Term Rewriting

What are terms?
Expressions built from variables, constant symbols, and function symbols.
E.g., Variables $x$, $y$, constant symbol 0, function symbols $s$ (unary) and + (binary, infix):

$$0, \ x + s(0), \ s(s(0)) + 0.$$ 

What does rewriting mean?
Rules that describe how one term can be rewritten into another one.

Examples

- **Rewriting as computation mechanism**: rules applied in one direction, computes normal forms
  - close relationship to functional programming
  - example: symbolic differentiation

- **Rewriting as deduction mechanism**: rules applied in both directions, defines equivalence classes of terms
  - equational reasoning in automated deduction
  - example: group theory
Symbolic differentiation

Arithmetic expressions that are built with the operations $+$ (binary function symbol), $\cdot$ (binary function symbol), the indeterminates $X, Y$ (constant symbols), and the numbers $0, 1$ (constant symbols).

Example: $((X + X) \cdot Y) + 1$

Additional (unary) function symbol $D_X$: partial derivative with respect to $X$

Rules for computing the derivative:

(R1) \[ D_X(X) \rightarrow 1, \]

(R2) \[ D_X(Y) \rightarrow 0, \]

(R3) \[ D_X(u + v) \rightarrow D_X(u) + D_X(v), \]

(R4) \[ D_X(u \cdot v) \rightarrow (u \cdot D_X(v)) + (D_X(u) \cdot v). \]

Important properties

of term rewriting systems

Termination:

Is it always the case that after finitely many rule applications we reach an expression to which no more rules apply (normal form)?

For the rules (R1)–(R4) this is the case. How can we show this?

\[ D_X(u \cdot v) \rightarrow (u \cdot D_X(v)) + (D_X(u) \cdot v). \]

Non-terminating rule \[ u + v \rightarrow v + u, \]

leads to an infinite sequence of rule applications

\[ (X \cdot 1) + (X \cdot 1) \rightarrow (X \cdot 1) + (X \cdot 1) \rightarrow (X \cdot 1) + (X \cdot 1) \rightarrow \ldots \]

Important properties

of term rewriting systems

Confluence:

If there are different ways of applying rules to a given term $t$, leading to different derived terms $t_1$ and $t_2$, can $t_1$ and $t_2$ be joined, i.e. can we always find a common term $s$ that can be reached both from $t_1$ and from $t_2$ by rule application?

For the rules (R1)–(R4) this is the case. How can we show this?

If we add the simplification rule \[ u + 0 \rightarrow u \]

to (R1)–(R4), we lose the confluence property.

Completion: confluence can be regained by adding \[ D_X(0) \rightarrow 0 \]

\[ 1 \rightarrow 1 + D_X(0) \]
**Group theory**

Let $\circ$ be a binary function symbol, $i$ be a unary function symbol, $e$ be a constant symbol, and $x, y, z$ be variable symbols.

The class of all groups is defined by the identities:

$$(G1) \quad (x \circ y) \circ z \approx x \circ (y \circ z) \quad \text{(associativity of } \circ)$$

$$(G2) \quad e \circ x \approx x \quad \text{(e left-unit)}$$

$$(G3) \quad i(x) \circ x \approx e \quad \text{(i yields left-inverse)}$$

Identities are rewrite rules that can be applied in both directions.

**Word problem**

Given a set of identities $E$ and terms $s, t$, can $s$ be rewritten into $t$ by using the identities in $E$ in both directions?

The identities (G1)-(G3) can be used to show that the left-inverse is also a right-inverse, i.e. $e$ can be rewritten into $x \circ i(x)$:

$$e \overset{G3}{\approx} i(x) \circ i(x) \overset{G2}{\approx} (x \circ i(x)) \overset{G1}{\approx} (x \circ i(x)) \circ i(x) \overset{G1}{\approx} x \circ i(x)$$

**Word problem**

Given a set of identities $E$ and terms $s, t$, can $s$ be rewritten into $t$ by using the identities in $E$?

Try to solve the word problem by (uni-directional) rewriting:

$$s \overset{\star}{\Rightarrow} t$$

Two problems:

- Equivalent terms can have distinct normal forms.
- Normal forms need not exist: the process of reducing a term may lead to an infinite chain of rule applications.

We will see that termination and confluence are the important properties that ensure existence and uniqueness of normal forms.

**Abstracts reduction systems**

abstract away the internal structure of the objects that are rewritten

A pair $(A, \to)$, where
- $A$ is an arbitrary set,
- the reduction $\to$ is a binary relation on $A$,

is called abstract reduction system (ARS).

$$\begin{align*}
\emptyset & := \{ (x, x) \mid x \in A \} \quad \text{identity} \\
\uparrow & := \to^i \quad \text{($i + 1$)-fold composition, } i \geq 0 \\
\to & := \bigcup_{i \geq 0} \uparrow \quad \text{transitive closure} \\
\rightarrow & := \downarrow \cup \downarrow \quad \text{reflexive transitive closure} \\
\rightarrow & := \to \cup \emptyset \quad \text{reflexive closure} \\
\leftarrow & := \{ (y, x) \mid x \to y \} \quad \text{inverse} \\
\leftrightarrow & := \downarrow \quad \text{inverse} \\
\leftrightarrow & := \to \cup \leftrightarrow \quad \text{symmetric closure} \\
\leftrightarrow & := (\leftrightarrow)^* \quad \text{transitive symmetric closure} \\
\leftrightarrow & := (\leftrightarrow)^* \quad \text{reflexive transitive symmetric closure}
\end{align*}$$
Let \((A, \rightarrow)\) be an ARS.

- \(x\) is reducible iff there is a \(y\) such that \(x \rightarrow y\).
- \(x\) is in normal form (irreducible) iff it is not reducible.
- \(y\) is a normal form of \(x\) iff \(x \rightarrow \downarrow y\) and \(y\) is in normal form.
  If \(x\) has a uniquely determined normal form, the latter is denoted by \(x \downarrow\).
- \(y\) is a direct successor of \(x\) iff \(x \rightarrow \downarrow y\).
- \(y\) is a successor of \(x\) iff \(x \rightarrow y\).
- \(x\) and \(y\) are joinable iff there is a \(z\) such that \(x \rightarrow z \leftarrow \downarrow y\),
  in which case we write \(x \leftarrow \downarrow y\).

**Example**

Let \(A := N - \{0, 1\}\) and
\[\rightarrow := \{(m, n) \mid m > n \text{ and } n \text{ divides } m\}.

1. \(m\) is in normal form iff \(m\) is prime.
2. \(p\) is a normal form of \(m\) iff \(p\) is a prime factor of \(m\).
3. \(m \downarrow n\) iff \(m\) and \(n\) are not relatively prime.
4. \(\downarrow \rightarrow = \rightarrow\) because \(\rightarrow\) and “divides” are already transitive.
5. \(\rightarrow = A \times A\).

**Definition**

A reduction \(\rightarrow\) is called

- **Church-Rosser** iff \(x \leftrightarrow y \Rightarrow x \downarrow y\)
- **confluent** iff \(y_1 \leftrightarrow x \rightarrow y_2 \Rightarrow y_1 \downarrow y_2\)
- **terminating** iff there is no infinite descending chain \(a_0 \rightarrow a_1 \rightarrow \cdots\)
- **convergent** iff it is both confluent and terminating.

**Theorem**

A reduction \(\rightarrow\) is confluent iff it is Church Rosser.
**Theorem**

If $\rightarrow$ is confluent and terminating, then

- every element $x$ has a unique normal form $x_\downarrow$.
- $x \leftrightarrow y$ iff $x_\downarrow = y_\downarrow$.

**How can we show termination and confluence of a given ARS?**

**Example**

Embedding into $(\mathbb{N}, >)$, which is obviously well-founded.

For strings, i.e. $A := X^*$ for some set $X$, the following are natural choices for mappings into $\mathbb{N}$:

1. **Length:** $\varphi$ is defined by $\varphi(w) := |w|$. This mapping proves termination of all length-decreasing reductions, like $\text{uabbv} \rightarrow_1 \text{uavv}$, where $u, v \in A$ are arbitrary and $a, b \in X$ are fixed.

2. **Letters:** For each $a \in X$ define $\varphi_a(w) := \text{“the number of occurrences of } a \text{ in } w\text{”}$. This mapping proves termination of reductions like $\text{uav} \rightarrow_2 \text{abv}$, where $u, v \in A$ are arbitrary and $a, b \in X$ are fixed.

**Showing termination**

A partial order $(B, >)$ is called well-founded iff it is terminating, i.e. there is no infinite descending chain $b_0 > b_1 > b_2 > b_3 > \ldots$

**Theorem**

Let $(A, \rightarrow)$ be an ARS. Then the following are equivalent:

- $\rightarrow$ is terminating.
- There is a well-founded partial order $(B, >)$ and a mapping $\varphi : A \rightarrow B$ such that $a \rightarrow a' \Rightarrow \varphi(a) > \varphi(a')$.

**How about termination of $\rightarrow_1 \cup \rightarrow_2$?**

Given two strict orders $(A, >_A)$ and $(B, >_B)$, the lexicographic product $>_A \times _B$ on $A \times B$ is defined by $(x, y) >_A \times _B (x', y') \Leftrightarrow (x >_A x') \lor (x = x' \land y >_B y')$.

**Theorem**

The lexicographic product of two well-founded partial orders is again a well-founded partial order.

$(a_0, b_0) > (a_1, b_1) > (a_2, b_2) > (a_3, b_3) > (a_4, b_4) > \cdots$

$a_0 \geq a_1 \geq a_2 \geq a_3 \geq a_4 \geq \cdots , a_k = a_{k+1} = a_{k+2} = \cdots$

$b_k > b_{k+1} > b_{k+2} > \cdots$
Example (continued)

Embedding into \((\mathbb{N} \times \mathbb{N}, \succ_{\mathbb{N} \times \mathbb{N}})\), which is well-founded by the above theorem.

3. Length in first component and letters in the second:
   \(\hat{\varphi}\) is defined by
   \[\hat{\varphi}(w) := (|w|, \varphi_\alpha(w)).\]
   This mapping proves termination of all \(\rightarrow_1 \cup \rightarrow_2\) with
   \[uabv \rightarrow_1 uav,\]
   \[uav \rightarrow_2 uvb,\]
   where \(u, v \in A\) are arbitrary and \(a, b \in X\), \(a \neq b\), are fixed.

Showing confluence

A reduction \(\rightarrow\) is locally confluent iff
\[y_1 \leftarrow x \rightarrow y_2 \Rightarrow y_1 \downarrow y_2.\]

Confluence implies local confluence, but not vice versa.

Theorem

If \(\rightarrow\) is locally confluent and terminating, then it is also confluent.

Proof by well-founded induction.

Well-founded induction

Let \((A, \rightarrow)\) be an ARS and \(P\) be a property of elements of \(A\).

\[\forall x \in A \quad (\forall y \in A, x \rightarrow y \Rightarrow P(y) \Rightarrow P(x) \quad \text{(WFI)}\]

To prove \(P(x)\) for all \(x\), it suffices to prove \(P(x)\) under the assumption that \(P(y)\) holds for all successors \(y\) of \(x\).

Theorem (correctness of WFI)

If \(\rightarrow\) terminates then WFI holds.
