
R_1: If x_1 is A_{11}, then x_2 is A_{21};
R_2: If x_1 is A_{12}, then x_2 is A_{22};
R_3: If x_2 is A_{23}, then x_3 is A_{31};
R_4: If x_2 is A_{24}, then x_3 is A_{32};
R_5: If x_2 is A_{25}, then x_4 is A_{41};
R_6: If x_2 is A_{26}, then x_4 is A_{42};
R_7: If x_3 is A_{33}, then x_5 is A_{51};
R_8: If x_3 is A_{34}, then x_5 is A_{52};
R_9: If x_4 is A_{43}, then x_5 is A_{53};
R_{10}: If x_4 is A_{44}, then x_5 isA_{54}.

Given $\beta_0 = 0.5$ and three observations, $x_1 = A_{13} = (7.0, 8.0, 9.0)$, $x_1 = A_{14} = (7.6, 8.6, 9.6)$ and $x_4 = A_{45} = (12.0, 13.0, 14.0)$, the interpolation procedures are illustrated in Fig. 6 and the original observations as well as interpolated results by scale and move transformation-based interpolation are presented in Fig. 7. Note that in this example, to keep the illustration simple, it has been assumed that the variable x, takes two different object values A_{13} and A_{14}. In practice, this may be caused by the fact that the observations are taken by different agents or that one is a real observation and the other may be produced by other inference mechanism.

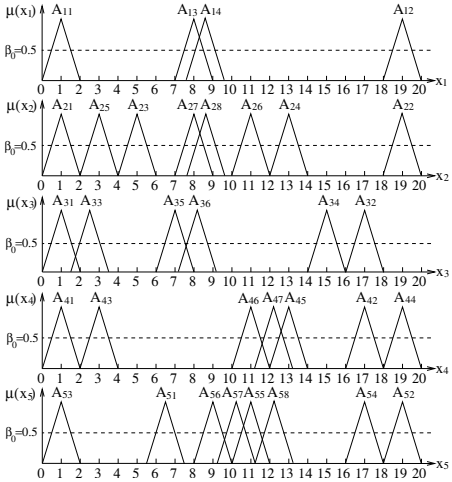

Fig. 7. Fuzzy sets used in the example

A. Certainty degree calculation for reasoning components

The certainty degree of each fuzzy reasoning component can be calculated by applying the approach obtained in Eq. 11. In particular, the distance between two fuzzy sets in this example is defined as the distance between their representative values. For instance, the certainty degree of fuzzy reasoning component R_1R_2 is calculated as follows:

$$\begin{aligned} c_{R_1R_2} &= 1 - \left| \frac{d(A_{11}, A_{12})}{max_1 - min_1} - \frac{d(A_{21}, A_{22})}{max_2 - min_2} \right| \\ &= 1 - \left| \frac{\mathrm{Rep}(A_{12}) - \mathrm{Rep}(A_{11})}{max_1 - min_1} - \frac{\mathrm{Rep}(A_{22}) - \mathrm{Rep}(A_{21})}{max_2 - min_2} \right| \\ &= 1 - \left| \frac{19-1}{20-0} - \frac{19-1}{20-0} \right| \\ &= 1.00, \end{aligned}$$

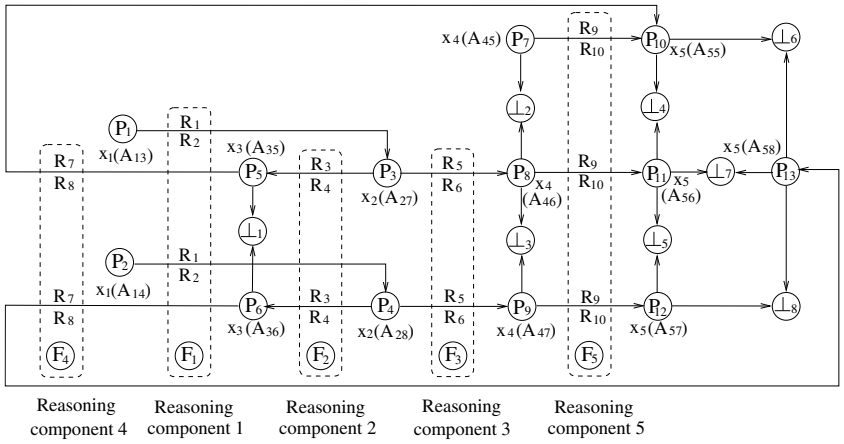

Fig. 6. Discrepancy records in ATMS

where $\mathrm{Rep}(A_{ij})$ denotes the representative value of fuzzy set A_{ij}, $i, j = 1, 2$. Similarly, the certainty degrees of all other fuzzy reasoning components can be calculated. The detailed calculation process is omitted here, but the results are: $c_{R_3R_4} = 0.60$, $c_{R_5R_6} = 0.60$, $c_{R_7R_8} = 1.00$, $c_{R_9R_{10}} = 1.00$.

B. Dependency recording by ATMS

In Fig. 6, an arrowed line which is flanked by two rules R_i and R_{i+1} represents a fuzzy reasoning component, which is denoted as R_iR_{i+1}, $i \in \{1, 3, 5, 7, 9\}$, where R_i and R_{i+1} are the neighboring rules used for interpolation. ATMS nodes and contradictions are represented by circles. Particularly, each F_j, $j \in \{1, 2, ..., 5\}$, is a node denoting a fuzzy reasoning component; each of P_k, $k \in \{1, 2, ..., 13\}$, is a node denoting a proposition; and each $\perp_l$, $l \in \{1, 2, ..., 8\}$, denotes a β_0-contradiction. These ATMS nodes and contradictions are listed as follows, with all justifications omitted:

$F_1 : \langle R_1R_2, 1.00, \{\{R_1R_2\}\}\rangle$;
$F_2 : \langle R_3R_4, 0.60, \{\{R_3R_4\}\}\rangle$;
$F_3 : \langle R_5R_6, 0.60, \{\{R_5R_6\}\}\rangle$;
$F_4 : \langle R_7R_8, 1.00, \{\{R_7R_8\}\}\rangle$;
$F_5 : \langle R_9R_{10}, 1.00, \{\{R_9R_{10}\}\}\rangle$;
$P_1 : \langle x_1 = A_{13}, 1.00, \{\{\}\}\rangle$;
$P_2 : \langle x_1 = A_{14}, 1.00, \{\{\}\}\rangle$;
$P_3 : \langle x_2 = A_{27}, 1.00, \{\{R_1R_2\}\}\rangle$;
$P_4 : \langle x_2 = A_{28}, 1.00, \{\{R_1R_2\}\}\rangle$;
$P_5 : \langle x_3 = A_{35}, 0.60, \{\{R_1R_2, R_3R_4\}\}\rangle$;
$P_6 : \langle x_3 = A_{36}, 0.60, \{\{R_1R_2, R_3R_4\}\}\rangle$;
$P_7 : \langle x_4 = A_{45}, 1.00, \{\{\}\}\rangle$;
$P_8 : \langle x_4 = A_{46}, 0.60, \{\{R_1R_2, R_5R_6\}\}\rangle$;
$P_9 : \langle x_4 = A_{47}, 0.60, \{\{R_1R_2, R_5R_6\}\}\rangle$;
$P_{10} : \langle x_5 = A_{55}, 1.00, \{\{R_1R_2, R_3R_4, R_7R_8\}, \{R_9R_{10}\}\}\rangle$;
$P_{11} : \langle x_5 = A_{56}, 0.60, \{\{R_1R_2, R_5R_6, R_9R_{10}\}\}\rangle$;
$P_{12} : \langle x_5 = A_{57}, 0.60, \{\{R_1R_2, R_5R_6, R_9R_{10}\}\}\rangle$;
$P_{13} : \langle x_5 = A_{58}, 0.60, \{\{R_1R_2, R_3R_4, R_7R_8\}\}\rangle$;
$\perp_1 : \langle \perp, \{\{R_1R_2, R_3R_4\}\}\rangle$;
$\perp_2 : \langle \perp, \{\{R_1R_2, R_5R_6\}\}\rangle$;
$\perp_3 : \langle \perp, \{\{R_1R_2, R_5R_6\}\}\rangle$;
$\perp_4 : \langle \perp, \{\{R_1R_2, R_5R_6, R_9R_{10}\}\}\rangle$;
$\perp_5 : \langle \perp, \{\{R_1R_2, R_5R_6, R_9R_{10}\}\}\rangle$;
$\perp_6 : \langle \perp, \{\{R_1R_2, R_3R_4, R_7R_8\}\}\rangle$;
$\perp_7 : \langle \perp, \{\{R_1R_2, R_3R_4, R_5R_6, R_7R_8, R_9R_{10}\}\}\rangle$;
$\perp_8 : \langle \perp, \{\{R_1R_2, R_3R_4, R_5R_6, R_7R_8, R_9R_{10}\}\}\rangle$.

Note that a certainty degree is attached to each fuzzy reasoning component and proposition, which is calculated and then recorded within the ATMS network, except the certainty degrees of any contradictions which are irrelevant to the present work and hence omitted. Also, as stated previously, the certainty degree of each observation is assumed to be 1 in this research. The certainty degree of any derived node can be calculated by Eq. 17. Within this illustrative example, maximum and algebraic product are used to implement $\oplus$ and $\otimes$ of Eq. 17, respectively. For example, the certainty degree of proposition P_{10} is computed by:

$$\begin{aligned} c_{P_{10}} &= \max\{c_{R_1R_2} \times c_{R_3R_4} \times c_{R_7R_8}, c_{R_9R_{10}}\} \\ &= \max\{1.00 \times 0.60 \times 1.00, 1.00\} \\ &= 1.00. \end{aligned}$$

A specific ATMS node "false", denoted by $P_\perp$, which collectively represents all the contradictions listed above from $\perp_1$ to $\perp_8$, is given as follows:

$P_\perp : \langle \perp, \{\{R_1R_2, R_3R_4\}, \{R_1R_2, R_5R_6\}\}\rangle$.

C. Candidate generation and prioritization

It is recorded in the ATMS that the label environment $\{R_1R_2, R_3R_4\}$ entails contradiction $\perp_1$, which is derived from propositions P_5 and P_6, while P_5 and P_6 are inferred through the same path. A ranking value is computed and attached to each component of this label using the procedure of Fig. 4. Similarly, each component in label environment $\{R_1R_2, R_5R_6\}$ is also attached by a ranking value by the same approach. The result is given as follows:

$\{(R_1R_2, 1.00), (R_3R_4, 0.60)\}$;
$\{(R_1R_2, 1.00), (R_5R_6, 0.60)\}$.

From this, by deliberately keeping all the duplications, four component candidates are generated as follows:

$$C_1 = [(R_1R_2, 1.00), (R_1R_2, 1.00)];$$
$$C_2 = [(R_1R_2, 1.00), (R_5R_6, 0.60)];$$
$$C_3 = [(R_1R_2, 1.00), (R_3R_4, 0.60)];$$
$$C_4 = [(R_3R_4, 0.60), (R_5R_6, 0.60)].$$

Because these four candidates have the same cardinality size, they can be prioritized following the algorithm of Fig. 4. The prioritized result is: C_4, C_2, C_3, C_1, in a descending order. After removing the duplicate candidate component R_1R_2 in component C_1, and then removing supersets C_2 and C_3 (of C_1), the final minimal candidate set consists of two candidates C_1' and C_4':

$$C_1' = [(R_1R_2, 1.00)];$$
$$C_4' = [(R_3R_4, 0.60), (R_5R_6, 0.60)],$$

where C_4' is of a higher priority.

D. Candidate modification

The candidate with the highest priority, i.e. candidate C_4' in this example, needs to be modified first according to the consistency restoring algorithm given in Fig. 2. Following the modification procedure for single candidates as outlined in Sec. II, a set of simultaneous equations and inequations can be calculated. One of the solutions resulting from solving these equations and inequations simultaneously is illustrated in Fig. 8. It is clear from this figure that there is no β_0-contradiction any more and thus consistency has been restored. This means that the original inconsistent interpolation process has been corrected with consistent interpolated results throughout. Note that the other candidate, C_1' cannot lead to any consistent solution although it has a smaller cardinality size, which shows the potential of the proposed work.

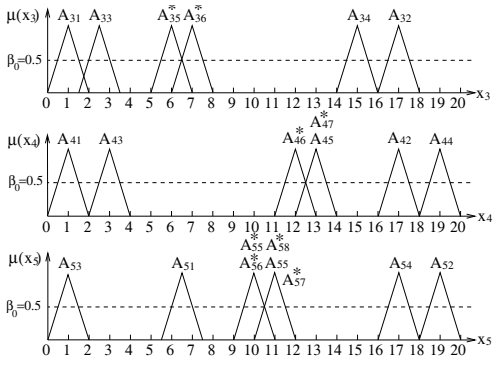

Fig. 8. The solution of the example

V. Conclusions

This paper has extended the recent work on adaptive fuzzy interpolation. It has introduced the concept of the certainty degree of a fuzzy reasoning component and that of the certainty degree of a derived proposition. From this, the classical ATMS has been extended not only to record the dependencies of a node but also to record to what degree the node can be derived from their supporting environments. This is followed by a modified GDE, which is able to prioritize all the generated minimal candidates by exploiting certainty degrees. The actual modification procedure, the same as the one described in [15], takes place, carrying out tentative modification to each minimal candidate of the highest priority until a solution is found. Whilst the working of this method has been illustrated with a practically significant example, real-world applications remain as further work.

Other improvements may enhance the potential of the proposed approach. Currently, the extended approach is only applicable to fuzzy interpolation with two single antecedent rules. It is worthwhile to generalize the approach for fuzzy interpolation with multiple antecedent rules and fuzzy extrapolation. Also, all the rules given in the initial rule base are assumed to be true and fixed. However, this may not be the case in certain real-world situations, despite that it is a common assumption made in the literature of interpolative reasoning. Thus, it is interesting to consider extending the proposed work to allow rules in the given rule base to become themselves diagnosable and modifiable. The initial investigation into such issue has been reported in [16].

Abstract— **Fuzzy Rule Interpolation (FRI) methods are efficient structures for knowledge representation with relatively few rules. In spite of the good knowledge representation efficiency, the usually high computational demand turns the FRI methods hardly suitable for embedded real-time applications, where the short reasoning time has a high importance. On the other hand the fact of increasing computational power of nowadays available devices gives an opportunity to the FRI methods for appearance in real-time embedded applications. The goal of this paper is to introduce the benefit of adapting low computational and resource demanded FRI methods in embedded behavior-based control applications.**

Keywords - fuzzy rule interpolation (FRI); low computational demand FRI; fuzzy automata; behavior-based control.

I. INTRODUCTION

The idea of behavior-based control is in a great extent originated from the existence of descriptive verbal models based on numerous observations of living creature's reactions in different situations. Many of them are built around a predefined sequence of environmental situations and events, where the reactions are in details noted and evaluated. The knowledge representation this case is a series of observations of various facts and action-reaction rules. For mathematical modeling of such a system, the rule-based knowledge representation is straightforward. Moreover the need of following observed sequences requires a model structure of a state machine or an automaton. Adding the fact, that the observable or hidden states are continuous measures, the situation is quite complicated. Summarizing the above requirements, the model has to have a rule-based knowledge representation, and the ability of describing event sequences of continuous values and continuous states. The suggested modeling method is the adaptation of the fuzzy automaton, where the state is a vector of membership values, the state-transitions are controlled by a fuzzy rule-base and the observations and conclusions are continuous values. The main problem in case of practical implementation of such a fuzzy automaton based model is the size of the state-transition rule base. In classical fuzzy reasoning the rule base size is exponential with the number of observations, in this case with the length of the state vector. In case of a behavior-based control model of moderate complexity it could be 10-20 state variables i.e. thousands of rules required for the complete classical rule base (e.g. the Zadeh-Mamdani-Larsen Compositional Rule of Inference (CRI) (Zadeh [1]) (Mamdani [2]) (Larsen [3]) or the Takagi-Sugeno fuzzy inference (Sugeno [4], Takagi-Sugeno [5]).

Moreover, having a verbal model, the existing knowledge is usually a few dozen verbal rules, which means, that most of the rules are undefined. In case of classical fuzzy reasoning this contradiction is hardly solvable.

The solution suggested in this paper for the exponential complexity problem of the required fuzzy automation state-transition rule base is the application of the Fuzzy Rule Interpolation (FRI) methods (one of the first methods was introduced in [6]). By the application of FRI methods the number of the rules required for the FRI state-transition fuzzy model can be reduced to the existing (known from the verbal model) rules. Moreover in case of automatic model generation or fine tuning based on given input-output sample data, the application of the FRI model can also lead to fewer rules and hence less parameters, which means better convergence of the optimization algorithm.

The behavior-based model implementation introduced in this paper is built upon the framework of fuzzy automaton and low computational demand Fuzzy Rule Interpolation (FRI) [7], [8], [9], and [10]. The knowledge representation style of FRI method fits well the conceptually "spare rule-based" structure of the descriptive verbal models, where the "completeness" of the rule-base is essentially not required. FRI methods can provide reasonable (interpolated) conclusions even if none of the existing rules fires under the current observation. From the beginning of 1990s numerous FRI methods have been proposed [11].

II. FUZZY RULE INTERPOLATION (FRI)

Traditional fuzzy rule based systems (e.g. the Zadeh-Mamdani-Larsen CRI ([1], [2], [3]) or the Takagi-Sugeno fuzzy inference ([4], [5]) requires a complete rule base with all of the possible rules set, even though lots of these rules are unimportant from the viewpoint of the actual application. A fuzzy rule base is called sparse or incomplete if an observation may exists, which does not hit any of the rules in the rule base. Accordingly there can be observations, where no conclusion can be gained with traditional fuzzy reasoning techniques. On

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the other hand, in many embedded control application areas having no conclusion is an avoidable situation. One real solution for the sparse rule base is the application of fuzzy rule interpolation (FRI) methods. This case the derivable rules are intentionally missing from the rule base, as FRI methods are capable of providing reasonable (interpolated) conclusions even if none of the existing rules fire under the current observation. The FRI rule base could contain the most significant fuzzy rules alone without risking the chance of having no conclusion for some of the observations. In this case having an efficient knowledge representation, a considerable amount of unnecessary work can be avoided during the rule base creation. On the other hand most of the FRI methods are sharing the burden of high computational demand, e.g. the task of searching for the two closest surrounding rules to the observation, and calculating the conclusion at least in some characteristic α-cuts. Moreover in some methods the interpretability of the fuzzy conclusion gained is also not straightforward [12]. There have been a lot of efforts to rectify the interpretability of the interpolated fuzzy conclusion [13]. In [14] Baranyi *et al.* give a comprehensive overview of the recent existing FRI methods. Beyond these problems, some of the FRI methods are originally defined for one dimensional input space, and need special extension for the multidimensional case (e.g. [15], [16]). In [11] Wong *et al.* gave a comparative overview of the multidimensional input space capable FRI methods. In [15] Jenei introduced a way for axiomatic treatment of the FRI methods. In [17] Johanyák introduces an automatic way for sparse fuzzy model identification from sample data. The high computational demand, mainly the search for the two closest surrounding rules to an arbitrary observation in the multidimensional antecedent space makes many of these methods hardly suitable for real-time applications. Some FRI methods, (e.g. the method introduced by Jenei *et al.* in [16], or FRIPOC [18]), eliminate the search for the two closest surrounding rules by taking all the rules into consideration, hence speeding up the reasoning process. On the other hand, keeping the goal of constructing fuzzy conclusion, and not simply speeding up the reasoning process, they still require some additional (or repeated) computational steps for the elements of the level set (or at least some relevant α levels). An application oriented aspect of the FRI, the low computational and resource demand is emerging in the concept of 'FIVE' (Fuzzy Interpolation based on Vague Environment). In the followings some details of this method will be briefly introduced.

III. FRI BASED ON VAGUE ENVIRONMENT: FIVE

In the concept of 'FIVE' an application oriented aspect, the need for low computational and resource demand has a high importance. The method was originally introduced in [7], [8], [9], and extended in [10] for satisfying the speed requirements of direct fuzzy control, where the conclusions of the fuzzy controller are applied directly as control actions in a real-time system.

The main idea of FIVE is based on the fact that most of the control applications serves crisp observations and requires crisp conclusions from the controller. Adopting the concept of the Vague Environment (VE) [19], FIVE can handle the antecedent and consequent fuzzy partitions of the fuzzy rule base by scaling functions [19] and therefore turn the fuzzy interpolation to crisp interpolation. The idea of a VE is based on the indistinguishability of elements. In VE the fuzzy membership function $\mu_A(x)$ is indicating level of similarity of x to a specific element a which is a representative or prototypical element of the fuzzy set $\mu_A(x)$, or, equivalently, as the degree to which x is indistinguishable from a (see e.g. on Figure 1) [19]. Two values in a VE are ε-indistinguishable if their distance is less or equal than ε. The distances in a VE are weighted distances (1). The weighting factor or function is called scaling function (factor) [19]:

$$\delta_s(a,b)=\left|\int_a^b s(x)dx\right|\le\varepsilon\ , \tag{1}$$

where $\delta_s(a,b)$ is the scaled distance of the values a, b and $s(x)$ is the scaling function on X.

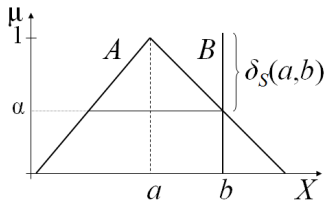

Figure 1. The α-cuts of $\mu_A(x)$ contain the elements that are (1−α)-indistinguishable from a.

If the VE of a fuzzy partition (the scaling function or at least the approximate scaling function [7], [8], [9]) exists, the member sets of the fuzzy partition can be characterized by points in that VE (see e.g. exact scaling function s on Figure 2 and an approximate scaling function on Figure 3).

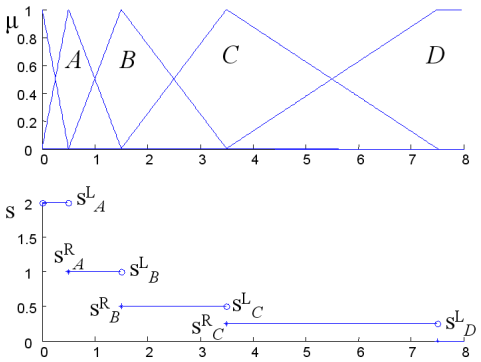

Figure 2. A Ruspini fuzzy (A, B, C, D) partition and its scaling function s.

Having the VE concept and the scaling function based similarity calculation, any crisp interpolation, extrapolation, or regression method can be adapted very simply for FRI [7], [8], [9]. Because of its simple multidimensional applicability, in FIVE the Shepard operator based interpolation (first introduced in [20]) is adapted (see e.g. Figure 4).

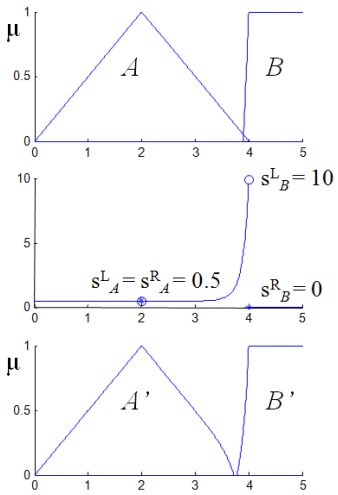

Figure 3. A fuzzy partition (A, B), its approximate scaling function s [7], [8] and the corresponding approximated partition (A', B').

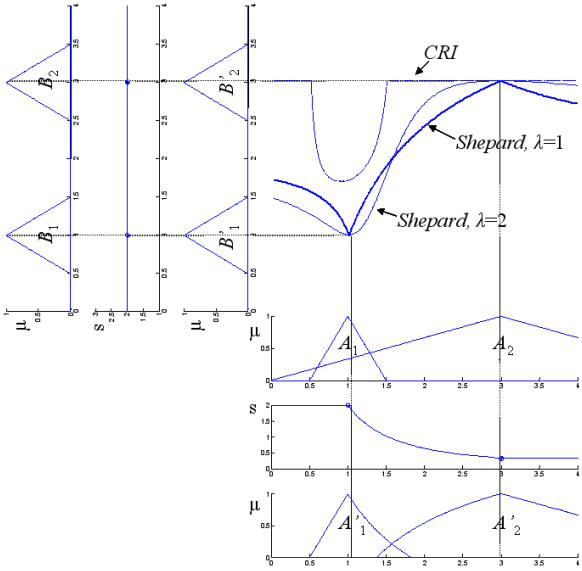

Figure 4. Interpolation of two fuzzy rules (R_i: $A_i \rightarrow B_i$), by the Shepard operator based FIVE (3), and for comparison the min-max CRI with centre of gravity defuzzification.

In case of singleton rule consequents (c_k) the fuzzy rules R_k has the following form:

$$\textbf{If } x_1 = A_{k,1} \textbf{ And } x_2 = A_{k,2} \textbf{ And } \ldots \textbf{ And } x_m = A_{k,m} \textbf{ Then } y = c_k \qquad (2)$$

Adapting the VE concept and the scaling function based similarity calculation to the Shepard operator based interpolation, the conclusion of the interpolative fuzzy reasoning can be obtained as:

$$y(\mathbf{x}) = \begin{cases} c_k & \text{if } \mathbf{x} = \mathbf{a}_k \text{ for some } k, \\ \left(\sum_{k=1}^{r} c_k / \delta_{s,k}^{\lambda}\right) \Big/ \left(\sum_{k=1}^{r} 1/\delta_{s,k}^{\lambda}\right) & \text{otherwise.} \end{cases} \qquad (3)$$

where $\delta_{s,k}$ are scaled distances:

$$\delta_{s,k} = \delta_s(\mathbf{a}_k, \mathbf{x}) = \left[\sum_{i=1}^{m}\left(\int_{a_{k,i}}^{x_i} s_{X_i}(x_i)dx_i\right)^2\right]^{1/2}, \qquad (4)$$

and s_{X_i} is the i^{th} scaling function of the m dimensional antecedent universe, $\mathbf{x}$ is the m dimensional crisp observation and $\mathbf{a}_k$ are the cores of the m dimensional fuzzy rule antecedents $\boldsymbol{A}_k$.

The code of the FIVE FRI together with other FRI methods is freely available as a MATLAB FRI Toolbox [21], and it can be downloaded from [22] and [23].

IV. FRI BASED FUZZY AUTOMATON

There are numerous versions and understanding of the fuzzy automaton can be found in the literature (a good overview van be found in [24]). In our case we start from the most common definition of Fuzzy Finite-state Automaton (FFA, summarized in [24]), where the FFA is defined by a tuple (according to [24], [25] and [26]):

$$\widetilde{F} = (Q, \Sigma, \delta, R, Z, \omega), \qquad (5)$$

where

Q is a finite set of states, $Q=\{q_1,q_2,...,q_n\}$.

Σ is a finite set of input symbols, $\Sigma=\{a_1,a_2,...,a_m\}$.

$R \in Q$ is the (possibly fuzzy) start state of $\widetilde{F}$.

Z is a finite set of output symbols, $Z=\{b_1,b_2,...,b_n\}$.

$\delta : Q \times \Sigma \times Q \rightarrow [0,1]$ is the fuzzy transition function which is used to map a state (current state) into another state (next state) upon an input symbol, attributing a value in the fuzzy interval [0,1] to the next state.

$\omega : Q \rightarrow Z$ is the output function which is used to map a (fuzzy) state to the output.

Extending the concept of FFA from finite set of input symbols to finite dimensional input values turns to the following:

$$\widetilde{F} = (S, X, \delta, P, Y, \omega), \qquad (6)$$

where

S is a finite set of fuzzy states, $S = \{\mu_{s1}, \mu_{s2}, ..., \mu_{sn}\}$.

X is a finite dimensional input vector, $X = \{x_1, x_2, ..., x_m\}$.

$P \in S$ is the fuzzy start state of $\widetilde{F}$.

Y is a finite dimensional output vector, $Y = \{y_1, y_2, ..., y_l\}$.

$\delta : S \times X \to S$ is the fuzzy state-transition function which is used to map the current fuzzy state into the next fuzzy state upon an input value.

$\omega : S \times X \to Y$ is the output function which is used to map the fuzzy state and input to the output value. See e.g. on Figure 5.

In case of fuzzy rule based representation of the state-transition function $\delta : S \times X \to S$, the rules have $n+m$ dimensional antecedent space, and n dimensional consequent space. Applying classical fuzzy reasoning methods, the complete state-transition rule base size can be approximated by the following formula:

$$|R| = n \cdot i^n \cdot j^m, \tag{7}$$

where n is the length of the fuzzy state vector S, m is the input dimension, i is the number of the term sets in each dimensions of the state vector, and j is the number of the term sets in each dimensions of the input vector.

According to (7) the state-transition rule-base size is exponential with the length of the fuzzy state vector and the number of the input dimensions.

Applying FRI methods for the state-transition function fuzzy model can dramatically reduce the rule base size. See e.g. [27], where the originally exponential sized state-transition rule base of a simple heuristic model turned to be polynomial thanks to the FRI.

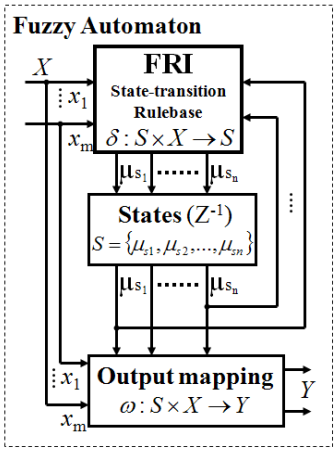

Figure 5. FRI based Fuzzy Automaton.

V. Behaviour-based Control

In behaviour-based control systems (a good overview can be found in [28]), the actual behaviour of the system is formed as one of the existing component behaviours (which fits best the actual situation), or a kind of fusion of the component behaviours appeared to be the most appropriate to handle the actual situation. Beyond the construction of the component behaviors, this structure has two main tasks. The first is the behavior coordination, the decision, which component behavior is needed, or in cases of behavior fusion the determination of the weights for each component behaviors in solving the actual situation. The second is the way of the behavior fusion.

In case of direct application of the suggested FRI based Fuzzy Automaton for behaviour-based control structures, the output function $\omega : S \times X \to Y$ can be decomposed to parallel component behaviors and independent behavior fusion. This case we can get a very similar structure as it is expected in behaviour-based control (see Figure 6).

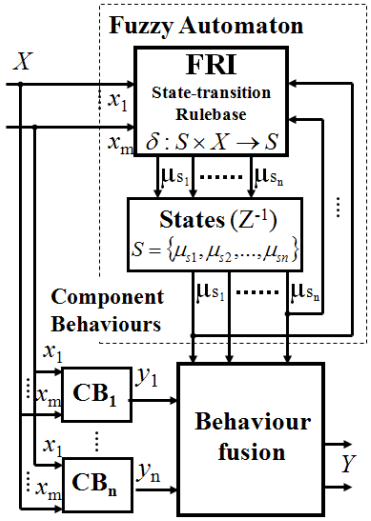

Figure 6. The suggested FRI behaviour-based structure.

VI. Navigation Example

The application example of the proposed structure is a simulated steering control of an automated guided vehicle (AGV) already introduce more detailed in [29], [30].

The reason of the application example in this paper is a demonstration for the simple state-transition FRI rule base creation concept, not for competing in collision avoidance performance with other solutions.

In the example application the steering control has two main goals, the path tracking (to follow a guide path) and the collision avoidance. The simulated AGV is first trying to follow a guide path with minimal path tracking error, and in the case if it is impossible (because of the obstacles) leave it, and as the collision situation is avoided try to find the guide path and follow it again (see Figure 8).

In the collision avoidance strategies, two different collision situations, the frontal and the side collision are distinguished. Having the preconditions of motionless obstacles, it is sufficient to have three ultrasonic distance sensors (on the front of the AGV, one in the middle (U_M) and one-one on both sides (U_L, U_R) (see Figure 7)) to approximate both the collision conditions [30].

In the example, there are four different component behaviours:

Path tracking and restricted collision avoidance strategy: The main goal of this strategy is following the guide path and

as a sub goal, avoiding obstacles if it is possible without risking the chance of losing the guide path [30].

The collision avoidance strategy: A simple collision avoidance steering strategy. Its only goal is to avoid collisions.

The collision avoidance with left/right tendency strategy: The same as the collision avoidance steering strategy, except the left or right turning tendencies in case of no left or right turning difficulties. These strategies are needed to aid finding the path after leaving it.

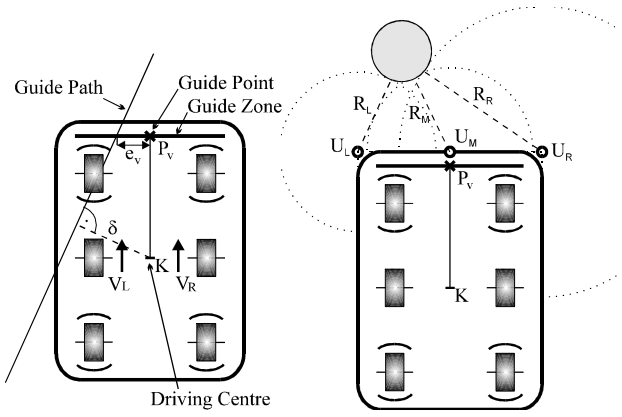

Figure 7. Differential steered AGV with guide zone, e_v is the distance of the guide path and the guide point, P_v is the guide point, K is the driving centre, R_L, R_R, R_M are the distances measured by the left, right and middle ultrasonic sensors (U_L, U_R, U_M).

Having four known component behaviours, the automaton has four state variables (see Figure 6). These are the weight for the path tracking and restricted collision avoidance strategy (S_P), the weight for the collision avoidance strategy (S_C), the weights for the collision avoidance strategy with right tendency (S_{CR}), and for the left tendency (S_{CL}). Having four conclusions, four state-transition rule bases are needed. The $\mathbf{R_{SP}}$ state-transition rule base is determining the next value of the S_P state variable, $\mathbf{R_{SC}}$ is for determining S_C, $\mathbf{R_{SCR}}$ for S_{CR}, and $\mathbf{R_{SCL}}$ for S_{CL}.

The observations of the state-transition rule bases are the distance between the guide path and the driving centre (e_v), the distance measured by the middle ultrasonic sensor ($R_{M)}$ (see Figure 7), the approximated maximal left and right turning angle without side collision (α_{ML}, α_{MR}), the previous state variables (S_P, S_{CR}, S_{CL}), and the availability of path sensing (P_V).

The rules of the state-transition rule bases have the following common form ($R_{Sx,i}$):

If $S_P=A_{1,i}$ **And** $S_{CR}=A_{2,i}$ **And** $S_{CL}=A_{3,i}$ **And** $e_v=A_{4,i}$ **And** $P_V=A_{5,i}$ **And** $R_M=A_{6,i}$ **And** $\alpha_{ML}=A_{7,i}$ **And** $\alpha_{MR}=A_{8,i}$ **Then** $S_x=B_i$.

The state-transition rule bases for the FRI fuzzy automaton are summarized in Tab. 1.

Figure 8 and Figure 9 introduces some results of the simulated application (see more detailed in [30]). The results on Figure 9 shows, that in the tested situation the suggested FRI based Fuzzy Automaton behavior coordination was able to follow the state changes in acceptable level.

TABLE I. STATE-TRANSITION RULE BASES

$\mathbf{R_{SP}}$:

S_P	S_{CR}	S_{CL}	e_v	PV	R_M	α_{ML}	α_{MR}	S_P
			Z	*V*	*L*			*L*
			PL	*V*			*S*	*Z*
			NL	*V*		*S*		*Z*
				NV				*Z*

$\mathbf{R_{SC}}$:

				V	*S*			*L*
				V	*L*			*Z*
				NV				*Z*

$\mathbf{R_{SCR}}$:

S_P	S_{CR}	S_{CL}	e_v	PV	R_M	α_{ML}	α_{MR}	S_P
L			*NL*	*V*				*L*
	L			*NV*				*L*
			Z	*V*	*L*			*Z*
		L						*Z*

$\mathbf{R_{SCL}}$:

S_P	S_{CR}	S_{CL}	e_v	PV	R_M	α_{ML}	α_{MR}	S_P
L			*PL*	*V*				*L*
		L		*NV*				*L*
			Z	*V*	*L*			*Z*
	L							*Z*

where the linguistic labels of the antecedent and consequent fuzzy sets are stand for *N*: negative, *P*: positive, *VL*: very large, *L*: large, *S*: small, *Z*: zero, *V*: path valid, *NV*: path not valid.

VII. CONCLUSION

The application of the suggested FRI based Fuzzy Automaton in embedded behavior-based control applications can dramatically simplify the state-transition rule base creation. In case of the simple example of the paper, the $\mathbf{R_{SP}}$ rule base has only 4 rules, while the complete rule base should have at least $5 \cdot 2 \cdot 2 \cdot 2^2 = 80$, $\mathbf{R_{SCR}}$ and $\mathbf{R_{SCL}}$ has 4 rules, while their complete counterpart has at least $2^3 \cdot 5 \cdot 2 \cdot 2 = 160$.

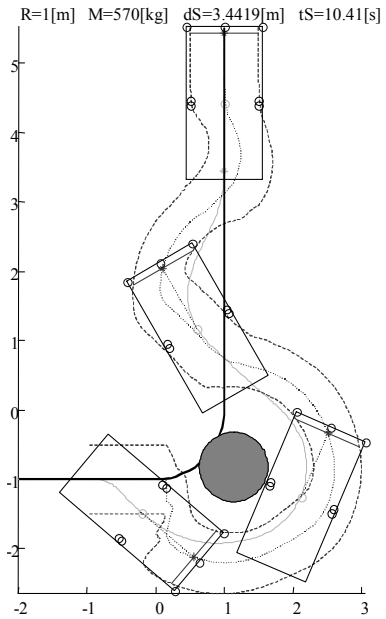

Figure 8. Track of a single run in case of one obstacle.

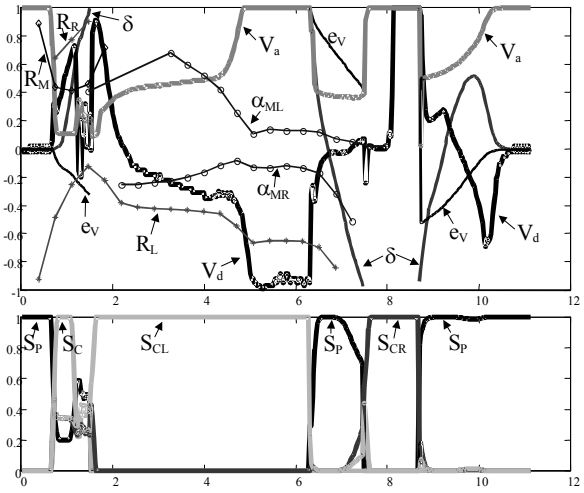

Figure 9. Time function of observations, conclusions and system state values (S_P, S_C, S_{CL}, S_{CR}) related to the track of Figure 8.

***Abstract*—In this paper, an Evolutionary-based Similarity Reasoning (ESR) scheme for preserving the monotonicity property of the multi-input Fuzzy Inference System (FIS) is proposed. Similarity reasoning (SR) is a useful solution for undertaking the incomplete rule base problem in FIS modeling. However, SR may not be a direct solution to designing monotonic multi-input FIS models, owing to the difficulty in getting a set of monotonically-ordered conclusions. The proposed ESR scheme, which is a synthesis of evolutionary computing, *sufficient conditions*, and SR, provides a useful solution to modeling and preserving the monotonicity property of multi-input FIS models. A case study on Failure Mode and Effect Analysis (FMEA) is used to demonstrate the effectiveness of the proposed ESR scheme in undertaking real world problems that require the monotonicity property of FIS models.**

Keywords- Multi-input fuzzy inference system, monotonicity propery, similarity reasoning, fuzzy rule interpolation

I. INTRODUCTION

Recent advances in fuzzy modeling focus on evolutionary fuzzy systems and similarity reasoning (SR)-based techniques. The former attempts to use Evolutionary Computation (EC) techniques to search, learn, or optimize a fuzzy model. Indeed, many problems in fuzzy modeling can be expressed as an optimization problem (either single objective or multi-objectives), and EC have shown to be a promising solution to these problems. Jang *et al*, [1] examined the use of a data-driven fuzzy modeling as a system identification problem which could be expressed as an optimization problem. Ishibuchi *et al.* [2] proposed a Genetic Algorithm (GA)-based technique for selecting a small number of significant fuzzy if-then rules to construct a compact fuzzy classification system with high accuracy. Besides, multi-objective GAs have been used to search for a pareto set of fuzzy models with interpretability and accuracy trade-off [3]. The latter has been proposed as a solution to undertake the incomplete rule base problems. Similarity Reasoning (SR) techniques, e.g. Analogical Reasoning (AR) [4] and Fuzzy Rule Interpolation (FRI) [5], have been exemplified as a type of qualitative reasoning by Zadeh [6]. A conventional Fuzzy Inference System (FIS) assumes that an observation of a rule is mapped to zero, if its conclusion is not defined [7]. However, this may not always be true, and is the so-called "tomato classification problem" [7]. SR is able to deduce a conclusion for an observation, based on a set of incomplete rule base, whereby each rule assumes in the form of antecedent and consequent. In short, a similarity measure (either based on overlapping of membership functions or distance) is obtained between the observation and antecedents of the available rules from the incomplete rule base. A mathematical function is adopted so that the property (or properties) of the conclusion is obtained from the consequent parts of the available rules [8], usually with a weighted addition or average. Similarity measure is then used to indicate the relative weightage of each consequent of the available rules contributing to the conclusion. In this paper, FRI is viewed as a type of SR technique. FRI considers the distance between the observation and the antecedent as a similarity measure, which is further used as an indication to what extend the property (or properties) of the consequent part contributes to the conclusion.

Another recent trend in FIS modeling is the fulfillment of the monotonicity property. Consider an FIS model, $y = f(x_1, x_2, \dots, x_i, \dots, x_n)$, that satisfies the monotonicity condition between its output, y, with respect to its i^{th} input, x_i. Output y monotonically increases or decreases as x_i increases, i.e. $f(x_1, x_2, \dots, x_i^1, \dots, x_n) \leq f(x_1, x_2, \dots, x_i^2, \dots, x_n)$ or $f(x_1, x_2, \dots, x_i^1, \dots, x_n) \geq f(x_1, x_2, \dots, x_i^2, \dots, x_n)$, respectively, for $x_i^1 < x_i^2$. The importance of this line of study has been highlighted in a number of recent publications [9-15]. Among the important aspects include: (1) many real-world systems and control problems obey the monotonicity property [10-11, 14-16]; (ii) the validity of the FIS output needs to be ensured for undertaking comparison, selection, and decision making problems [10, 12-13]; (iii) in the case when the number of data samples is small or the fuzzy rule set is incomplete, it is important to fully exploit the available qualitative information/ knowledge [9]; (iv) taking the additional qualitative information/knowledge of the system into consideration makes the model identification process less vulnerable to noise and inconsistencies in data samples, as well as mitigates the over-fitting phenomenon [9]. However, there are only a few articles that address the issues on how to design monotonicity-preserving FIS models [10].

From the literatures, several investigations on the mathematical conditions for a monotonic FIS model have been reported. Generally, theoretical proof of exact monotonicity in FIS is difficult [11]. But, there are some mathematical conditions that are useful for preserving monotonicity in FIS models. In [14], a set of mathematical conditions (i.e., the *sufficient conditions*) have been derived with the assumption that the first derivative of a Sugeno FIS is always *greater than or equal to* zero, or *less than or equal to* zero, for a

monotonically increasing or decreasing function, respectively. The *sufficient conditions* suggest that two mathematical conditions (at the antecedent and consequent parts) are essential to obtain a monotonicity-preserving FIS model. For a fuzzy partition (at rule antecedent), maintaining a monotonically-ordered rule base can preserve the monotonicity property. This condition has been used and extended in [10, 12-13, 15]. In [9], it has been verified that for three basic T-norms (minimum, product, and Lukasiewicz), a monotonic input-output behavior is obtained for any monotonic rule bases. Some useful guidelines have also been proposed [9]. The relationships among the monotonicity property, monotonic rule base, and comparable fuzzy sets for single-input-rule-modules-connected FIS model are discussed in [11]. The findings in [9-15] indicate that it is important to maintain a monotonic rule base for FIS models.

The aim of this paper is to investigate on the use of SR for preserving the monotonicity property of multi-input FIS models. The focus is on the zero-order Sugeno FIS model coupled with the *sufficient conditions*. In our previous work [17-18], it has been shown that conventional SR that attempts to deduce each FIS rule consequent separately, with a simple weighted average or addition, is useful; but, it may not be a direct solution to preserving the monotonicity property in multi-input FIS models. This is because SR suffers from the difficulty in getting a set of monotonically-ordered conclusions, with respect to a set of observations which are comparable among themselves as well as comparable with the existing incomplete rule base. Thus, in [18], we have investigated the use of optimization techniques for SR with simulated data.

In this study, an Evolutionary-based SR (ESR) scheme is investigated. Instead of a simple weighted average or weighted addition, SR for monotonicity-preserving multi-input FIS models is formulated as a constrained optimization problem. The proposed ESR scheme adopts the *sufficient conditions* [14] as the hard constraints, and employs certain features of SR as the objective function. An evolutionary computing technique is used to search for a set of conclusions for the associated observations. This is a practical SR model, as the constraints in monotonicity-preserving multi-input FIS models are included. We further demonstrate the use of the ESR scheme with a real case study, i.e., an FIS-based Risk Priority Number (RPN) model in Failure Mode and Effect Analysis (FMEA) methodology.

This paper is organized as follows. In section II, the background of FIS models, the *sufficient conditions*, and SR is presented. A summary of our previous analysis [17-18] is also described. In section III, the proposed ESR scheme is explained in detail. A case study and the results are reported in section IV. Concluding remarks are presented in section V.

II. BACKGROUND

A. Fuzzy Inference Systems

The fuzzy production rules for an n-input FIS model, where $n > 1$ can be represented as follows.

$R^{j_1,j_2,\ldots,j_n}$:

$If\ (x_1 is\ A_1^{j_1})AND\ (x_2 is\ A_2^{j_2})\ldots AND(x_n is\ A_n^{j_n})$,

$THEN(y\ is\ B^{j_1,j_2,\ldots,j_n})$

The AND operator in the rule antecedent part is the product function. For the x_i domain, its membership functions are $\mu_i^1(x_i), \mu_i^2(x_i)$, …, and $\mu_i^{n_i}(x_i)$. The output is obtained by using the weighted average of a representative value, $b^{j_1,j_2,\ldots,j_n}$, with respect to its compatibility grade, as in (1).

$$y = \frac{\sum_{j_{n=1}}^{j_{n=M_n}} \ldots \sum_{j_{2=1}}^{j_{2=M_2}} \sum_{j_{1=1}}^{j_{1=M_1}} \left(\mu_1^{j_1}(x_1) \times \mu_2^{j_2}(x_2) \times .. \times \mu_n^{j_n}(x_n) \times b^{j_1,j_2,\ldots,j_n}\right)}{\sum_{j_{n=1}}^{j_{n=M_n}} \ldots \sum_{j_{2=1}}^{j_{2=M_2}} \sum_{j_{1=1}}^{j_{1=M_1}} \left(\mu_1^{j_1}(x_1) \times \mu_2^{j_2}(x_2) \times .. \times \mu_n^{j_n}(x_n)\right)} \quad (1)$$

where $b^{j_1,j_2,\ldots,j_n}$ is a representative value of $B^{j_1,j_2,\ldots,j_n}$, i.e., $b^{j_1,j_2,\ldots,j_n} = Rep\,(B^{j_1,j_2,\mathrm{e}\,j_n})$. The representative value represents the overall location of the membership function (MF). It can be obtained with defuzzification, or with the point that the membership value is 1.

B. Sufficient Conditions

The first derivative of an FIS model, as in (1), returns a weighted addition series. The *sufficient conditions* assume that all the components in the weighted addition series are always *greater than or equal to* zero, or *less than* or *equal to* zero. In general, two conditions can be derived [10, 12-14]:

Condition 1. At the rule antecedent part, $(d\mu_i^p(x)/dx)/\mu_i^p(x) \geq (d\mu_i^q(x)/dx)/\mu_i^q(x)$, where $p > q$. Note that $(d\mu(x)/dx)/\mu(x)$ is the ratio between the rate of change in the membership degree and the membership degree itself. The derivative of a Gaussian MF with respect to x is $G'(x) = -((x-c)/\sigma^2)G(x)$. Note that $(d\mu(x)/dx)/\mu(x)$ for a Gaussian MF , i.e., $(G'(x)/G(x))$, returns a linear function, i.e. $E(x) = G'(x)/G(x) = -(1/\sigma^2)x + (c/\sigma^2)$.

Condition 2. At the rule consequent part, $b^{j_1,j_2,\ldots,j_i=p,..,j_n} - b^{j_1,j_2,\ldots,j_i=q,..,j_n} \geq 0$ or $b^{j_1,j_2,\ldots,j_i=p,..,j_n} - b^{j_1,j_2,\ldots,j_i=q,..,j_n} \leq 0$ for $dy/dx_i \geq 0$ or $dy/dx_i \leq 0$, respectively. This condition suggests that a monotonically-ordered rule base is required.

C. Similarity Reasoning

In this paper, SR is viewed as a computing paradigm, as in Fig. 1. An example of SR [6] is as follows.

If pressure is *high* Then volume is *small*

If pressure is *low* Then volume is *large*

Thus: If pressure is *medium* Then volume is $(w_1 \wedge small + w_2 \wedge large)$, where $w_1 = sup(high \wedge medium)$, and $w_2 = sup(low \wedge medium)$.

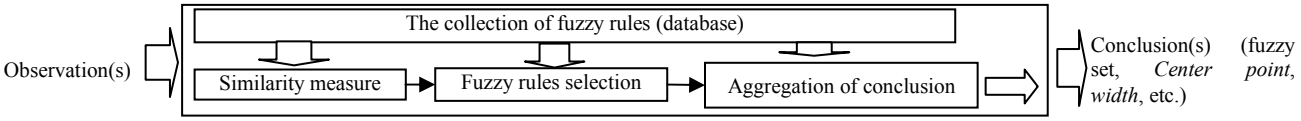

Figure 1 The Similarity reasoning paradigm

The above notion was further extended, and a number of SR schemes have been proposed to allow an unknown conclusion of an observation (in the form of a fuzzy set) to be deduced or predicted, based on a collection of fuzzy rules (database). Note that the "If" part of a fuzzy rule is called the antecedent while the "Then" part is called the consequent. The "If" part of an unknown rule is called the observation, while the "Then" part is called the conclusion.

An observation (in the form of a fuzzy set) acts as an input to the computing paradigm. The observation is compared with the antecedent of each fuzzy rule in the database, and a similarity measure is produced for each fuzzy rule. The similarity measure represents how similar a fuzzy rule is with respect to the observation. There are many ways how this similarity measure can be derived. For example, similarity measure models have been reviewed, compared, and analyzed in [4,8]. In [5, 7, 19], another class of similarity measure that is based on distance has been proposed.

Fuzzy rules from the database are selected for aggregation and for arriving at the conclusions. As an example, in [4], a threshold has been introduced to select fuzzy rules with similarity measure above the threshold. In [19], the n closest fuzzy rules from the observation are selected for use with the Fuzzy Rule Interpolation (FRI) scheme. The importance of the ordering criteria in the selection of fuzzy rules is pointed out in [5,17].

The conclusion is formed by aggregating the selected fuzzy rules. In this stage, a mathematical function is adopted so that the property (or properties) of the conclusion is obtained. The similarity measure is used as an indication of the degree to which the property (or properties) of the consequent of each selected fuzzy rule contributes to the conclusion. In [5], the *center point* and *width* of the conclusion are aggregated using a distance-based similarity measure via a weighted average function. In [6], the conclusion is aggregated using a similarity measure via a weighted addition function. Usually, each conclusion is predicted separately.

D. An Example

In the following section, a summary of our previous work [17-18] is presented. In order to have a better understanding of the work, a numerical example is provided, as follows. A monotonic two-input FIS model, $z = f(x, y)$, is considered. It is known that the relationship between $f(x, y)$ and its inputs, x and y, increases monotonically. Each x and y consists of five Gaussian MFs, i.e., , mf_{x1}, mf_{x2}, mf_{x3}, mf_{x4} and mf_{x5}, and mf_{y1}, mf_{y2} , mf_{y3} , mf_{y4} and mf_{y5} , respectively. These MFs fulfil ***Condition 1***, and can be projected using the ratio as suggested in ***Condition 1*** $(d\mu_i(x)/dx)/\mu_i(x)$, for x and y, respectively.

A complete rule base is expected to have 25 rules. The output domain, z , consists of five MFs , namely mf_{z1} , mf_{z2}, mf_{z3}, mf_{z4} and mf_{z5}, with the representative values of 1, 2, 3, 4, and 5, respectively. In this example, assume that there are eight available rules, as summarized in Fig. 2. Note that the available rules satisfy ***Condition 2***. This problem can also be presented as a rule matrix, as in Fig. 3. As an example, R_1 from Fig. 2 is represented as R_1: mf_{z1}, and located in the cell with coordinate (mf_{x1}, mf_{y1}). Observation $\boldsymbol{A_1^*}$, with coordinate (mf_{x1}, mf_{y2}) is mapped to an unknown conclusion, $\boldsymbol{B_1^*}$, which needs to be predicted by using SR.

R_1: If x is mf_{x1} and y is mf_{y1}, Then z is mf_{z1}
R_2: If x is mf_{x1} and y is mf_{y3}, Then z is mf_{z3}
R_3: If x is mf_{x2} and y is mf_{y4}, Then z is mf_{z5}
R_4: If x is mf_{x3} and y is mf_{y1}, Then z is mf_{z2}
R_5: If x is mf_{x3} and y is mf_{y2}, Then z is mf_{z2}
R_6: If x is mf_{x5} and y is mf_{y1}, Then z is mf_{z3}
R_7: If x is mf_{x5} and y is mf_{y3}, Then z is mf_{z4}
R_8: If x is mf_{x5} and y is mf_{y5}, Then z is mf_{z5}

Figure 3 Rule matrix for a numerical example

Fig. 4 depicts a surface plot of z versus x and y, using FRI based on a weighted average function. A simple distance, i.e., the Euclidian distance, between the representative values of fuzzy sets, is used. Note that the use of the representative values has been suggested in [19]. In short, a non-monotonic surface is obtained.

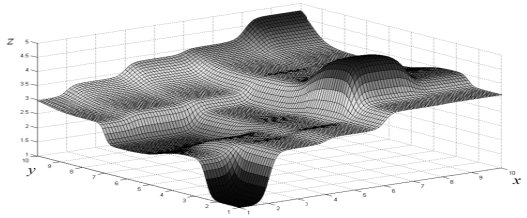

Figure 4 Surface plot of z versus x and y, using an FRI

This phenomenon occurs because a set of non-monotonically-ordered conclusions is deduced by FRI. Two situations as highlighted in [17-18] are:

Situation 1*:* A deduced conclusion of an observation may not be comparable with the collection of fuzzy rules.

Situation 2: It is difficult to deduce a set of conclusions (for a set of observations) that are comparable among one another.

Situation 1 can be solved by adding an ordering criterion [17]. But, ***Situation 2*** suggests that it is necessary to consider the relationship among the conclusions in an SR model. Based on the example, how do we ensure that $B_6^* \geq B_5^*$? Optimization techniques provide a solution to this problem.

III. THE EVOLUTIONARY-BASED SIMILARITY REASONING SCHEME

A. A General Formulation

Consider a multi-input FIS model with $n_{available}$ ($n_{available} > 1$) fuzzy rules $(R_1, R_2, \dots, R_{n_{available}})$, $R_n: A_n \rightarrow B_n$,. There are n_{empty} observations ($A_1^*, A_2^*, \dots, A_{n_{empty}}^*$), where $n_{empty} > 1$. The conclusions for the n_{empty} observations are $B_1^*, B_2^*, \dots, B_{n_{empty}}^*$, respectively. We suggest a SR scheme for monotonicity-preserving multi-input FIS models as a constrained optimization problem. Here, we predict the representative value, instead of the actual membership function, i.e.,

Minimizing

$f\left(b_1^*, b, \dots, b_{n_{empty}}^*\right)$, where $b = rep(B)$

Subject to

Constraint #1: Each conclusion is comparable with the rule collection, i.e, $\overline{b_i} \geq b_i \geq \underline{b_i}$. $\overline{b_i}$ and $\underline{b_i}$ are the highest and lowest possible representative values for the consequent of the observation, respectively. As an example, in Fig. 3, the conclusion of observation $\boldsymbol{A_6^*}$ is $\boldsymbol{B_6^*}$, $\overline{b_6^*} \geq b_6^* \geq \underline{b_6^*}$. The fuzzy rules that are expected to have higher and lower consequents are highlighted in dark-grey and light-grey, respectively. Hence, $\overline{b_6^*}$= **min** (*rep* (mf_{z5}), *rep* (mf_{z4}), *rep* (mf_{z5})), $\underline{b_6^*}$= **max** (*rep* (mf_{z1}), *rep* (mf_{z3})).

Constraint #2: Conclusions are comparable among themselves. In other words, a monotonic ordering of conclusions exist, i.e., $b_i \geq b_j \geq b_k$. As an example, in Fig. 3, $rep(\boldsymbol{B_4^*}) \leq rep(\boldsymbol{B_5^*}) \leq rep(\boldsymbol{B_6^*}) \leq rep(\boldsymbol{B_7^*})$.

In this paper, we investigate the use of a *proximity measure* function that is to be minimized in SR. Each conclusion is further predicted with an SR scheme (as explained in section II(C)), and a set of *reference consequents* is obtained. A *reference conclusion* of a conclusion, $Rep\,(B^*)$, is denoted by $Rep\,(B^*)_R$. For a set of candidates denoted by $(Rep\,(B_1^*)_C, Rep\,(B_2^*)_C, \dots, Rep\,(B_{n_{empty}}^*)_C)$, the *proximity measure* is expressed with a root mean square function, as in (2). It is a measure of "closeness" between the candidates and the *reference conclusions*. The lower the *proximity measure*, the closer the candidate is.

$$Proximity\ measure = \sqrt[2]{\sum_{n=1}^{n_{empty}} (b_{n\,R}^* - b_{n\,C}^*)^2}, \quad (2)$$

where $b = rep(B)$

B. Genetic Algorithem Search

The problem formulated in Section III (A) can be solved using an evolutionary computation technique, e.g. the Genetic Algorithm (GA) [20]. GA is a population-based stochastic optimization technique. Each potential solution set, in a form of $\left(b_1^*, b, \dots, b_{n_{empty}}^*\right)$, is represented by a chromosome. The GA search procedure is used to find the solution set with the best fitness value. Fig. 5 shows the GA procedure.

```
%Note: Initialize variable
Determine the lowest possible representative value and highest
possible representative value of each conclusion.
Determine an reference Conclusion for each conclusion with an SR
scheme

Evaluate conclusion_candidate_set(s) with (3)
Record the best conclusion_candidate_set(s)
Crossover
Mutation
Evaluate the stopping criteria
}
```

Figure 5. Pseudo-code of the proposed GA based SR scheme

The hard constraints, i.e., **constraints #1** and **#2**, are considered as penalties of the objective function to be minimized, as in (3).

$$\begin{aligned} &Objective\ function \\ &= w \times \left(\begin{cases} 0\ if\ constraints\ \#1 \text{ and } \#2\ fulfilled \\ 1\ if\ constraints\ \#1 \text{ and } \#2\ not\ fulfilled \end{cases}\right) \\ &+ proximity\ measure \end{aligned} \quad (3)$$

IV. EXPERIMENTAL RESULTS AND DISCUSSION

A. Failure Mode and Effect Analysis

Failure Mode and Effective Analysis (FMEA) is a popular problem prevention methodology that can be interfaced with many engineering and reliability models [13, 21]. FMEA uses an RPN model to evaluate the risk associated with each failure mode. The RPN model considers three risk factors, i.e., severity (S), occurrence (O), and detect (D), and produces a RPN score ($RPN = g_{RPN}(S, O, D)$). The three input factors are estimated by domain experts in accordance with the scale from "1" to "10" based on a set of commonly agreed evaluation criteria, which are presented in the scale tables.

In this paper, the focus is on designing a monotonicity-preserving FIS-based RPN model. FIS-based RPN models are popular, and they have been widely used [13, 21]. They act as a solution for decision making and selection problems for FMEA methodology. An FIS-based RPN model considers S, O, and D as the inputs and the RPN as the output. MFs of S, O, and D are generated from the designated scale tables. The relationships between S, O, and D and the RPN are expressed by a set of fuzzy If-Then rules. In our previous work [13, 21], it has been shown that an effective FIS-based RPN model should satisfy the monotonicity property. This is because the inputs (i.e., S, O, and D ratings) are defined in such a way that the higher the rating, the more critical the situation is. The output (i.e., the RPN score) is a measure of the failure risk. The monotonicity property is important to allow a valid comparison among all failure modes to be made [12-13]. A prediction is deemed illogical if the RPN model yields a contradictory result [12-13].

To validate the proposed procedure, a series of experiments with data and information collected from a semiconductor manufacturing process is conducted. Specifically, the test handler process of the Flip Chip Ball

Grid Array (FCBGA) product is considered. MFs of S, O, and D of the FIS-based RPN model are constructed using the scale tables in [21]. A fuzzy rules base is formed by collecting information from the domain experts, i.e., engineers in charge of the test handler process. Experiments are conducted according to the following conditions : (1) the fuzzy rule base is incomplete (50% of the fuzzy rules are randomly selected) and without SR; (2) the fuzzy rule base is incomplete (50% of the fuzzy rules are randomly selected) and FRI is used to deduce the missing fuzzy rules; (3) the fuzzy rule base is incomplete (50% of the fuzzy rules are randomly selected) and the ESR scheme (as in section III) is used to deduce the missing fuzzy rules. Note that when SR is not used, the conclusions are mapped to zero.

B. Experimental Results

Fig. 6 depicts the objective function versus the number of generations of the GA simulation, with, $w = 20$, for 150 iterations. The objective function of the best individual is subject to GA operations, i.e., crossover and mutation.

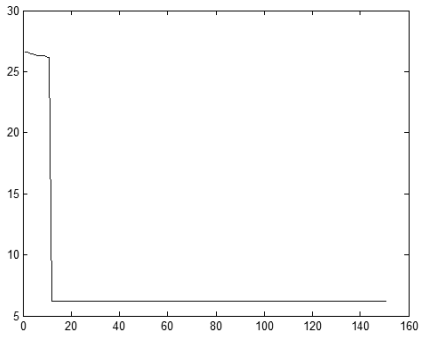

Figure 6 Objective function versus the number of generations of the GA-based procedure for 150 iterations.

The monotonicity property of an FIS model can be observed by using the surface plot. Figures 7, 8, and 9 depict the surface plots of the RPN scores versus O and D when S is fixed at 8, for 50% fuzzy rules.

Without FRI, the surface plot, as shown in Fig. 7, is not monotonic. There are areas where the RPN scores are close to zero because some of the conclusions are undefined, and they are mapped to zero. This is the co-called "tomato classification problem".

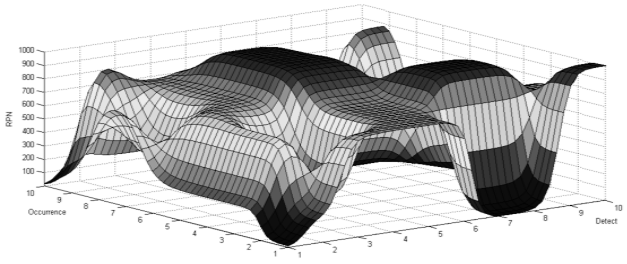

Figure 7 Surface plot for 50% fuzzy rules and without FRI

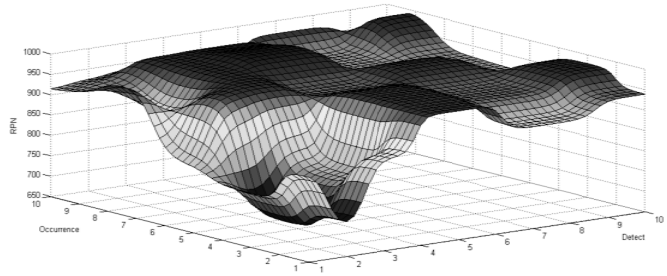

Figure 8 Surface plot for 50% fuzzy rules and with FRI

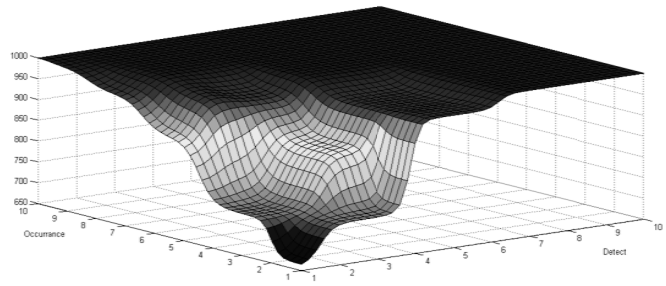

Figure 9 Surface plot for 50% fuzzy rules and with ESR

The use of FRI improves the situation partially. Fig. 8 depicts a "smoother" surface than that of Fig. 7. The effect of the "tomato classification problem" is reduced, as the RPN scores are not mapped to zero. However, the monotonicity property is not satisfied. This is because the rule base obtained is not monotonically-ordered. With the ESR scheme, a monotonic surface plot is obtained, as shown in Fig. 9. In short, the monotonicity property is fulfilled by using the proposed ESR scheme.

C. Evaluation

Fulfillment of the monotonicity property of FIS models can also be evaluated by a test for monotonicity [22]. In this paper, the test for monotonicity of the FIS-based RPN model is conducted by comparing the outputs in pairs. The aim of the test is to examine the relationships between the output (the RPN score) and the inputs (S, O, or D). The test allows the monotonic relationship to be represented by a numerical value, from 0 to 1. We attempt to generate all possible comparable pairs between the output and each of the inputs. The number of monotonic pairs is counted, and the degree of monotonicity is obtained as in (4).

$$Degree\ of\ monotonicity = \frac{\#\ Monotone\ pairs(D)}{\#Comparable\ pairs\ (D)} \qquad (4)$$

The $Degree\ of\ monotonicity$ is 1 for an ideal monotonic FIS model. The $Degree\ of\ monotonicity$ is 0 if the FIS model violates totally the condition of monotonicity. A higher $Degree\ of\ monotonicity$ implies a better fulfillment of the monotonicity property by the FIS model under test.

As an example, comparable pairs in the form of [S,O,D] are generated, i.e., [1,1,1] and [2,1,1], [2,1,1] and [3,1,1],…, [9,1,1] and [10, 1,1], …, and finally [9, 10, 10] and [10, 10, 10]. The RPN scores for [1,1,1] and [2,1,1] are compared, and its fulfillment towards monotonicity is checked. The same goes to other comparable pairs. In this case, 900 comparable pairs are generated between the RPN and S. The same applies to the RPN and O as well as the RPN and D. Thus, a total of 2700 comparable pairs are available. Table 1 shows the results.

Table1 The measure of monotonicity

Experiment	#Comparable pairs	#Monotonic pairs	Degree of monotonicity
Without SR	2700	1376	0.51
With FRI	2700	1981	0.73
With ESR	2700	2700	1.00

As can be seen in Table 1, without SR, there are 1376 monotonic pairs, and the *degree of monotonicity* is 0.51. An improvement is achieved with FRI, i.e., 1981 monotonic pairs, with the *degree of monotonicity* of 0.73. The ESR scheme is able to generate 2700 monotonic pairs, with the *Degree of monotonicity* of 1. This indicates that a full fulfilment of monotonicy among the RPN and S, O, and D ratings. In other words, the monotonicity property is fully perserved with the use of the ESR scheme.

V. SUMMARY

In this paper, it is argued that SR that predicts each rule consequent separately, using a simple weighted average function, may not be a direct solution for designing a monotonic multi-input FIS model. An alternative SR scheme, i.e., ESR, is thus proposed. It is formulated as a constrained optimization problem. An optimization procedure, i.e., GA, is adopted to search for a set of conclusions that obey the *sufficient conditions*, with the minimum proximity measure. An experiment has been conducted with real data collected from industry, i.e., an FIS-based RPN model for FMEA. The results show that without SR, the output does not fulfill the monotonicity property, and some regions are mapped to zero, hence leading to the "tomato classification problem". With SR, the situation is improved, but the output is still not able to satisfy the monotonicity property. With the proposed ESR scheme, the monotonicity property can be preserved. As a result, ESR provides a solution to designing multi-input FIS models that preserve the monotonicity property.

For further work, investigations into other evolutionary models, e.g. particle swarm optimization, harmonic search etc., can be conducted. Alternative methods of handling constraints will be studied. In addition to FMEA, experiments in different domains are needed to fully evaluate the proposed ESR scheme in designing useful monotonic multi-input FIS models for various applications.

ACKNOWLEDGMENT

The financial support provided by the Fundamental Research grant (No. FRGS/02(10)/752/2010(38)) and USM RU Grant (No. 814089) for this work is highly appreciated.

***Abstract*—In this paper, we present a new method for fuzzy rule interpolation with interval type-2 Gaussian fuzzy sets for sparse fuzzy rule-based systems based on genetic algorithms. The proposed fuzzy rule interpolation method deals with the interpolation of fuzzy rules based on the multiple fuzzy rules interpolation scheme. We also present a new learning method to learn optimal interval type-2 Gaussian fuzzy sets for sparse fuzzy rule-based systems based on genetic algorithms. We apply the proposed fuzzy rule interpolation method and the proposed learning method to deal with the Mackey-Glass chaotic time series prediction problem. The experimental result shows that the proposed fuzzy rule interpolation method using the optimally learned interval type-2 Gaussian fuzzy sets obtained by the proposed learning method gets higher average accuracy rates than the existing methods to deal with the Mackey-Glass chaotic time series prediction problem.**

Keywords-Fuzzy rule interpolation; sparse fuzzy rule-based systems; interval type-2 Gaussian fuzzy sets; type-1 Gaussian fuzzy sets; genetic algorithms

I. INTRODUCTION

In recent years, some methods [4], [6], [7], [17] have been presented to deal with fuzzy rule interpolation in sparse fuzzy rule-based systems based on interval type-2 fuzzy sets [18]. In [4], Chang and Chen presented a method for fuzzy rule interpolation based on the principle membership functions and the uncertainty grade functions of interval type-2 fuzzy sets. In [6], Chen and Chang presented a method for fuzzy rule interpolation based on the ratios of fuzziness of interval type-2 fuzzy sets. In [7], Chen and Chang presented a method for fuzzy rule interpolation based on the uncertainty ratios of interval type-2 fuzzy sets. In [17], Lee and Chen presented a method for fuzzy rule interpolation based on the ranking values of interval type-2 fuzzy sets.

In this paper, we present a new method for fuzzy rule interpolation with the learned interval type-2 Gaussian fuzzy sets for sparse fuzzy rule-based systems based on genetic algorithms. The proposed fuzzy rule interpolation method deals with the interpolation of fuzzy rules based on the multiple fuzzy rules interpolation scheme. We also present a new learning method to learn optimal interval type-2 Gaussian fuzzy sets for sparse fuzzy rule-based systems based on genetic algorithms. We apply the proposed learning method and the proposed fuzzy rule interpolation method to deal with the Mackey-Glass chaotic time series prediction problem. The experimental result shows that the proposed fuzzy rule interpolation method using the optimally learned interval type-2 Gaussian fuzzy sets obtained by the proposed learning method gets higher average accuracy rates than the existing methods [2], [8], [13] to deal with the Mackey-Grass chaotic time series prediction problem.

II. PRELIMINARIES

In this section, we briefly introduce the concepts of interval type-2 Gaussian fuzzy sets [16], [18]. A type-1 Gaussian fuzzy set $\widetilde{A}$ represented by the membership function $e^{-\frac{(x-m)^2}{2\sigma^2}}$ can be denoted by $\widetilde{A} = <m, \sigma>$, as shown in Fig. 1, where m and σ denote the mean and the standard deviation of the type-1 Gaussian fuzzy set $\widetilde{A}$, respectively.

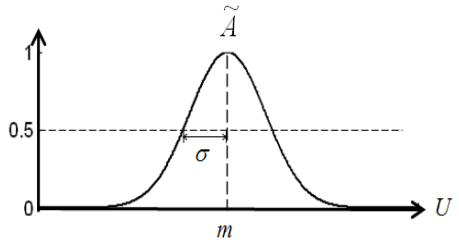

Fig. 1. A type-1 Gaussian fuzzy set $\widetilde{A}$.

Definition 2.1 **[18]:** An interval type-2 Gaussian fuzzy set $\widetilde{\widetilde{A}}$ can be represented by $< \widetilde{\widetilde{A}}^{U}, \widetilde{\widetilde{A}}^{L} >$, where $\widetilde{\widetilde{A}}^{U}$ and $\widetilde{\widetilde{A}}^{L}$ denote the upper membership function and the lower membership function of $\widetilde{\widetilde{A}}$, respectively, and both $\widetilde{A}^{U}$ and $\widetilde{A}^{L}$ are type-1 Gaussian fuzzy sets.

Let us consider the adjacent type-1 Gaussian fuzzy sets $\widetilde{A}_1 = <m_1, \sigma_1>$ and $\widetilde{A}_2 = <m_2, \sigma_2>$ shown in Fig. 2. Based on [16], we can get an interval type-2 Gaussian fuzzy set $\widetilde{\widetilde{A}} = < \widetilde{\widetilde{A}}^{U}, \widetilde{\widetilde{A}}^{L} >$ obtained from $\widetilde{A}_1$ and $\widetilde{A}_2$, as shown in Fig. 3, where

$$\widetilde{\widetilde{A}} = <[m_1, m_2], \sigma_1; \sigma_2>, \quad (1)$$

$[m_1, m_2]$ denotes the interval-valued mean of the interval type-2 Gaussian fuzzy set $\widetilde{\widetilde{A}}$, σ_1 and σ_2 are called the left standard deviation and the right standard deviation of the interval type-2 Gaussian fuzzy set $\widetilde{\widetilde{A}}$, respectively, $m_1 \le m_2$, $\sigma_1 > 0$ and $\sigma_2 > 0$.

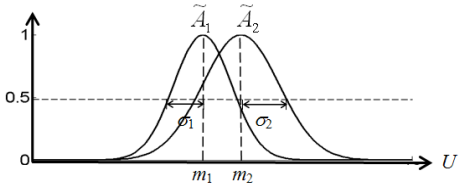

Fig. 2. Two adjacent type-1 Gaussian fuzzy sets $\tilde{A}_1 = <m_1, \sigma_1>$ and $\tilde{A}_2 = <m_2, \sigma_2>$.

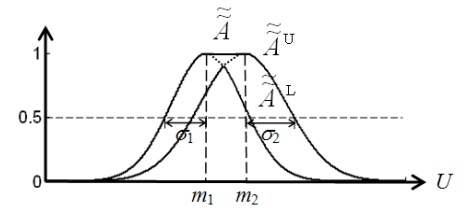

Fig. 3. An interval type-2 Gaussian fuzzy set $\tilde{\tilde{A}} = <[m_1, m_2], \sigma_1; \sigma_2>$.

Let us consider an interval type-2 Gaussian fuzzy set $\tilde{\tilde{A}}$ having an interval-valued mean $[m_1, m_2]$, a left standard deviation σ_1 and a right standard deviation σ_2, as shown in Fig. 3, where $\tilde{\tilde{A}} = <[m_1, m_2], \sigma_1; \sigma_2>$, $m_1 < m_2$, $\sigma_1 > 0$ and $\sigma_2 > 0$. If $m_1 = m_2$ and $\sigma_1 = \sigma_2$, then the interval type-2 Gaussian fuzzy set $\tilde{\tilde{A}}$ becomes the type-1 Gaussian fuzzy set $\tilde{A}$, as shown in Fig. 1.

Definition 2.2: The representative value $Rep(\tilde{\tilde{A}})$ of the Gaussian interval type-2 fuzzy set $\tilde{\tilde{A}} = <[m_1, m_2], \sigma_1; \sigma_2>$ is calculated as follows:

$$Rep(\tilde{A}) = \frac{m_1 \times \sigma_1 + m_2 \times \sigma_2}{\sigma_1 + \sigma_2}, \tag{2}$$

where $m_1 \le Rep(\tilde{A}) \le m_2$, $\sigma_1 > 0$ and $\sigma_2 > 0$

From Eq. (2), we can see that the larger the value of the standard deviation σ_i, the closer the representative value $Rep(\tilde{\tilde{A}})$ to m_i, where $1 \le i \le 2$.

III. A New Method For Fuzzy Rule Interpolation Based on Interval Type-2 Gaussian Fuzzy Sets

In this section, we present a new method for fuzzy rule interpolation based on interval type-2 Gaussian fuzzy sets. Let us consider the following multiple fuzzy rules interpolation scheme using interval type-2 Gaussian fuzzy sets:

Rule 1: If X_1 is $\tilde{\tilde{A}}_{1,1}$ and X_2 is $\tilde{\tilde{A}}_{1,2}$ and ... and X_m is $\tilde{\tilde{A}}_{1,m}$ **Then** Y is $\tilde{\tilde{B}}_1$

Rule 2: If X_1 is $\tilde{\tilde{A}}_{2,1}$ and X_2 is $\tilde{\tilde{A}}_{2,2}$ and ... and X_m is $\tilde{\tilde{A}}_{2,m}$ **Then** Y is $\tilde{\tilde{B}}_2$

$\vdots$

Rule p: If X_1 is $\tilde{\tilde{A}}_{p,1}$ and X_2 is $\tilde{\tilde{A}}_{p,2}$ and ... and X_m is $\tilde{\tilde{A}}_{p,m}$ **Then** Y is $\tilde{\tilde{B}}_p$

Observation: X_1 is $\tilde{\tilde{A}}_1^*$ and X_2 is $\tilde{\tilde{A}}_2^*$ and ... and X_m is $\tilde{\tilde{A}}_m^*$

Conclusion: Y is $\tilde{\tilde{B}}^*$

the jth antecedent variable X_j, $\tilde{\tilde{B}}^* = <[m_{\tilde{\tilde{B}}^*,1}, m_{\tilde{\tilde{B}}^*,2}], \sigma_{\tilde{\tilde{B}}^*,1}; \sigma_{\tilde{\tilde{B}}^*,2}>$ is the interval type-2 Gaussian fuzzy set of the fuzzy interpolated result, m denotes the number of antecedent variables in the fuzzy rules, p denotes the number of fuzzy rules, $1 \le j \le m$ and $1 \le k \le p$. In this paper, we use the neighboring fuzzy rules [5] with respect to the observation as the closest fuzzy rules with respect to the observation for fuzzy rule interpolation, where each antecedent fuzzy set $\tilde{\tilde{A}}_{k,j}$ of the closest fuzzy rule *Rule k* is either the left nearest fuzzy set or the right nearest fuzzy set with respect to the observation fuzzy set $\tilde{\tilde{A}}_j^*$, where $1 \le j \le m$ and $1 \le k \le p$.

The proposed method for fuzzy rule interpolation using interval type-2 Gaussian fuzzy sets is now presented as follows:

Step 1: Based on Eq. (2), calculate the representative values $Rep(\tilde{\tilde{A}}_{k,j})$ of each antecedent interval type-2 fuzzy set $\tilde{\tilde{A}}_{k,j}$ appearing in fuzzy rule *Rule k* and calculate the representative values $Rep(\tilde{\tilde{A}}_j^*)$ of each observation interval type-2 fuzzy set $\tilde{\tilde{A}}_j^*$, respectively, where

$$Rep(\tilde{\tilde{A}}_{k,j}) = \frac{m_{\tilde{\tilde{A}}_{k,j},1} \times \sigma_{\tilde{\tilde{A}}_{k,j},1} + m_{\tilde{\tilde{A}}_{k,j},2} \times \sigma_{\tilde{\tilde{A}}_{k,j},2}}{\sigma_{\tilde{\tilde{A}}_{k,j},1} + \sigma_{\tilde{\tilde{A}}_{k,j},2}}, \tag{3}$$

$$Rep(\tilde{\tilde{A}}_j^*) = \frac{m_{\tilde{\tilde{A}}_j^*,1} \times \sigma_{\tilde{\tilde{A}}_j^*,1} + m_{\tilde{\tilde{A}}_j^*,2} \times \sigma_{\tilde{\tilde{A}}_j^*,2}}{\sigma_{\tilde{\tilde{A}}_j^*,1} + \sigma_{\tilde{\tilde{A}}_j^*,2}}, \tag{4}$$

$1 \le k \le p$ and $1 \le j \le m$.

Step 2: Calculate the weight W_k of the closest fuzzy rule *Rule k* with respect to the observation fuzzy sets [3], where

$$w_k = \min_{1 \le j \le m} \left(1 - \left| \frac{Rep(\tilde{\tilde{A}}_j^*) - Rep(\tilde{\tilde{A}}_{k,j})}{Rep(\tilde{\tilde{A}}_{r_j,j}) - Rep(\tilde{\tilde{A}}_{l_j,j})} \right| \right), \tag{5}$$

$$W_k = \frac{w_k}{\sum_{q=1}^{p} w_q}, \tag{6}$$

$Rep(\tilde{\tilde{A}}_{l_j,j})$ and $Rep(\tilde{\tilde{A}}_{r_j,j})$ are the representative values of the left nearest antecedent fuzzy sets $\tilde{\tilde{A}}_{l_j,j}$ and the right nearest antecedent fuzzy set $\tilde{\tilde{A}}_{r_j,j}$ with respect to the observation fuzzy set $\tilde{\tilde{A}}_j^*$, respectively, $0 \le W_k \le 1$, $\sum_{k=1}^{p} W_k = 1$ and $1 \le k \le p$.

Step 3: Construct an intermediate interpolated fuzzy rule, shown as follows:

If X_1 is $\tilde{\tilde{A}}_1'$ and X_2 is $\tilde{\tilde{A}}_2'$ and ... and X_m is $\tilde{\tilde{A}}_m'$ Then Y is $\tilde{\tilde{B}}'$.

where $\tilde{\tilde{A}}'_j = <[\, m_{\tilde{\tilde{A}}'_j,1}, \, m_{\tilde{\tilde{A}}'_j,2}\,], \, \sigma_{\tilde{\tilde{A}}'_j,1}; \, \sigma_{\tilde{\tilde{A}}'_j,2}>$ is an interval type-2 Gaussian fuzzy set appearing in the *j*th antecedent of the constructed intermediate interpolated fuzzy rule, $\tilde{\tilde{B}}' = <[\, m_{\tilde{\tilde{B}}',1}, \, m_{\tilde{\tilde{B}}',2}\,], \, \sigma_{\tilde{\tilde{B}}',1}; \, \sigma_{\tilde{\tilde{B}}',2}>$ is an interval type-2 Gaussian fuzzy set appearing in the consequence of the constructed intermediate interpolated fuzzy rule and $1 \le j \le m$. The interval-valued mean $[\, m_{\tilde{\tilde{A}}'_j,1}, \, m_{\tilde{\tilde{A}}'_j,2}\,]$, the left standard deviation $\sigma_{\tilde{\tilde{A}}'_j,1}$ and the right standard deviation $\sigma_{\tilde{\tilde{A}}'_j,2}$ of the interval type-2 Gaussian fuzzy set $\tilde{\tilde{A}}'_j = <[\, m_{\tilde{\tilde{A}}'_j,1}, \, m_{\tilde{\tilde{A}}'_j,2}\,], \, \sigma_{\tilde{\tilde{A}}'_j,1}; \, \sigma_{\tilde{\tilde{A}}'_j,2}>$ are calculated as follows:

$$m_{\tilde{\tilde{A}}'_j,1} = \sum_{k=1}^{p} (W_k \times m_{\tilde{\tilde{A}}_{k,j},1}), \tag{7}$$

$$m_{\tilde{\tilde{A}}'_j,2} = \sum_{k=1}^{p} (W_k \times m_{\tilde{\tilde{A}}_{k,j},2}), \tag{8}$$

$$\sigma_{\tilde{\tilde{A}}'_j,1} = \sum_{k=1}^{p} (W_k \times \sigma_{\tilde{\tilde{A}}_{k,j},1}), \tag{9}$$

$$\sigma_{\tilde{\tilde{A}}'_j,2} = \sum_{k=1}^{p} (W_k \times \sigma_{\tilde{\tilde{A}}_{k,j},2}), \tag{10}$$

where $0 \le W_k \le 1$, $\sum_{k=1}^{p} W_k = 1$, $1 \le k \le p$ and $1 \le j \le m$. The interval-valued mean $[\, m_{\tilde{\tilde{B}}',1}, \, m_{\tilde{\tilde{B}}',2}\,]$, the left standard deviation $\sigma_{\tilde{\tilde{B}}',1}$ and the right standard deviation $\sigma_{\tilde{\tilde{B}}',2}$ of the interval type-2 Gaussian fuzzy set $\tilde{\tilde{B}}' = <[\, m_{\tilde{\tilde{B}}',1}, \, m_{\tilde{\tilde{B}}',2}\,], \, \sigma_{\tilde{\tilde{B}}',1}; \, \sigma_{\tilde{\tilde{B}}',2}>$ are calculated as follows:

$$m_{\tilde{\tilde{B}}',1} = \sum_{k=1}^{p} (W_k \times m_{\tilde{\tilde{B}}_k,1}), \tag{11}$$

$$m_{\tilde{\tilde{B}}',1} = \sum_{k=1}^{p} (W_k \times m_{\tilde{\tilde{B}}_k,2}), \tag{12}$$

$$\sigma_{\tilde{\tilde{B}}',1} = \sum_{k=1}^{p} (W_k \times \sigma_{\tilde{\tilde{B}}_k,1}), \tag{13}$$

$$\sigma_{\tilde{\tilde{B}}',2} = \sum_{k=1}^{p} (W_k \times \sigma_{\tilde{\tilde{B}}_k,2}), \tag{14}$$

where $0 \le W_k \le 1$, $\sum_{k=1}^{p} W_k = 1$ and $1 \le k \le p$.

Step 4: Get the interval-valued mean $[\, m_{\tilde{\tilde{B}}^*,1}, \, m_{\tilde{\tilde{B}}^*,2}\,]$, the left standard deviation $\sigma_{\tilde{\tilde{B}}^*,1}$ and the right standard deviation $\sigma_{\tilde{\tilde{B}}^*,2}$ of the fuzzy interpolated result $\tilde{\tilde{B}}^* = <[\, m_{\tilde{\tilde{B}}^*,1}, \, m_{\tilde{\tilde{B}}^*,2}\,], \, \sigma_{\tilde{\tilde{B}}^*,1}; \, \sigma_{\tilde{\tilde{B}}^*,2}>$, respectively, where

$$m_{\tilde{\tilde{B}}^*,1} = m_{\tilde{\tilde{B}}',1}, \tag{15}$$

$$m_{\tilde{\tilde{B}}^*,2} = m_{\tilde{\tilde{B}}',2}, \tag{16}$$

$$\sigma_{\tilde{\tilde{B}}^*,1} = \sigma_{\tilde{\tilde{B}}',1} \times \frac{\sum_{j=1}^{m} \sigma_{\tilde{\tilde{A}}^*_j,1}}{\sum_{j=1}^{m} \sigma_{\tilde{\tilde{A}}'_j,1}}, \tag{17}$$

$$\sigma_{\tilde{\tilde{B}}^*,2} = \sigma_{\tilde{\tilde{B}}',2} \times \frac{\sum_{j=1}^{m} \sigma_{\tilde{\tilde{A}}^*_j,2}}{\sum_{j=1}^{m} \sigma_{\tilde{\tilde{A}}'_j,2}}. \tag{18}$$

Then, we can get the fuzzy interpolated result $\tilde{\tilde{B}}^*$, where $\tilde{\tilde{B}}^* = <[\, m_{\tilde{\tilde{B}}^*,1}, \, m_{\tilde{\tilde{B}}^*,2}\,], \, \sigma_{\tilde{\tilde{B}}^*,1}; \, \sigma_{\tilde{\tilde{B}}^*,2}>$.

IV. A New Method To Learn the Optimal Interval Type-2 Gaussian Fuzzy Sets for Sparse Fuzzy Rule-Based Systems Based on Genetic Algorithms

In this section, we present a new learning method to learn optimal interval type-2 Gaussian fuzzy sets for sparse fuzzy rule-based systems based on genetic algorithms [11], [12], [15]. Given a sparse fuzzy rule base with type-1 Gaussian fuzzy sets constructed by the existing fuzzy rule base generation method [20], we can construct a new sparse fuzzy rule base with interval type-2 Gaussian fuzzy sets, where each interval type-2 Gaussian fuzzy set corresponds to a type-1 Gaussian fuzzy set in the original sparse fuzzy rule base. Assume that the new sparse fuzzy rule base has *m* antecedent variables $X_1, X_2, \ldots, X_m$ and has a consequence variable *Y*, where each antecedent variable and the consequence variable has *n* possible interval type-2 Gaussian fuzzy sets in the universe of discourse, the *k*th possible interval type-2 Gaussian fuzzy set $\tilde{\tilde{A}}_{k,j}$ of the *j*th antecedent variable X_j is denoted by $\tilde{\tilde{A}}_{k,j} = <[\, m_{\tilde{\tilde{A}}_{k,j},1}, \, m_{\tilde{\tilde{A}}_{k,j},2}\,], \, \sigma_{\tilde{\tilde{A}}_{k,j},1}; \, \sigma_{\tilde{\tilde{A}}_{k,j},2}>$, the *k*th possible interval type-2 Gaussian fuzzy set $\tilde{\tilde{B}}_k$ of the consequence variable *Y* is denoted by $\tilde{\tilde{B}}_k = <[\, m_{\tilde{\tilde{B}}_k,1}, \, m_{\tilde{\tilde{B}}_k,2}\,], \, \sigma_{\tilde{\tilde{B}}_k,1}; \, \sigma_{\tilde{\tilde{B}}_k,2}>$, $1 \le k \le n$ and $1 \le j \le m$. Given a set of *P* training samples, where the input observations of each training sample S_i are represented by $(x_{i1}, x_{i2}, \ldots, x_{im})$, the target output of the training sample S_i is represented by y_i, $1 \le i \le P$ and *P* denotes the number of training samples. Because

the shape of an interval type-2 Gaussian fuzzy set $\tilde{\tilde{A}} = <[m_1, m_2], \sigma_1; \sigma_2>$ varies with its left standard deviation σ_1 and its right standard deviation σ_2, the proposed method encodes the left standard deviations and the right standard deviations of interval type-2 Gaussian fuzzy sets appearing in the rules into the genes of a chromosome, where each chromosome in a population has $2n\times(m + 1)$ genes $g_{1,1,1}$, $g_{1,1,2}$, $g_{2,1,1}$, $g_{2,1,2}$, …, $g_{k,j,1}$, $g_{k,j,2}$, …, $g_{n,m,1}$, $g_{n,m,2}$, $g_{1,m+1,1}$, $g_{1,m+1,2}$, $g_{2,m+1,1}$, $g_{2,m+1,2}$, …, $g_{k,m+1,1}$, $g_{k,m+1,2}$, …, $g_{n,m+1,1}$ and $g_{n,m+1,2}$, where the two successive genes $g_{k,j,1}$ and $g_{k,j,2}$ represent the values $\sigma_{\tilde{\tilde{A}}_{k,j},1}$ and $\sigma_{\tilde{\tilde{A}}_{k,j},2}$ of the kth possible interval type-2 Gaussian fuzzy set $\tilde{\tilde{A}}_{k,j} = <[m_{\tilde{\tilde{A}}_{k,j},1}, m_{\tilde{\tilde{A}}_{k,j},2}], \sigma_{\tilde{\tilde{A}}_{k,j},1}; \sigma_{\tilde{\tilde{A}}_{k,j},2}>$ of the antecedent variable X_j, respectively, $0 \le g_{k,j,1} \le \frac{\left| m_{\tilde{\tilde{A}}_{k,j},2} - m_{\tilde{\tilde{A}}_{k,j},1} \right|}{2}$, $0 \le g_{k,j,2} \le \frac{\left| m_{\tilde{\tilde{A}}_{k,j},2} - m_{\tilde{\tilde{A}}_{k,j},1} \right|}{2}$, the two successive genes $g_{k,m+1,1}$ and $g_{k,m+1,2}$ represents the values of $\sigma_{\tilde{\tilde{B}}_k,1}$ and $\sigma_{\tilde{\tilde{B}}_k,2}$ of the kth possible interval type-2 Gaussian fuzzy set $\tilde{\tilde{B}}_k = <[m_{\tilde{\tilde{B}}_k,1}, m_{\tilde{\tilde{B}}_k,2}], \sigma_{\tilde{\tilde{B}}_k,1}; \sigma_{\tilde{\tilde{B}}_k,2}>$ of the consequence variable Y, respectively, $0 \le g_{k,m+1,1} \le \frac{\left| m_{\tilde{\tilde{B}}_k,2} - m_{\tilde{\tilde{B}}_k,1} \right|}{2}$, $0 \le g_{k,m+1,2} \le \frac{\left| m_{\tilde{\tilde{B}}_k,2} - m_{\tilde{\tilde{B}}_k,1} \right|}{2}$, $1 \le k \le n$ and $1 \le j \le m$. Fig. 4 shows the genes of a chromosome encoding the left standard deviations and the right standard deviations of the interval type-2 Gaussian fuzzy sets appearing in the fuzzy rules.

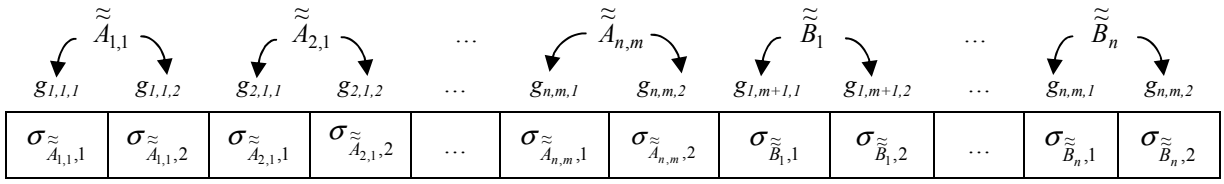

Fig. 4. A chromosome.

The proposed learning method to learn the optimal left standard deviations and the optimal right standard deviations of interval type-2 Gaussian fuzzy sets for sparse fuzzy rule-based systems is now presented as follows:

Step 1: Construct a new sparse fuzzy rule base with the interval type-2 Gaussian fuzzy sets, where each interval type-2 Gaussian fuzzy set $\tilde{\tilde{A}} = <[m_1, m_2], \sigma_1; \sigma_2>$ appearing in the new fuzzy rules is constructed from the corresponding type-1 Gaussian fuzzy set $\tilde{A} = <m, \sigma>$ in the original fuzzy rule, $m_1 = m - \frac{\sigma}{t}$, $m_2 = m + \frac{\sigma}{t}$, t is a parameter determining the values m_1 and m_2 of $\tilde{\tilde{A}}$, $2 \le t \le \infty$, $\sigma_1 = \sigma$ and $\sigma_2 = \sigma$.

Step 2: Encode the left standard deviations and the optimal right standard deviations of the interval type-2 Gaussian fuzzy sets appearing in the fuzzy rules into the genes of the chromosomes. Randomly generate N chromosomes to form the initial population.

Step 3: Decode each chromosome of the population into the left standard deviations and the optimal right standard deviations of the interval type-2 Gaussian fuzzy sets appearing in the fuzzy rules. Apply the proposed fuzzy rule interpolation method to generate the interpolated consequence fuzzy set with respect to the input observations (x_{i1}, x_{i2}, …, x_{im}) of each training sample S_i and then calculate the representative value of the fuzzy interpolated result as the inferred output with respect to the input observations of the training sample S_i, where $1 \le i \le P$ and P denotes the number of training samples. Based on the target output and the inferred output of each training sample, calculate the fitness value *Fitness* of each chromosome using the following fitness function:

$$RMSE = \sqrt{\frac{\sum_{i=1}^{P} \left(y_i - y_i^* \right)^2}{P}}, \tag{19}$$

$$Fitness = \frac{1}{RMSE}, \tag{20}$$

where *RMSE* denotes the root mean square error between the inferred outputs $y_1^*, y_2^*, \ldots, y_P^*$ and the target outputs $y_1, y_2, \ldots, y_P$ of the training samples $S_1, S_2, \ldots$ and S_P, and P denotes the number of training samples. The larger the fitness value *Fitness* of a chromosome, the better the chromosome.

Step 4: Select chromosomes from the current population using the binary tournament selection method [12] to form a mating pool. The system repeatedly randomly selects two chromosomes from the current population and puts the chromosome having the larger fitness value into the mating pool and then puts the two selected chromosomes back into the current population. Repeatedly perform the above process until the number of chromosomes in the mating pool is equal to N, where N is the number of chromosomes in a population.

Step 5: Apply the multi-points crossover method [15] to the chromosomes in the mating pool. For each chromosome C_i in the mating pool, the system randomly generates a real value between 0 and 1. If the randomly generated real value is smaller than a predefined crossover rate γ, where $\gamma \in [0, 1]$, then the system randomly chooses another chromosome C_j

from the mating pool. Then, the system randomly chooses $\left\lfloor \frac{m \times n}{4} \right\rfloor$ crossover points to replace the values of the genes of the crossover points between the selected chromosomes C_i and C_j.

Step 6: Decode each chromosome of the mating pool into the left standard deviations and the optimal right standard deviations of the interval type-2 Gaussian fuzzy sets appearing in the fuzzy rules. Apply the proposed fuzzy rule interpolation method to generate the interpolated consequence fuzzy set with respect to the input observations (x_{i1}, x_{i2}, …, x_{im}) of each training sample S_i and then calculate the representative value of the fuzzy interpolated result as the inferred output with respect to the input observations of the training sample S_i, where $1 \le i \le P$ and P denotes the number of training samples. Based on the target outputs and the inferred outputs of training samples, calculate the fitness value *Fitness* of each chromosome based on the fitness function shown in Eq. (20).

Step 7: Perform the elitist replacement method [11] to form the population of the next generation. The system selects the chromosomes having the top N largest fitness values in the current population and the mating pool to form the population of the next generation. If the number of selected chromosomes from the mating pool is equal to zero, go to **Step 8**. Otherwise, go to **Step 9**.

Step 8: Reinitialize the population using the cataclysmic mutation method [11]. The system puts the best chromosome having the largest fitness value in the current population into the population of the next generation. Mutates the remaining $N - 1$ chromosomes of the current population to generate the $N - 1$ chromosomes in the population of the next generation.

Step 9: If the number of generations is larger than a predefined number of generations, then go to **Step 10**, else go to **Step 3**.

Step 10: Decode the best chromosome having the largest fitness value in the current population into the left standard deviations and the right standard deviations of the interval type-2 Gaussian fuzzy sets appearing in the fuzzy rules. Output the fuzzy rules represented by the optimally learned interval type-2 Gaussian fuzzy sets for the sparse fuzzy rule-based system.

V. Experimental Results

In this section, we apply the proposed fuzzy rule interpolation method and the proposed learning method to deal with the Mackey-Glass chaotic time series prediction problem [10]. We also compare the experimental results of the proposed method with the results obtained by the existing methods [2], [8], [13]. The goal of the Mackey-Glass chaotic time series prediction problem [10] is to achieve a high prediction accuracy for forecasting the time series based on the following equation:

$$\frac{dx(t)}{dt} = \frac{0.2x(t-\tau)}{1+x^{10}(t-\tau)} - 0.1x(t). \tag{21}$$

In [10], Cowder extracted 1000 input-output data pairs using four past values for predicting the Mackey-Glass chaotic time series, shown as follows:

$$[x(t-18), x(t-12), x(t-6), x(t); x(t+6)], \tag{22}$$

where $x(t-18)$, $x(t-12)$, $x(t-6)$ and $x(t)$ are the four input attributes of the data pair at time $t-18$, $t-12$, $t-6$ and t, respectively, $x(t+6)$ is the output attribute of the data pair at time $t+6$, $\tau = 17$, $x(0) = 1.2$ and $0.42 \le x(t) \le 1.31$. In this paper, we also use the 1000 input-output data pairs (i.e., from $x(1)$ to $x(1000)$) as the data set of the Mackey-Glass chaotic time series prediction problem, where the first 500 input-output data pairs (i.e., from $x(1)$ to $x(500)$) are used as the training data set and the remaining 500 input-output data pairs (i.e., from $x(501)$ to $x(1000)$) are used as the testing data set. We apply the fuzzy rules generation method presented in [20] to construct a sparse fuzzy rule base consisting of 116 fuzzy rules using type-1 Gaussian fuzzy sets for the Mackey-Glass chaotic time series prediction problem based on the 500 training input-output data pairs, where each linguistic variable has seven possible type-1 Gaussian fuzzy sets $\tilde{A}_1$, $\tilde{A}_2$, $\tilde{A}_3$, $\tilde{A}_4$, $\tilde{A}_5$, $\tilde{A}_6$ and $\tilde{A}_7$, as shown in Fig. 5, which are evenly distributed over the universe of discourse, where $\tilde{A}_1$ = <0.42, 0.07>, $\tilde{A}_2$ = <0.57, 0.07>, $\tilde{A}_3$ = <0.72, 0.07>, $\tilde{A}_4$ = <0.87, 0.07>, $\tilde{A}_5$ = <1.02, 0.07>, $\tilde{A}_6$ = <1.17, 0.07> and $\tilde{A}_7$ = <1.31, 0.07>. Then, we apply the rule-cutting threshold 0.3 to reduce the constructed sparse fuzzy rule base of 116 fuzzy rules into a more compact sparse fuzzy rule base of 51 fuzzy rules by removing the fuzzy rules whose degrees of brief are smaller than 0.3.

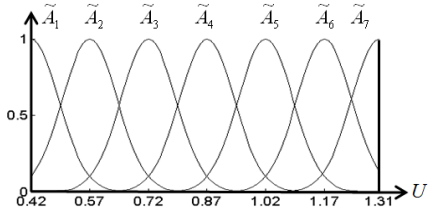

Fig. 5. Seven type-1 Gaussian fuzzy sets used in each variable for the Mackey-Glass chaotic time series prediction problem.

Based on Step 1 of the proposed learning method shown in Section IV, we can construct a new sparse fuzzy rule base using interval Gaussian type-2 fuzzy sets, where each interval type-2 Gaussian fuzzy set $\tilde{\tilde{A}}_i$ = < $[m_{i,1}, m_{i,2}]$, $\sigma_{i,1}$; $\sigma_{i,2}$> appearing in the fuzzy rules corresponds to the original type-1 Gaussian fuzzy set $\tilde{A}_i$ = <m_i, σ_i> appearing in the fuzzy rules of the original sparse fuzzy rule base, $m_{i,1} = m_i - \frac{\sigma_i}{4}$, $m_{i,2} = m_i + \frac{\sigma_i}{4}$, $\sigma_{i,1} = \sigma_i$, $\sigma_{i,2} = \sigma_i$ and $1 \le i \le 7$. Fig. 6 shows the seven possible interval type-2 Gaussian fuzzy sets used for each variable for the Mackey-Glass chaotic time series prediction problem.

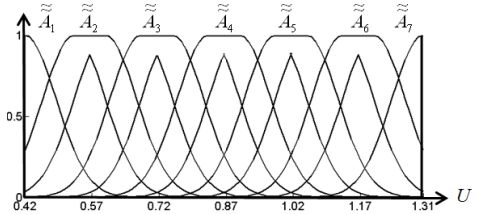

Fig. 6. Seven interval type-2 Gaussian fuzzy sets used in each variable for the Mackey-Glass chaotic time series problem.

After applying Step 1 of the proposed learning method, the above 51 fuzzy rules using type-1 Gaussian fuzzy sets are transformed into the 51 fuzzy rules using interval type-2 Gaussian fuzzy sets, where $\tilde{\tilde{A}}_1$ = <[0.42, 0.42], [0.07, 0.07]>, $\tilde{\tilde{A}}_2$ = <[0.53, 0.6], [0.07, 0.07]>, $\tilde{\tilde{A}}_3$ = <[0.68, 0.75], [0.07, 0.07]>, $\tilde{\tilde{A}}_4$ = <[0.83, 0.9], [0.07, 0.07]>, $\tilde{\tilde{A}}_5$ = <[0.98, 1.05], [0.07, 0.07]>, $\tilde{\tilde{A}}_6$ = <[1.13, 1.2], [0.07, 0.07]> and $\tilde{\tilde{A}}_7$ = <[1.31, 1.31], [0.07, 0.07]>, as shown in Fig. 6. Because there are four antecedent variables and one consequence variable appearing in the fuzzy rules and because each antecedent variable and the consequence variable have seven possible interval type-2 Gaussian fuzzy sets shown in Fig. 5, there are a total of 35 (i.e., (4 + 1) × 7 = 35) individual interval type-2 Gaussian fuzzy sets appearing in the 51 fuzzy rules. Therefore, we encode the left standard deviations and the right standard deviations of the 35 individual interval type-2 Gaussian fuzzy sets into chromosomes, and each chromosome has 70 genes representing the left standard deviations and the right standard deviations of the 35 interval type-2 Gaussian fuzzy sets. Each two successive genes represents the left standard deviation $\sigma_{i,1}$ and the right standard deviation $\sigma_{i,2}$ of the corresponding Gaussian interval type-2 fuzzy set $\tilde{\tilde{A}}_i$ = < [$m_{i,1}$, $m_{i,2}$], $\sigma_{i,1}$; $\sigma_{i,2}$>, where $1 \le i \le 7$. Based on the new sparse fuzzy rule base with the interval type-2 Gaussian fuzzy sets and the training data set of the 500 training data pairs of the Mackey-Glass chaotic time series prediction problem, we apply the proposed learning method to learn the optimal left standard deviations and the optimal right standard deviations of the interval type-2 Gaussian fuzzy sets appearing in the fuzzy rules, where the population size is 60, the number of evolutions is 300 and the crossover rate is 0.9. Fig. 7 shows an example of the learned optimal interval type-2 Gaussian fuzzy sets obtained by the proposed learning method.

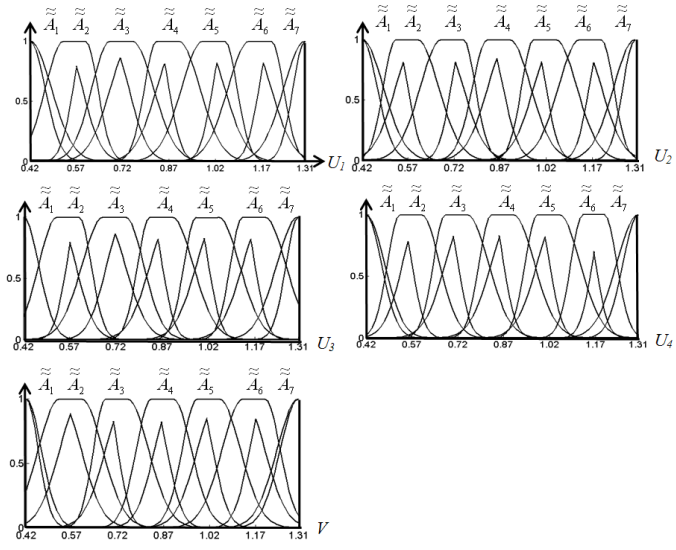

Fig. 7. Optimally learned interval type-2 Gaussian fuzzy sets for the Mackey-Glass chaotic time series problem based on the proposed learning method.

Based on the 51 fuzzy rules with the optimally learned interval type-2 Gaussian fuzzy sets obtained by the proposed learning method, we apply the proposed fuzzy rule interpolation method to produce the interpolated outputs with respect to the testing samples in the 500 testing data pairs. For example, based on the 51 fuzzy rules with the optimally learned interval type-2 Gaussian fuzzy sets shown in Fig. 7, the proposed fuzzy rule interpolation method has the root mean square error 0.0486 with respect to the testing data set.

We have implemented a program based on the proposed learning method and the proposed fuzzy rule interpolation method using Eclipse Version 3.4.2 in a Core 2 duo x86 PC. The system executes the program ten times and the mean of the RMSEs of these ten runs is used as the average RMSE of the proposed method. We then compare the experimental results of the proposed method with the HS method [13], the CCL method [2] and the CK method [8]. Table I shows a comparison of the average root mean square errors for different methods for dealing with the Mackey-Glass chaotic time series prediction problem [10]. From Table I, we can see that the proposed fuzzy rule interpolation method using the optimally learned interval type-2 Gaussian fuzzy sets gets a smaller average root mean square error than the HS method [13], the CCL method [2] and the CK method [8].

TABLE I
A COMPARISON OF THE AVERAGE ROOT MEAN SQUARE ERRORS FOR DIFFERENT METHODS FOR THE MACKEY-GLASS CHAOTIC TIME SERIES PREDICTION PROBLEM

Methods	HS Method [13] (Using Type-1 Gaussian Fuzzy Sets)	CCL Method [2] (Using Type-1 Gaussian Fuzzy Sets)	CK Method [8] (Using Type-1 Gaussian Fuzzy Sets)	The Proposed Method (Using Type-1 Gaussian Fuzzy Sets)	The Proposed Method (Using the Optimally Learned Interval Type-2 Gaussian Fuzzy Sets)
Average RMSE	0.0546	0.1547	0.0630	0.0515	0.0485

Note: The system executes the proposed fuzzy rule interpolation method and the proposed learning method to deal with the Mackey-Glass chaotic time series prediction problem ten times, where the population size of the genetic algorithm is 60, the number of evolutions is 300 and the crossover rate is 0.9.

VI. CONCLUSION

In this paper, we have presented a new method for fuzzy rule interpolation with the learned interval type-2 Gaussian fuzzy sets for sparse fuzzy rule-based systems based on genetic algorithms. The proposed fuzzy rule interpolation method deals with the interpolation of fuzzy rules based on the multiple fuzzy rules interpolation scheme. We also have presented a new learning method to learn optimal Gaussian interval type-2 fuzzy sets for sparse fuzzy rule-based systems based on genetic algorithms. We also have applied the proposed learning method and the proposed fuzzy rule interpolation method to deal with the Mackey-Glass chaotic time series prediction problem. From Table I, we can see that the proposed fuzzy rule interpolation method using the optimally learned interval type-2 Gaussian fuzzy sets obtained by the proposed learning method gets a higher average accuracy rate than the existing methods [2], [8], [13].

***Abstract*—In this paper, we present an original fuzzy interpolation method. In contrast to existing approaches, our method is able to always construct an interpolated fuzzy interval without a need of a special step dedicated to the "standardization" of non-viable solutions, which fractures the sense of the interpolation. In fact, these "standardization" steps imply that, for instance, a point obtained from the interpolation of the upper limit (right side) of the fuzzy sets, is used to build the lower limit (left side) of the interpolated conclusion, breaking the underlying hypothesis of (linear) graduality. To achieve the direct interpolation, our method is based on the deviation of the observation from the expected linearly interpolated solution and constrains of the constructed solution between extreme cases. We illustrate and discuss the behavior of our method by comparison to other well-known fuzzy interpolation methods.**

Keywords: **Fuzzy Interpolation, approximate reasoning, sparse rule base.**

I. Introduction

Interpolation of fuzzy rules has been intensively studied since 1991 with a first paper proposing a method [1] (or more accessible [2]). Since then, many different points of views were adopted: α-cuts approaches (recent ones proposed in [3], [4], [5] or [6]), analogy or similarity based approaches ([7], [8], [9]), logical approaches, among others. The interested reader can find a quasi exhaustive list of references in [10] and [11].

Some methods suppose that fuzzy data are represented only by trapezoidal fuzzy intervals, some others are more general and propose methods applicable to all membership function. Frameworks were proposed to compare different existing methods [10], [12], [13], or to unify them [11], [14]. The latter framework is an interesting theoretical approach enabling to write many methods in a unique way thanks to an analytic approach, but, unfortunately, it is not easy to instantiate the different behaviors in concrete situations.

Most methods agree on the *position* of the interpolated conclusion. Thus differences arise when dealing with the challenge of constructing an adequate shape, with the risk of obtaining a non viable fuzzy set. The reason of the latter, as shown in this paper, is that the shape of the fuzzy sets can *not* be linearly interpolated. Thus, very often a standardization step dedicated to ensure that the obtained membership is actually a viable normalized function is proposed. Unfortunately, as we point out in this paper, these steps break several fundamental underlying hypotheses, as for instance the graduality one. In fact, state of the art "standardization" steps always imply that, for instance, a point obtained from the interpolation of the upper limit (right side) of the fuzzy sets, is used to build the lower limit (left side) of the interpolated conclusion, breaking the underlying hypothesis of (linear) graduality. Moreover, the fact of "swaping" points in a "standardization" steps also implies that the associated uncertainty (which was actually used to identify the concerned points for the interpolation) is ignored. As consequence, for instance, almost uncertain values may be used (via the "standardization" step) to build the totally certain kernel of the interpolated solution.

To achieve a direct estimation of the solution, we perform a double linear interpolation by, first, linearly interpolating the expected shape value based on the known rules and secondly, by linearly interpolating the deviation from that value.

Another major difference of the method described in this paper compared to the state of the art is that it constrain the solutions between two know natural boundaries. In the one extreme, we know that the shape of the solution cannot be more precise than a certain single value and in the other limit we assume that the solution has to fall between the *know* rules. In other words, our solution takes into account, indirectly, the spread between the rules to constrain the solution: a novelty.

Our paper is organized as follows. In the next section we present the notations, before describing our method which is divided in two phases: the interpolation of the position as described in Section III and the interpolation of the shape as described in Section IV. In SectionV, we present some empirical comparisons with known methods putting in contrast the differences and common behaviors. Finally, we conclude and provide some hints about future works.

II. Interpolative Reasoning and Notations

A. Interpolative reasoning general principles

Let us consider two numerical variables X and Y defined on the universe $\mathbf{R}$ of real numbers. Let $\mathbf{F}$ denote the set of fuzzy sets of $\mathbf{R}$. We suppose that we are given fuzzy sets A_i in $\mathbf{F}$, $1 \leq i \leq n$, such that: $A_1 \preceq A_2 ... \preceq A_i \preceq A_{i+1} ... \preceq A_n$, for a given order $\preceq$ on $\mathbf{F}$. We also suppose that we are given fuzzy sets B_i in $\mathbf{F}$, $1 \leq i \leq n$, which are also ordered according to $\preceq$.

The context of study concerns sparse fuzzy rule-based systems where fuzzy rules are of the type : (R_i): "if X is A_i then Y is B_i". The sparsity of the system means that the premises of the rules do not cover the input space $\mathbf{F}$ and there exist inputs A_* such that $\exists i / A_i \preceq A_* \preceq A_{i+1}$.

The aim of a fuzzy interpolation method is to provide the conclusion corresponding to the observation A_* by considering only the two rules R_i and R_{i+1} when $A_i \preceq A_* \preceq A_{i+1}$.

B. Notations and hypotheses

Our approach is based on three fundamental hypothesis. The first hypothesis lies in the fact that Y has a *gradual behavior* with regard to X. The second hypothesis is that there is a *gradual behavior* for the space of forms. This hypothesis translates the intuition that if an observation is smaller (i.e more precise) than the premisses, then the conclusion should be smaller than the known conclusions. The third hypothesis is that the interpolated conclusion has to be *between* the conclusions of the adjacent rules. Intuitively, we know that on the extremes, rules 1 and 2 apply, and thus, if something is observed in the middle, the conclusion should also be in the middle.

Moreover, we require that for $A_i \preceq A_{i+1}$ the order $\preceq$ verifies no value of the support (respectively kernel) of A_{i+1} is smaller than any value of the support ((respectively kernel) of A_i and no value of the support (respectively kernel) of A_i is greater than any value of the support (respectively kernel) of A_{i+1}.

In this paper we focus on trapezoidal fuzzy sets. We choose to describe such a fuzzy set $A_i = [a_{i1}, a_{i2}, a_{i3}, a_{i4}]$, with the following four parameters. For a visual illustration see Fig. 1:

- its position defined as the center of its kernel:

$$A_i^P = \frac{a_{i2} + a_{i3}}{2} \tag{1}$$

- its certain values range characterized by the kernel's amplitude left and right from its center, as computed by:

$$\overline{A}_i^L = \overline{A}_i^R = \frac{a_{i3} - a_{i2}}{2} \tag{2}$$

- the extend of the uncertainty on the left and on the right, defined by:

$$\underline{A}_i^L = a_{i2} - a_{i1} \tag{3}$$

$$\underline{A}_i^R = a_{i4} - a_{i3} \tag{4}$$

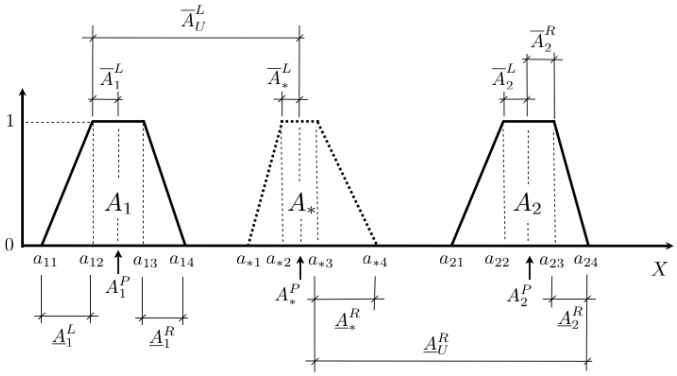

Fig. 1. A trapezoidal fuzzy set $A_i = [a_{i1}, a_{i2}, a_{i3}, a_{i4}]$ has a position A_i^P. Its kernel's form is described by its left and right length: $\overline{A}_i^L = \overline{A}_i^R$. $\underline{A}_i^L$ (and $\underline{A}_i^R$) describe its left (and right) uncertainties. We claim that in an interpolative reasoning problem it is necessary to know the range of values between the known rules to constraint the solutio. Thus, we define the global uncertainty for the kernel on the left $\overline{A}_U^L$ and on the right $\overline{A}_U^R$. Analogously $\underline{A}_U^R$ defines the global uncertainty right, ranging from the largest possible value of the left premise A_2 to the largest certain value of the observation A_*.

III. Interpolating the position

The linear hypothesis for the position states that the position of the observation A_* and the premises A_1 and A_2 are in a linear relationship with coefficient α and that the interpolated conclusion B_* and the conclusions B_1 and B_2 are also in a linear relationship with the *same* coefficient α. Formally, we have:

$$A_*^P = \alpha \cdot A_1^P + (1 - \alpha) \cdot A_2^P \tag{5}$$

$$B_*^P = \alpha \cdot B_1^P + (1 - \alpha) \cdot B_2^P \tag{6}$$

Now, using these two equations we can easily compute the position of the interpolated conclusion B_*. First, based on equation 5, we obtain α:

$$\alpha = \frac{A_2^P - A_*^P}{A_2^P - A_1^P} \tag{7}$$

Second, using that value in equation 5, we obtain the position B_*^P.

IV. Interpolating the shape

On Fig. 2 we observe that the shape of observation A_* is not necessarily in a linear relationship with the shapes of the premises A_1 and A_2, when considered in the universe of description X (which coincides with position). One could argue that this lack of linearity depends upon the way the shapes are measured, but in fact for any non trivial measure it is easy to imagine a case breaking the linearity.

In fact, a simple way to achieve this is by, first computing the expected shape value (linearly) and then building a fuzzy set observation A_* (the counterexample), which has a different shape value. This counterexample exists because the measure is assumed not trivial.

Moreover, this non linearity applies not only to any general description of the shape but also to any shape measure based on a length descriptor. Thus, any α-cut based method will suffer from this non-linearity. This fundamental limitation has also been been observed in [15].

One of the direct consequences is that any method attempting to linearly interpolate the shape (based on the position) will produce degenerated shapes, as pointed out in [7]. The more recent methods avoid ill solutions, by using heuristics that wisely choose among a set of points the ones providing a viable solution. Unfortunately these heuristics are solely designed to avoid degenerative solutions, ignoring any interpolative argumentation.

To overcome the above fundamental reality, we propose to compute the value of the interpolated conclusion in a two step interpolation: first linearly interpolate the *expected shape values* (between the premises and between the conclusions) and then linearly interpolate the *shape deviation* between the expected shape and a limit case, which follows our fundamental assumptions. De facto, our two limit cases correspond, in the one extreme, to zero (assuming that any shape measure is positive), and in the other extreme, to the shape measure of the global uncertainty. The latter corresponds to the assumption,

mentioned in Section II-B, that the interpolated conclusion must be between the known conclusions.

As a result, the solutions are constrained to a reasonable range, corresponding to the limit cases, in which they linearly evolve. The shapes of the premises and conclusions influence *only indirectly* the solution via the double linear interpolation: first the linear interpolation of the expected value and second the linear interpolation of the deviation.

A. Describing the shape of a trapezoidal fuzzy set

The shape of a fuzzy set, and in particular of a trapezoidal one, can be described in numerous ways. For instance it could be described by a single value, as the surface (or integral of the membership function), which summarizes the global spread of uncertainty. But more refined ways, with several parameters, can also be imagined. In this paper we choose to describe the shape of a trapezoidal fuzzy set with the four parameters $\overline{A}_i^L$, $\overline{A}_i^R$, $\underline{A}_i^L$ and $\underline{A}_i^R$, defined in Section II-B. This description focuses on the amplitudes, and symmetry, of the kernel and the support sets.

Since these are all length-descriptors, the double linear interpolation required by the nature of the problem, as described above, has to be applied. In the following we describe how this is performed, analogously in the four cases.

B. Interpolating the kernel's length

In order to interpolate the kernel's shape, we compute two double linear interpolations: one for the left lengths $\overline{A}_i^L$ and one for the right ones $\overline{A}_i^R$. Since the calculations are identical, in the following we only describe the left case.

For the first linear interpolation, we estimate the linearly expected shapes $\overline{A}_E^L$ and $\overline{B}_E^L$ using the kernels' left lengths of the premises $\overline{A}_1^L$ and $\overline{A}_2^L$, and of the conclusions' $\overline{B}_1^L$ and $\overline{B}_2^L$. As illustrated on Fig. 2 and 3, using simple mathematics we obtain :

$$\overline{A}_E^L = \left(\overline{A}_1^L - \overline{A}_2^L\right) \cdot \left(\frac{A_2^P - A_*^P}{A_2^P - A_1^P}\right) + \overline{A}_2^L \tag{8}$$

$$\overline{B}_E^L = \left(\overline{B}_1^L - \overline{B}_2^L\right) \cdot \left(\frac{B_2^P - B_*^P}{B_2^P - B_1^P}\right) + \overline{B}_2^L \tag{9}$$

Then, for the second interpolation, we linearly calculate the deviation of the observed kernel $\overline{A}_*^L$ from the expected kernel $\overline{A}_E^L$. As we will see below two scenarios appear depending on the relative magnitude of $\overline{A}_*^L$ with respect to $\overline{A}_E^L$. It is noteworthy to observe that both scenarios can not be integrated in a single linear transformation.

1) Smaller-shape deviation: Let us assume that $\overline{A}_*^L < \overline{A}_E^L$. In this case the observation is more precise than the expected interpolation. Knowing that any shape measure, and in particular one based on the length, is always positive (or equals to 0), using the linear hypothesis for the deviation we have:

$$\overline{A}_*^L = \beta_L \cdot \overline{A}_E^L + (1 - \beta_L) \cdot 0 = \beta_L \cdot \overline{A}_E^L \tag{10}$$

$$\overline{B}_*^L = \beta_L \cdot \overline{B}_E^L + (1 - \beta_L) \cdot 0 = \beta_L \cdot \overline{B}_E^L \tag{11}$$

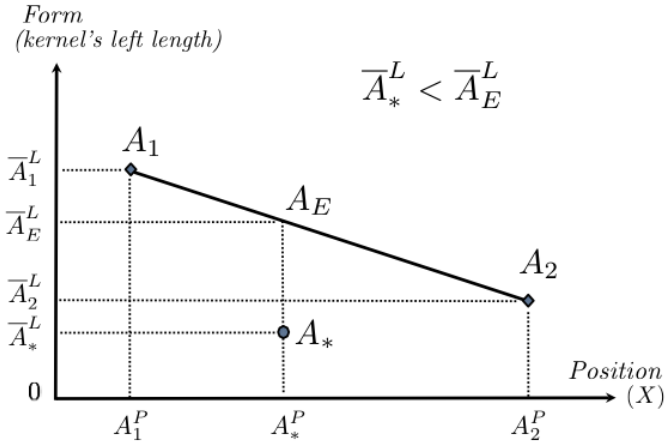

Fig. 2. The shape description of observation A_* is not necessarily in a linear relationship with the shape descritions of the premises A_1 and A_2.

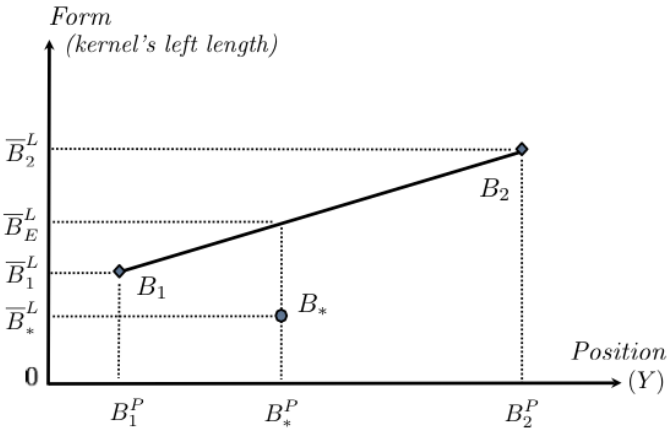

Fig. 3. The shape description of the interpolated conclusion B_* should be in the same linear deviation from the expected shape value, as is the case for the premises.

Thus, in order to obtain the interpolated conclusion's kernel left length, we use Equation 10 to obtain:

$$\beta_L = \frac{\overline{A}_*^L}{\overline{A}_E^L} \tag{12}$$

Which is then used in Equation 11 to obtain the length $\overline{B}_*^L$. The same exact equations, replacing L by R, can be used for the right description of the kernels and, thus, obtain $\overline{B}_*^R$.

2) Larger-shape deviation: It may happen that the observation is less precise than the linearly expected value: $\overline{A}_*^L \geq \overline{A}_E^L$. In that case Equation 10 do not apply, since we have a deviation that implies an increase of the shape and therefore can not be constrained, by a lower boundary, as in a reduction scenario. In other words, since the length of the observation is larger than expected, we would like the length of the conclusion to be *also* larger than the expected linearly interpolated conclusion $\overline{B}_E^L$. In addition, the third of hypothesis mentioned in Section II-B implies that its range can not be larger that the gap between the rules. In the case of the kernel's

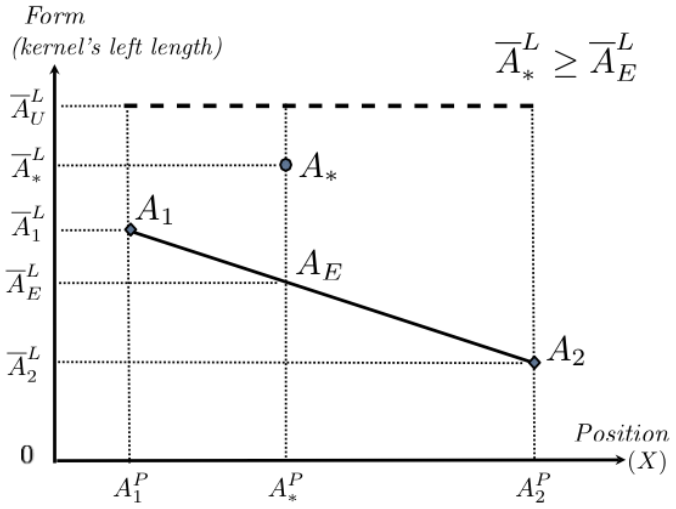

Fig. 4. The shape description of observation A_*, as for instance here the left kernel length $\overline{A}_*^L$, may be larger than the linearly expected value $\overline{A}_E^L$. We propose to constrain the solution by linearly interpolating between the linearly expected shape and the left kernel uncertainty $\overline{A}_U^L$.

left length calculations the uncertainty left between the kernel's premises estimated by:

$$\overline{A}_U^L = A_*^P - a_{12} \tag{13}$$

as shown on Fig. 1.

Consequently, assuming a linear hypothesis for the deviation, we obtain:

$$\overline{A}_*^L = \beta_L \cdot \overline{A}_E^L + (1 - \beta_L) \cdot \overline{A}_U^L \tag{14}$$

$$\overline{B}_*^L = \beta_L \cdot \overline{B}_E^L + (1 - \beta_L) \cdot \overline{B}_U^L \tag{15}$$

The same way as with the smaller shape reduction, in order to obtain the conclusion's kernel-left-length, we use Equation 14 to obtain:

$$\beta_L = \left(\frac{\overline{A}_U^L - \overline{A}_*^L}{\overline{A}_U^L - \overline{A}_E^L} \right) \tag{16}$$

which is then used in Equation 15 to obtain the length $\overline{B}_*^L$. Again, by replacing in the equations L by R we know how to obtain $\overline{B}_*^R$.

C. Interpolating the left and right uncertainties

At this point we know the interpolated conclusion's fuzzy set position (Section III) and its kernel's shape (Section IV-B). Now we interpolate, analogously as for the kernel's lengths, the left and right uncertainties. We first interpolate the expected forms, here only for the right uncertainties:

$$\underline{A}_E^R = \left(\underline{A}_1^R - \underline{A}_2^R\right) \cdot \left(\frac{a_{23} - a_{*3}}{a_{23} - a_{13}} \right) + \underline{A}_2^R \tag{17}$$

$$\underline{B}_E^R = \left(\underline{B}_1^R - \underline{B}_2^R\right) \cdot \left(\frac{b_{23} - b_{*3}}{b_{23} - b_{13}} \right) + \underline{B}_2^R \tag{18}$$

where $b_{*3} = B_*^P + \overline{B}_*^R$. Notice that we anchor, as for the kernels, the length description to the point where the interval starts.

Now, in the same way as for the kernels, we have two scenarios depending of the the relative value of the expected length and the observed length.

If $\underline{A}_*^R < \underline{B}_E^R$, then the double interpolated right uncertainty is obtained by:

$$\underline{B}_*^R = \gamma_R \cdot \underline{B}_E^R = \left(\frac{\underline{A}_*^R}{\underline{A}_E^R} \right) \cdot \underline{B}_E^R \tag{19}$$

But, if $\overline{A}_*^L \geq \overline{A}_E^L$, , then the double interpolated right uncertainty is obtained by:

$$\underline{B}_*^R = \gamma_R \cdot \underline{B}_E^R + (1 - \gamma_R) \cdot \underline{B}_U^R \tag{20}$$

where

$$\gamma_R = \left(\frac{\underline{A}_U^R - \underline{A}_*^R}{\underline{A}_U^R - \underline{A}_E^R} \right) \tag{21}$$

V. Empirical comparisons

In this section, we compare the double-linear fuzzy interpolation method (DoLFIn for short) with some well-known methods: [16] (DP), [10] (BTKY), and [7] (BMR). We consider several scenarios:

- all the shapes are similar
- specific observation
- specific premises or specific conclusions
- extremely unspecific observation

Moreover, to extend our comparison to other state of the art approaches, we use some examples shared by the following papers [3] (HS), [4] (CK), [17] (CCL).

Figures Fig. 5 to Fig. 12 should be read as follows. The first row shows the two premises A_1 and A_2 and the observation A_*. The other four rows present the conclusions by each of the four studied approaches. For the comparison the two known conclusions B_1 and B_2 are always the same, and only the obtained result B_* changes between the rows.

A. All the shapes are similar

A first interesting scenario arises when the observation is similar to the premise. In this case, the observation can be considered as a translation of one of the premises. It is a typical case of interpolative reasoning.

In Fig. 5 and Fig. 6, it can be seen that the three approaches BTKY, BMR, and DolFIn propose the exact same conclusion. The unique method which offers a different solution is the DP, which is very unspecific and uncertain.

B. Precise observation

A second interesting case arises when the observation is precise. It is often the case in real-world applications for decision-making process when no fuzzification of the input data is processed.

In Fig. 7 and Fig. 8, it can be seen that the results are different for the four methods. As previously seen, again DP

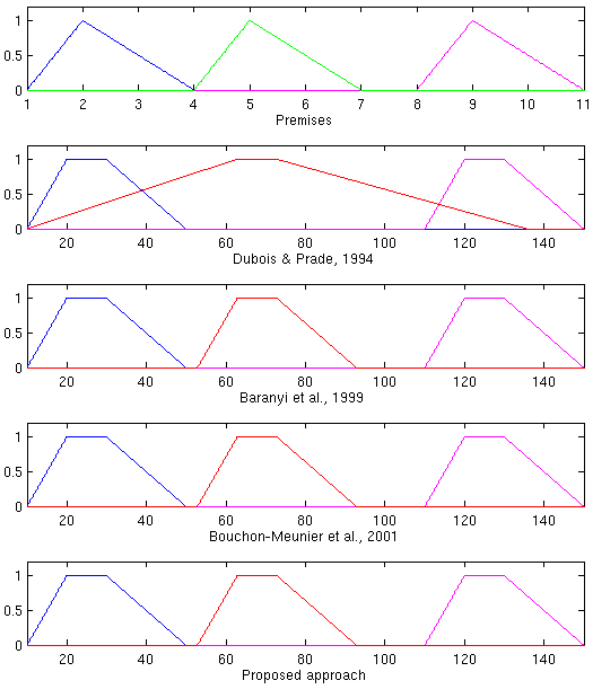

Fig. 5. All the shapes are similar (1)

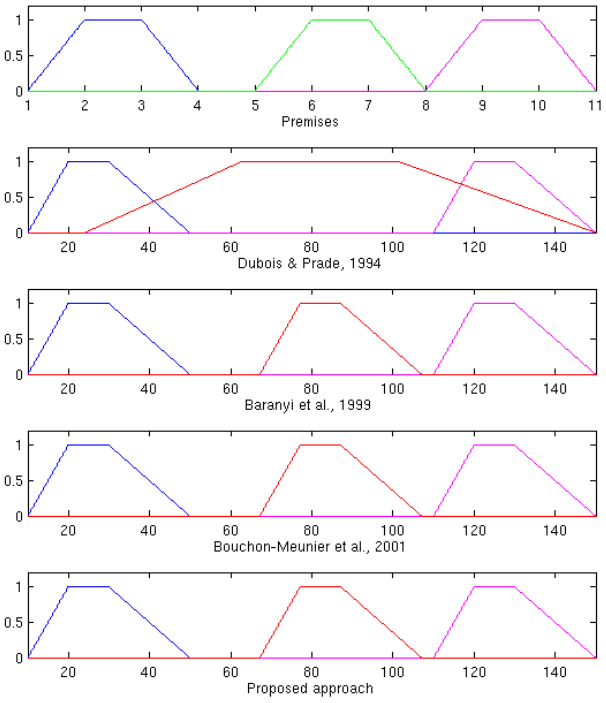

Fig. 6. All the shapes are similar (2)

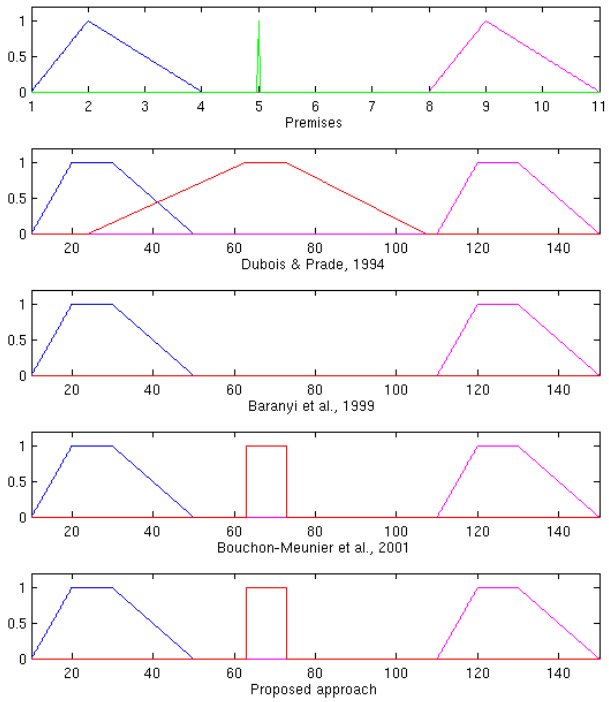

Fig. 7. Precise observation (1)

offers a very specific solution that can hardly be linked to the preciseness of the observation. BTKY proposes a non viable solution. Concerning BMR and DoLFIn, the results are different depending on the form of the premises and the conclusions. In a case, Fig. 7, BMR and DoLFIn methods propose a similar result. On the other case, Fig. 8, the results are very different: BMR proposes a fuzzy solution where DoLFIn constructs a precise solution.

The difference between the situations of Fig. 7 and Fig. 8 is that the forms of the premises are smaller than the forms of the conclusions on the first one, and greater on the second one. In this case, BMR method does not always provide a specific conclusion in presence of a specific observation.

In general, for a precise observation we obtain either a vague solution or no solution at all. While DoLFIn guarantees a specific conclusion in this case.

C. Precise premises

When premises are precise and the observation is imprecise and uncertain (see Fig. 9) all the methods except DoLFIn provide a solutions very imprecise and uncertain, sometimes going beyond the scope of the conclusions.

DoLFIn method proposes an interesting solution with a reasonable support size. Moreover, as for the observation and the premises, the solution respects the requirements imposed by the order $\preceq$ defined in Section II-B.

D. Extremely unspecific observations

When the observation is in the limit case of an extremely unspecific but precise interval that covers the whole space between the premises, see Fig. 10, DoLFIn is the only approach

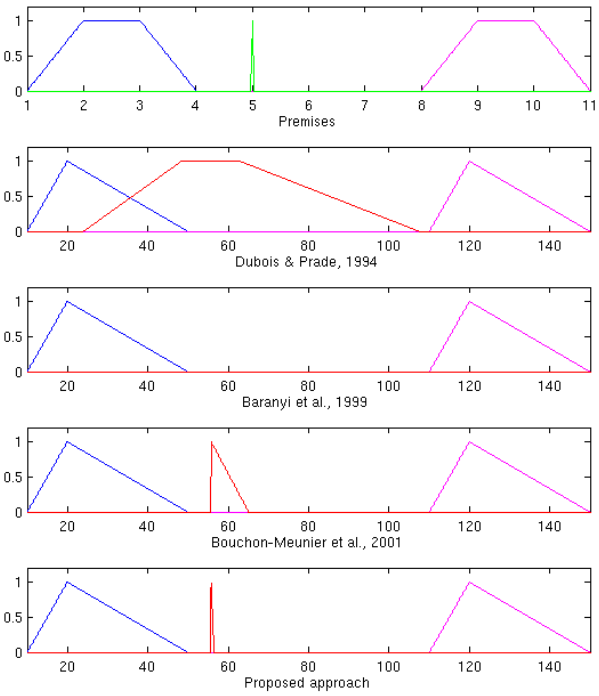

Fig. 8. Precise observation (2)

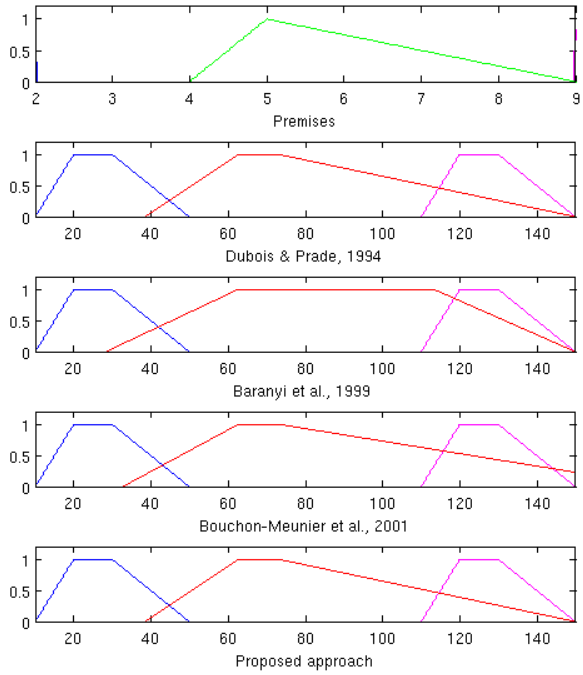

Fig. 9. Precise premises

that leads to an unspecific and precise conclusion. In this case, BTKY does not propose a viable solution, and BMR and DP construct imprecise solutions.

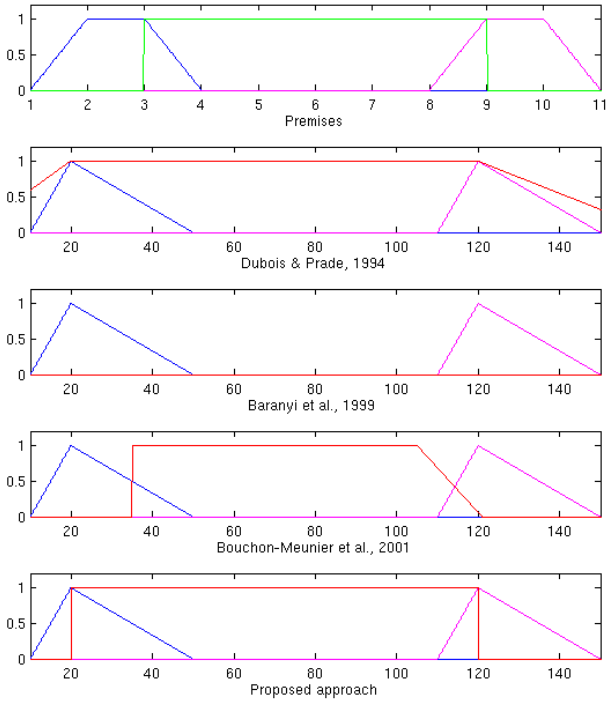

Fig. 10. Extremely unspecific observations

E. Remarkable examples

In figures Fig. 11 to Fig. 12, we extend our comparison by using some remarkable examples pointed out and shared by the following papers [3] (HS), [4] (CK), [17] (CCL). We invite the reader to refer to those papers for further details.

In Fig. 11, it can been seen that DP produces a very unspecific solution and BTKY constructs a non viable solution. The remaining approaches provide similar results with slight differences. BMR proposes a solution with a very steep right slope due to the fact that there is a strong transformation from the right slope of the premises to the observation. The result by DoLFIn is more fuzzy and with a different location than the solution by HS and CK. DoLFIn and CCL produce an almost identical conclusion.

A second remarkable example is presented in Fig. 12. Here again, it can been seen that DP produces a very unspecific conclusion. BTKY constructs a non viable solution. This time all the remaining approaches[1] (BMR, DoLFIn, CCL, and CK) produce a very similar result.

In general DoLFIn is able to provide a reasonable solution to all the remarquable examples identified by the above mentioned authors.

[1]The comparison with HS is not available because this example is not treated in [3].

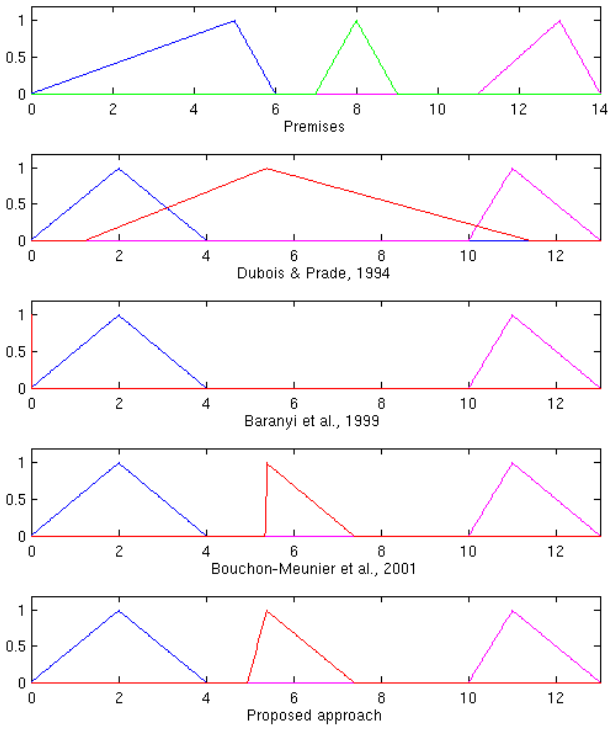

Fig. 11. Remarkable example (1)

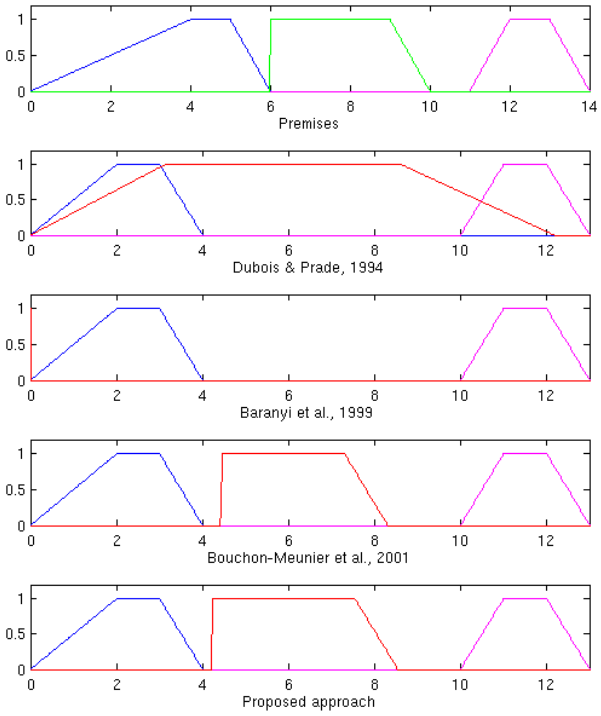

Fig. 12. Remarkable example (2)

F. Discussion

It can be seen in the presented comparison that for each of the scenarios, a group of methods (not always the same ones) provides adequate solutions.

DP proposes always a solution which is very unspecific and imprecise. BTKY generates conclusions often very pertinent but suffers of a problem of viability. BMR is very robust and can handle a large set of particular cases without having a problem of viability thanks to its standardization step [7]. However, the constructed solution can have a fuzzy conclusion with a precise observation, or a conclusion which is out of the scope of the known conclusions.

The proposed DoLFIn method has none of the mentioned drawbacks and proposes a pertinent and viable solution in all the studied cases without the use of a standardization step.

VI. Conclusion

Our method is based on the deviation to the expected linearly interpolated solution and constrains the constructed solution between extreme cases. We discovered that from the fundamental assumptions, mathematically, two scenarios appear: one where the form is expected to diminish but constrained to be positive and a second where the form is expected to grow but is constrained by the two known rules.

The presented study suggests that DoLFIn produces always a pertinent solution for a large set of diverse situations. Its pertinence is reinforced by the fact that each time the solution coincides with at least the result of another method.

An extensive and detailed comparison with a larger set of examples and methods coded in the FRI toolbox [18], is under development. We believe that its conclusion will not reveal any major differences with the conclusions of the presented paper. Future works will focus on the extension of the presented method to general shaped fuzzy sets and to the more complex multi-premise rules interpolation problem.

Michigan State University, East Lansing, MI 48824
E-mail: havenst@gmail.com, {chittara, jain, rongjin}@msu.edu

***Abstract*—The ubiquity of personal computing technology has produced an abundance of staggeringly large data sets—the Library of Congress has stored over 160 terabytes of web data and it is estimated that Facebook alone logs over 25 terabytes of data per day. There is a great need for systems by which one can elucidate the similarity and dissimilarity among and between groups in these data sets. Clustering is one way to find these groups. In this paper, we propose an approximation method for the fuzzy and possibilistic kernel c-means clustering algorithms. Our approximation constrains the cluster centers to be linear combinations of a size m randomly selected subset of the n input objects, where $m << n$. The proposed algorithm only requires an $m \times n$ rectangular portion of the full $n \times n$ kernel matrix and the n diagonal values, resulting in significant memory savings. Furthermore, the computational complexity of the c-means algorithm is substantially reduced. We demonstrate that up to 3 orders of magnitude of speedup are possible while achieving almost the same performance as the original kernel c-means algorithm.**

***Index Terms*—clustering, large-scale data, kernel methods, fuzzy partitions, possibilistic partitions**

I. Introduction

Clustering algorithms are an integral part of both computational intelligence and pattern recognition. Often researchers are mired in data sets that are large and unlabeled. There are many methods, under the heading exploratory data analysis, by which researchers can elucidate these data. Clustering is one such exploratory tool for deducing the nature of the data by providing labels to individual objects that describe how the data separate into groups. Clustering has also been shown to improve the performance of other algorithms or systems by separating the problem-domain into manageable sub-groups—a different algorithm or system is tuned to each cluster [1, 2]. Also, clustering has been used to infer the properties of unlabeled objects by clustering these objects together with a set of labeled objects (of which the properties are well understood) [3, 4].

The problem domains and applications of clustering are innumerable. Virtually every field, including biology, engineering, medicine, finance, mathematics, and the arts, have used clustering. Its function—grouping objects according to a measure of similarity—is a basic part of intelligence and is ubiquitous to the scientific endeavor.

Consider a set of n objects, denoted $O = \{o_1, \ldots, o_n\}$, e.g., sets of vintage bass guitars, freshwater fish, or genes in a microarray experiment. Each object is typically represented by an associated set of vectors $X = \{\mathbf{x}_1, \ldots, \mathbf{x}_n\} \in \mathbb{R}^d$, where each $\mathbf{x}$ is a numerical feature vector that describes the objects' attributes — examples include height, weight, length, or expression value.

Clustering in unlabeled data X is defined as the assignment of *labels* to groups of similar (unlabeled) objects O. In other words, objects are *partitioned* into groups such that each group is composed of objects with similar attributes. There are two important factors that all clustering algorithms must consider: 1) the number (and, perhaps, type) of clusters to seek and, 2) a mathematical way to determine the similarity between various objects (or groups of objects). Let c denote the integer number of clusters. The number of clusters can take the values $c = 1, 2, \ldots, n$, where $c = 1$ results in the universal cluster—every object is in one cluster—and $c = n$ results in single-object clusters—each object is a cluster. A wide array of algorithms exists for clustering unlabeled object data O. Descriptions of many of these algorithms, both relational and not, can be found in the following general references on clustering: [5–12].

A *partition* of the objects is defined as the set of cn values, where each value $\{u_{ik}\}$ represents the degree to which an object o_k is in the ith cluster. The c-partition is often represented as a $c \times n$ matrix $U = [u_{ik}]$, where each row represents a cluster and each column represents an object. There are three main types of partitions, crisp, fuzzy (or probabilistic), and possibilistic [7, 13]. *Crisp* partitions of the unlabeled objects are non-empty mutually-disjoint subsets of O such that the union of the subsets covers O. The set of all non-degenerate (no zero rows) crisp c-partition matrices for the object set O is described in (1), where u_{ik} is the *membership* of object o_k in cluster i; the partition element $u_{ik} = 1$ if o_k is labeled i and is 0 otherwise.

Fuzzy (or probabilistic) partitions are more flexible than crisp partitions in that each object can have membership in more than one cluster. Note, if U is probabilistic, the partition values are interpreted as a probability $p(i|o_k)$ that o_k is in the i-th class. We assume, in this paper, that fuzzy and probabilistic partitions are essentially equivalent from the point of view of clustering algorithm development. The set of all fuzzy c-partitions is described in (2). Each column of the fuzzy partition U must sum to 1, thus ensuring that every object is involved in a partition ($\sum_i u_{ik} = 1$).

Possibilistic partitions relax this condition, allowing partition columns that do not necessarily sum to 1. Possibilistic

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

$$M_{hcn} = \left\{ U \in \mathbb{R}_{0,+}^{c\times n} | u_{ij} \in 0,1, \forall j,i; 0 < \sum_{i=1}^{n} u_{ij} < n, \forall j; \sum_{j=1}^{c} u_{ij} = 1, \forall i \right\} \quad (1)$$

$$M_{fcn} = \left\{ U \in \mathbb{R}_{0,+}^{c\times n} | u_{ij} \in [0,1], \forall j,i; 0 < \sum_{i=1}^{n} u_{ij} < n, \forall j; \sum_{j=1}^{c} u_{ij} = 1, \forall i \right\} \quad (2)$$

$$M_{pcn} = \left\{ U \in \mathbb{R}_{0,+}^{c\times n} | u_{ij} \in [0,1], \forall j,i; 0 < \sum_{i=1}^{n} u_{ij} < n, \forall j; \max_{1\le j\le c} u_{ij} > 0, \forall i \right\} \quad (3)$$

$$\min_{U} \left\{ J_m(U;H,K) = \sum_{j=1}^{c} \left(\sum_{i=1}^{n}\sum_{k=1}^{n} \left(u_{ij}^m u_{kj}^m d_\kappa(\mathbf{x}_i,\mathbf{x}_k) \right) / 2 \sum_{l=1}^{n} u_{lj}^m \right) + \sum_{j=1}^{c} \nu_j \sum_{i=1}^{n} (1-u_{ij})^m \right\} \quad (4)$$

clustering has been shown to be especially effective in partitioning data that has outliers and intersecting clusters [13]. The set of all possibilistic c-partitions is described in (3), where u_{ik} is the possibility that o_k is in cluster i (this was also described in [13] as the *typicality* of o_k to cluster i). Notice that the possibilistic partition ensures that there is at least one object that has a non-zero possibility of being in each cluster (the empty cluster cannot exist). An interesting property of these three types of partitions is that all crisp partitions are fuzzy partitions and all fuzzy partitions are possibilistic partitions. Equations (1), (2), and (3), show that $M_{hcn} \subset M_{fcn} \subset M_{pcn}$.

All cluster analyses address the same questions, independent of the type of partition. The three main questions are: i) *Cluster tendency*—are there clusters, and how many clusters are there? ii) *Partitioning*—which objects belong to which cluster and to what degree? And iii) *cluster validity*—are the partitions "good"? There are many algorithms that attempt to answer these questions. This paper focuses on a specific form of question ii), namely soft c-means partitioning of large datasets in kernel-induced spaces.

A. Kernel c-Means

Consider some non-linear mapping function $\phi : \mathbf{x} \rightarrow \phi(\mathbf{x}) \in \mathbb{R}^{D_K}$, where D_K is the dimensionality of the transformed feature vector $\mathbf{x}$. With kernel clustering, we do not need to explicitly transform $\mathbf{x}$, we simply need to represent the dot product $\phi(\mathbf{x}) \cdot \phi(\mathbf{x}) = \kappa(\mathbf{x},\mathbf{x})$. The kernel function κ can take many forms, with the polynomial $\kappa(\mathbf{x},\mathbf{y}) = (\mathbf{x}^T\mathbf{y}+1)^p$ and radial-basis-function (RBF) $\kappa(\mathbf{x},\mathbf{y}) = \exp(||\mathbf{x}-\mathbf{y}||^2/\sigma)$ being two of the most well known. Given a set of n objects X, we can thus construct an $n \times n$ kernel matrix $K = [K_{ij} = \kappa(\mathbf{x}_i,\mathbf{x}_j)]^{n\times n}$. This kernel matrix K represents all pairwise dot products of the feature vectors associated with n objects in the transformed high-dimensional space—called the Reproducing Kernel Hilbert Space (RKHS).

Given a kernel matrix K, the kernel c-means can be generally defined as the constrained optimization in (4), where $U \in M_{pcn}$, $H = \{\nu_1,\ldots,\nu_c\} \in \mathbb{R}_{0,+}$ is the cluster radii set (which only applies to possibilistic clustering), $m \geq 1$ is the fuzzification parameter, and $d_\kappa(\mathbf{x}_i,\mathbf{x}_k)$ is the kernel-based distance between the ith and kth objects. All three of the major c-means algorithms—hard, fuzzy, and possibilistic—can be instantiated by adjusting the parameters appropriately in the objective function in (4). Table I shows how the parameters of (4) are set for each algorithm. For simplicity, we denote the cluster center to object distance $d_\kappa(\mathbf{v}_j,\mathbf{x}_i)$ as $d_\kappa(j,i)$.

TABLE I: Hard, Fuzzy, and Possibilistic Variations of Solving the c-Means Optimization in Eq. (4) [14]

Algorithm	m	H	U
Hard (Crisp)	$m=1$	$\nu_j = 0,\ \forall j$	Use Eq. (5)
Fuzzy	$m>1$	$\nu_j = 0,\ \forall j$	Use Eq. (6)
Possibilistic	$m>1$	$\nu_j > 0,\ \forall j$	Use Eq. (7)

Hard c-means membership update [15]:

$$u_{ij} = \begin{cases} 1, & d_\kappa(j,i) = \min_{1\le k\le c} d_\kappa(k,i) \\ 0, & \text{else} \end{cases}, \ \forall j,i \quad (5)$$

Fuzzy c-means membership update [15]:

$$u_{ij} = \left(\sum_{k=1}^{c} \left(\frac{d_\kappa(j,i)}{d_\kappa(k,i)} \right)^{\frac{2}{m-1}} \right)^{-1}, \ \forall i,j \quad (6)$$

Possibilistic c-means membership update [15]:

$$u_{ij} = \left(1 + \left(\frac{d_\kappa(j,i)}{\nu_j} \right)^{\frac{2}{m-1}} \right)^{-1}, \ \forall i,j \quad (7)$$

The partition update equations in Table I are all based on a kernel distance between an object and a cluster center, which is computed as

$$d_\kappa(j,i) = ||\phi(\mathbf{v}_j) - \phi(\mathbf{x}_i)||^2, \quad (8)$$

where

$$\phi(\mathbf{v}_j) = \frac{\sum_{l=1}^{n} u_{lj}^m \phi(\mathbf{x}_l)}{\sum_{l=1}^{n} u_{lj}^m}. \quad (9)$$

We can simplify (8) by using the identity $K_{ij} = \phi(\mathbf{x}_i) \cdot \phi(\mathbf{x}_j)$ and denoting $\tilde{\mathbf{u}}_j = \mathbf{u}_j^m / ||\mathbf{u}_j^m||_1$ ($\mathbf{u}_j$ is the jth column of U),

which gives

$$\begin{aligned} d_\kappa(j,i) &= \frac{\sum_{l=1}^n \sum_{s=1}^n u_{lj}^m u_{sj}^m \phi(\mathbf{x}_l)\cdot\phi(\mathbf{x}_s)}{\sum_{l=1}^n u_{lj}^{2m}} \\ &\quad +\phi(\mathbf{x}_i)\cdot\phi(\mathbf{x}_i) - 2\frac{\sum_{l=1}^n u_{lj}^m \phi(\mathbf{x}_l)\cdot\phi(\mathbf{x}_i)}{\sum_{l=1}^n u_{lj}^m} \\ &= \tilde{\mathbf{u}}_j^T K \tilde{\mathbf{u}}_j + \mathbf{e}_i^T K \mathbf{e}_i - 2\tilde{\mathbf{u}}_j^T K \mathbf{e}_i \\ &= \tilde{\mathbf{u}}_j^T K \tilde{\mathbf{u}}_j + K_{ii} - 2(\tilde{\mathbf{u}}_j^T K)_i, \end{aligned} \tag{10}$$

where $\mathbf{e}_i$ is a length n unit vector with the ith element equal to 1.

In *possibilistic c-means* (PCM), the parameters ν determine the influence of each cluster on the value of the objective function in (4), where the second term in (4) penalizes the trivial solution of $u_{ij} = 0,\ \forall i, j$.

Algorithms 1, 2, and 3 outline the kernel-based variants of *hard c-means* (HCM), *fuzzy c-means* (FCM), and PCM, respectively. This variant of the PCM algorithm first initializes the memberships by using FCM, then the ν parameter is estimated by

$$\nu_j = \Theta \frac{\sum_{i=1}^n u_{ij}^m d_\kappa(j,i)}{\sum_{i=1}^n u_{ij}^m},\ \forall j, \tag{11}$$

where $\Theta > 0$ and is usually set to $\Theta = 1$ [8, 13].

Algorithm 1: Hard c-Means (HCM) Kernel Clustering Algorithm

Input: K - $n \times n$ kernel matrix
Data: $m = 1$, $U \in \{0,1\}^{c\times n}$ cluster membership matrix
Initialize U
while $\max\{|U - U'|\} > 0$ **do**
  $U' = U$
  Compute $d_\kappa(j,i)$, $\forall i, j$, using Eq.(10)
  Update U using Eq. (5)

Algorithm 2: Fuzzy c-Means (FCM) Kernel Clustering Algorithm

Input: K - $n \times n$ kernel matrix; m - fuzzifier
Data: $U \in [0,1]^{c\times n}$ cluster membership matrix
Initialize U
while $\max\{|U - U'|\} > \epsilon$ **do**
  $U' = U$
  Compute $d_\kappa(j,i)$, $\forall i, j$, using Eq.(10)
  Update U using Eq. (6)

In all these c-means variants, Eq.(10) is computationally expensive for large number of objects n as it requires $O(n^2)$ operations. Furthermore, the entire kernel matrix K is required and producing and storing this matrix for the entire data set is often very computationally expensive; e.g., $n = 100,000$ requires 40 gigabytes of memory, which is not a small amount by today's standards. We approximate $d_\kappa(j,i)$ by constraining the space in which the cluster centers exist.

Algorithm 3: Possibilistic c-Means (PCM) Kernel Clustering Algorithm [13, 16]

Input: K - $n \times n$ kernel matrix; m - fuzzifier
Data: $U \in [0,1]^{c\times n}$ cluster membership matrix
Run FCM to initialize U
Estimate ν_j by Eq. (11)
while $\max\{|U - U'|\} > \epsilon$ **do**
  $U' = U$
  Compute $d_\kappa(j,i)$, $\forall i, j$, using Eq. (10)
  Update U using Eq.(7)

II. Large Scale c-Means Approximation Algorithms

The cluster centers in kernel c-means algorithms are represented by a linear sum of the high-dimensional transformed features $\phi(\mathbf{x}_i)$,

$$\phi(\mathbf{v}_j) = \sum_{i=1}^n \tilde{u}_{ij}\phi(\mathbf{x}_i), \tag{12}$$

where this equation is equivalent to (9) with $\tilde{u}_{ij}$ substituted. In data where the number of objects n is large, we hypothesize that the cluster centers $\phi(\mathbf{v}_j)$ can be accurately represented by a subset of the feature vectors $\phi(\mathbf{x})$. Let $\xi = (\xi_1, \ldots, \xi_n)$ be binary variables indicating the instances that are selected for constructing the cluster centers, with $\xi_i = 1$ if $\mathbf{x}_i$ is selected and 0 otherwise. Let s denote the number of selected objects, where $s = \sum_i \xi_i$. The following derivation follows, very closely, that of our previous work [17] on approximating HCM for large-scale data.

In our approximation, the cluster centers are approximated by a linear sum of the selected feature vectors

$$\hat{\phi}(\mathbf{v}) = \sum_{i=1}^n a_i \xi_i \phi(\mathbf{x}_i), \tag{13}$$

where a_i is the weight of the ith feature vector. We are only interested in the values of a_i when $\xi_i = 1$; hence, we denote the weights for the jth cluster center as $\alpha_j = (\alpha_{1j} = a_{(1)}, \ldots, \alpha_{sj} = a_{(s)})$, where $a_{(1)}, \ldots, a_{(s)}$ are the set of associated weights where $\xi = 1$. Although this notation seems cumbersome, it dramatically simplifies the description of our derivation. With this notation, we can rewrite (13) for the jth cluster center as

$$\hat{\phi}(\mathbf{v}_j) = \sum_{i=1}^s \alpha_{ij}\phi(\mathbf{x}_{(i)}), \tag{14}$$

where it is clear now that we are representing the cluster center $\phi(\mathbf{v}_j)$ as a linear sum of s selected objects.

Now we want to solve for the weights α_j such that the distance between the true cluster center and the approximated cluster center, $||\phi(\mathbf{v}_j) - \hat{\phi}(\mathbf{v}_j)||^2$, is minimized. This distance

can be written as

$$||\phi(\mathbf{v}_j) - \hat{\phi}(\mathbf{v}_j)||^2 = \left|\left|\sum_{i=1}^{n} \tilde{u}_{ij}\phi(\mathbf{x}_i) - \sum_{i=1}^{n} a_i\xi_i\phi(\mathbf{x}_i)\right|\right|^2$$
$$= \tilde{\mathbf{u}}_j^T K \tilde{\mathbf{u}}_j + (\mathbf{a}\circ\xi)_j^T K (\mathbf{a}\circ\xi)_j - 2\tilde{\mathbf{u}}_j^T K(\mathbf{a}\circ\xi)_j, \quad (15)$$

where $\circ$ indicates the Hadamard product or element-by-element multiplication (.* in MATLAB) and $(\mathbf{a}\circ\xi)_j$ is an n-length vector that represents the weights of the approximated cluster center $\hat{\phi}(\mathbf{v}_j)$. We can substitute α_j into (15) by defining two sub-matrices of the kernel matrix K,

$$K_{\xi\xi} = [K_{ij}]^{s\times s},\ \xi_i = 1, \xi_j = 1, \quad (16)$$
$$K_{\xi} = [K_i]^{n\times s},\ \xi_i = 1, \quad (17)$$

where K_i is the ith column of K. Notice that $K_{\xi\xi}$ is the $s\times s$ square matrix corresponding to the pairwise elements of K for the ξ-selected objects. K_ξ is the $n\times s$ rectangular matrix corresponding to the columns of K for the ξ-selected objects; also, $K_{\xi\xi}$ is a sub-matrix of K_ξ. Hence, we can now rewrite (15) as

$$||\phi(\mathbf{v}_j) - \hat{\phi}(\mathbf{v}_j)||^2 = \tilde{\mathbf{u}}_j^T K \tilde{\mathbf{u}}_j + \alpha_j^T K_{\xi\xi}\alpha_j - 2\tilde{\mathbf{u}}_j^T K_\xi \alpha_j. \quad (18)$$

We determine α_j by minimizing (18) with respect to α, which is solved by setting the derivative of (18) with respect to α_j to zero,

$$\frac{d||\phi(\mathbf{v}_j) - \hat{\phi}(\mathbf{v}_j)||^2}{d\alpha_j} = 2K_{\xi\xi}\alpha_j - 2\tilde{\mathbf{u}}_j^T K_\xi = 0,$$

leading to the solution

$$\alpha_j = -\left(K_{\xi\xi}^{-1} K_\xi^T \tilde{\mathbf{u}}_j\right)^T. \quad (19)$$

In practice, $K_{\xi\xi}$ could be rank-deficient (have a number of relatively small eigenvalues); hence, it is advisable to use a pseudo-inverse when computing $K_{\xi\xi}^{-1}$, which we denote as $K_{\xi\xi}^\dagger$. Also, the calculation of $K_{\xi\xi}^{-1}K_\xi^T$ only needs to be performed once, at the beginning of the algorithm, with the result stored.

The key element of our approximation algorithms is the redefinition of Eq. (10) using the solution of α_j, i.e.,

$$\hat{d}_\kappa(j,i) = \alpha_j^t K_{\xi\xi}\alpha_j + K_{ii} - 2(K_\xi\alpha_j)_i. \quad (20)$$

Notice that we no longer require the full kernel matrix to compute the distance $\hat{d}_\kappa(j,i)$; the only required kernel matrix elements are the diagonal elements (which for the RBF are all equal to one) and the s columns of K corresponding to the selected objects.

We are now ready to define our large-scale approximations of the kernel FCM and PCM algorithms. Algorithms 4 and 5 outline the approximations of the kernel FCM and PCM algorithms, respectively, which we call akFCM and akPCM.

The computational complexity of the distance calculation in (20) is $O(sn)$, which for $s << n$ is a significant improvement on the $O(n^2)$ complexity of the full-kernel distance calculation in (10). Furthermore, only $sn + n - s$ elements of K need to be calculated—the sn elements of K_ξ and the $n - s$ additional diagonal elements—which both reduces the computation time to produce the kernel elements and the storage requirements. However, for very large n both the computational and memory requirements can still be significant—e.g. a $10,000\times 1,000,000$ array of floats (4 bytes) requires 40 gigabytes of working memory. While this memory requirement is large (at the time this paper was written), it is manageable compared to the 4 terabyte memory requirement for the full $1,000,000\times 1,000,000$ kernel matrix.

The computational complexity of the pseudo-inverse of $K_{\xi\xi}$ is $O(m^3)$, which could lead to problems for large m. However, in practice, one could employ gradient descent to solve for α.

Next, we move on to some experiments.

Algorithm 4: Approximate Fuzzy c-Means (akFCM) Kernel Clustering Algorithm

Input: K_ξ - $n\times s$ kernel sub-matrix; diag(K) - Kernel matrix diagonal; m - fuzzifier; ξ - selection vector
Data: $U\in[0,1]^{c\times n}$ cluster membership matrix
Initialize U
$\hat{K} = -K_{\xi\xi}^\dagger K_\xi^T$
while $\max\{|U - U'|\} > \epsilon$ **do**
  $U' = U$
  $\alpha_j = \left(\hat{K}\tilde{\mathbf{u}}_j\right)^T,\ \forall j$
  $\hat{d}_\kappa(j,i) = \alpha_j^t K_{\xi\xi}\alpha_j + K_{ii} - 2(K_\xi\alpha_j)_i,\ \forall i,j$
  Update U using Eq. (6)

Algorithm 5: Approximate Possibilistic c-Means (akPCM) Kernel Clustering Algorithm

Input: K_ξ - $n\times s$ kernel sub-matrix; diag(K) - Kernel matrix diagonal; m - fuzzifier; ξ - selection vector
Data: $U\in[0,1]^{c\times n}$ cluster membership matrix
$\hat{K} = -K_{\xi\xi}^\dagger K_\xi^T$
Run akFCM to initialize U
Estimate ν_j by Eq. (11)
while $\max\{|U - U'|\} > \epsilon$ **do**
  $U' = U$
  $\alpha_j = \left(\hat{K}\tilde{\mathbf{u}}_j\right)^T,\ \forall j$
  $\hat{d}_\kappa(j,i) = \alpha_j^t K_{\xi\xi}\alpha_j + K_{ii} - 2(K_\xi\alpha_j)_i,\ \forall i,j$
  Update U using Eq. (7)

III. Experiments

We performed two sets of experiments. The first compared the performance of the proposed algorithms with the full kernel solution. The second set of experiments applies the proposed algorithms to data sets for which computing the full kernel solution was impossible because of memory limitations.

The experiments described in this paper were performed on a single core of an AMD Opteron in a Sun Fire X4600 M2 server with 256 gigabytes of memory. All code was written in the MATLAB [18] computing environment.

A. Evaluation Criteria

We judge the performance of our proposed algorithms with three criteria. Each criteria is computed for 20 independent runs. For each run, we initialize the full kernel c-means and the sampled kernel c-means algorithms with the same initialization. Thus, both the approximation algorithm and the full kernel algorithm begin with the same initial partition, with a different initialization for each run. We initialize U by choosing c objects as the initial cluster centers. The value of $\epsilon = 1 \times 10^{-3}$ and the fuzzifier $m = 2$.

1) Speedup Factor: This criteria represents an actual run-time comparison. Speedup is defined as t_{full}/t_{samp}, where these values are times in seconds for computing the membership matrix U. Note that we de not include the time savings from having to only compute a portion of the kernel matrix in our calculation. Thus, the speedup we present is a conservative measure. In practice, one would see further improvement by only calculating the necessary portions of the kernel matrix—the $m \times n$ rectangular matrix K_ξ and the diagonal of K.

2) Cluster Purity: This measure is defined as

$$P = \frac{1}{n} \sum_{j=1}^{c} \max_{\omega \in \Omega} |\omega \cap C_j|, \tag{21}$$

where Ω is the set of all class labels and C_j is the set of labels of the objects in the jth cluster. This measure cannot be directly applied to soft partitions; hence, we first *harden* the partitions before applying (21). Hardening is the process of setting the maximum cluster membership in each column of U to 1 and all else to 0.

The figures in this paper show *relative purity*, which is calculated as $P_{samp} - P_{full}$ for each run.

3) Squared Error Distortion: This criteria is the c-means objective and is defined as

$$E = \sum_{j=1}^{c} \sum_{i=1}^{n} u_{ji}^m ||\phi(\mathbf{v}_j) - \phi(\mathbf{x}_i)||^2 = \sum_{j=1}^{c} \sum_{i=1}^{n} u_{ji}^m d_\kappa(j,i). \tag{22}$$

We present the % error in E, which is calculated as

$$\%\ \text{Error} = \frac{E_{samp} - E_{full}}{E_{full}} * 100.$$

As with relative purity, % Error is only calculated between the approximation result and the full kernel result that start with the same initialization. By doing this, we are negating the effect that the initialization has on the result.

B. Comparison with Full Kernel c-Means

We compared the proposed approximation to the full kernel method on two different data sets.

1) **A3**: These data are composed of 7,500 2-dimensional vectors, with a visually-preferred grouping into 50 clusters.[1] Figure 1 shows a plot of these data. We used the RBF kernel with $\sigma = 0.5$.

[1]The A3 data was designed by Ilja Sidoroff and can be downloaded at http://cs.joensuu.fi/~isido/clustering/.

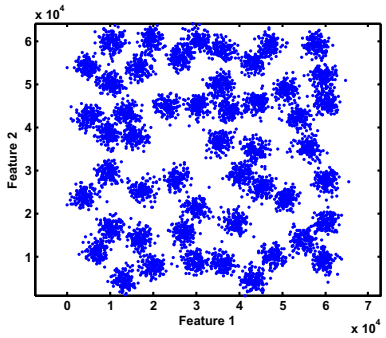

Fig. 1: Plot of A3 data set.

2) **MNIST**: This data set is a subset of the collection of handwritten digits available from the *National Institute of Standards and Technology* (NIST)[2]. There are 70,000 28×28 pixel images of the digits 0 to 9. Each pixel has an integer value between 0 and 255. We normalize the the pixel values to the interval $[0, 1]$ by dividing by 255 and concatenate each image into a 784-dimensional column vector. The kernel used for this example was a degree-5 polynomial kernel $\kappa(\mathbf{x}, \mathbf{y}) = (\mathbf{x}^T\mathbf{y} + 1)^5$, which was shown to be effective in [19].

Figure 2 illustrates the evaluation criteria for the sFCM clustering algorithm on the A3 data set. The error-bars indicate the maximum and minimum values of each criteria over 20 independent runs. View (a) shows that an order of magnitude speedup is attained with sample sizes $m \leq 250$, or at a 3% sampling rate. Views (b) and (c) show that even at very low sample rates, the quality of the approximated clustering solution is equal to that of the full kernel solution and in one instance, at sample size $m = 1500$, the cluster purity was 2% greater than that of the full kernel solution.

The results of the akPCM algorithm on the A3 data set are illustrated in Fig. 3. View (a) shows that akPCM provides similar speedup results as akFCM and views (b) and (c) demonstrate that the quality of the solution is better than that of the full kernel algorithm. We conjecture that this is because the influence of objects in regions where classes overlap is perhaps lessened by the sampling process.

Figures 4 and 5 show the results of the experiments performed on the MNIST data set. The results of the akFCM algorithm show significant speedup at low sampling rates (the two lowest sampling rates are 0.1% and 0.2%, respectively) with negligible difference in the quality of the clustering, relative to the full kernel c-means. Figure 3(a) shows that 1-2 orders of magnitude in speedup is achieved; however, in the akPCM experiments, a degradation in the cluster purity of about 3% was observed. Again, the lower sampling rates perform better than the higher sampling rates. We aim to investigate this phenomenon in subsequent studies and conjecture that this behavior is either due to the psuedo-inverse calculation in the approximation algorithm or because of the influence of outlier

[2]The MNIST data can be downloaded at http://yann.lecun.com/exdb/mnist/.

and overlapping classes.

C. Performance on Very Large Data Sets

Now we present the results of our proposed approximation algorithms on two data sets which are considerably larger than than the those in the previous experiments.

To store the full kernel matrix for either of the data sets in this section in single-precision format would require 1+ terabytes (1,000 gigabytes) of memory. At the time of this study, 1 terabyte of memory was an exceptionally large amount. Without considering distributed memory architectures, this is out of reach for most researchers and consumers.

1) **Forest Cover Type** [20][3]: These data are composed of cartographic variables obtained from *United States Geological Survey* (USGS) and *United State Forest Service* (USFS) data. There are 10 quantitative variables, such as elevation and horizontal distance to hydrology, 4 binary wilderness area designation variables, and 40 binary soil type variables. These features were collected from a total of 581,012 30×30 meter cells, which were then determined to be one of 7 forest cover types by the USFS. We normalize the features to the interval $[0, 1]$.

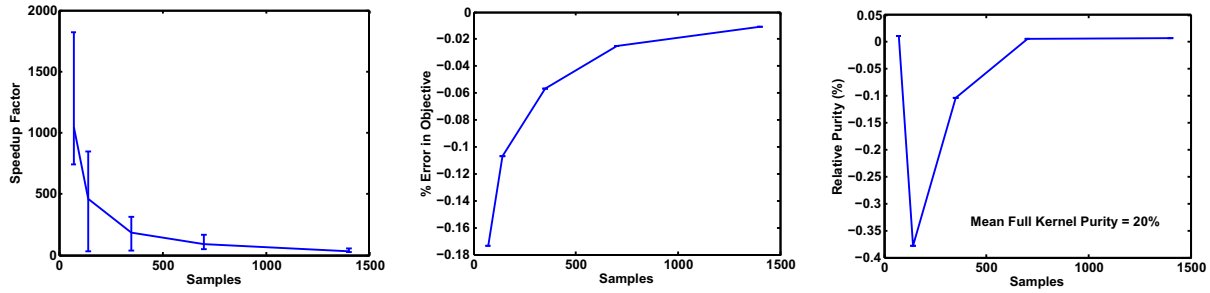
[3]The *Forest Cover Type* and *Quadreped Mammals* data sets can be downloaded at http://uisacad2.uis.edu/dstar/data/clusteringdata.html.

2) **Quadruped Mammals** [20]: These data are generated by the program animals.c, which can be downloaded from the UCI Machine Learning depository. The program generates instances of 72-dimensional feature vectors which belong to one of 4 classes of animals: dogs, cats, horses, and giraffes. We use 500,000 examples from this data set, with an approximately equal number of each class.

These problems become manageable by applying our approximation algorithms. We collected results for these two data sets at sample rates, $m = 0.01\%n$, $0.05\%n$, and $0.1\%n$. We produced 5 random draws of the selection variable ξ and for each random draw computed the akFCM and akPCM solutions for 5 different initializations; thus, a total of 25 experiments were done at each sample rate. Two different kernels were used, a degree-2 polynomial and an RBF with $\sigma = 2$.

Table II contains the run-time and cluster purity values for the two very large data sets. These results show that the akFCM algorithm can be used to cluster the Mammals data set in 8 seconds, with a cluster purity of 85%, and the Cover Type data set in 58 seconds, with a cluster purity of 52%.

For comparison, it was reported in [21] that the CLUTO [22] hard clustering algorithm achieved a purity score of 0.49 in on the Cover Type data and 0.82 purity on the Mammals data set. Our approximation algorithm produces results slightly



(a) Speedup — t_{full}/t_{samp} (b) % Error in squared distortion — $(J_{samp} - J_{full})/J_{full}$ (c) Relative cluster purity — $P_{samp} - P_{full}$

Fig. 4: Performance of akFCM on *MNIST* data set using degree-5 polynomial kernel, $n = 70000$, $c = 10$. Lines denote mean values over independent 21 runs; error-bars represent maximum and minimum values. Membership matrix was hardened to compute cluster purity.

akPCM	$c = 4$						$c = 7$					
Run-time (secs)	30	129	199	35	151	224	125	352	600	87	215	570
Purity	0.68	0.69	0.71	0.68	0.69	0.69	0.50	0.50	0.50	0.49	0.49	0.49

better to those of CLUTO on these data. The GARDEN$_{HD}$ hard clustering algorithm [21] achieved a purity score of 0.65 on the Cover Type data; although, this algorithm is based on recursive division of the vector data and determined that the Cover Type data has 84 clusters. Cluster purity, by definition, tends to increase as the number of clusters increases; e.g., when the number of clusters $c = n$, purity $= 1$. Thus, comparing our results directly against GARDEN$_{HD}$ is not advised. The GARDEN$_{HD}$ algorithm achieved a purity of 0.76 with 1250 clusters and a purity of 1 with 6314 clusters on the Mammals data set. In comparison, akFCM achieved a purity of 0.86 with 4 clusters on this data and many of the individual runs in our experiment did produce a perfect cluster purity of 1. We believe that these results show that our algorithm is producing results that are as good as or better than existing algorithms that work on large scale data.

IV. Conclusion

We proposed an approximation of the fuzzy and possibilistic kernel c-means that has a reduced computational complexity and memory requirement. Our experimental results show that run-time can be decreased by 1-2 orders of magnitude, while achieving equal clustering performance to the classical kernel c-means. Furthermore, the memory requirements of our approximation is $O(mn)$, compared to $O(n^2)$ for the full kernel solution, where $m << n$.

In the future we are going to do a theoretical analysis on the loss imposed on the fuzzy and possibilistic c-means objective functions by the error in our approximation of the kernel-based

distance between the cluster-center and objects. We have done analysis on a related approximation of the hard c-means, which can be found in [17]. In short, we discovered that with some modest assumptions the error imposed by our approximation on the hard c-means objective decreases at the rate of $O(1/m)$, which is intuitively pleasing. We expect similar results with the soft partitioning algorithms.

Also, we plan to investigate other sampling methods. There have been many sampling methods, both random and deterministic, proposed and analyzed for the Nyström method of approximating a kernel matrix [23, 24]. We aim to further investigate and build upon these methods to optimize the trade-off between the computational complexity and memory requirements and the imposed error.

Adaptive Fuzzy Interpolation with Uncertain Observations and Rule Base

Longzhi Yang and Qiang Shen

***Abstract*—Adaptive fuzzy interpolation strengthens the potential of fuzzy interpolative reasoning. It views interpolation procedures as artificially created system components, and identifies all possible sets of faulty components that may each have led to all detected contradictory results. From this, a modification procedure takes place, which tries to modify each of such components, termed candidates, in an effort to remove all the contradictions and thus restore consistency. This approach assumes that the employed interpolation mechanism is the only cause of contradictions, that is all given observations and rules are believed to be true and fixed. However, this may not be the case in certain real situations. It is common in fuzzy systems that each observation or rule is associated with a certainty degree. This paper extends the adaptive approach by taking into consideration both observations and rules also, treating them as diagnosable and modifiable components in addition to interpolation procedures. Accordingly, the modification procedure is extended to cover the cases of modifying observations or rules in a given rule base along with the modification of fuzzy reasoning components. This extension significantly improves the robustness of the existing adaptive approach.**

***Index Terms*—Fuzzy interpolation, uncertain observations, uncertain rules.**

I. Introduction

Fuzzy rule interpolation enables inference in systems with sparse rule bases and helps reduce the complexity of fuzzy models. When given observations have no overlap with any antecedent values, no rule can be fired in classical inference. However, interpolative reasoning through a sparse rule base may still obtain certain conclusions and thus improve the applicability of fuzzy models. Also, with the help of fuzzy interpolation, the complexity of a large rule base can be reduced by omitting those fuzzy rules which may be approximated from their neighboring ones. A number of important interpolation approaches have been presented in the literature, including [1], [2], [3], [7], [8], [9], [12], [13]. In particular, the scale and move transformation-based approach can handle both interpolation and extrapolation, which involve multiple fuzzy rules with each rule consisting of multiple antecedents. This approach also guarantees the uniqueness as well as the normality and convexity of the resulting interpolated fuzzy sets. Yet, it is possible that more than one object value of a single variable may be derived in fuzzy interpolation. This implies that certain inconsistencies may result.

To address this problem, *adaptive fuzzy interpolation* has recently been proposed [14], [15]. This approach is capable of efficiently detecting inconsistencies, locating possible fault candidates and effectively modifying the candidates in an effort to remove all the inconsistencies. It works by viewing the interpolative inference procedures as artificial system components, and then utilizing an assumption-based truth maintenance system (ATMS) [4] to record the dependencies between an interpolated value and its proceeding interpolative procedures. From this, the classical algorithm of general diagnostic engine (GDE) [5] is employed to hypothesize all possible candidates of defective rules, by manipulating the sets of the artificial (fuzzy reasoning) components that led to the detected contradictions.

The adaptive approach of [14], [15] presumes that the underlying interpolation procedures have caused all the contradictory interpolated results. This limits its application to the reasoning components only. However, in general, observations and rules in a given rule base may also be faulty and be so to a certainty degree. Fortunately this is not fundamentally restricted by the underlying approach. This work extends that of [14], in order to allow that observations and rules are also diagnosable and modifiable. Due to the ability of using more information, this extension will considerably improve the approach in two aspects. First, one interpolative solution may still be derived when the existing approach fails. Second, the solution generated may be more reasonable than that by the existing approach.

The reminder of this paper is structured as follows. Sec. II reviews the adaptive fuzzy interpolation approach. Sec. III extends the candidate generation procedure by taking observations, rules, and fuzzy interpolative procedures as diagnosable components. Sec. IV generalizes the candidate modification procedure in order that all kinds of candidate component are modifiable. Sec. V reconsiders the example given in [14] to illustrate how this extension can improve the original approach. Sec. VI concludes the paper and points out important future research directions.

II. Adaptive Fuzzy Interpolation

Adaptive interpolative reasoning [14] provides a way to ensure that inference results remain consistent throughout the fuzzy interpolative process. In this work, the fuzzy interpolation procedure based on each pair of neighboring rules R_i and R_j $(i \neq j)$ is defined as a *fuzzy reasoning component*, denoted

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

as R_iR_j. Such a component takes an input, an observation or a previously interpolated result, including that obtained by extrapolation (which are all hereafter referred to as an observation for simplicity), and produces another (the consequent of the interpolated rule) as output. The process of adaptive interpolation is summarized in Fig. 1. Firstly, the interpolator carries out interpolation and passes the interpolated results to the ATMS for dependency-recording. Then, the ATMS relays to the GDE any β_0-*contradiction* (i.e. inconsistency between two values for a common variable that at least differ to the degree of a given threshold β_0, $0 \leq \beta_0 \leq 1$) as well as their dependent fuzzy reasoning components. Next, GDE diagnoses the problem and generates all possible component candidates which may have led to the detected inconsistencies. After that, a modification process takes place to correct a certain candidate in order to restore consistency. A brief description of each of these key methods is given below.

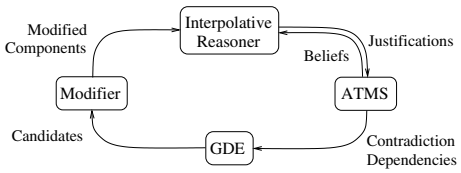

Fig. 1. Adaptive interpolative reasoning

A. Truth maintenance

ATMS is utilized to record the dependency of the interpolated results and that of contradictions, upon the fuzzy reasoning components from which they are inferred. Thus, propositions, contradictions and fuzzy interpolative reasoning components are all represented as ATMS nodes. In addition to the so-called datum field, which trivially denotes the actual meaning of the node, an ATMS node has two other fields: justification and label.

1) Justification: Briefly, a justification describes how a node is derivable from other nodes. Any ATMS node with an inferred proposition can be verified by an ATMS justification:

$$O, R_iR_j \Rightarrow C, \tag{1}$$

which means that the outcome C is inferred form observations O through the interpolation procedure R_iR_j $(i \neq j)$ by firing rules R_i and R_j.

By definition, any two propositions P (x_i is A_{ij}) and P'(x_i is A_{ik}) concerning the same variable x_i are contradictory if the values differ at least by a given degree β_0, which can be represented as:

$$P, P' \Rightarrow_{\beta_0} \perp. \tag{2}$$

2) Label and label-updating: A label is a set of environments, each of which supports their associated node. In particular, an environment is a minimal set of fuzzy reasoning components that jointly entail the supported node, thereby describing how the node ultimately depends on those fuzzy reasoning components. An environment is said to be β_0-*inconsistent* if β_0-contradiction is derivable propositionally by the environment and a given justification. An environment is said to be $(1-\beta_0)$-*consistent* if it is not β_0-inconsistent.

The label of each node is guaranteed to be $(1-\beta_0)$-consistent, sound, minimal and complete by the label updating algorithm, except that the label of the special "false" node is guaranteed to be β_0-inconsistent rather than $(1-\beta_0)$-consistent. In particular, the label of the special "false" node gathers all minimal β_0-inconsistent environments. The corresponding label-updating process for this special node is given as follows. Whenever a β_0-contradiction is detected, each environment in its label is added into the label of "false" node and all such environments and their supersets are removed from the label of every other node. Also, any such environment which is a superset of another is removed from the label of the node "false".

B. Candidate generation

GDE [5] generates minimal candidates by manipulating the label of the specific "false" node. A candidate is a particular set of nodes or fuzzy reasoning components which may be responsible for the whole set of current contradictions. Because a β_0-inconsistent environment indicates that at least one of its elements is faulty (contradictory to the extent of β_0), a candidate must have a non-empty intersection with each β_0-inconsistent environment. Thus, each candidate is constructed by taking one fuzzy reasoning component from each environment in the label of "false" node. Supersets removal then ensures such generated candidates to be minimal. In light of this, a successful correction of any single candidate will remove all the contradictions.

C. Candidate modification

Consistency can be restored by successfully correcting any single candidate because each single candidate explains the entire set of current contradictions. Given a set of candidates, the modification procedure is shown in Fig. 2.

CONSISTENCYRESTORING($\mathbb{Q}$)
$\mathbb{Q}$, the candidate set sorted in descending cardinality, each element of which is a set of fuzzy reasoning components (f);
MODIFY(f), the modification procedure for a single fuzzy reasoning component (f), which returns **true** when modification succeeds and **false** otherwise.

```
(1)  success ← false
(2)  do
(3)      C ← Dequeue(ℚ)
(4)      foreach f ∈ C
(5)          success ← MODIFY(f)
(6)          if (success ==false)
(7)              break
(8)  until ((success ==true) or (ℚ == ∅))
(9)  return success
```

Fig. 2. The CONSISTENCYRESTORING procedure

For convenience, in the rest of this paper, A^*_{ij} is used to denote the modified consequence of a culprit interpolated

rule whose consequent value is A_{ij}, and $A_{ij}^{*\prime}$ and λ_{ij}^{*} are used to denote the corresponding modified intermediate rule consequence and the *relative placement factor* [14] of A_{ij}^{*}, respectively. Also, for simplicity, only rules with a single antecedent are considered here, though extension to multi-antecedent rules is straightforward. Suppose that the neighboring rules $A_{11} \Rightarrow A_{21}$ and $A_{1n} \Rightarrow A_{2n}$ are the two rules used for interpolation by a defective fuzzy reasoning component, that $A_{12}, A_{13}, ..., A_{1(n-1)}$ are observations or previously interpolated results located in between A_{11} and A_{1n}, and that A_{1j} $(2 \leq j \leq n-1)$ is the middle most observation (which informally, is the one that is closest to both antecedent values of the neighboring rules). The modification procedure for a single fuzzy reasoning component is summarized as follows:

1. Find the rule $(A_{1j} \Rightarrow A_{2j})$ whose antecedent is located in the middle most of the neighborhood of the antecedents of any two rules that may be used for interpolation, with respect to their representative values [7]. Assume that the *relative placement factor* of its consequence λ_{2j} is modified to λ_{2j}^{*}.

2. Calculate the *correction rate pair* according to the *relative placement factor* modification of rule $A_{1j} \Rightarrow A_{2j}$:

$$\begin{cases} c^{-} = \frac{\lambda_{2j}^{*}}{\lambda_{2j}} \\ c^{+} = \frac{1-\lambda_{2j}^{*}}{1-\lambda_{2j}}. \end{cases} \tag{3}$$

3. Calculate the modified *relative placement factors* of the consequences of all other interpolated rules which are generated from the same defective fuzzy reasoning component as per the *correction rate pair* computed above, where $i \in \{2, 3, ..., j-1\}$ and $k \in \{j+1, j+2, ..., n-1\}$:

$$\begin{cases} \lambda_{2i}^{*} = \lambda_{2i} \cdot c^{-} \\ 1 - \lambda_{2k}^{*} = (1 - \lambda_{2k}) \cdot c^{+}. \end{cases} \tag{4}$$

4. Calculate the modified consequences of all interpolated rules which are generated from the same defective fuzzy reasoning component in accordance with their modified *relative placement factors*:

$$\begin{cases} A_{2x}^{*\prime} = (1 - \lambda_{2x}^{*}) A_{21} + \lambda_{2x}^{*} A_{2n} \\ T(A_{1x}^{\prime}, A_{1x}) = T(A_{2x}^{*\prime}, A_{2x}^{*}), \end{cases} \tag{5}$$

where $x \in \{2, 3, ..., n-1\}$, and $T(A', A)$ represents the scale and move transformations [7], [8] from fuzzy set A' to A.

5. Restrict the modified consequence such that if m object values $A_{i1}, A_{i2}, ..., A_{im}$ are obtained for variable x_i then they must satisfy:

$$\bigcap_{j=1}^{m} (A_{ij})_{\beta_0} \neq \varnothing, \tag{6}$$

where $(A_{ij})_{\beta_0}$ denotes the β_0-*cut* of fuzzy set A_{ij} That is, all derived values for a given variable are at least $(1 - \beta_0)$-consistent.

6. Restrict the propagations of all modified consequences so that they are mutually consistent to the extent of at least $(1 - \beta_0)$. For simplicity, let function $I(A_{ij}, R_l R_r) = A_{kj}$ denote the standard interpolation from the antecedent fuzzy set A_{ij} to the consequent value A_{kj}, through fuzzy reasoning component $R_l R_r$. Suppose that m object values $A_{i1}, A_{i2}, ..., A_{im}$ of variable x_i, located between the antecedent values of rules R_l and R_r, are modified, that the corresponding modified object values of variable x_k are A_{kj}^{*}, $j \in \{1, 2, ..., m\}$, and that n object values A_{kl}, $l \in \{1, 2, ..., n\}$, of variable x_k are already derived previously. If the modified consequences A_{kj}^{*} are all $(1 - \beta_0)$-consistent, then they must satisfy:

$$\begin{cases} A_{kl}^{*} = I(A_{ij}^{*}, R_l R_r) \\ \left(\bigcap_{j=1}^{m} (A_{kj}^{*})_{\beta_0} \right) \bigcap \left(\bigcap_{l=1}^{n} (A_{kl})_{\beta_0} \right) \neq \varnothing. \end{cases} \tag{7}$$

7. Solve all these simultaneous equations. The result is the modified solution which ensures β_0-inconsistency-free.

III. Generalizing Candidate Generation

The approach described above assumes that observations and rules in a given rule base are true and fixed and thus, inference procedures are the only possible cause of any inconsistencies. Consequently, only inference procedures (i.e. fuzzy reasoning components) are treated as diagnosable and modifiable components. However, this may not be true in real-world problems as observations and rules in a given rule base may also be faulty to a certain degree. Therefore, observations and rules in a rule base may also need to be diagnosed and modified. A generalization of the existing approach is described below.

A. Certainty degrees of observations and rules

Conceptually, inexact information may be classified into the following four general categories [6]: i) vagueness, which arises due to lack of sharp distinctions or boundaries between pieces of information and is usually modeled by a fuzzy set that identifies a soft constraint on a set of elements; ii) uncertainty, which depicts the reliability or confidential weight of a given piece of information stated in a proposition and can be captured by a numerical value or a fuzzy set; iii) both vagueness and uncertainty, which means that information of type i) and type ii) coexists but the uncertainties are expressed by numerical values; iv) Both vagueness and uncertainty with the latter also expressed in vague terms (i.e. fuzzy sets). The previous work [14] involves in type i information only. This work extends that by introducing type ii information into the system, but using numerical uncertainty representation only. This results in the use of type iii information. How to further extend this work to deal with type iv information remains active research.

In particular, an observation in this work is of the form:

$$O\text{: } x_i \text{ is } A_{ij} \ (c), \tag{8}$$

where c, a crisp number between 0 and 1, represents the certainty degree of observation O. According to the aforementioned categories of inexactness, an object value is modeled as a fuzzy set because no clear boundary between pieces of information is available; the certainty degree of the observation is expressed as a crisp number because the current description

of the object value (i.e. the fuzzy set) may not be of full confidence or fully reliable.

Since c represents the certainty degree, $1-c$ then naturally describes the uncertainty degree of the same piece of information. Thus, an uncertainty degree value as given in Eq. 8 may be interpreted being the extent to which the factual object value of O is located on the left side or right side of its current position. From this, intuitively, the modifiable range of object value O is bounded to the proportion of $1-c$ in reference to the entire variable domain. That is, it can shift leftwards or rightwards to a maximal distance of $\frac{1-c}{2}(max_i - min_i)$, where max_i and min_i are the maximum and minimum of the domain values of variable x_i. Note that the shifting of a fuzzy set does not affect the vague term (i.e. the shape and area of the fuzzy set). It is equivalent to add a crisp number to the representative value of the original fuzzy set [10]. In summary, the modified value A^*_{ij} of observation O as given in Eq. 8 must satisfy:

$$\begin{cases} A^*_{ij} \geq A_{ij} - \frac{1-c}{2}(max_i - min_i) \\ A^*_{ij} \leq A_{ij} + \frac{1-c}{2}(max_i - min_i). \end{cases} \tag{9}$$

It is possible that the shifting may be out of the variable domain. In order to keep the shifting result within the underlying domain, the shifting also needs to satisfy:

$$\begin{cases} min(supp(A^*_{ij})) \geq mix_i \\ max(supp(A^*_{ij})) \leq max_i, \end{cases} \tag{10}$$

where $supp(A^*_{ij})$ is the support of fuzzy set A^*_{ij}.

A uncertain rule is of the form as follows:

$$R: \text{ If } x_k \text{ is } A_{kj}, \text{ then } x_i \text{ is } A_{ij} \ (c), \tag{11}$$

which indicates that rule R is certain to the degree of c. Similar to the meaning of the certainty degree of an observation, this is interpreted as that the factual consequence object value A_{ij} may be located in the left or right side of the current position. Again, the shifting must satisfy Eqs. 9 and 10.

B. Dependency recording

In adaptive fuzzy interpolation, ATMS is used to record the dependencies of the interpolated results and contradictions upon the artificial (fuzzy reasoning) components. In this extended work, such dependencies can also be upon observations and rules in a given rule base. That is, propositions (including observations), contradictions, fuzzy reasoning components, and rules in a rule base are all represented as ATMS nodes.

Recall that a justification describes how a node is derivable from other nodes. Observations, rules in a given rule base and fuzzy reasoning components are assumed to be initially true and may be established to be false subsequently. For each of such nodes (i.e. assumptions in classical ATMS terms [4]), its justification simply assumes itself to be true. Any ATMS node with an inferred proposition (i.e. a derived node in [4]), which is obtained through the scale and move transformation-based interpolation, may now be verified by an ATMS justification:

$$O, R_i, R_j, R_iR_j \Rightarrow C. \tag{12}$$

Note that when rules R_i and R_j $(i \neq j)$ are fixed and true, there is no point to keep these dependencies and then Eq. 12 degenerates to Eq. 1. The justification of a β_0-contradiction in this extended work is the same as that in the existing work.

Note that if a consequence that is justified by a new interpolation does not already exist in the ATMS network, a new node will be created. Then, the label of every node will be updated, which is achieved by the so called label-updating algorithm. In order to avoid duplications, the label-updating algorithm is omitted here because it is basically the same as that used in the existing approach to adaptive fuzzy interpolation [14].

C. Candidate generation

From recorded dependencies of all contradictions within the ATMS network, GDE is employed to generate the candidate set. In particular, each candidate is formed by taking one element from each label environment of each contradiction. Of course, duplication and superset removal takes place for each candidate to ensure that the generated candidate set is minimal. Although candidate generation procedure in this work is similar to that in [14], the constituent components of the generated candidates hence may be different from those in the existing approach. This is obvious because an element of a certain candidate may now be an observation, a rule in a given rule base or a fuzzy reasoning component rather than just a fuzzy reasoning component.

To facilitate the modification of a candidate, it is necessary to determine whether multiple related components with respect to a single step of interpolation can appear within one candidate. If any candidate contains at most one element with respect to a single interpolation step, the modification of the candidate can be decomposed to the modification of its individual elements. Otherwise, the modification of related components needs to be implemented jointly.

Suppose that a step of interpolation $O, R_i, R_j, R_iR_j \Rightarrow C$ is given. Let N_O, N_{R_i}, N_{R_j}, $N_{R_iR_j}$ and N_C be the identity nodes, regarding O, R_i, R_j, R_iR_j and C, respectively. As stated previously, each observation, rule or fuzzy reasoning component has an environment containing only one node which represents itself. According to the label updating algorithm, each label environment of node N_O and those of nodes $\{N_{R_i}, N_{R_j}, N_{R_iR_j}\}$ jointly form a label environment of node N_C. Without losing generality, assume that N_C contributes to a certain contradiction directly or indirectly. Then, if any of its label environments contains $N_{R_iR_j}$, it must also contain N_{R_i} and N_{R_j}, and vice versa. Therefore, it is impossible that $\{N_{R_i}, N_{R_iR_j}\}$ or $\{N_{R_j}, N_{R_iR_j}\}$ is contained within one candidate in the minimal candidate set. This is because a candidate is generated by taking one element from each label environment of each contradiction and any candidate which is a superset of any other candidate is removed.

Similarly, if O is an observation, $\{N_O, N_{R_i}\}$, $\{N_O, N_{R_j}\}$, or $\{N_O, N_{R_iR_j}\}$ cannot be contained in any one candidate in the minimal candidate set. However, it is possible that N_{R_i} and N_{R_j} are contained within the same candidate. This is because

N_{R_i} may also be used in conjunction with another rule to carry out interpolation rather than N_{R_j}, and vice versa. Thus, one label environment of the special "false" node may only contains N_{R_i} but not N_{R_j} while another may only contains N_{R_j} but not N_{R_i}. Therefore, it is possible to generate a candidate in the minimal candidate set such that it contains both N_{R_i} and N_{R_j}.

IV. Generalizing Candidate Modification

Having generated the minimal candidate set, a certain candidate needs to be selected for modification in an effort to remove all the contradictions and thus to restore consistency. The principle underlying the consistency-restoring algorithm as outlined in Fig. 2 can be extended for use here. However, the extension is not straightforward due to the involvement of vague and uncertain information. This is because the constituent components of a fault candidate can now also be observations or rules given in a rule base apart from fuzzy reasoning components. However, as indicated in Sec. III-C, for the particular application of GDE in the present problem, elements contained within any minimal candidate returned by the GDE are independent amongst themselves except that a pair of rules that were used for interpolation may be contained within one certain candidate. Thus, their modification can be carried out independently except that the modification of a pair of neighboring rules should be carried out jointly. The modification of fuzzy reasoning components has been outlined in Sec. II-C. The modifications of observations and rules in a given rule base are described in the rest of this section.

A. Observation modification

For a given defective observation associated with certainty degree c, what the modification needs to do is to shift the fuzzy set along the variable axis while fixing its shape and area. This follows a naturally appealing interpretation of certainty degrees in the present context. In particular, the shifting must satisfy the three constraints below:

1) The shifting must be bounded by Eqs. 9 and 10, with respect to the given c.
2) The shifted observation needs to be consistent with the rest observations (or interpolated results), which corresponds to point 5 of the modification procedure for fuzzy reasoning components as outlined in Sec. II-C.
3) The propagation of the shifted observation needs to be mutually consistent with other consequences, which corresponds to point 6 of the modification procedure for fuzzy reasoning components outlined in Sec. II-C.

All three constraints can be satisfied by posing and then solving a set of simultaneous equations and inequations. The solution guarantees that the interpolated results using the modified observation are at least $(1-\beta_0)$-consistent throughout.

B. Rule modification

The situation that only one of two neighboring rules is defective is considered first. Similar to the modification of an observation, given a defective rule with certainty degree c, what the modification needs to do is to shift the consequence of the rule along with the consequent axis by satisfying Eqs. 9 and 10. However, because the defective rule has been used for interpolation, all the interpolated results which have been generated by employing this defective rule also need to be modified accordingly. There are two cases to consider in order to modify the defective rule, depending on whether the antecedent of the other rule that was used together with it to carry out interpolation is on which side of its own antecedent.

Without losing generality, suppose that $x_1 = A_{1i} \Rightarrow x_2 = A_{2i}$ and $x_1 = A_{1d} \Rightarrow x_2 = A_{2d}$ are the two neighboring rules which flank a given observation A_{1j} and that the second rule is defective, where $1 \leq i, d \leq N$ with N being the cardinality of the rule base, and $1 \leq j \leq M$ with M being the number of all given observations (including derived values) for x_1. Assume that A_{1i} is on the left hand side of A_{1d}, the antecedent of the defective rule.

Note that in implementing the scale and move transformation-based fuzzy interpolation, given an observation and two neighboring rules which flank the observation, the logical consequence of the observation is derived from the consequent fuzzy set of an artificially created intermediate rule via the scale and move transformations. This is achieved by minimizing the area and shape differences between the observation and the antecedent of the intermediate rule. Therefore, the area and shape of the logical consequence ultimately depend on the value of the relative placement factor λ (see [14] for details), the areas and shapes of the observation, and all the fuzzy sets defined in the rules used for interpolation. Thus, to maintain the interpretability of the fuzzy models and reasoning, it is desirable to modify a defective rule without changing the shape and area of its consequence. The only aspect that is modifiable is its location.

The overall location of a fuzzy set may be approximately captured by a crisp number, termed representative value [7]. In carrying out interpolation, the location relation between A_{1j} and its corresponding interpolated consequence A_{2j} can be mapped by a line which is determined by the locations of the the antecedents and consequences of two neighboring rules used for interpolation. This corresponds to the line P_1P_3 shown in Fig. 3. Suppose that the consequence of the defective rule

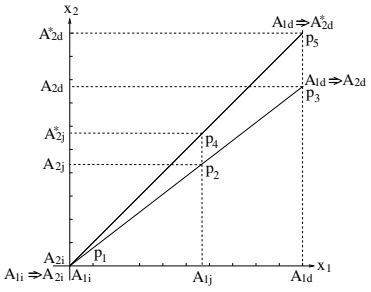

Fig. 3. Rule modification propagation

is modified to A^*_{2d}, then the location relation line P_1P_3 is accordingly shifted to line P_1P_5. In order to measure the extent

of such shifting, the following *correction rate* c^- is introduced:

$$c^- = \frac{d(A_{2i}, A^*_{2d})}{d(A_{2i}, A_{2d})}, \tag{13}$$

where $d(A, A')$ stands for the distance between the locations of the two fuzzy sets A and A' (shorted as the distance between fuzzy sets A and A' hereafter for simplicity). Denote the modified result of A_{2j} as A^*_{2j}, then the distance between A_{2i} and A^*_{2j} can be calculated by applying the correction rate c^- to the distance between A_{2i} and A_{2j}. Having known the locations of A_{2i} and A_{2j}, the location of A^*_{2j} can be calculated. Given only location is modified, A^*_{2j} is then obtained. For any other given interpolated results, if their corresponding observations are flanked by the same pair of original neighboring rules, their locations are corrected in a similar manner.

Of course, such modified results need to be consistent with the rest, so do their propagations. The procedure required is the same as points 5 and 6 of the modification procedure of a fuzzy reasoning component as outlined in Sec. II-C. Putting the above together, a set of constraints in terms of equations and inequations is constructed. The solution of these equations and inequations in conjunction with those imposed by all other elements of the same candidate in question guarantees the modified result of the candidate to be β_0-contradiction-free.

The case discussed so far covers the situation where all the observations which have invoked the use of the defective rule for interpolation are located on the left side of its antecedent. For the case where observations are located on the right side of its antecedent, the modification follows a mirrored procedure, with a different *correction rate* c^+. Suppose that a given observation A_{1k}, $1 \leq k \leq M$ is flanked by the defective rule and its right neighboring rule, $x_1 = A_{1l} \Rightarrow x_2 = A_{2l}$, $1 \leq l \leq N$, then c^+ is calculated by:

$$c^+ = \frac{d(A^*_{2d}, A_{2l})}{d(A_{2d}, A_{2l})}. \tag{14}$$

Similar to the left hand side case, the modified result of observation A_{1k} can then be computed by utilizing this correction rate. From this, the rest of the modification procedure is the same as the previous case.

The above has addressed the situations where only one of the two neighboring rules is defective. For the situation where both neighboring rules are defective, the modification can be done by modifying the two individual defective rules separately in a sequence. This is because the modified result is independent of the order of modifications.

The independence of the order of modifications carried out is proven below. Without losing generality, following the above description, suppose that rule $x_1 = A_{1l} \Rightarrow x_2 = A_{2l}$ is also defective, that the modified consequence of the left neighboring rule is A^*_{2d}, and that the modified consequence of the right neighboring rule is A^*_{2l}. Then, the final modification corresponds to the replacement of the location mapping line P_1P_3 by line P_6P_5 as illustrated in Fig. 4(b). This is because if the left defective rule is modified first as shown in Fig. 4(a), the modification of the right defective rule will be performed using the result of the modification of the left rule as illustrated in the final result of Fig. 4(b). If, however, the modification starts from the right defective rule, then the modification process is illustrated in Fig. 5, which also leads to the final result that is the same as the one given in the line P_6P_5 of Fig. 4(b). Thus, the modification in this case is simply a combination of the two procedures previously introduced.

V. An illustrative Example

To illustrate the potential of this extended adaptive approach, the problem given in [14] is reconsidered, with information on certainty degrees added. The rule base is given as follows:

R_1: If x_1 is A_{11}, then x_2 is A_{21} (0.82);
R_2: If x_1 is A_{12}, then x_2 is A_{22} (0.79);
R_3: If x_2 is A_{23}, then x_3 is A_{31} (0.93);
R_4: If x_2 is A_{24}, then x_3 is A_{32} (0.64);
R_5: If x_2 is A_{25}, then x_4 is A_{41} (0.75);
R_6: If x_2 is A_{26}, then x_4 is A_{42} (0.88);
R_7: If x_3 is A_{33}, then x_5 is A_{51} (0.82);
R_8: If x_3 is A_{34}, then x_5 is A_{52} (0.86);
R_9: If x_4 is A_{43}, then x_5 is A_{53} (0.90);
R_{10}: If x_4 is A_{44}, then x_5 isA_{54} (0.62).

Given $\beta_0 = 0.5$ and three observations, $x_1 = A_{13} = (7.0, 8.0, 9.0)$ (0.95), $x_1 = A_{14} = (7.6, 8.6, 9.6)$ (0.83) and $x_4 = A_{45} = (12.0, 13.0, 14.0)$ (0.92), the interpolation procedures are illustrated in Fig. 6 and the original observations as well as the results obtained by scale and move transformation-based interpolation are presented in Fig. 7. Note that in this example, to keep the illustration simple, it has been assumed that the variable x_1 takes two different object values A_{13} and A_{14} with different certainty degrees. In practice, this may be caused by the fact that the observations are taken by different

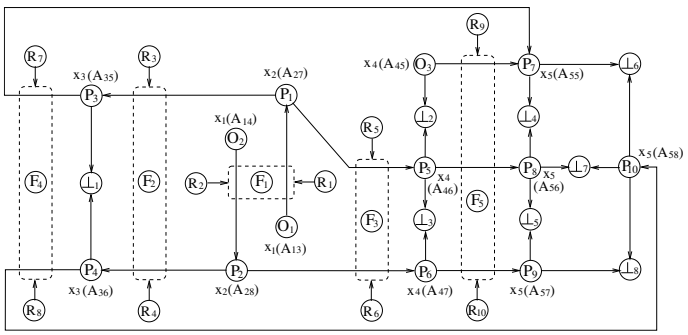

Fig. 6. Discrepancy records in ATMS

agents or that one is a real observation and the other may be produced by another inference mechanism.

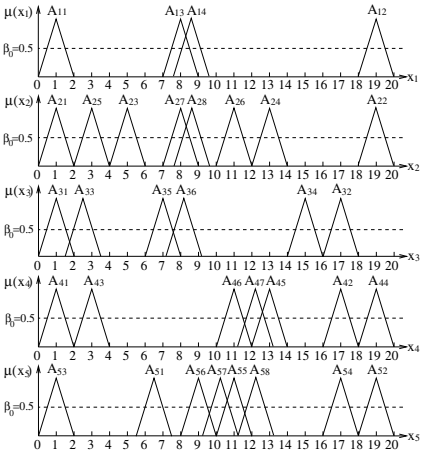

Fig. 7. Fuzzy sets used in the example

A. Dependency recording

In Fig. 6, ATMS nodes and contradictions are represented by circles. Particularly, each of $O_g,\ g \in \{1,2,3\}$, is a node denoting an observation; each of $R_h,\ h \in \{1,2,...,10\}$, is a node denoting a rule in the rule base; each of $F_i,\ i \in \{1,2,...,5\}$, is a node denoting a fuzzy reasoning component; each of $P_j,\ j \in \{1,2,...,10\}$, is a node denoting a proposition; and each of $\perp_k,\ k \in \{1,2,...,8\}$, denotes a β_0-contradiction. These ATMS nodes and contradictions are listed as follows, with all justifications omitted:

$R_1 : \langle x_1 = A_{11} \Rightarrow x_2 = A_{21}, \{\{R_1\}\}\rangle$;
$R_2 : \langle x_1 = A_{12} \Rightarrow x_2 = A_{22}, \{\{R_2\}\}\rangle$;
$R_3 : \langle x_2 = A_{23} \Rightarrow x_3 = A_{31}, \{\{R_3\}\}\rangle$;
$R_4 : \langle x_2 = A_{24} \Rightarrow x_3 = A_{32}, \{\{R_4\}\}\rangle$;
$R_5 : \langle x_2 = A_{25} \Rightarrow x_4 = A_{41}, \{\{R_5\}\}\rangle$;
$R_6 : \langle x_2 = A_{26} \Rightarrow x_4 = A_{42}, \{\{R_6\}\}\rangle$;
$R_7 : \langle x_3 = A_{33} \Rightarrow x_5 = A_{51}, \{\{R_7\}\}\rangle$;
$R_8 : \langle x_3 = A_{34} \Rightarrow x_5 = A_{52}, \{\{R_8\}\}\rangle$;
$R_9 : \langle x_4 = A_{43} \Rightarrow x_5 = A_{53}, \{\{R_9\}\}\rangle$;
$R_{10} : \langle x_4 = A_{44} \Rightarrow x_5 = A_{54}, \{\{R_{10}\}\}\rangle$;
$O_1 : \langle x_1 = A_{13}, \{\{O_1\}\}\rangle$;
$O_2 : \langle x_1 = A_{14}, \{\{O_2\}\}\rangle$;
$O_3 : \langle x_4 = A_{45}, \{\{O_3\}\}\rangle$;
$F_1 : \langle R_1 R_2, \{\{F_1\}\}\rangle$;
$F_2 : \langle R_3 R_4, \{\{F_2\}\}\rangle$;
$F_3 : \langle R_5 R_6, \{\{F_3\}\}\rangle$;
$F_4 : \langle R_7 R_8, \{\{F_4\}\}\rangle$;
$F_5 : \langle R_9 R_{10}, \{\{F_5\}\}\rangle$;
$P_1 : \langle x_2 = A_{27}, \{\{O_1, R_1, R_2, F_1\}\}\rangle$;
$P_2 : \langle x_2 = A_{28}, \{\{O_2, R_1, R_2, F_1\}\}\rangle$;
$P_3 : \langle x_3 = A_{35}, \{\{O_1, R_1, R_2, F_1, R_3, R_4, F_2\}\}\rangle$;
$P_4 : \langle x_3 = A_{36}, \{\{O_2, R_1, R_2, F_1, R_3, R_4, F_2\}\}\rangle$;
$P_5 : \langle x_4 = A_{46}, \{\{O_1, R_1, R_2, F_1, R_5, R_6, F_3\}\}\rangle$;
$P_6 : \langle x_4 = A_{47}, \{\{O_2, R_1, R_2, F_1, R_5, R_6, F_3\}\}\rangle$;
$P_7 : \langle x_5 = A_{55}, \{\{O_1, R_1, R_2, F_1, R_3, R_4, F_2, R_7, R_8, F_4\},$
$\{O_3, R_9, R_{10}, F_5\}\}\rangle$;
$P_8 : \langle x_5 = A_{56}, \{\{O_1, R_1, R_2, F_1, R_5, R_6, F_3, R_9, R_{10}, F_5\}\}\rangle$;
$P_9 : \langle x_5 = A_{57}, \{\{O_2, R_1, R_2, F_1, R_5, R_6, F_3, R_9, R_{10}, F_5\}\}\rangle$;
$P_{10} : \langle x_5 = A_{58}, \{\{O_2, R_1, R_2, F_1, R_3, R_4, F_2, R_7, R_8, F_4\}\}\rangle$;
$\perp_1 : \langle \perp, \{\{O_1, O_2, R_1, R_2, F_1, R_3, R_4, F_2\}\}\rangle$;
$\perp_2 : \langle \perp, \{\{O_1, O_3, R_1, R_2, F_1, R_5, R_6, F_3\}\}\rangle$;
$\perp_3 : \langle \perp, \{\{O_1, O_2, R_1, R_2, F_1, R_5, R_6, F_3\}\}\rangle$;
$\perp_4 : \langle \perp, \{\{O_1, O_3, R_1, R_2, F_1, R_5, R_6, F_3, R_9, R_{10}, F_5\}\}\rangle$;
$\perp_5 : \langle \perp, \{\{O_1, O_2, R_1, R_2, F_1, R_5, R_6, F_3, R_9, R_{10}, F_5\}\}\rangle$;
$\perp_6 : \langle \perp, \{\{O_2, O_3, R_1, R_2, F_1, R_3, R_4, F_2, R_7, R_8, F_4\}\}\rangle$;
$\perp_7 : \langle \perp, \{\{O_1, O_2, R_1, R_2, F_1, R_3, R_4, F_2, R_5, R_6, F_3, R_7, R_8, F_4, R_9,$
$R_{10}, F_5\}\}\rangle$;
$\perp_8 : \langle \perp, \{\{O_2, R_1, R_2, F_1, R_3, R_4, F_2, R_5, R_6, F_3, R_7, R_8, F_4, R_9, R_{10},$
$F_5\}\}\rangle$.

In particular, a specific ATMS node "false", denoted by $P_\perp$, which collectively represents all the contradictions listed above from $\perp_1$ to $\perp_8$, is given as follows:

$P_\perp : \langle \perp, \{\{O_1, O_2, R_1, R_2, F_1, R_3, R_4, F_2\},$
$\{O_1, O_3, R_1, R_2, F_1, R_5, R_6, F_3\},\ \{O_1, O_2, R_1, R_2, F_1, R_5, R_6, F_3\},$
$\{O_2, O_3, R_1, R_2, F_1, R_3, R_4, F_2, R_7, R_8, F_4\}\}\rangle$.

B. Candidate generation

After removing all duplications in each candidate and all candidates which are supersets of any other candidate, twenty four minimal candidates are generated, each of which is formed by taking one element from each environment in the label of the "false" node:

$C_1 = [R_1];\ C_2 = [R_2];\ C_3 = [F_1];\ C_4 = [O_1, O_2];\ C_5 = [O_1, O_3];$
$C_6 = [O_1, R_3];\ C_7 = [O_1, R_4];\ C_8 = [O_1, F_2];\ C_9 = [O_1, R_7];$
$C_{10} = [O_1, R_8];\ C_{11} = [O_1, F_4];\ C_{12} = [O_2, R_5];\ C_{13} = [O_2, O_3];$
$C_{14} = [O_2, R_6];\ C_{15} = [O_2, F_3];\ C_{16} = [R_3, R_5];\ C_{17} = [R_3, R_6];$
$C_{18} = [R_3, F_3];\ C_{19} = [R_4, R_5];\ C_{20} = [F_2, R_5];\ C_{21} = [R_4, F_3];$
$C_{22} = [R_4, R_6];\ C_{23} = [F_2, R_6];\ C_{24} = [F_2, F_3].$

C. Candidate modification

As with the existing approach, candidates of the smallest cardinality are examined first. Those candidates which only contain one element, i.e. candidates C_1, C_2 and C_3 in this example, are therefore chosen to be modified first. Particularly, C_1 is randomly chosen as the first to be modified in this case. According to Eqs. 9 and 10, the modified consequence of rule R_1 must satisfy:

$$\begin{cases} A^*_{21} \geq A_{21} - \frac{1-0.82}{2}(20-0) \\ A^*_{21} \leq A_{21} + \frac{1-0.82}{2}(20-0) \\ min(supp(A^*_{21})) \geq 0 \\ max(supp(A^*_{21})) \leq 20. \end{cases}$$

Note that each of the following two rules has been used to form the neighboring rules in conjunction with the defective rule R_1 to carry out interpolation:

IR_1 : If x_1 is A_{13}, then x_2 is A_{27};
IR_2 : If x_1 is A_{14}, then x_2 is A_{28}.

Since both the antecedent of IR_1 and that of IR_2 are on the right hand side of their counterpart of the defective rule, the following correction rate is used:

$$c^+ = \frac{d(A^*_{21}, A_{22})}{d(A_{21}, A_{22})}$$

Then, the locations of the modified interpolated results must satisfy:

$$\begin{cases} d(A^*_{27}, A_{22}) = d(A_{27}, A_{22}) \cdot c^+, \\ d(A^*_{28}, A_{22}) = d(A_{28}, A_{22}) \cdot c^+. \end{cases}$$

These are in turn, used to calculate the modified interpolated results as follows:

$$\begin{cases} A^*_{27} = A_{27} + (d(A^*_{27}, A_{22}) - d(A_{27}, A_{22})) \\ A^*_{28} = A_{28} + (d(A^*_{28}, A_{22}) - d(A_{28}, A_{22})). \end{cases}$$

From this, the rest of the modification is to pose a set of equations and inequations to ensure that the modified results and their propagations are consistent with the rest, which is the same as that of the modification of a fuzzy reasoning component and thus omitted here. Unfortunately, solving all these simultaneous equations and inequations does not lead to any solution. This is also the case when the single candidates C_2 and C_3 are examined.

According to the general candidate modification procedure given in Fig. 2, a candidate of a cardinality of 2 is then randomly taken for modification. In this particular case, suppose that candidate C_4 is taken first, which is comprised of two observations O_1 and O_2. By satisfying the first constraint of a modified observation as given in Sec. IV-A, the modified result of O_1 must satisfy:

$$\begin{cases} A^*_{13} \geq A_{13} - \frac{1-0.95}{2}(20-0) \\ A^*_{13} \leq A_{13} + \frac{1-0.95}{2}(20-0) \\ min(supp(A^*_{13})) \geq 0 \\ max(supp(A^*_{13})) \leq 20. \end{cases}$$

Similarly, a set of constraining inequations can be posed on the modified observation O_2. From this, the rest of the modification, which correspond to the second and third constraints outlined in Sec. IV-A, is the same as that of the modification of a fuzzy reasoning component and thus omitted. Again, this leads to no solution.

The tentative modification continues until one modification succeeds. In this case, candidate C_{12} leads to one solution as illustrated in Fig. 8. It is clear from this figure that there is no β_0-contradiction any more and thus consistency has been successfully restored. This means that the original inconsistent interpolation process has been corrected with consistent interpolated results throughout.

VI. Conclusions

This paper has extended the recent work on adaptive fuzzy interpolation by allowing observations and rules in a given rule base to be diagnosable and modifiable. In particular, it first represents the concepts of generalized adaptive fuzzy interpolation in ATMS terms. Then, GDE is employed to generate the minimal candidates by making use of the label of the specific "false" node within the ATMS. The consequence of this is that a candidate may consist of observations, rules and/or fuzzy reasoning components. While the modification method for individual fuzzy reasoning components has been given previously, this work proposes an extended approach to modifying individual observations and individual rules. The working of this method is illustrated with an example, though scale-up applications remain as active research. Theoretical analysis of the general properties of the work however, requires future investigation.

Further improvements may enhance the potential of the proposed research. Firstly, the extended approach can only be applied to fuzzy interpolation with two single-antecedent rules. It is worthwhile to generalize the approach to cope with fuzzy interpolation with multi-antecedent rules and fuzzy extrapolation. Also, due to more complex and uncertain information has been introduced into the underlying knowledge representative scheme used, the number of candidates grows dramatically. Thus, how to reduce the candidate set size and prioritize these candidates require further research. Use of an uncertainty-based ATMS such as that of [11] may help addressing this issue.

***Abstract*— Several type-1 fuzzy membership function (T1 FMF) generation methods have been proposed to model the uncertainty of pattern data. However, if we cannot obtain satisfactory results using type-1 fuzzy sets, employment of type-2 fuzzy sets (T2 FSs) for managing uncertainty may allow us to obtain desirable results. In this paper, a general T2 FMF design method and its application to back propagation (BP) neural networks is proposed. The general T2 FMF is designed using data histograms and then type-1 fuzzy membership values which are extracted from the centroid of the T2 FMF are used as inputs to the BP neural network. Applying our proposed membership assignment to the BP neural networks shows improvement of the classification performance since the uncertainty of pattern data are desirably controlled by the T2 fuzzy memberships. Experimental results for several data sets are given.**

Keywords - type-2 fuzzy membership function generation; neural network; fuzzy input

I. INTRODUCTION

The generation of appropriate fuzzy membership functions has been an important issue in fuzzy data analysis. Several T1 FMF generation methods have been proposed [1]-[4]. However, in the real world, there are several problems where T1 FMF may not properly represent the uncertainty of the pattern data [5]-[12]. To overcome this issue, many applications of T2 FSs using interval type-2 fuzzy membership functions (IT2 FMF) have been proposed [7]-[13]. However, the generation methods of IT2 FMF have been very rarely discussed. Recently, B. Choi and F. Rhee [7] proposed several IT2 FMF generation methods to effectively represent a pattern set.

Although IT2 FMF has been used primarily due to the computational complexity of general T2 FSs, our interest in using general T2 FMF cannot be overlooked since it may manage the uncertainties of the data more effectively due to the flexibility in its secondary membership. Moreover, the computational complexity can be reduced by employing the α-plane representation to compute the centroid of T2 FSs using α-plane computations that are very simple. This is possible since computations can be performed using Karnik-Mendel algorithms that are applied to each α-plane [14]-[15].

In this paper, we propose a general T2 FMF generation method, where the upper and lower membership functions for each class and feature are obtained by fitting appropriate parameterized functions to the histograms of the pattern data and the secondary membership functions are estimated by again fitting appropriate parameterized functions to the histograms of the upper and lower membership values for each vertical slice. In Section II, we briefly review histogram based IT2 FMF generation method [7]-[8]. In Section III, we propose our general T2 FMF generation method. In Section IV, we apply our proposed general T2 FMF generation method to back propagation (BP) neural networks. Experimental results are given in Section V. Finally, in Section VI, we present some conclusions.

II. INTERVAL TYPE-2 FUZZY MEMBERSHIP FUNCTION GENERATION METHODS

In this section, we briefly introduce histogram based IT2 FMF generation method [7]-[8]. The histogram of the feature values describes the distribution of input patterns for each feature. Therefore, the membership function generated from the histogram of the input data can suitably represent the data. To generate the histogram based IT2 FMF, the histogram of the pattern data is obtained for each labeled class and feature by smoothing the domain of each feature using a symmetric window (e.g., a triangular window). In doing so, the vertex of the triangular function is positioned at the first bin of the histogram and the weighted moving average is calculated, then the vertex is moved to the next bin. This procedure is repeated for all of the bins. For simplicity, we use a one class data set. Fig. 1(a) and (b) shows a scatter plot of pattern data and the histogram of the data for feature 1, respectively.

Next, appropriate parameterized functions are fitted to the histogram. To do so, a polynomial function is first fitted to the histogram to determine the number and approximate parameter values for the parameterized function(s). The parameter values for each function are then optimized to fit the histogram using the gradient descent method. In this example, we selected a Gaussian function as our parameterized function. Fig. 1(c) shows a Gaussian function fitted to the histogram of the data.

Then, to estimate an IT2 FMF, Gaussian function fitting to the upper and lower histogram values is needed. Gaussian function fitted to the upper (lower) histogram is used as the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

upper (lower) membership function. Fig. 1(d) shows the upper and lower membership function obtained that represent the IT2 FMF. The region between upper and lower membership function represents the FOU of the IT2 FMF and hence represents the IT2 FMF, since its secondary membership values are all 1.

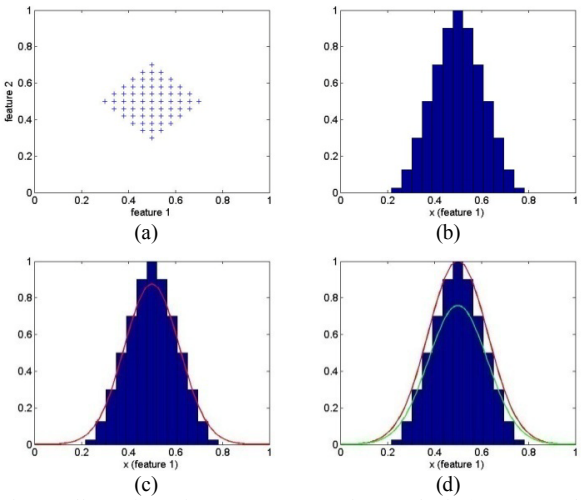

Fig. 1. Illustration of IT2 FMF generation method: (a) scatter plot, (b) histogram for feature 1, (c) Gaussian function fitting for histogram of data, and (d) upper and lower membership function.

III. General Type-2 Fuzzy Membership Function Design Method

In this section, we propose a general T2 FMF design method. For explanation purposes, we use the same data as in Fig. 1. First, to estimate the FOU of a general T2 FMF, we perform Gaussian function fitting to the histogram of data set as in the IT2 FMF generation method. The difference between the general T2 FMF and IT2 FMF generation method is to use window functions of different size for smoothing to obtain the histogram. For example, if we choose to use 6 triangular window functions of size 3, 5, 6, 7, 9, and 13 (i.e., base length), we can obtain 6 smoothed histograms each having a upper and lower membership function. Among all upper and lower membership functions, the smallest value is considered to be the lower membership value and the largest value is considered to be upper membership value for each vertical slice. For illustration purposes, Fig. 2(a) and (b) shows the smoothed histogram and upper/lower membership function for only window size 3 and 7, respectively. Fig. 2(c) represents upper and lower membership functions obtained by fitting Gaussian functions to all 6 smoothed histograms and Fig. 2(d) shows FOU of the general T2 FMF.

Next, the histogram for the upper and lower membership values is obtained at each vertical slice x domain values. For example, if six windows of different size are used we can get six upper and lower membership values at each vertical slice x domain value. Then we can obtain the histogram for the membership value domain at each vertical slice. Here, a smoothing window is again used to smooth the histogram. To estimate the secondary membership function, Gaussian function fitting to this histogram is performed. Fig. 2(e) illustrates the secondary membership function estimated by fitting the histogram of upper and lower membership values at $x = 0.35$, which denotes the vertical slice at $x = 0.35$. With this procedure, we can estimate the secondary membership function for all x domain values. Fig. 2(f) shows the 3D version of the general T2 FMF.

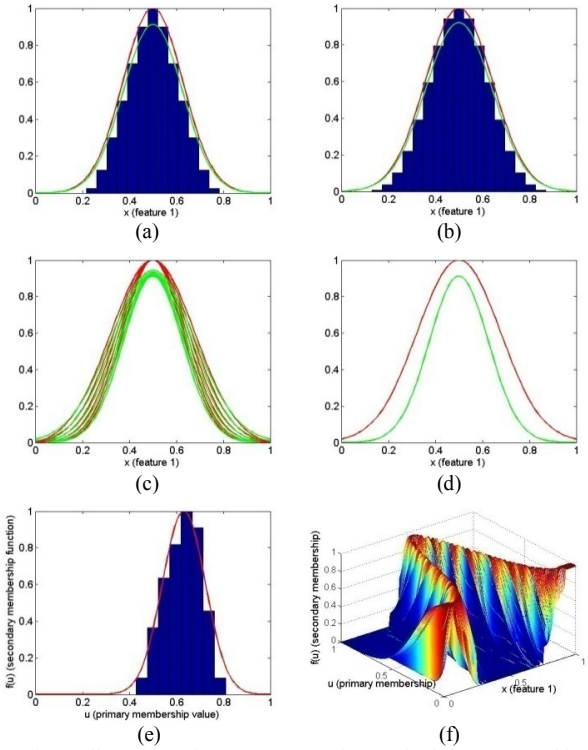

Fig. 2. Illustration of T2 FMF generation method: (a) upper and lower membership functions using 3-window size, (b) upper and lower membership functions using 7-window size, (c) all upper and lower membership functions, (d) FOU, (e) vertical slice at $x = 0.35$, and (f) 3D plot

IV. Application to Backpropagation Neural Network

To apply T2 FSs to the BP neural network, we extract type-1 fuzzy membership values using the centroid of each T2 FMF which is calculated by performing type reduction and defuzzification. The centroid of a T2 FS, which is $C_{\tilde{A}}(x)$, can be represented by the union of the centroids of all the embedded T2 FSs of $\tilde{A}$, i.e., [12]

$$C_{\tilde{A}}(x) = \int_{\forall\theta_1 \in J_{x_1}} \cdots \int_{\forall\theta_N \in J_{x_N}} \min\left(f_{x_1}(\theta_1),\ldots,f_{x_N}(\theta_N)\right) / \frac{\sum_{i=1}^{N} x_i\theta_i}{\sum_{i=1}^{N}\theta_i}, \quad (1)$$

where x_i is input feature pattern and θ_i is the primary membership for x_i. This centroid can be computed using α-plane representations [14]-[15].

The α-plane representation is as follows,

$$C_{\tilde{A}}(x) = \bigcup_{\alpha\in[0,1]} \alpha / C_{\tilde{A}_\alpha}(x), \quad (2)$$

where $C_{\tilde{A}_\alpha}(x)$ is the centroid of the α-plane, $\tilde{A}_\alpha$. Since each $\tilde{A}_\alpha$ is an IT2 FS, its centroid is an interval set, i.e.,

$$C_{\tilde{A}_\alpha}(x) = \left[l_{\tilde{A}_\alpha}, r_{\tilde{A}_\alpha} \right]. \quad (3)$$

This centroid can be obtained using the enhanced Karnik-Mendel algorithms [13] that are applied to each α-plane and the defuzzification value of each α-plane can be calculated as follows,

$$C_\alpha = \frac{l_{\tilde{A}_\alpha} + r_{\tilde{A}_\alpha}}{2}. \quad (4)$$

Then, the centroid of $\tilde{A}$, C, is obtained by calculating the mean value of defuzzification values of each α-plane, i.e.,

$$C = \frac{\sum_{\text{All } \alpha} \alpha C_\alpha}{\sum_{\text{All } \alpha} \alpha}. \quad (5)$$

Now, we can extract the type-1 fuzzy membership value of input pattern **x** for class *j* according to the distance between the centroid and input pattern, i.e., [7]-[8]

$$f_j(\mathbf{x}) = 1 - \left| \mathbf{x} - C_j \right|, \quad (6)$$
